**A**LGEBRA is that branch of the mathematical sciences which has for its object the carrying on of operations either in an order different from that which exists in arithmetic, or of a nature not contemplated in fixing the boundaries of that science. The circumstance that algebra has its origin in arithmetic, however widely it may in the end differ from that science, led Sir Isaac Newton to designate it "Universal Arithmetic," a designation which, vague as it is, indicates its character better than any other by which it has been attempted to express its functions—better certainly, to ordinary minds, than the designation which has been applied to it by Sir William Rowan Hamilton, one of the greatest mathematicians the world has seen since the days of Newton—"the Science of Pure Time;" or even than the title by which De Morgan would paraphrase Hamilton's words—"the Calculus of Succession."

To express in few words what it is which effects the transition from the science of arithmetic into a new field is not easy. It will serve, probably, to convey some notion of the position of the boundary line, when it is stated that the operations of arithmetic are all capable of direct interpretation *per se*, whilst those of algebra are in many cases interpretable only by comparison with the assumptions on which they are based. For example, multiplication of fractions—which the older writers on arithmetic, Lucas de Burgo in Italy, and Robert Recorde in England, clearly perceived to be a new application of the term multiplication, scarcely at first sight reconcilable with its original definition as the exponent of equal additions,—multiplication of fractions becomes interpretable by the introduction of the idea of multiplication into the definition of the fraction itself. On the other hand, the independent use of the sign *minus*, on which Diophantus, in the 4th century, laid the foundation of the science of algebra in the West, by placing in the forefront of his treatise, as one of his earliest definitions, the rule of the sign minus, "that *minus* multiplied by *minus* produces *plus*"—this independent use of the sign has no originating operation of the same character as itself, and might, if assumed in all its generality as existing side by side with the laws of arithmetic, more especially with the commutative law, have led to erroneous conclusions. As it is, the unlimited applicability of this definition, in connection with all the laws of arithmetic standing in their integrity, pushes the dominion of algebra into a field on which the oldest of the Greek arithmeticians, Euclid, in his unbending march, could never have advanced a step without doing violence to his convictions.

In asserting that the independent existence of the sign *minus*, side by side with the laws of arithmetic, might have led to anomalous results, had not the operations been subject to some limitation, we are introducing no imaginary hypothesis, but are referring to a fact actually existing. The most recent advance beyond the boundaries of algebra, as it existed fifty years ago, is that beautiful extension to which Sir W. R. Hamilton has given the designation of Quaternions, the very foundation of which requires the removal of one of the ancient axioms of arithmetic, "that operations may be performed in any order."

## HISTORY.

At what period and in what country algebra was invented? is a question that has been much discussed. Who were the earliest writers on the subject? What was the progress of its improvement? And lastly, by what means and at what period was the science diffused over Europe? It was a common opinion in the 17th century that the ancient Greek

mathematicians must have possessed an analysis of the nature of modern algebra, by which they discovered the theorems and solutions of the problems which we so much admire in their writings; but that they carefully concealed their instruments of investigation, and gave only the results, with synthetic demonstrations.

This opinion is, however, now exploded. A more intimate acquaintance with the writings of the ancient geometers has shown that they had an analysis, but that it was purely geometrical, and essentially different from our algebra.

Although there is no reason to suppose that the great geometers of antiquity derived any aid in their discoveries from the algebraic analysis, yet we find that at a considerably later period it was known to a certain extent among the Greeks.

About the middle of the 4th century of the Christian era, a period when the mathematical sciences were on the decline, and their cultivators, instead of producing original works of genius, contented themselves with commentaries on the works of their more illustrious predecessors, there was a valuable addition made to the fabric of ancient learning.

This was the treatise of Diophantus on arithmetic, consisting originally of thirteen books, of which only the first six, and an incomplete book on polygonal numbers, supposed to be the thirteenth, have descended to our times.

This precious fragment does not exhibit anything like a complete treatise on algebra. It lays, however, an excellent foundation of the science, and the author, after applying his method to the solution of simple and quadratic equations, such as to "find two numbers of which the sum and the sum or difference of the squares are given," proceeds to a peculiar class of arithmetical questions, which belong to what is now called the indeterminate analysis.

Diophantus may have been the inventor of the Greek algebra, but it is more likely that its principles were not unknown before his time; and that, taking the science in the state in which he found it as the basis of his labours, he enriched it with new applications. The elegant solutions of Diophantus show that he possessed great address in the particular branch of which he treated, and that he was able to resolve determinate equations of the second degree. Probably this was the greatest extent to which the science had been carried among the Greeks. Indeed, in no country did it pass this limit, until it had been transplanted into Italy on the revival of learning.

The celebrated Hypatia, the daughter of Theon, composed a commentary on the work of Diophantus. This, however, is now lost, as well as a similar treatise, on the *Conics* of Apollonius, by this illustrious and ill-fated lady, who, as is commonly known, fell a sacrifice to the fury of a fanatical mob about the beginning of the 5th century.

About the middle of the 16th century, the work of Diophantus above referred to, written in the Greek language, was discovered at Rome in the Vatican library, having probably been brought there from Greece when the Turks possessed themselves of Constantinople. A Latin translation, without the original text, was given to the world by Xylander in 1575; and a more complete translation, by Bachet de Mezeriac (one of the earliest members of the French Academy), accompanied by a commentary, appeared in 1621. Bachet was eminently skilful in the indeterminate analysis, and therefore well qualified for the work he had undertaken; but the text of Diophantus was so much in-

jured, that he was frequently obliged to guess the meaning of the author, or supply the deficiency. At a later period, the celebrated French mathematician Fermat supplemented the commentary of Bachet by notes of his own on the writings of the Greek algebraist. These are extremely valuable, on account of Fermat's profound knowledge of this particular branch of analysis. This edition, the best which exists, appeared in 1670.

Although the revival of the writings of Diophantus was an important event in the history of mathematics, yet it was not from them that algebra became first known in Europe. This important invention, as well as the numeral characters and decimal arithmetic, was received from the Arabians. That ingenious people fully appreciated the value of the sciences; for at a period when all Europe was enveloped in the darkness of ignorance, they preserved from extinction the lamp of knowledge. They carefully collected the writings of the Greek mathematicians; they translated them into their language, and illustrated them with commentaries. It was through the medium of the Arabic tongue that the elements of Euclid were first introduced into Europe; and a part of the writings of Apollonius are only known at the present day by a translation from the Arabic, the Greek original being lost.

The Arabians ascribe the invention of their algebra to one of their mathematicians, Mahommed-ben-Musa, or Moses, called also Mahommed of Buziana, who flourished about the middle of the 9th century, in the reign of the Caliph Almamoun.

It is certain that this person composed a treatise on this subject, because an Italian translation was known at one time to have existed in Europe, although it is now lost. Fortunately, however, a copy of the Arabic original is preserved in the Bodleian Library at Oxford, bearing a date of transcription corresponding to the year 1342. The title-page identifies its author with the ancient Arabian. A marginal note concurs in this testimony, and further declares the work to be the first treatise composed on algebra among the faithful; and the preface, besides indicating the author, intimates that he was encouraged by Almamoun, commander of the faithful, to compile a compendious treatise of calculation by algebra.

The circumstance of this treatise professing to be only a compilation, and, moreover, the first Arabian work of the kind, has led to an opinion that it was collected from books in some other language. As the author was intimately acquainted with the astronomy and computations of the Hindoos, he may have derived his knowledge of algebra from the same quarter. The Hindoos, as we shall presently see, had a science of Algebra, and knew how to solve indeterminate problems. Hence we may conclude, with some probability, that the Arabian algebra was originally derived from India.

The algebraic analysis, having been once introduced among the Arabians, was cultivated by their own writers. One of these, Mahommed Abulwafa, who flourished in the last forty years of the 10th century, composed commentaries on the writers who had preceded him. He also translated the writings of Diophantus.

It is remarkable, that although the mathematical sciences were received with avidity, and sedulously cultivated during a long period by the Arabians, yet in their hands they received hardly any improvement. It might have been expected that an acquaintance with the writings of Diophantus would have produced some change in their algebra. This, however, did not happen: their algebra continued nearly in the same state, from their earliest writer on the subject, to one of their latest, Behaudin, who lived between the years 953 and 1031.

Writers on the history of algebra were long under a

mistake as to the time and manner of its introduction into Europe. It has now, however, been ascertained that the science was brought into Italy by Leonardo, a merchant of Pisa. This ingenious man resided in his youth in Barbary, and there learned the Indian method of counting by the nine numeral characters. Commercial affairs led him to travel into Egypt, Syria, Greece, and Sicily, where we may suppose he made himself acquainted with everything known respecting numbers. The Indian mode of computation appeared to him to be by far the best. He accordingly studied it carefully; and, with this knowledge, and some additions of his own, and also taking some things from Euclid's Geometry, he composed a treatise on arithmetic. At that period algebra was regarded only as a part of arithmetic. It was indeed the sublime doctrine of that science; and under this view the two branches were handled in Leonardo's treatise, which was originally written in 1202, and again brought forward under a revised form in 1228. When it is considered that this work was composed two centuries before the invention of printing, and that the subject was not such as generally to interest mankind, we need not wonder that it was but little known; hence it has always remained in manuscript, as well as some other works by the same author. Indeed it was not known to exist from an early period until the middle of the last century, when it was discovered in the Magliabecchian library at Florence.

The extent of Leonardo's knowledge was pretty much the same as that of the preceding Arabian writers. He could resolve equations of the first and second degrees, and he was particularly skilful in the Diophantine analysis. He was well acquainted with geometry, and he employed its doctrines in demonstrating his algebraic rules. Like the Arabian writers, his reasoning was expressed in words at length; a mode highly unfavourable to the progress of the art. The use of symbols, and the method of combining them so as to convey to the mind at a single glance a long process of reasoning, was a much later invention.

Considerable attention was given to the cultivation of algebra between the time of Leonardo and the invention of printing. It was publicly taught by professors. Treatises were composed on the subject; and two works of the oriental algebraists were translated from the Arabian language into Italian. One was entitled *the Rule of Algebra*, and the other was the oldest of all the Arabian treatises, that of Mahommed-ben-Musa of Corasan.

The earliest printed book on algebra was composed by Lucas Paciolus, or Lucas de Burgo, a minorite friar. It was first printed in 1494, and again in 1523. The title is *Summa de Arithmetica, Geometria, Proportioni, et Proportionalita*.

This is a very complete treatise on arithmetic, algebra, and geometry, for the time in which it appeared. The author followed close on the steps of Leonardo; and, indeed, it is from this work that one of his lost treatises has been restored.

Lucas de Burgo's work is interesting, inasmuch as it shows the state of algebra in Europe about the year 1500: probably the state of the science was nearly the same in Arabia and Africa, from which it had been received.

The power of algebra as an instrument of research is in a very great degree derived from its notation, by which all the quantities under consideration are kept constantly in view; but in respect of convenience and brevity of expression, the algebraic analysis in the days of Lucas de Burgo was very imperfect: the only symbols employed were a few abbreviations of the words or names which occurred in the processes of calculation, a kind of short-hand, which formed a very imperfect substitute for that compactness of expression which has been attained by the modern notation.

The application of algebra was also at this period very limited; it was confined almost entirely to the resolution of certain questions of no great interest about numbers. No idea was then entertained of that extensive application which it has received in modern times.

The knowledge which the early algebraists had of their science was also circumscribed: it extended only to the resolution of equations of the first and second degrees; and they divided the last into cases, each of which was resolved by its own particular rule. The important analytical fact, that the resolution of all the cases of a problem may be comprehended in a single formula, which may be obtained from the solution of one of its cases, merely by a change of the signs, was not then known: indeed, it was long before this principle was fully comprehended. Dr Halley expresses surprise, that a formula in optics which he had found, should by a mere change of the signs give the focus of both converging and diverging rays, whether reflected or refracted by convex or concave specula or lenses; and Molyneux speaks of the universality of Halley's formula as something that resembled magic.

The rules of algebra may be investigated by its own principles, without any aid from geometry; and although in some cases the two sciences may serve to illustrate each other, there is not now the least necessity in the more elementary parts to call in the aid of the latter in expounding the former. It was otherwise in former times. Lucas de Burgo found it to be convenient, after the example of Leonardo, to employ geometrical constructions to prove the truth of his rules for resolving quadratic equations, the nature of which he did not completely comprehend; and he was induced by the imperfect nature of his notation to express his rules in Latin verses, which will not now be read with the kind of satisfaction we receive from the perusal of the well-known poem, "the Loves of the Triangles."

As Italy was the first European country where algebra became known, it was there that it received its earliest improvements. The science had been nearly stationary from the days of Leonardo to the time of Pacioli, a period of three centuries; but the invention of printing soon excited a spirit of improvement in all the mathematical sciences. Hitherto an imperfect theory of quadratic equations was the limit to which it had been carried. At last this boundary was passed, and about the year 1505 a particular case of equations of the third degree was resolved by Scipio Ferreus, a professor of mathematics in Bononia. This was an important step, because it showed that the difficulty of resolving equations of the higher orders, at least in the case of the third degree, was not insurmountable, and a new field was opened for discovery. It was then the practice among the cultivators of algebra, when they advanced a step, to conceal it carefully from their contemporaries, and to challenge them to resolve arithmetical questions, so framed as to require for their solution a knowledge of their own new-found rules. In this spirit did Ferreus make a secret of his discovery: he communicated it, however, to a favourite scholar, a Venetian named Florido. About the year 1535 this person, having taken up his residence at Venice, challenged Tartalea of Brescia, a man of great ingenuity, to a trial of skill in the resolution of problems by algebra. Florido framed his questions so as to require for their solution a knowledge of the rule which he had learned from his preceptor Ferreus; but Tartalea had, five years before this time, advanced further than Ferreus, and was more than a match for Florido. He therefore accepted the challenge, and a day was appointed when each was to propose to the other thirty questions. Before the time came, Tartalea had resumed the study of cubic equations, and had discovered the solution of two cases in addition to two which

he knew before. Florido's questions were such as could be resolved by the single rule of Ferreus; while, on the contrary, those of Tartalea could only be resolved by one or other of three rules, which he himself had found, but which could not be resolved by the remaining rule, which was also that known to Florido. The issue of the contest is easily anticipated; Tartalea resolved all his adversary's questions in two hours, without receiving one answer from him in return.

The celebrated Cardan was a contemporary of Tartalea. Cardan This remarkable person was a professor of mathematics at Milan, and a physician. He had studied algebra with great assiduity, and had nearly finished the printing of a book on arithmetic, algebra, and geometry; but being desirous of enriching his work with the discoveries of Tartalea, which at that period must have been the object of considerable attention among literary men in Italy, he endeavoured to draw from him a disclosure of his rules. Tartalea resisted for a time Cardan's entreaties. At last, overcome by his importunity, and his offer to swear on the holy Evangelists, and by the honour of a gentleman, never to publish them, and on his promising on the faith of a Christian to commit them to cypher, so that even after his death they would not be intelligible to any one, he ventured with much hesitation to reveal to him his practical rules, which were expressed by some very bad Italian verses, themselves in no small degree enigmatical. He reserved, however, the demonstrations. Cardan was not long in discovering the reason of the rules, and he even greatly improved them, so as to make them in a manner his own. From the imperfect essays of Tartalea he deduced an ingenious and systematic method of resolving all cubic equations whatsoever; but with a remarkable disregard for the principles of honour, and the oath he had taken, he published in 1545 Tartalea's discoveries, combined with his own, as a supplement to a treatise on arithmetic and algebra, which he had published six years before. This work is remarkable for being the second printed book on algebra known to have existed.

In the following year Tartalea also published a work on algebra, which he dedicated to Henry VIII., king of England.

It is to be regretted that in many instances the authors of important discoveries have been overlooked, while the honours due to them have been transferred to others having only secondary pretensions. The formulæ for the resolution of cubic equations are now called Cardan's rules, notwithstanding the prior claim of Tartalea. It must be confessed, however, that he evinced considerable selfishness in concealing his discovery; and although Cardan cannot be absolved from the charge of bad faith, yet it must be recollected that by his improvements in what Tartalea communicated to him, he made the discovery in some measure his own; and he had moreover the high merit of being the first to publish this important improvement in algebra to the world.

The next step in the progress of algebra was the discovery of a method of resolving equations of the fourth order. An Italian algebraist had proposed a question which could not be resolved by the newly invented rules, because it produced a biquadratic equation. Some supposed that it could not be resolved at all; but Cardan was of a different opinion. He had a pupil named Lewis Ferrari, a young man Ferrari of great genius, and an ardent student in the algebraic analysis: to him Cardan committed the solution of this difficult question, and he was not disappointed. Ferrari not only resolved the question, but he also found a general method of resolving equations of the fourth degree, by making them depend on the solution of equations of the third degree.

This was another great improvement; and although the precise nature of an equation was not then fully understood, nor was it indeed until half a century later, yet, in the general resolution of equations, a point of progress was then reached which the utmost efforts of modern analysis have never been able to pass.

There was another Italian mathematician of that period who did something for the improvement of algebra. This was Bombelli. He published a valuable work on the subject in 1572, in which he brought into one view what had been done by his predecessors. He explained the nature of the *irreducible case* of cubic equations, which had greatly perplexed Cardan, who could not resolve it by his rule; he showed that the rule would apply sometimes to particular examples, and that all equations of this case admitted of a real solution; and he made the important remark, that the algebraic problem to be resolved in this case corresponds to the ancient problem of the trisection of an angle.

There were two German mathematicians contemporary with Cardan and Tartalea, viz., Stifelius and Scheubelius. Their writings appeared about the middle of the 16th century, before they knew what had been done by the Italians. Their improvements were chiefly in the notation. Stifelius, in particular, introduced for the first time the characters which indicate addition and subtraction, and the symbol for the square root.

The first treatise on algebra in the English language was written by Robert Recorde, teacher of mathematics and practitioner in physic at Cambridge. At this period it was common for physicians to unite with the healing art the studies of mathematics, astrology, alchemy, and chemistry. This custom was derived from the Moors, who were equally celebrated for their skill in medicine and calculation. In Spain, where algebra was early known, the title of physician and algebraist were nearly synonymous. Accordingly, in the romance of Don Quixote, when the bachelor Samson Carasco was grievously wounded in his rencounter with the knight, an *algebraista* was called in to heal his bruises.

Recorde published a treatise on arithmetic, which was dedicated to Edward VI.; and another on algebra, with the title, *The Whetstone of Wit*, &c. Here, for the first time, the modern sign for equality was introduced.

By such gradual steps did algebra advance in improvement from its first introduction by Leonardo, each succeeding writer making some change for the better; but with the exception of Tartalea, Cardan, and Ferrari, hardly any one rose to the rank of an inventor. At length came Vieta, to whom this branch of mathematical learning, as well as others, is highly indebted. His improvements in algebra were very considerable; and some of his inventions, although not then fully developed, have yet been the germs of later discoveries. He was the first that employed general characters to represent known as well as unknown quantities. Simple as this step may appear, it has yet led to important consequences. He must also be regarded as the first that applied algebra to the improvement of geometry. The older algebraists had indeed resolved geometrical problems, but each solution was particular; whereas Vieta, by introducing general symbols, produced general formulae, which were applicable to all problems of the same kind, without the trouble of going over the same process of analysis for each.

This happy application of algebra to geometry produced great improvements: it led Vieta to the doctrine of angular sections, one of the most important of his discoveries, which is now expanded into the arithmetic of sines or analytical trigonometry. He also improved the theory of algebraic equations, and he was the first that gave a

general method of resolving them by approximation. As he lived between the years 1540 and 1603, his writings belong to the latter half of the 16th century. He printed them at his own expense, and liberally bestowed them on men of science.

The Flemish mathematician Albert Girard was one of the improvers of algebra. He extended the theory of equations somewhat further than Vieta, but he did not completely unfold their composition; he was the first that showed the use of the negative sign in the resolution of geometrical problems, and the first to speak of *imaginary quantities*. He also inferred by induction that every equation has precisely as many roots as there are units in the number that expresses its degree. His algebra appeared in 1629.

The next great improver of algebra was Thomas Harriot, an Englishman. As an inventor he has been the boast of this country. The French mathematicians have accused the British of giving discoveries to him which were really due to Vieta. It is probable that some of these may be justly claimed for both, because each may have made the discovery for himself, without knowing what had been done by the other. Harriot's principal discovery, and indeed the most important ever made in algebra, was, that every equation may be regarded as formed by the product of as many simple equations as there are units in the number expressing its order. This important doctrine, now familiar to every student of algebra, developed itself slowly. It was quite within the reach of Vieta, who unfolded it in part, but left its complete discovery to Harriot.

We have seen the very inartificial form in which algebra first appeared in Europe. The improvements of almost 400 years had not given its notation that compactness and elegance of which it is susceptible. Harriot made several changes in the notation, and added some new signs; he thus gave to algebra greater symmetry of form. Indeed, as it came from his hands, it differed but little from its state at the present time.

Oughtreed, another early English algebraist, was a contemporary with Harriot, but lived long after him. He wrote a treatise on the subject, which was long taught in the universities.

In tracing the history of algebra, we have seen, that in the form under which it was received from the Arabs, it was hardly distinguishable as a peculiar mode of reasoning, because of the want of a suitable notation; and that, poor in its resources, its applicability was limited to the resolution of a small number of uninteresting numeral questions. We have followed it through different stages of improvement, and we are now arrived at a period when it was to acquire additional power as an instrument of analysis, and to admit of new and more extended applications. Vieta saw the great advantage that might be derived from the application of algebra to geometry. The essay he made in his theory of angular sections, and the rich mine of discovery thus opened, proved the importance of his labours. He did not fully explore it, but it has seldom happened that one man began and completed a discovery. He had, however, an able and illustrious successor in Descartes, who, employing in the study of algebra that high power of intellect with which he was endowed, not only improved it as an abstract science, but, more especially by its application to geometry, laid the foundation of the great discoveries which have since so much engaged mathematicians, and have made the last two centuries ever memorable in the history of the progress of the human mind.

Descartes' grand improvement was the application of algebra to the doctrine of curve lines. As in geography we refer every place on the earth's surface to the equator, and

to a determinate meridian, so he referred every point of a curve to some line given by position. For example, in a circle, every point in the circumference might be referred to the diameter. The perpendicular from any point in the curve, and the distance of that perpendicular from the centre or from the extremity of a diameter, were lines which, although varying with every change of position in the point from which the perpendicular was drawn, yet had a determinate relation to each other, which was the same for all points in the curve depending on its nature, and which, therefore, served as a characteristic to distinguish it from all other curves.

The relations of lines drawn in this way could be readily expressed in algebraic symbols; and the expression of this relation in general terms constituted what is called the *equation* of the curve.

This might serve as its definition; and from the equation by the processes of algebra, all the properties of the curve could be investigated.

Descartes' *Geometry* (or, as it might have been named, the application of algebra to geometry) appeared first in 1637. This was six years after the publication of Harriot's discoveries, which was a posthumous work. Descartes availed himself of some of Harriot's views, particularly the manner of generating an equation, without acknowledgment; and on this account Dr Wallis, in his algebra, has reflected with considerable severity on the French algebraist. This spirit has engendered a corresponding eagerness in the French mathematicians to defend him. Montucla, in his history of the mathematics, has evinced a strong national prejudice in his favour; and, as usually happens, in order to exalt him, he hardly does justice to Harriot, the idol of his adversaries.

The new views which the labours of Vieta, Harriot, and Descartes opened in geometry and algebra were seized with avidity by the powerful minds of men eager in the pursuit of real knowledge. Accordingly, we find in the 17th century a whole host of writers on algebra, or algebra combined with geometry.

Our limits will not allow us to enter minutely into the claims which each has on the gratitude of posterity. Indeed, in pure algebra the new inventions were not so conspicuous as the discoveries made by its applications to geometry, and the new theories which were suggested by their union. The curious speculations of Kepler concerning the solids formed by the revolutions of curvilinear figures, the *Geometry of Indivisibles* by Cavalerius, the *Arithmetic of Infinites* of Wallis, and, above all, the *Method of Fluxions* of Newton, and the *Differential and Integral Calculus* of Leibnitz, are fruits of the happy union. All these were agitated incessantly by their inventors and contemporaries; by such men as Barrow, James Gregory, Wren, Cotes, Taylor, Halley, De Moivre, Maclaurin, Stirling, and others, in this country; and abroad by Roberval, Fermat, Huyghens, the two Bernoullis, Pascal, and many others.

The first half of the 18th century produced little in the way of addition either to pure algebra or to its applications. Men were employed rather in elaborating and working out what Newton, Leibnitz, and Descartes had originated, than in exercising themselves in independent investigations. There are, indeed, to be found some names of eminence associated with the science of algebra, such as Maclaurin, but their eminence will be found to depend on their connection with the extensions of the science, rather than with the science itself. It was reserved for Lagrange, in the latter part of the century, to give a new impulse to extension in pure algebra, in a direction which has led to most important results. Not only did he, in his *Traité de la Résolution des Equations Numériques*, lay the foundation on which Budan, Fourier, Sturm, and others, have built a goodly fabric after

the pattern of the *Universal Arithmetic* of Newton, but in his *Théorie des fonctions analytiques*, and *Calcul des fonctions*, he endeavoured, and with a large amount of success, to reduce the higher analysis (the Fluxions of Newton), to the domain of pure algebra. Nor must the labours of a fellow-workman, Euler, be forgotten. In his voluminous Euler, and somewhat ponderous writings will be found a perfect storehouse of investigations on every branch of algebraical and mechanical science. Especially pertinent to our present subject is his demonstration of the Binomial Theorem in the *Novi Commentarii*, vol. xix., which is probably the original of the development that Lagrange makes the basis of his analysis (*Calcul des fonctions*, leçon seconde), and which for simplicity and generality leaves nothing to be desired.

This brings the history down to the close of the last century. We have been as copious as our limits would permit on the early history, because it presents the interesting spectacle of the progress of a science from an almost imperceptible beginning, until it has attained a magnitude too great to be fully grasped by the human mind.

It will be seen from what precedes, that we have not limited "algebra" to the pure science, but have retained the name when it has encroached on the territories of geometry, trigonometry, and the higher analysis. To continue to trace its course through all these branches during the present century, when it has extended into new directions within its own borders, would far exceed the limits of an introductory sketch like the present. We must, therefore, necessarily limit ourselves to what has been done in the Theory of Equations (which may be termed algebra proper), and in Determinants.

*Theory of Equations.*—That every numerical equation Theory has a root—that is, some quantity in a numerical form, real Equation or imaginary, which, when substituted for the unknown quantity in the equation, shall render the equation a numerical identity—appears to have been taken for granted by all writers down to the time of Lagrange. It is by no means self-evident, nor is it easy to afford evidence for it which shall be at the same time convincing and free from limitations. The demonstrations of Lagrange, Gauss, and Ivory, have for simplicity and completeness given way to that of Cauchy, published first in the *Journal de l'École Polytechnique*, and subsequently in his *Cours d'Analyse Algébrique*.

The demonstration of Cauchy (which had previously Cauchy been given by Argand, though in an imperfect form, in *Gergonne's Annales des Mathématiques*, vol. v.) consists in showing that the quantity which it is wished to prove capable of being reduced to zero, can be exhibited as the product of two factors, one of which is incapable of assuming a minimum value, or, in other words, that a less value than one assigned can always be found, and therefore that it is capable of acquiring the value zero. This argument, if not absolutely free from objection, is less objectionable than any of the others. The reader may consult papers by Airy and De Morgan, in the tenth volume of the *Transactions of the Cambridge Philosophical Society*.

Admitting, then, that every equation has a root, it becomes a question to what extent are we in possession of an analysis by which the root can be ascertained. If the question be put absolutely, we fear the answer must be, that in this matter we are in the same position that we have held for the last three centuries. Cubic and biquadratic equations can be solved, whatever they may be; but equations of higher orders, in which there exists no relation amongst the several coefficients, and no known or assumed connection between the different roots, have baffled all

Lagrange.

General solution of the equation of the first and higher orders, a desideratum.

attempts at their solution. Much skill and ingenuity have been displayed by writers of more or less eminence in the attempt to elaborate a method of solution applicable to equations of the fifth degree, but they have failed; whether it be that, like the ancient problems of the quadrature of the circle, and the duplication of the cube, an absolute solution is an impossibility, or whether it is reserved for future mathematicians to start in the research in some new path, and reach the goal by avoiding the old tracks which appear to have been thoroughly traversed in vain.

It is scarcely necessary to refer to such writers as Hocne de Wronski, who, in 1811, announced a general method of solving all equations, giving formulæ without demonstration. In 1817, the Academy of Sciences of Lisbon proposed as the subject of a prize, the demonstration of Wronski's formulæ. The prize was in the following year awarded to M. Torriani for the refutation of them.

The reader will find in the fifth volume of the *Reports of the British Association*, an elaborate report by Sir W. R. Hamilton on a Method of Decomposition, proposed by Mr G. B. Jerrard in his *Mathematical Researches*, published at Bristol in a work of great beauty and originality, but which Hamilton is compelled to conclude fails to effect the desired object. In fact, the method which is valid when the proposed equation is itself of a sufficiently elevated degree, fails to reduce the solution of the equation of the fifth degree to that of the fourth.

But although the absolute solution of equations of higher orders than the fourth remains amongst the things uneffected, and rather to be hoped for than expected, a very great deal has been done towards preparing the way for approximate, if not for absolute solutions.

In the first place, equations of the higher orders, when they assume certain forms, have been shown to be capable of solution. An equation of this kind, to all appearance of a very general and comprehensive form, had been solved by De Moivre in the *Philosophical Transactions* for 1737. Binomial equations had advanced under the skilful hands of Gauss, who, in his *Disquisitiones Arithmeticae*, which appeared in 1801, added largely to what had been done by Vandermonde in the classification and solution of such equations; and subsequently, Abel, a mathematician of Norwegian birth, who died too early for science, completed and extended what Gauss had left imperfect. The collected writings of Abel published at Christiania in 1839, contain original and valuable contributions to this and many other branches of mathematics.

But it is not in the solution of equations of certain forms that the greatest advance has been made during the present century. The basis of all methods of solution must evidently be found in the previous separation of the roots, and the efforts of mathematicians have been directed to the discovery of methods of effecting this. The object is not so much to classify the roots into positive and negative, real and imaginary, as to determine the situation and number of the real roots of the equation. The first writer on the subject whose methods appeared in print is Budan, whose treatise, entitled *Nouvelle méthode pour la résolution des équations numériques*, appeared in 1807. But there is evidence that Fourier had delivered lectures on the subject prior to the publication of Budan's work, and consequently, without detriment to the claims of Budan, we may admit that the most valuable and original contribution to the science is to be found in Fourier's posthumous work, published by Navier in 1831, entitled *Analyse des équations déterminées*. The theorem which Fourier gave for the discovery of the position, within narrow limits, of a root of an equation, is one of two theorems, each of which is known by mathematicians as "Fourier's Theorem." The other is a theorem of integration, and occurs

in the author's magnificent work *Théorie de la Chaleur*. During the interval between the publication of Budan's work and that of Fourier, there appeared a paper in the *Philosophical Transactions of the Royal Society* for 1819, by W. G. Horner, upon a new method of solving arithmetical equations. From its being somewhat obscurely expressed, the great originality of the memoir did not at once appear. Gradually, however, Mr Horner's method came to be appreciated, and it now ranks as one of the best processes, approaching, in some points, to Fourier's. In the *Mémoires des savans étrangers* for 1835, appears a memoir, which, if it does not absolutely supersede all that had been previously done in assigning the positions of the real roots of equations, yet in simplicity, completeness, and universality of application, surpasses them all. The author, M. Sturm, of French extraction, but born at Geneva, has in this memoir linked his name to a theorem which is likely to retain its place amongst the permanent extensions of the domain of analysis as long as the study of algebra shall last. It was presented to the Academy in 1829.

*Determinants*.—The solution of simultaneous equations of the first degree may be presented under the form of a set of fractions, the numerators and denominators of which are symmetric products of the coefficients of the unknown quantities in the equations. These products were originally known as *resultants*, a name applied to them by Laplace, and retained as late as 1841 by Cauchy in his *Exercices d'analyse et de physique mathématique*, vol. ii. p. 161, but now replaced by the title *determinants*, a name first applied to certain forms of them by Gauss. In his *Cours d'analyse algébrique*, Cauchy terms them *alternate functions*. The germ of the theory of determinants is to be found in the writings of Leibnitz, who, indeed, was far-seeing enough to anticipate for it some of the power which, about a century after his time, it began to attain. More than half that period had indeed elapsed before any trace of its existence can be found in the writings of the mathematicians who succeeded Leibnitz. The revival of the method is due to Cramer, who, in a note to his *Analyse des lignes courbes algébriques*, published at Geneva in 1750, gave the rule which establishes the sign of a product as *plus* or *minus*, according as the number of displacements from the typical form has been even or odd. Cramer was followed in the last century by Bézout, Laplace, Lagrange, and Vandermonde. In 1801 appeared the *Disquisitiones Arithmeticae* of Gauss, of which a French translation by M. Poulet-Delisle was given in 1807. Notwithstanding the somewhat obscure form in which this work was presented, its originality gave a new impetus to investigations on this and kindred subjects. To Gauss is due the establishment of the important theorem, that the product of two determinants both of the second and third orders is a determinant. Binet, Cauchy, and others followed, and applied the results to geometrical problems. In 1826, Jacobi commenced a series of papers on the subject in *Crelle's Journal*. In these papers, which extended over a space of nearly twenty years, the subject was recast and made available for ordinary readers; and at the same time it was enriched by new and important theorems, through which the name of Jacobi is indissolubly associated with this branch of science. Following the steps of Jacobi, a number of mathematicians of no mean power have entered the field. Pre-eminent above all others are two British names, those of Sylvester and Cayley. By their originality, by their fecundity, by their grasp of all the resources of analysis, these two powerful mathematicians have enriched the *Transactions of the Royal Society*, *Crelle's Journal*, the *Cambridge and Dublin Mathematical Journal*, and the *Quarterly Journal of Mathematics*, with papers on this and on kindred branches of science of such value as

to have placed their authors at the head of living mathematicians. The reader will find the subject admirably treated in Baltzer's *Theorie und Anwendung der Determinanten*; and more briefly in Salmon's *Higher Algebra*. Elementary treatises have also been published by Spottiswoode in 1851, by Brioschi in 1854, by Todhunter in his *Theory of Equations* in 1861, and by Dodgson in 1867.

The attention of the learned has, during the present century, been called to a branch of the history of algebra, in no small degree interesting; we mean the cultivation of the science to a considerable extent, and at a remote period, in India.

We are indebted, we believe, to Mr Reuben Burrow for some of the earliest notices which reached Europe on this very curious subject. His eagerness to illustrate the history of the mathematical sciences led him to collect oriental manuscripts, some of which, in the Persian language, with partial translations, were bequeathed to his friend Mr Dalby of the Royal Military College, who communicated them to such as took an interest in the subject, about the year 1800.

In the year 1813, Mr Edward Strachey published in this country a translation from the Persian of the *Bija Ganita* (or *Vija Ganita*), a Hindoo treatise on algebra; and in 1816 Dr John Taylor published at Bombay a translation of *Lelavati* (or *Lilavati*), from the Sanscrit original. This last is a treatise on arithmetic and geometry, and both are the production of an oriental algebraist, Bhascara Acharya. Lastly, in 1817, there came out a work entitled *Algebra, Arithmetic, and Mensuration, from the Sanscrit of Brahme-gupta and Bhascara*, translated by Henry Thomas Colebrooke, Esq. This contains four different treatises, originally written in Sanscrit verse, viz., the *Vija Ganita* and *Lilavati* of Bhascara Acharya, and the *Ganitad'haya* and *Cuttaca'Uhyaya* of Brahme-gupta. The first two form the preliminary portion of Bhascara's Course of Astronomy, entitled *Siddhanta Siromani*, and the last two are the twelfth and eighteenth chapters of a similar course of astronomy, entitled *Brahma-siddhanta*.

The time when Bhascara wrote is fixed with great precision, by his own testimony and other circumstances, to a date that answers to about the year 1150 of the Christian era. The works of Brahme-gupta are extremely rare, and the age in which he lived is less certain. Mr Davis, an oriental scholar, who first gave the public a correct view of the astronomical computations of the Hindoos, is of opinion that he lived in the 7th century; and Dr William Hunter, another diligent inquirer into Indian science, assigns the year 628 of the Christian era as about the time he flourished. From various arguments, Mr Colebrooke concludes that the age of Brahme-gupta was antecedent to the earliest dawn of the culture of the sciences among the Arabians, so that the Hindoos must have possessed algebra before it was known to that nation.

Brahme-gupta's treatise is not, however, the earliest work known to have been written on this subject. Ganessa, a distinguished astronomer and mathematician, and the most eminent scholiast of Bhascara, quotes a passage from a much older writer, Arya-Bhatta, specifying algebra under the designation of *Vija*, and making separate mention of *Cuttaca*, a problem subservient to the resolution of indeterminate problems of the first degree. He is understood by another of Bhascara's commentators to be at the head of the older writers. They appear to have been able to resolve quadratic equations by the process of completing the square; and hence Mr Colebrooke presumes that the treatise of Arya-Bhatta then extant extended to quadratic equations in the determinate analysis, and to indeterminate

equations of the first degree, and probably to those of the second.

The exact period when Arya-Bhatta lived cannot be determined with certainty; but Mr Colebrooke thinks it probable that this earliest of known Hindoo algebraists wrote as far back as the fifth century of the Christian era, and perhaps earlier. He lived therefore nearly as early as the Grecian algebraist Diophantus, who is reckoned to have flourished in the time of the emperor Julian, or about A.D. 360.

Mr Colebrooke has instituted a comparison between the Indian algebraist and Diophantus, and found reason to conclude that in the whole science the latter is very far behind the former. He says the points in which the Hindoo algebra appears particularly distinguished from the Greek are, besides a better and more convenient algorithm, 1st, the management of equations of more than one unknown quantity; 2d, the resolution of equations of a higher order, in which, if they achieved little, they had at least the merit of the attempt, and anticipated a modern discovery in the resolution of biquadratics; 3d, general methods for the resolution of indeterminate problems of the first and second degrees, in which they went far indeed beyond Diophantus, and anticipated discoveries of modern algebraists; and 4th, the application of algebra to astronomical investigations and geometrical demonstration, in which also they hit upon some matters which have been re-invented in modern times.

When we consider that algebra made little or no progress among the Arabians, a most ingenious people, and particularly devoted to the study of the sciences, and that centuries elapsed from its first introduction into Europe until it reached any considerable degree of perfection, we may reasonably conjecture that it may have existed in one shape or other in India long before the time of Arya-Bhatta; indeed, from its close connection with their doctrines of astronomy, it may be supposed to have descended from a very remote period along with that science. Professor Playfair, adopting the opinion of Bailly, the eloquent author of the *Astronomie Indienne*, with great ingenuity attempted to prove, in a *Memoir on the Astronomy of the Brahmans*, that the observations on which the Indian astronomy is founded were of great antiquity, indeed more than 3000 years before the Christian era. The very remote origin of the Indian astronomy had been strongly questioned by many in this country, and also on the Continent; particularly by Laplace, and by Delambre in his *Histoire de l'Astronomie Ancienne*, tome i. p. 400, &c., and again in *Histoire de l'Astronomie du Moyen Age, Discours Préliminaire*, p. 18, &c., where he speaks slightly of their algebra; and in this country, Professor Leslie, in his *Philosophy of Arithmetic*, pp. 225 and 226, calls the *Lilavati* "a very poor performance, containing merely a few scanty precepts couched in obscure memorial verses." We are disposed to agree with Professor Leslie as to the value, and with Professor Playfair as to the antiquity of this Hindoo algebra. That it should have remained in a state of infancy for so many centuries is accounted for by the latter author in the following passage:—"In India everything [as well as algebra] seems equally insurmountable, and truth and error are equally assured of permanence in the stations they have once occupied. The politics, the laws, the religion, the science, and the manners, seem all nearly the same as at the remotest period to which history extends. Is it because the power which brought about a certain degree of civilisation, and advanced science to a certain height, has either ceased to act, or has met with such a resistance as it is barely able to overcome? or is it because the discoveries which the Hindoos are in possession of are an inheritance from some more inventive and more ancient

people, of whom no memorial remains but some of their attainments in science?"

*Writers on Algebra.*

- Diophantus, *Arithmetico-rum Libri sex*, about A.D. 360 (First edition of his writings, 1575; the best, 1670.)
- Leonardo Bonacci (his works described in Cossali) .....1202

NOTATION AND FIRST PRINCIPLES.

1. In arithmetic there are ten characters, which being variously combined, according to certain rules, serve to denote all numerical magnitudes whatever. But this method of expressing quantities (a phrase used to designate

something more than mere numbers), is found to be inadequate, taken by itself, to the more difficult cases of mathematical investigation; and it is therefore necessary, in many inquiries concerning the relations of magnitude, to have recourse to that more general mode of notation, and more extensive system of operations, which constitute the science of algebra.

In algebra quantities of every kind may be denoted by any characters whatever, but those commonly used are the letters of the alphabet; and as in the simplest mathematical problems there are certain magnitudes given, in order to determine other magnitudes which are unknown, the first letters of the alphabet, *a, b, c, &c.*, are used to denote known quantities, while those to be found are represented by *v, x, y, &c.*, the last letters of the alphabet.

2. The sign + (*plus*) denotes, in arithmetic, that the quantity before which it is placed is to be added to some other quantity. Thus,  $a + b$  denotes the sum of *a* and *b*;  $3 + 5$  denotes the sum of 3 and 5, or 8.

The sign - (*minus*) signifies that the quantity before which it is placed is to be subtracted. Thus,  $a - b$  denotes the excess of *a* above *b*;  $6 - 2$  is the excess of 6 above 2, or 4.

Quantities which have the sign + prefixed to them are called *positive*, and such as have the sign - are called *negative*.

When no sign is prefixed to a quantity, + is always understood, or the quantity is to be considered as positive.

Quantities which have the same sign, either + or -, are said to have like signs. Thus,  $+a$  and  $+b$  have like signs, but  $+a$  and  $-c$  have unlike signs.

3. A quantity which consists of one *term* is said to be *simple*; but if it consist of several terms, connected by the signs + or -, it is then said to be compound. Thus,  $+a$  and  $-c$  are simple quantities; and  $b + c$ , and  $a + b - d$ , are compound quantities.

4. To denote the product arising from the multiplication of quantities, they are either joined together, as if intended to form a word, or else they are connected together, with the sign  $\times$  or  $\cdot$  interposed between every two of them. Thus,  $ab$ , or  $a \times b$ , or  $a \cdot b$ , denotes the product of *a* and *b*; also  $abc$ , or  $a \times b \times c$ , or  $a \cdot b \cdot c$ , denotes the product of *a, b, and c*. If some of the quantities to be multiplied be compound, each of these has a line drawn over it called a vinculum, and the sign  $\times$  is interposed, as before. Thus,  $a \times c + d \times e - f$  denotes that *a* is to be considered as one quantity, the sum of *c* and *d* as a second, and the difference between *e* and *f* as a third; and that these three quantities are to be multiplied into one another. Instead of placing a line over such compound quantities as enter a product, we may enclose each of them between two parentheses, so that the last product may be otherwise expressed thus,  $a(c + d)(e - f)$ ; or thus,  $a \times (c + d) \times (e - f)$ .

A number prefixed to a letter is called a *numerical coefficient*, and denotes how often that quantity is to be taken. Thus,  $3a$  signifies that *a* is to be taken three times. When no number is prefixed, the coefficient is understood to be unity.

5. The quotient arising from the division of one quantity by another is often expressed by placing the *dividend* above a line, and the *divisor* below it. Thus,  $\frac{12}{3}$  denotes the quotient arising from the division of 12 by 3, or 4;  $\frac{b}{a}$  denotes the quotient arising from the division of *b* by *a*.

6. The equality of two quantities is expressed by putting the sign = between them. Thus,  $a + b = c - d$  denotes that the sum of *a* and *b* is equal to the excess of *c* above *d*.

7. Simple quantities, or the terms of compound quantities, are said to be *like*, which consist of the same letter or letters taken together in the same way. Thus,  $+ab$  and  $-5ab$  are like quantities, but  $+ab$  and  $+abb$  are unlike.

There are some other characters, such as  $>$  for *greater than*,  $<$  for *less than*,  $\therefore$  for *therefore*, which will be explained when we have occasion to use them; and in what follows we shall suppose that the operations and notation of common arithmetic are sufficiently understood.

8. As the science extends itself beyond its original boundaries, it begins gradually to appear that the limits imposed by these definitions have been transgressed, so that almost insensibly the symbols have acquired for themselves significations much more comprehensive than those originally attached to them. Thus, were  $+a$  to signify a gain of £*a*,  $-a$  would signify a loss of the same sum; were  $+a$  to signify motion *forwards* through *a* feet,  $-a$  would signify motion *backwards* through the same space. The extended definitions of + and - may now be such as the following: + and - are *collective* symbols of operations the reverse of each other. From similar considerations to those by which the signification of + and - has been extended, we extend that of  $\times$  and  $\div$  to something like the following:  $\times$  and  $\div$  are *cumulative* symbols of operations the inverse of each other. We may now exhibit the most general definition of the four symbols in the following form: + and - are symbols of operations prefixed to algebraical symbols of quantity, and are such that  $+a - a = +0$  or  $-0$ , where  $+0$  means simply or very nearly *increased* by 0;  $-0$ , *diminished* by 0.  $\times$  and  $\div$  are symbols of operations prefixed to algebraical symbols of quantity, and are such that  $\times a \div a = \times 1$  or  $\div 1$ , where  $\times 1$  means simply or very nearly *multiplied* by 1;  $\div 1$ , *divided* by 1.

9. The laws by which the symbols are combined are the same as in arithmetic. It is desirable, however, to exhibit them. They are three,—

LAW I. Quantities affected by the signs + and - are in no way influenced by the quantities to which they are united by these signs.

LAW II. *The Distributive Law*.—Additions and subtractions may be performed in any order.

LAW III. *The Commutative Law*.—Multiplications and divisions may be performed in any order.

We may remark that these laws are *assumed* for algebra, so that the science is limited by their applicability. Algebra has been extended into the science of quaternions by freeing it from part of the limitation imposed by the third of these laws. In this new science  $ab$  is *not* the same thing as  $ba$ .

We add a few examples of the substitution of numbers for letters. (*Ex.* 3 and 4 involve processes that will be explained later.)

*Ex.* 1. If  $a = 1, b = 2, c = 3$ , find the value of  $(a + b + c) \cdot (a + 2b - c) \cdot (b + 2c - a)$ .

It is  $(1 + 2 + 3) \cdot (1 + 4 - 3) \cdot (2 + 6 - 1) = 84$ .

*Ex.* 2. If  $a = \frac{1}{2}, b = \frac{1}{3}, c = \frac{1}{4}, x = 0$  find the value of  $\frac{a}{b} + \frac{b}{c} + \frac{c}{a} + x^2$

It is  $\frac{3}{2} + \frac{4}{3} + \frac{1}{2} + 0 = 3\frac{1}{3}$

*Ex.* 3. With the same data as in example 2, find the value of  $\frac{a^2 - b^2}{x} - \frac{b^2 - c^2}{x^2}$

The first term is infinite, and the second is infinitely greater than the first, because  $x^2 = x \times x \therefore$  the answer is  $-\infty$ .

*Ex.* 4. If  $x = \frac{1}{y} = \frac{1}{z} = 0$ ; find the value of

$$2xy - \frac{z}{2x} + \frac{x}{z} + \frac{2y}{x} - \frac{3}{2} \left( \frac{x}{z} + y \right) \left( \frac{x}{y} + z \right).$$

definitions of signs.

Extension of definitions.

Laws of combination.

Examples.

Write down the expression in  $x$  by putting  $\frac{1}{x}$  for  $y$ , &c.  
 It becomes  

$$2 - \frac{1}{2x^2} + x^2 + \frac{2}{x^2} - \frac{3}{2} \left( x^2 + \frac{1}{x} \right) \left( x^2 + \frac{1}{x} \right)$$

$$= 2 + \frac{3}{2} \frac{1}{x^2} + x^2 - \frac{3}{2} \frac{1}{x^2} + \text{\&c.}$$

$$= 2 \cdot \text{because } x=0.$$

SECT. I.—FUNDAMENTAL OPERATIONS.

The primary operations in algebra are the same as in common arithmetic—namely, addition, subtraction, multiplication, and division; and from the various combinations of these four, all the others are derived.

I. Addition.

10. In addition there may be three cases: the quantities to be added may be like, and have like signs; or they may be like, and have unlike signs; or, lastly, they may be unlike.

Case 1. To add quantities which are like, and have like signs.

Rule. Add together the coefficients of the quantities, prefix the common sign to the sum, and annex the letter or letters common to each term.

EXAMPLES.

Add together $\left\{ \begin{array}{l} + 7a \\ + 3a \\ + a \\ + 2a \end{array} \right.$	Add together	$\left\{ \begin{array}{l} - 2ax \\ - ax \\ - 5ax \\ - 12ax \end{array} \right.$
Sum, $+13a$		Sum, $-20ax$

Case 2. To add quantities which are like, but have unlike signs.

Rule. Add the positive coefficients into one sum, and the negative ones into another; then subtract the less of these sums from the greater, prefix the sign of the greater to the remainder and annex the common letter or letters as before

EXAMPLES.

Add together $\left\{ \begin{array}{l} + 2ax \\ - ax \\ - 3ax \\ + 9ax \end{array} \right.$	Add together	$\left\{ \begin{array}{l} + 6ab + 7 \\ - 4ab + 9 \\ + ab - 5 \\ + 7ab - 13 \end{array} \right.$
Sum of the pos. $+11ax$	Sum of the pos. $+14ab + 16$	
Sum of the neg. $-4ax$	Sum of the neg. $-4ab - 18$	
Sum required, $+7ax$	Sum required, $+10ab - 2$	

Case 3. To add unlike quantities.

Rule. Put down the quantities, one after another, in any order, with their signs and coefficients prefixed.

EXAMPLES.

$2a$	$ax + 2ay$
$3b$	$bb - 3bz$
$-4c$	
Sum, $2a + 3b - 4c$	Sum, $ax + 2ay + bb - 3bz$

II. Subtraction.

11. General Rule.—Change the signs of the quantities to be subtracted, or suppose them changed, and then add them to the other quantities, agreeably to the rules of addition.

EXAMPLES

From $5a - 12b$	From $6x - 8y + 3$
Subtract $2a - 5b$	Subtract $2x + 9y - 2$
Remainder $3a - 7b$	Remainder $4x - 17y + 5$
$5xy - 2 + 8x - y$	$aa - ax - yy$
$3xy - 8 - 8x - 3y$	$bb - by + zz$
$2xy + 6 + 16x + 2y$	$aa - ax - yy - bb + by - zz$

The reason of the rule for subtraction may be explained thus. Let it be required to subtract  $2p - 3q$  from  $m + n$ . If we subtract  $2p$  from  $m + n$ , there will remain  $m + n - 2p$ , but if we are to subtract  $2p - 3q$ , which is less than  $2p$ , it is evident that the remainder will be greater by a quantity equal to  $3q$ ; that is, the remainder will be  $m + n - 2p + 3q$ , hence the reason of the rule is evident.

III. Multiplication.

12. General Rule for the Signs.—If the quantities to be multiplied have like signs, the sign of the product is +; but if they have unlike signs, the sign of the product is -.

This rule, which is given by Diophantus<sup>1</sup> as the definition of + and -, may be said to constitute the basis of algebra as distinct from arithmetic.

If we admit the definitions given above, the rule may be demonstrated in the following way:—

(1.)  $+a \times +b = +ab$  is assumed.

(2.)  $+a \times -b$  will have the same value, whatever  $-b$  may be connected with, as it has when  $-b$  is connected with  $+b$  (Law 1).

Now  $+a \times (+b - b) = +a \times +0 = 0$  (Def.)

But  $+a \times (+b - b) = +a \times +b$ , and  $+a \times -b$  (Law 2).

$\therefore +a \times +b$  and  $+a \times -b$  make up 0.

i.e.,  $+ab$  and  $+a \times -b$  make up 0.

Now  $+ab - ab = 0$ ,  $\therefore +a \times -b = -ab$ .

(3.) Similarly  $-a \times -b = +ab$ .

The examples of multiplication may be referred to two cases; the first is when both the quantities are simple, and the second when one or both of them are compound.

Case 1. To multiply simple quantities.

Rule. Find the sign of the product by the general rule, and annex to it the product of the numeral coefficients; then set down all the letters, one after another, as in one word.

EXAMPLES.

1. Multiply $+a$	2. $\left\{ \begin{array}{l} + 5b \\ - 4a \end{array} \right.$	3. $\left\{ \begin{array}{l} - 3ax \\ + 7ab \end{array} \right.$
By $+c$		
Product $+ac$	$-20ab$	$-21aabx$

Case 2. To multiply compound quantities.

Rule. Multiply every term of the multiplicand by all the terms of the multiplier, one after another, according to the preceding rule, and collect their products into one sum, which will be the product required.

EXAMPLES.

1. Mult. $2x + y$	2. $a - b + c$
By $x - 2y$	$a + b - c$
Prod. $2xx + xy$	$aa - ab + ac$
$-4xy - 2yy$	$+ab - bb + bc$
$2xx - 3xy - 2yy$	$-ac + bc - cc$
	$aa * * - bb + 2bc - cc$

<sup>1</sup> Λιψης: ἰπὶ λιψίν παλαιαπλασιασθῆσα, ποιῶ ὑπαρξῶν λιψίς δι' ἰπὶ ὑπαρξῶν ποιῶ λιψίη.—Diophantus, Ed. Fermat, Tolosa, 1670, p. 7, Def. 9.

When several quantities are multiplied together so as to constitute a product, each of them is called a *factor* of that product: thus  $a$ ,  $b$ , and  $c$  are factors of the product  $abc$ ; also,  $a+x$  and  $b-x$  are factors of the product  $(a+x)(b-x)$ .

The products arising from the continual multiplication of the same quantity are called *powers* of that quantity, which is called the *root*. Thus  $aa$ ,  $aaa$ ,  $aaaa$ , &c., are powers of the root  $a$ . These powers are commonly expressed by placing above the root, towards the right hand, a figure, denoting how often the root is repeated. This figure serves to denominate the power, and is called its *index* or *exponent*. Thus, the quantity  $a$  being considered as the root, or as the first power of  $a$ , we have  $aa$  or  $a^2$  for its second power,  $aaa$  or  $a^3$  for its third power,  $aaaa$  or  $a^4$  for its fourth power, and so on.

The second and third powers of a quantity are generally called its *square* and *cube*.

By considering the notation of powers, and the rules for multiplication, it appears that powers of the same root are multiplied by adding their exponents. Thus  $a \times a^3 = a^4$ , also  $x^3 \times x^4 = x^7$ ; and in general  $a^m \times a^n = a^{m+n}$ .

When the quantities to be multiplied appear under a symmetrical form, the operation of multiplying them may sometimes be shortened by *detached coefficients*, by *symmetry*, and by *general considerations* suggested by the particular examples under consideration.

13. *Detached Coefficients.*

*Ex. 1.* Multiply  $x^4 - 3x^3 + 2x^2 - 7x + 3$  by  $x^2 - 5x + 4$ . Here the powers of  $x$  occur in regular order, so that we need only write down the coefficients of the several terms during the operation, having it in our power to supply the  $x$ 's whenever we require them; we write, therefore,—

$$\begin{array}{r} 1-3+2-7+3 \\ 1-5+4 \\ \hline 1-3+2-7+3 \\ -5+15-10+35-15 \\ +4-12+8-28+12 \\ \hline 1-8+21-29+46-43+12 \end{array}$$

The last line (for which the result might have been written down in full at once) is equivalent to

$$x^6 - 8x^5 + 21x^4 - 29x^3 + 46x^2 - 43x + 12.$$

When any terms are wanting, they may be supplied by zeros; thus,

*Ex. 2.* Multiply  $x^4 - 7x^3 + x - 1$  by  $x^3 - x + 2$ .

We write

$$\begin{array}{r} 1-7+0+1-1 \\ 1+0-1+2 \\ \hline 1-7+0+1-1 \\ -1+7-0-1+1 \\ +2-14+0+2-2 \\ \hline x^7-7x^6-x^5+10x^4-15x^3-x^2+3x-2 \end{array}$$

the product required.

14. *Symmetry.*

We may take advantage of symmetry by two considerations either separately or combined.

(1.) *Symmetry of a Symbol.*

*Ex.* Find the sum of  $(a+b-2c)^2 + (a+c-2b)^2 + (b+c-2a)^2$ .

Here  $a^2$  occurs with 1 as a multiplier in the first square, with 1 as a multiplier in the second square, and with 4 as a multiplier in the third square,

$\therefore 6a^2$  is part of the result;

$ab$  occurs with 2 as a multiplier in the first square, with  $-4$  in the second, and with  $-4$  in the third

$\therefore -6ab$  is part of the result.

But  $a^2$ ,  $b^2$ ,  $c^2$ , are similarly circumstanced, as also  $ab$ ,  $ac$ ,  $bc$ ; hence the whole result must be  $6(a^2+b^2+c^2-ab-ac-bc)$ .

(2.) *Symmetry of an Expression.*

*Ex.* Find the sum of  $(a+b+c)(x+y+z) + (a+b-c)(x+y-z) + (a-b+c)(x-y+z) + (-a+b+c)(-x+y+z)$ ;

First, the product of  $(a+b+c)$  by  $x+y+z$  is to be found by multiplying out term by term.

It is  $ax+ay+az+bx+by+bz+cx+cy+cz$ .

The product of  $(a+b-c)(x+y-z)$  is now simply written down from the above, (by changing the sign of every term which contains *one only* of the two quantities affected with a  $-$  sign, i.e., in this case  $c$  and  $z$ .)

Lastly, the four products may be arranged below each other, the signs alone being written down; thus,

$$\begin{array}{cccccccc} ax+ay+az+bx+by+bz+cx+cy+cz \\ + & + & - & + & - & - & - & + \\ + & - & + & - & + & - & + & - \\ + & - & - & - & + & + & - & + \end{array}$$

and the sum required is therefore  $4ax+4by+4cz$ .

15. *General Considerations.*

*Ex.* Find  $(a+b+c)^3$ .

By multiplying out we get

$$(a+b+c)^3 = a^3 + 3a^2b + \dots$$

Now  $a$ ,  $b$ ,  $c$  are similarly involved in  $(a+b+c)^3$ ;  $\therefore b^3$  and  $c^3$  must appear along with  $a^3$ ,  $3a^2c$ ,  $3b^2a$ , &c., along with  $3a^2b$ , and hence we can at once write down all the terms except that which contains  $abc$ . To obtain the coefficient of  $abc$ , we observe that if  $a$ ,  $b$ , and  $c$ , are each equal to 1,  $(a+b+c)^3$  is reduced to  $3^3$  or 27. In other words, there are 27 terms, if we consider  $3a^2b$  and every similar expression as three terms; and as the terms preceding  $abc$  are in this way found to be 21 in number, we require  $6abc$  to make up the full number 27;

$$\therefore (a+b+c)^3 = a^3 + b^3 + c^3 + 3a^2b + 3a^2c + 3b^2a + 3b^2c + 3c^2a + 3c^2b + 6abc.$$

It is desirable to introduce here some examples of the application of the process of the substitution of a letter for any number or fraction to the properties of numbers, inequalities, &c.

16. *Properties of Numbers.*

*Ex. 1.* If unity is divided into any two parts, the difference of their squares is equal to the difference of the parts themselves.

Let  $x$  stand for one part;  $1-x$  for the other.

Now  $(1-x)^2 - x^2 = 1 - 2x + x^2 - x^2 = 1 - 2x = (1-x) - x$ . i.e., the difference of the squares of the parts is equal to the difference of the parts.

*Ex. 2.* The product of three consecutive even numbers is divisible by 48.

Let  $2n$ ,  $2n+2$ ,  $2n+4$ , be the three numbers.  $\therefore$  their product is  $8n(n+1)(n+2)$ . Now, of three consecutive numbers,  $n$ ,  $n+1$ ,  $n+2$ , one must be divisible by 2, and one by 3,  $\therefore n(n+1)(n+2)$  is divisible by 6, whence the product is.

*Ex. 3.* The sum of the squares of three consecutive odd numbers, when increased by 1, is divisible by 12, but never by 24.

Let  $2n-1$ ,  $2n+1$ ,  $2n+3$ , be the three odd numbers.

The sum of their squares when increased by 1 is  $12n^2 + 12n + 12 = 12(n^2 + n + 1) = 12(n \cdot \overline{n+1} + 1)$ .

Now, either  $n$  or  $n+1$  is even,  $\therefore n(n+1)+1$  is odd; hence the sum under consideration is 12 times an odd number, whence the proposition.

*Additional Examples in Symmetry, &c.*

Ex. 1.  $(a+b+c)^2 + (a+b-c)^2 + (a+c-b)^2 + (b+c-a)^2 = 4(a^2 + b^2 + c^2)$ .

This is written down at once, from observing that  $a^2$  occurs in each of the four expressions, and that  $2ab$  occurs with a + sign in two, and with a - sign in the other two. There is no other form.

Ex. 2.  $(a+b+c)^3 + (a+b-c)^3 + (a+c-b)^3 + (b+c-a)^3 = 2(a^3 + b^3 + c^3) + 6(a^2b + a^2c + b^2a + b^2c + c^2a + c^2b) - 12abc$ .

1st,  $a^3$  occurs + in three, and - in one term.

2d,  $3a^2b$  occurs + in three, and - in one term.

3d, When  $a, b, c$  are all units, the number resulting is 30;  $\therefore$  there are 30 terms, and as (1st) and (2d) make up 42, there fall to be subtracted 12, i.e., the coefficient of  $abc$  is -12.

Ex. 3.  $(ax+by+cz)^2 + (ax+cy+bz)^2 + (bx+ay+cz)^2 + (bx+cy+az)^2 + (cx+ay+bz)^2 + (cx+by+az)^2 = 2(a^2 + b^2 + c^2)(x^2 + y^2 + z^2) + 4(ab+ac+bc)(xy+xz+yz)$ .

Ex. 4. The difference of the squares of two consecutive numbers is equal to the sum of the numbers.

Ex. 5. The sum of the cubes of three consecutive numbers is divisible by the sum of the numbers.

Ex. 6. If  $x$  is an odd number,  $x^5 - x$  is divisible by  $24$ , and  $(x^2+3)(x^2+7)$  by 32.

Ex. 7. If  $(pq-r)^2 + 4(p^2-q)(pr-q)^2 = 0$ , then will  $4(p^2-q)^3 = (2p^2-3pq+r)^2$ , and  $4(q^2-pr)^3 = (2q^2-3pqr+r^2)^2$ .

Ex. 8. Given  $x+y+z=0, X+Y+Z=0$ , to prove that  $(x^2+X^2)yz + (y^2+Y^2)zx + (z^2+Z^2)xy = (x^2+X^2)YZ + (y^2+Y^2)ZX + (z^2+Z^2)XY$ .

Let the left hand side equal the right +  $u$ ; then multiplying out,

$$\begin{aligned} &xyz(x+y+z) + X^2yz + Y^2zx + Z^2xy = \\ &XYZ(X+Y+Z) + x^2YZ + y^2ZX + z^2XY + u, \\ \text{i.e.,} & \quad X^2yz + Y^2zx + (X+Y)^2xy = \\ & \quad x^2YZ + y^2ZX + (x+y)^2XY + u, \\ \text{or,} & \quad X^2y(z+x) + Y^2x(z+y) = \\ & \quad x^2Y(Z+X) + y^2X(Z+Y) + u, \\ \text{or,} & \quad -X^2y^2 - Y^2x^2 = -x^2Y^2 - y^2X^2 + u \\ & \quad \therefore u = 0. \end{aligned}$$

Ex. 9. If  $4a^2b^2c^2(x^2+y^2+z^2)(a^2x^2+b^2y^2+c^2z^2) = \{(b^2+c^2)a^2x^2 + (c^2+a^2)b^2y^2 + (a^2+b^2)c^2z^2\}^2$ ,

when  $a$  is greater than  $b$ , and  $b$  greater than  $c$ ; then is  $y=0$ . As the argument concerns  $y$ , multiply out, and arrange in order of powers of  $y$ . After reduction this results in

$$(a^2-c^2)b^4y^4 + 2\{(a^2-c^2)(b^2-c^2)a^2x^2 + (a^2-c^2)(a^2-b^2)c^2z^2\}b^2y^2 + \{(b^2-c^2)a^2x^2 - (a^2-b^2)c^2z^2\}^2 = 0.$$

Now each of these three terms is a positive quantity, if it be not zero, and as the sum of three positive quantities cannot be equal to zero, it follows that each term must be separately equal to zero,

i.e.,  $y=0$ , and  $(b^2-c^2)a^2x^2 = (a^2-b^2)c^2z^2$ .

17. Inequalities.

The demonstrations of inequalities are of so simple and instructive a character, that a somewhat lengthened exhibition of them forms a valuable introduction to the higher processes of the science. In all that follows under this head, the symbols  $x, y, z$  stand for positive numbers or fractions, usually unequal.

Ex. 1.  $x^2 + y^2 > 2xy$ .

Because  $(x-y)^2$  is +, whether  $x$  be greater or less than  $y$ , it follows that  $x^2 - 2xy + y^2$  is +, i.e., is some positive number or fraction,

$$\therefore x^2 + y^2 > 2xy.$$

It will be remarked that when  $x$  and  $y$  are equal, the inequality rises into an equality, and this is common to all inequalities of the character under discussion.

Cor.  $\frac{x}{y} + \frac{y}{x} > 2$ ; i.e., the sum of a fraction and its reciprocal is greater than 2.

Ex. 2.  $x^2 + y^2 + z^2 > xy + xz + yz$ .

For  $x^2 + y^2 > 2xy, x^2 + z^2 > 2xz, y^2 + z^2 > 2yz$ ; which being added and divided by 2, gives the result required.

Ex. 3.  $x^{m+n} + y^{m+n} > x^m y^n + x^n y^m$ .

For  $(x^m - y^m)(x^n - y^n)$  is +, whether  $x$  be greater or less than  $y$ .

As a particular case  $x^3 + y^3 > x^2y + xy^2$ .

Ex. 4.  $x^{2n} + 1 > x^{2n-2r} + x^{2r}$ .

For  $(x^{2n-2r} - 1)(x^{2r} - 1)$  is positive.

Cor. 1.  $x^n + \frac{1}{x^n} > x^{n-2r} + \frac{1}{x^{n-2r}}$ .

Cor. 2. Similarly,  $x^n + \frac{1}{x^n} > x^{n-1} + \frac{1}{x^{n-1}}$ ,

i.e., as  $n$  increases  $x^n + \frac{1}{x^n}$  increases,  $\therefore$  as a particular case

$$x^n + \frac{1}{x^n} > x + \frac{1}{x}.$$

Ex. 5. If  $a, b, c$  are the sides of a triangle,  $a^2 + b^2 + c^2 > ab + ac + bc < 2(ab + ac + bc)$ . The former inequality is proved in example 2. For the latter we have

(Euclid, I. 20),  $a < b + c \therefore a^2 < ab + ac$ .

Similarly,  $b^2 < ab + bc, c^2 < ac + bc$ .

$$\therefore a^2 + b^2 + c^2 < 2(ab + ac + bc).$$

Ex. 6. The arithmetic mean of any number of quantities (all positive) is greater than the geometric.

(The arithmetic mean is the sum of the quantities divided by their number; the geometric is that root of their product which is represented by their number.) Let the quantities be denoted by  $x_1, x_2, x_3, \dots, x_n$ , the numbers 1, 2, 3, placed under the  $x$ , indicating order only, so that  $x_1$  may be read the first  $x, x_2$  the second  $x$ , &c. Example 1 gives  $\frac{x_1+x_2}{2} > \sqrt{x_1x_2}$ , if we suppose the  $x$  and  $y$  of that example to be  $\sqrt{x_1}, \sqrt{x_2}$  of the present.

$$\begin{aligned} \text{It also gives } \frac{x_1+x_2}{2} + \frac{x_3+x_4}{2} &> \sqrt{\frac{x_1+x_2}{2} \cdot \frac{x_3+x_4}{2}} \\ &> \sqrt{\sqrt{x_1x_2} \cdot \sqrt{x_3x_4}} \\ &> \sqrt[4]{x_1x_2x_3x_4} \end{aligned}$$

In the same way we prove the proposition for 8, 16, or any number of quantities which is a power of 2.

For any other number, such, for instance, as 5, the following process is employed:—The number is made up to 8 by the insertion of three quantities, each equal to the arithmetic mean of the other five, viz.,  $\frac{x_1+x_2+x_3+x_4+x_5}{5}$ .

Call this quantity  $y$ ; then

$$\frac{x_1+x_2+\dots+x_5+3y}{8} > \sqrt[8]{x_1x_2\dots x_5yyy}$$

i.e.,  $\frac{8y}{8} > \sqrt[8]{x_1x_2\dots x_5y^3}$

or,  $y^5 > x_1x_2\dots x_5y^3$

$$\therefore y^2 > x_1 x_2 \dots x_3$$

$$\therefore y \text{ or } \frac{x_1 + x_2 + \dots + x_3}{5} > \sqrt[5]{x_1 x_2 x_3 x_4 x_5}$$

Cor. As a particular case,  $x^3 + y^3 + z^3 > 3xyz$ .

Ex. 7. Given  $x_1 x_2 \dots x_n = y^n$ , to prove that  $(1 + x_1)(1 + x_2) \dots (1 + x_n) > (1 + y)^n$ .

The demonstration will be perfectly general in fact, though limited in form, if we suppose the number of quantities to be 5; in which case,

$$x_1 x_2 \dots x_5 = y^5$$

Make the number up to 8 by introducing three  $y$ 's; then

$$(1 + x_1)(1 + x_2) > (1 + \sqrt{x_1 x_2})^2 \text{ by example 1.}$$

$$(1 + x_3)(1 + x_4) > (1 + \sqrt{x_3 x_4})^2$$

$$(1 + x_5)(1 + y) > (1 + \sqrt{x_5 y})^2$$

$$(1 + y)(1 + y) = (1 + \sqrt{yy})^2$$

$\therefore$  Multiplying these products together, and combining the right hand factors two and two,

$$(1 + x_1)(1 + x_2) \dots (1 + x_5)(1 + y)^3$$

$$> \{(1 + \sqrt{x_1 x_2})(1 + \sqrt{x_3 x_4})(1 + \sqrt{x_5 y})(1 + y)\}^2$$

$$> \{(1 + \sqrt[4]{x_1 x_2 x_3 x_4})(1 + \sqrt[4]{x_5 y^3})\}^4$$

$$> (1 + \sqrt[8]{x_1 x_2 x_3 x_4 x_5 y^3})^8$$

$$> (1 + y)^8$$

$$\therefore (1 + x_1)(1 + x_2) \dots (1 + x_5) > (1 + y)^5$$

Ex. 8. If the sum of  $n$  fractions makes up 1, the sum of their reciprocals is greater than the square of their number.

Let  $x_1 + x_2 + \dots + x_n = 1$ ,

then,  $\frac{1}{x_1} + \frac{1}{x_2} + \dots + \frac{1}{x_n} > n \sqrt[n]{\frac{1}{x_1 x_2 \dots x_n}}$  (example 6).

But  $\sqrt[n]{x_1 x_2 \dots x_n} < \frac{x_1 + x_2 + \dots + x_n}{n}$  (example 6)  $< \frac{1}{n}$

$$\therefore \sqrt[n]{\frac{1}{x_1 x_2 \dots x_n}} > n,$$

whence  $\frac{1}{x_1} + \frac{1}{x_2} + \dots + \frac{1}{x_n} > n^2$ .

$$\text{Ex. 9. } \frac{1 + x^2 + x^4 + \dots + x^{2n}}{x + x^3 + \dots + x^{2n-1}} < \frac{n+1}{2n} \left(x^n + \frac{1}{x^n}\right) > \frac{n+1}{2n} \left(x + \frac{1}{x}\right)$$

Let the numerator and denominator of this fraction be designated by N and D. N may be divided into pairs of terms, at the same distance from either end, viz.,  $1 + x^{2n}$ ,  $x^2 + x^{2n-2}$ , &c., with or without a middle term, each of which (after  $1 + x^{2n}$ ) is, by example 4, less than that quantity; the middle term, if there be one, being less than

$$\frac{1}{2} (1 + x^{2n}),$$

$$\therefore \text{ in either case } N < \frac{n+1}{2} (1 + x^{2n}) \dots \quad (1)$$

$$\text{Again (example 6), } D > n \sqrt[n]{x x^3 \dots x^{2n-1}} > n x^n \dots \quad (2)$$

$$\therefore \text{ the fraction } \frac{N}{D} < \frac{n+1}{2n} \left(x^n + \frac{1}{x^n}\right)$$

To prove the second proposition, that the fraction is greater than  $\frac{n+1}{2n} \left(x + \frac{1}{x}\right)$ , it is only necessary to multiply up and reduce the result; thus,

$$\frac{n+1}{2n} \left(x + \frac{1}{x}\right) (x + x^3 + \dots + x^{2n-1})$$

$$= \frac{n+1}{2n} (2N - 1 - x^{2n})$$

$$< \frac{n+1}{n} N - \frac{N}{n} \text{ (by 1)}$$

$$< N.$$

Whence the proposition.

Additional Examples.

Ex. 1.  $(x + y + z)^2 < 3(x^2 + y^2 + z^2)$ , and generally,  $(x + y + z)^n < 3^{n-1}(x^n + y^n + z^n)$ . (See Induction.)

Ex. 2.  $(x + y)(y + z)(z + x) > 8xyz < \frac{8}{3}(x^3 + y^3 + z^3)$ .

Ex. 3.  $(x^2 + y^2 + z^2) > xyz(x + y + z)$ .

Ex. 4.  $(a^2 + b^2 + c^2)(x^2 + y^2 + z^2) > (ax + by + cz)^2$ .

Ex. 5. The arithmetic mean of the  $p$ th powers of  $n$  positive quantities is greater than the  $p$ th power of their mean, and also greater than the mean of their combinations  $p$  together.

$$\text{Ex. 6. } (ax + by + cz)^2 + (ax + cy + bz)^2 + (bx + ay + cz)^2$$

$$+ (bx + cy + az)^2 + (cx + ay + bz)^2 + (cx + by + az)^2$$

$$> 6(ab + ac + bc)(xy + xz + yz)$$

$$< 6(a^2 + b^2 + c^2)(x^2 + y^2 + z^2)$$

18. Induction.

It will be noted that the numerical multiplier of the second term of the powers of  $a + x$  already obtained is the same as the index. It is easy to see that this law is general. To demonstrate the fact formally we employ the method of induction.

The argument may be divided into four distinct steps—1. Inference; 2. Hypothesis; 3. Comparison; 4. Conclusion.

The first step, *inference*, is the discovery of the probable existence of a law.

The second step, *hypothesis*, is the assumption that that law holds to a certain point, up to which the opponent to the argument may be presumed to admit it.

The third step consists in basing on this assumption the demonstration of the law to a stage beyond what the opponent was prepared to admit.

The fourth step argues that as the law starts fair, and advances beyond a point at which any opponent is prepared to admit its existence, it is necessarily true.

Ex. 1. To prove that  $(a + x)^n = a^n + na^{n-1}x + \dots$

I. By multiplication we get

$$(a + x)^1 = a^1 + 4a^0x + \dots$$

II. Let it be granted that  $(a + x)^m = a^m + ma^{m-1}x + \dots$ , where  $m$  is the extreme limit to which the opponent will admit of its truth.

III. By multiplying the equals by  $a + x$ , we get

$$(a + x)^{m+1} = a^{m+1} + ma^m x + \dots,$$

$$+ a^m x + \dots,$$

$$= a^{m+1} + (m+1)a^m x + \dots,$$

i.e., if the law be *admitted* true for  $m$  it is *proved* true for  $m + 1$ ; in other words, at whatever point the opponent compels us to limit our assumption, we can advance one step higher by argument.

IV. Now, the law is true for 4,  $\therefore$  it is proved true for 5; and being true for 5, it is proved true for 6, and so on, *ad infinitum*.

Ex. 2. The sum of the cubes of the natural numbers is the square of the sum of the numbers,

$$1^3 + 2^3 = 9 = (1 + 2)^2 = \left(\frac{2 \cdot 3}{2}\right)^2$$

I. Let us assume that

$$1^3 + 2^3 + \dots + x^3 = \left(\frac{x(x+1)}{2}\right)^2$$

II. If this be so, then by adding  $(x + 1)^3$  we get

$$1^3 + 2^3 + \dots + (x + 1)^3 = \left(\frac{x(x+1)}{2}\right)^2 + (x + 1)^3$$

$$= \left(\frac{(x+1)(x+2)}{2}\right)^2$$

III. Hence, if the law be true for any one number  $x$ , it is also true for  $x + 1$ .

IV. But it is true for 2, ∴ for 3, ∴ for 4, &c.

Ex. 3. To prove the inequality,

$$(x + y + z)^n < 3^{n-1}(x^n + y^n + z^n).$$

From the second example of inequalities we get at once  $(x + y + z)^2 < 3(x^2 + y^2 + z^2)$ .

Let us assume that  $(x + y + z)^m < 3^{m-1}(x^m + y^m + z^m)$ , then by multiplication we get

$$(x + y + z)^{m+1} < 3^m(x^{m+1} + y^{m+1} + z^{m+1} + x^m y + y^m x + x^m z + z^m x + y^m z + z^m y).$$

Now, inequality, example 3, gives

$$x^m y + y^m x < x^{m+1} + y^{m+1}, \text{ \&c.}$$

∴  $x^m y + y^m x + x^m z + z^m x + y^m z + z^m y < 2(x^{m+1} + y^{m+1} + z^{m+1})$ , and  $(x + y + z)^{m+1} < 3^m(x^{m+1} + y^{m+1} + z^{m+1})$ ,

i.e., the law is true for  $m + 1$ , if true for  $m$ ; but it is true for 2, ∴ it is always true.

IV. Division.

19. *General Rule for the Signs.*—If the signs of the divisor and dividend be like, the sign of the quotient is +; but if they be unlike, the sign of the quotient is -.

This rule is derived from the general rule for the signs in multiplication, by considering that the quotient must be such a quantity as, when multiplied by the divisor, shall produce the dividend, with its proper sign.

This definition of division is the same as that of a fraction; hence the quotient arising from the division of one quantity by another may be expressed by placing the dividend above a line, and the divisor below it; but it may also be often reduced to a more simple form by the following rules.

Case 1. When the divisor is simple, and a factor of every term of the dividend.

Rule. Divide the coefficient of each term of the dividend by the coefficient of the divisor, and expunge out of each term the letter or letters in the divisor: the result is the quotient.

Ex. Divide  $16a^3xy - 28a^2xz^2 + 4a^2x^3$  by  $4a^2x$ .

The process requires no explanation. It is founded on Laws II. and III., together with the rule of signs.

The quotient is  $4ay - 7z^2 + x^2$ .

If the divisor and dividend be powers of the same quantity, the division will evidently be performed by subtracting the exponent of the divisor from that of the dividend. Thus  $a^5$ , divided by  $a^3$ , has for a quotient  $a^{5-3} = a^2$ .

Case 2. When the divisor is simple, but not a factor of the dividend.

Rule. The quotient is expressed by a fraction, of which the numerator is the dividend, and the denominator the divisor.

Thus the quotient of  $3ab^2$ , divided by  $2mbc$ , is the fraction  $\frac{3ab^2}{2mbc}$ .

It will sometimes happen that the quotient found thus may be reduced to a more simple form, as shall be explained when we come to treat of fractions.

Case 3. When the divisor is compound.

Rule. The terms of the dividend are to be arranged in the order of the powers of some one of its letters, and those of the divisor according to the powers of the same letter. The operation is then carried on precisely as for division of numbers.

To illustrate this rule, let it be required to divide  $8a^2 + 2ab - 15b^2$  by  $2a + 3b$ , the operation will stand thus:

$$\begin{array}{r} 2a + 3b \overline{) 8a^2 + 2ab - 15b^2} \\ \underline{4a \phantom{+ 2ab} - 15b^2} \\ -10ab - 15b^2 \\ \underline{-10ab - 15b^2} \end{array}$$

Here the terms of the divisor and dividend are arranged according to the powers of the quantity  $a$ . We now divide  $8a^2$ , the first term of the dividend, by  $2a$ , the first term of the divisor; and thus get  $4a$  for the first term of the quotient. We next multiply the divisor by  $4a$ , and subtract the product  $8a^2 + 12ab$  from the dividend; we get  $-10ab - 15b^2$  for a new dividend.

By proceeding in all respects as before, we find  $-5b$  for the second term of the quotient, and no remainder: the operation is therefore finished, and the whole quotient is  $4a - 5b$ .

The following examples will also serve to illustrate the manner of applying the rule.

Ex. 1.

$$\begin{array}{r} 3a - b \overline{) 3a^3 - 12a^2 - a^2b + 10ab - 2b^2} \\ \underline{3a^3 \phantom{- 12a^2} - a^2b} \end{array}$$

$$\begin{array}{r} \phantom{3a - b} \overline{) -12a^2 + 10ab} \\ \underline{-12a^2 \phantom{+ 10ab} + 4ab} \\ \phantom{3a - b} \phantom{) } \phantom{-12a^2} \phantom{+ 10ab} + 6ab - 2b^2 \\ \phantom{3a - b} \phantom{) } \phantom{-12a^2} \phantom{+ 10ab} \phantom{+ 6ab} - 2b^2 \end{array}$$

Ex. 2.

$$(1 - x) \overline{) 1 + x + x^2 + \&c.}$$

$$\begin{array}{r} 1 - x \overline{) 1 + x + x^2 + \&c.} \\ \underline{+ x} \\ \phantom{1 - x} \phantom{) } \phantom{1 + x} + x - x \\ \phantom{1 - x} \phantom{) } \phantom{1 + x} \phantom{+ x - x} + x^2 \\ \phantom{1 - x} \phantom{) } \phantom{1 + x} \phantom{+ x - x} \phantom{+ x^2} + x^2 - x^3 \\ \phantom{1 - x} \phantom{) } \phantom{1 + x} \phantom{+ x - x} \phantom{+ x^2} \phantom{+ x^2 - x^3} + x^3 \end{array}$$

Sometimes, as in this last example, the quotient will never terminate; in such a case it may either be considered as an infinite series, the law according to which the terms are formed being in general sufficiently obvious; or the quotient may be completed as in arithmetical division, by annexing to it a fraction (with its proper sign), the numerator of which is the remainder, and denominator the divisor. Thus the completed quotient, in last example, is—

$$1 + x + x^2 + \frac{x^3}{1 - x}.$$

If  $x$  be small compared with unity, the remainders, as we advance, continually become smaller and smaller. If, on the other hand,  $x$  be large compared with unity, the remainders continually become larger and larger. In this case the quotient is worthless. To obtain a quotient which shall be of any practical value, we must reverse the order of arrangement, putting  $-x + 1$  in place of  $1 - x$ . The division then becomes

$$(-x + 1) \overline{) \left( -\frac{1}{x} - \frac{1}{x^2} - \&c. \right)}$$

$$\begin{array}{r} 1 - \frac{1}{x} \overline{) -\frac{1}{x} - \frac{1}{x^2} - \&c.} \\ \underline{+ \frac{1}{x}} \\ \phantom{1 - \frac{1}{x}} \phantom{) } \phantom{-\frac{1}{x}} - \frac{1}{x^2} \\ \phantom{1 - \frac{1}{x}} \phantom{) } \phantom{-\frac{1}{x}} \phantom{-\frac{1}{x^2}} + \frac{1}{x^2} \end{array}$$

As it is generally the largest of the quantities that we desire to divide out, we observe that, in order to effect this, we have had to begin with that quantity. Hence the Rule—

The terms of the divisor and dividend are to be arranged according to the powers of that letter which it is wished (if possible) to divide out.

Ex. 3. Divide  $a^4 + b^4 + b(a+b)^3$  by  $a^2 + b^2 - ab$ , where  $a$  is large compared with  $b$ .

We must arrange according to powers of  $a$ .

$$\begin{array}{r} a^2 - ab + b^2 \overline{) a^4 + a^3b + 3a^2b^2 + 3ab^3 + 2b^4(a^2 + 2ab + 4b^2)} \\ \underline{a^4 - a^3b + a^2b^2} \phantom{+ 3ab^3 + 2b^4(a^2 + 2ab + 4b^2)} \\ \phantom{a^4} + 2a^3b + 2a^2b^2 + 3ab^3 \\ \phantom{a^4} \phantom{+ 2a^3b} + 2a^2b^2 + 2ab^3 \\ \phantom{a^4} \phantom{+ 2a^3b} \phantom{+ 2a^2b^2} + 4a^2b^2 + ab^3 + 2b^4 \\ \phantom{a^4} \phantom{+ 2a^3b} \phantom{+ 2a^2b^2} \phantom{+ 4a^2b^2} + 4a^2b^2 - 4ab^3 + 4b^4 \\ \phantom{a^4} \phantom{+ 2a^3b} \phantom{+ 2a^2b^2} \phantom{+ 4a^2b^2} \phantom{+ 4ab^3} + 5ab^3 - 2b^4 \end{array}$$

We have spoken as if magnitude alone was the circumstance which should determine the precedence of the letters in a division. In the more advanced processes of algebra there are other circumstances which give precedence to certain letters, such, for example, as the fact that  $x$  may and often does stand for the phrase "quantity," whilst  $a$  stands for some determinate numerical quantity. This leads us to exhibit a proposition in division of the greatest value and most extensive application. It is as follows:—

20. PROPOSITION.—If any function of  $x$ , consisting of powers of that letter with numerical multipliers, is divided by  $x - a$ , the remainder, when all the  $x$ 's are divided out, is the same function of  $a$  that the dividend is of  $x$ ; in other words, the remainder is the dividend altered by writing  $a$  in place of  $x$ .

To prove this proposition we shall employ the following

AXIOM:—If two expressions in  $x$  are identical in form and value, but one multiplied out farther than the other, we may write any numerical quantity we please in place of  $x$  in both, and the results will be equal.

For example,  $(x-1)^2 + (x-1) - 3$  is identical with  $x^2 - 2(x+1) + x - 1$ ; and it is evident that if we write any number (say 1) for  $x$ , the results are the same in both.

We now proceed to prove the proposition.

Let the dividend be  $a^n + px^{n-1} + qx^{n-2}$ , &c., where  $n$  is a whole number, and  $p, q$ , &c., positive or negative numerical quantities.

Let the quotient, when this is divided by  $x - a$ , be  $Q$ , the remainder, which does not contain  $x$ ,  $R$ ; then

$$a^n + px^{n-1} + qx^{n-2} + \dots = Q(x - a) + R$$

by the definition of Division.

Now this equality is in reality an identity in terms of the axiom. If then we write  $a$  in place of  $x$ , the results will be equal; this gives

$$\begin{aligned} a^n + pa^{n-1} + qa^{n-2} + \dots &= Q \cdot 0 + R \\ &= R, \end{aligned}$$

which is the proposition to be proved.

*Examples.*

Ex. 1. If  $n$  be any whole number,  $x^n - a^n$  is divisible by  $x - a$  without remainder.

For the remainder, by the proposition, is  $a^n - a^n = 0$ .

Ex. 2. If  $n$  be an even number,  $x^n - a^n$  is divisible by  $x + a$  without remainder.

For the remainder is  $(-a)^n - a^n = 0$ , since  $n$  is even.

Observe that the divisor here has to be changed to  $x - (-a)$ , so that  $-a$  stands in place of the  $a$  of the proposition.

Ex. 3. If  $n$  be an odd number,  $x^n + a^n$  is divisible by  $x + a$  without remainder.

For the remainder is  $(-a)^n + a^n = 0$ , because  $n$  is odd.

Ex. 4. To prove that  $4b^2c^2 - (b^2 + c^2 - a^2)^2$  is divisible by  $-a + b + c$ ; and hence to resolve it into simple factors. Here the  $x - a$  of the proposition is replaced by  $a - (b + c)$  (the negative sign of the whole divisor being of no consequence).

To determine the remainder, therefore, we write  $b + c$  in

place of  $a$  in the dividend, or thing to be divided; the result is,

$$4b^2c^2 - (b^2 + c^2 - \overline{b+c}^2) = 0,$$

hence  $4b^2c^2 - (b^2 + c^2 - a^2)^2$  is divisible by  $-a + b + c$ .

Now, since the dividend contains only squares of  $a$ , and  $b$ , and  $c$ , any change in the sign of  $a$ , or  $b$ , or  $c$ , produces no change in the dividend. What we have just proved then becomes (putting  $-a$  for  $a$ ) the following:—

$$4b^2c^2 - (b^2 + c^2 - a^2)^2 \text{ is divisible by } a + b + c.$$

This last becomes (putting  $-b$  for  $b$ , and then  $-c$  for  $c$ ):—  
 $4b^2c^2 - (b^2 + c^2 - a^2)^2$  is divisible by  $a - b + c$ , and by  $a + b - c$ .

Hence finally,  $4b^2c^2 - (b^2 + c^2 - a^2)^2 = (a + b + c)(-a + b + c)(a + b - c)$ .

The above example is a good exercise for the student. The result may be more simply arrived at by employing a proposition of very great value and frequent use—that *the difference of the squares of two quantities is the product of the sum and difference of the quantities.*

Ex. 5. To prove that  $(1 - a^2)(1 - b^2)(1 - c^2) - (c + ab)(b + ac)(a + bc)$  is divisible by  $1 + abc$ .

It is simpler here to write a single letter  $x$  for  $abc$ , whereby the given quantity becomes

$$(1 - a^2)(1 - b^2)(1 - c^2) - \frac{1}{x}(x + a^2)(x + b^2)(x + c^2),$$

which is obviously under the form  $p - p$ , when  $-1$  is written for  $x$ , and  $\therefore$  is divisible by  $1 + abc$ .

Ex. 6. Prove that  $(x^2 - x + 1)(x^4 - x^2 + 1)(x^8 - x^4 + 1)(x^{16} - x^8 + 1) \dots (x^{2^n} - x^{2^{n-1}} + 1)$  is the quotient of  $x^{4^n} + x^{2^n} + 1$  by  $x^2 + x + 1$ ;  $n$  being any power of 2.

The divisor  $(x^2 + x + 1)$  being multiplied by  $x^2 - x + 1$  gives  $x^4 + x^2 + 1$ ; which, being again multiplied by  $x^4 - x^2 + 1$ , gives  $x^8 + x^4 + 1$ ; and so on to the end.

*Additional Examples in Division.*

Ex. 1. Divide  $1 - 10x^3 + 15x^4 - 6x^5$  by  $(1 - x)^3$ .

We must first multiply out  $(1 - x)^3$ , and then divide the given expression by the product,  $1 - 3x + 3x^2 - x^3$ . The quotient is  $1 + 3x + 6x^2$ .

Ex. 2. Divide  $65x^2y^2 - (x^4 + 64y^4)$  by  $x^2 - 7xy - 8y^2$ .

We must arrange dividend and divisor in terms of powers of one of the letters, say  $x$ ; the division will then assume the form

$$\begin{array}{r} x^2 - 7xy - 8y^2 \overline{) x^4 + 65x^2y^2 - 64y^4} \\ \phantom{x^4} - 7x^3y - 8x^2y^2 \\ \phantom{x^4} \phantom{- 7x^3y} + 7x^2y^2 \\ \phantom{x^4} \phantom{- 7x^3y} \phantom{+ 7x^2y^2} - 64y^4 \end{array}$$

giving  $-x^2 - 7xy + 8y^2$ .

Ex. 3. Divide  $x^3 + y^3 + z^3 - 3xyz$  by  $x + y + z$ . We must give exclusive attention to some one letter, say  $x$ , in dividing out; thus

$$\begin{array}{r} x + y + z \overline{) x^3 + y^3 + z^3 - 3xyz} \\ \phantom{x^3} - x^2(y + z) \\ \phantom{x^3} \phantom{- x^2(y + z)} + x^2(y + z) \\ \phantom{x^3} \phantom{- x^2(y + z)} \phantom{+ x^2(y + z)} - x(y + z)^2 \\ \phantom{x^3} \phantom{- x^2(y + z)} \phantom{+ x^2(y + z)} \phantom{- x(y + z)^2} \phantom{+ x^2(y + z)^2} \\ \phantom{x^3} \phantom{- x^2(y + z)} \phantom{+ x^2(y + z)} \phantom{- x(y + z)^2} \phantom{+ x^2(y + z)^2} \phantom{+ x^2(y^2 - yz + z^2) + y^3 + z^3} \end{array}$$

the quotient being  $x^2 + y^2 + z^2 - xy - xz - yz$ .

Ex. 4. Divide the product of

$$x^2 + 3x + 2, x^2 - 5x + 4, x^4 + 5x^2 - 14,$$

by the product of  $x^2 - 1, x^2 - 2$ . Here we observe that  $x^2 - 1$  is the product of  $x + 1, x - 1$ .

Now (Art. 20),  $x^2 + 3x + 2$  is divisible by  $x + 1$ , and  $x^2 - 5x + 4$  by  $x - 1$ . Hence, if the product is divisible by  $x^2 - 1, x^2 - 2$ , without remainder, the third factor,  $x^4 + 5x^2 - 14$  must be divisible by  $x^2 - 2$ , which is found to be the case. The quotient required is therefore the product of

$$(x + 2)(x - 4)(x^2 + 7) = x^4 - 2x^3 - x^2 - 14x - 56.$$

Ex. 5. Divide  $12x^4 - 10x^3y - 3x^2y^2 + 30xy^3 - 25y^4$  by  $3x^2 - 4xy + 5y^2$ .

We will employ this example to indicate Horner's method of synthetic division.

Let the dividend be represented by

$$Ax^4 + Bx^3 + Cy^2 + Dx + E,$$

the divisor by

$$ax^2 + bx + c,$$

and the quotient by  $cx^2 + \beta x + \gamma + \&c.$

Then, multiplying the quotient by the divisor, we produce the dividend, which, exhibited by the method of detached coefficients, stands thus—

$$\begin{array}{r} aa + a\beta + a\gamma + \&c. \\ + ba + b\beta + \&c. \\ + ca + \&c. \\ \hline A + B + C + \&c. \end{array}$$

The last line being the sum column by column of the three preceding lines. Now, as the upper of these three lines contains term by term the quantities required, we convert this addition into subtraction; thus,

$$\begin{array}{r} A + B + C + D + E \\ - b \quad -ba - b\beta - b\gamma - \&c. \\ - c \quad \quad -ca - c\beta - \&c. \\ \hline a \quad aa + a\beta + a\gamma + a\delta + \&c. \end{array}$$

The first vertical column gives  $a$ ; the second  $\beta$ , and so on.

In the example before us we write,—

$$\begin{array}{r} 12 - 10 - 3 \quad + 30 - 25 \\ + 4 \quad + 4a + 4\beta + 4\gamma + \&c. \\ - 5 \quad \quad - 5a - 5\beta - \&c. \\ \hline 3 \quad 3a + 3\beta + 3\gamma + \&c., \end{array}$$

whence  $3a = 12$  gives  $a = 4$ ;  $3\beta = -10 + 4a$  gives  $\beta = 2$ ;  $3\gamma = -3 + 4\beta - 5a$  gives  $\gamma = -5$ .

Therefore the quotient required is  $4x^2 + 2x - 5$ .

SECT. II.—INVOLUTION AND EVOLUTION.

21. In treating of multiplication, we have observed, that when a quantity is multiplied by itself any number of times, the product is called a *power* of that quantity, while the quantity itself, from which the powers are formed, is called the *root*. Thus,  $a$ ,  $a^2$ , and  $a^3$  are the first, second, and third powers of the root  $a$ ; and in like manner  $\frac{1}{a}$ ,  $\frac{1}{a^2}$

and  $\frac{1}{a^3}$  denote the same powers of the root  $\frac{1}{a}$ .

But before considering more particularly what relates to powers and roots, it will be proper to observe, that the quantities  $\frac{1}{a}$ ,  $\frac{1}{a^2}$ ,  $\frac{1}{a^3}$ , &c., admit of being expressed under a different form; for, just as the quantities  $a$ ,  $a^2$ ,  $a^3$ , &c., are expressed as *positive* powers of the root  $a$ , so the quantities  $\frac{1}{a}$ ,  $\frac{1}{a^2}$ ,  $\frac{1}{a^3}$ , &c., may be respectively expressed thus  $a^{-1}$ ,  $a^{-2}$ ,  $a^{-3}$ , &c., and considered as *negative* powers of the root  $a$ .

This method of expressing the fractions  $\frac{1}{a}$ ,  $\frac{1}{a^2}$ ,  $\frac{1}{a^3}$ , as powers of the root  $a$ , but with negative indices, is a consequence of the rule which has been given for the division of powers; for we consider  $\frac{1}{a}$  as the quotient arising from the division of any power of  $a$  by the next higher power; for example, from the division of the 2d by the 3d, and so we have  $\frac{1}{a} = \frac{a^2}{a^3}$ ; but since powers of the same quantity are

divided by subtracting the exponent of the divisor from that of the dividend (Art. 19), it follows that  $\frac{a^2}{a^3} = a^{2-3} = a^{-1}$ ; therefore the fraction  $\frac{1}{a}$  may also be expressed thus,  $a^{-1}$ . By considering  $\frac{1}{a^2}$  as equal to  $\frac{a^2}{a^4}$ , it will appear in the same manner that  $\frac{1}{a^2} = \frac{a^2}{a^4} = a^{-2}$ ; and proceeding in this way, we get  $\frac{1}{a^3} = \frac{a^2}{a^5} = a^{-3}$ ,  $\frac{1}{a^4} = \frac{a^2}{a^6} = a^{-4}$ , &c., and so on, as far as we please. It also appears that unity or 1 may be represented by  $a^0$ , where the exponent is a cypher, for  $1 = \frac{a^2}{a^2} = a^{2-2} = a^0$ .

The rules which have been given for the multiplication and division of powers with positive integral exponents will apply in every case, whether the exponents be positive or negative, integral or fractional, provided we assume as the *definition* of the index in such cases, the law of combination  $a^m \times a^n = a^{m+n}$ .

Involution.

22. Involution is the method of finding any power of any assigned quantity, whether it be simple or compound: hence its rules are easily derived from the operation of multiplication.

Case 1. When the quantity is simple.

Rule. Multiply the exponents of the letters by the index of the power required, and raise the coefficient to the same power.

Note. If the sign of the quantity be +, all its powers will be positive; but if it be -, then all its powers whose exponents are even numbers are positive, and all its powers whose exponents are odd numbers are negative.

Ex. 1. Required the cube, or third power, of  $2a^2x$ ,  $(2a^2x)^3 = 2 \times 2 \times 2a^{2 \times 3}x^{1 \times 3} = 8a^6x^3$ , the answer.

Ex. 2. Required the fifth power of  $-3a^2x^3$ .  $(-3a^2x^3)^5 = -243a^{10}x^{15}$ , the answer.

Ex. 3. Required the fourth power of  $-\frac{2ax^2}{3b^2y}$ .

$$\left(\frac{-2ax^2}{3b^2y}\right)^4 = \frac{16a^4x^8}{81b^8y^4}, \text{ the answer.}$$

Case 2. When the quantity is compound.

Rule. The powers must be found by a continual multiplication of the quantity by itself.

Ex. 4. Required the first four powers of the binomial quantity  $a + x$ .

$a + x$  the root, or first power.

$$\frac{a+x}{a^2+ax}$$

$$+ ax + x^2$$

$a^2 + 2ax + x^2$  the square, or second power.

$$a + x$$

$$\frac{a^3 + 2a^2x + ax^2}{a^3 + 2a^2x + ax^2}$$

$$+ a^2x + 2ax^2 + x^3$$

$a^3 + 3a^2x + 3ax^2 + x^3$  the cube, or third power.

$$a^4 + 3a^3x + 3a^2x^2 + ax^3$$

$$+ a^3x + 3a^2x^2 + 3ax^3 + x^4$$

$a^4 + 4a^3x + 6a^2x^2 + 4ax^3 + x^4$  the fourth power.

If it be required to find the same powers of  $a - x$ , it will be found, writing  $-x$  for  $x$ , that

$a - x$  being the root, or first power; then  
 $a^2 - 2ax + x^2$  is the square, or second power;  
 $a^3 - 3a^2x + 3ax^2 - x^3$ , the cube, or third power;  
 $a^4 - 4a^3x + 6a^2x^2 - 4ax^3 + x^4$ , the fourth power.

Hence it appears that the powers of  $a + x$  differ from the powers of  $a - x$  only in this respect, that in the former the signs of the terms are all positive, but in the latter they are positive and negative alternately.

Besides the method of finding the powers of a compound quantity by multiplication, which we have just now explained, there is another more general, as well as more expeditious, by which a quantity may be raised to any power whatever without the trouble of finding any of the inferior powers, namely, by means of what is commonly called the *binomial theorem*, to be proved hereafter. This theorem may be expressed as follows:—Let  $a + x$  be a binomial quantity, which is to be raised to any power denoted by the number  $n$ , then  $(a + x)^n =$

$$a^n + \frac{n}{1} a^{n-1}x + \frac{n(n-1)}{1 \cdot 2} a^{n-2}x^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} a^{n-3}x^3 + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} a^{n-4}x^4 + \frac{n(n-1)(n-2)(n-3)(n-4)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} a^{n-5}x^5 + \&c.$$

This series will always terminate when  $n$  is any whole positive number, by reason of some one of the factors  $n - 1, n - 2, \&c.$ , becoming  $= 0$ ; but if  $n$  be either a negative or fractional number, the series will consist of an infinite number of terms. As, however, we mean to treat in this section only of the powers of quantities when their exponents are whole positive numbers, we shall make no further remarks upon any other. The  $n$ th power of  $a - x$  will not differ from the same power of  $a + x$ , except in the signs of the terms which compose it, for it will stand thus:  $(a - x)^n =$

$$a^n - \frac{n}{1} a^{n-1}x + \frac{n(n-1)}{1 \cdot 2} a^{n-2}x^2 - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} a^{n-3}x^3 + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} a^{n-4}x^4 - \&c.,$$

where the signs are + and - alternately.

Let it be required, for instance, to raise  $a + x$  to the fifth power.

Here  $n$ , the exponent of the power, being 5, the first term  $a^n$  of the general theorem will be equal to  $a^5$ , the second  $na^{n-1}x = 5a^4x$ , the third  $\frac{n(n-1)}{1 \cdot 2} a^{n-2}x^2 = \frac{5 \times 4}{1 \times 2} a^3x^2 = 10a^3x^2$ , the fourth  $\frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} a^{n-3}x^3 = \frac{5 \times 4 \times 3}{1 \times 2 \times 3} a^2x^3 = 10a^2x^3$ , the fifth  $\frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} a^{n-4}x^4 = \frac{5 \times 4 \times 3 \times 2}{1 \times 2 \times 3 \times 4} a^1x^4 = 5ax^4$ , and the sixth and last  $\frac{n(n-1)(n-2)(n-3)(n-4)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} a^{n-5}x^5 = \frac{5 \times 4 \times 3 \times 2 \times 1}{1 \times 2 \times 3 \times 4 \times 5} a^0x^5 = x^5$ ; the remaining terms of the general theorem all vanish, by reason of the factor  $n - 5 = 0$  by which each of them is multiplied, so that we get  $(a + x)^5 = a^5 + 5a^4x + 10a^3x^2 + 10a^2x^3 + 5ax^4 + x^5$ .

If the quantity to be involved consists of more than two terms, as, if  $p + q - r$  were to be raised to the second power, put  $p = a$  and  $q - r = b$ , then  $(p + q - r)^2 = (a + b)^2 = a^2 + 2ab + b^2 = p^2 + 2p(q - r) + (q - r)^2$ , but  $2p(q - r) = 2pq - 2pr$ , and by the general theorem  $(q - r)^2 = q^2 - 2qr + r^2$ , therefore we get  $(p + q - r)^2 = p^2 + 2pq - 2pr + q^2 - 2qr + r^2$ ; and by a similar method of proceeding a quantity consisting of four or more terms may be raised to any power.

Additional Examples.

Ex. 1. From the value of  $(a + x)^4$  found in example 4, to find that of  $(a + b + c)^4$ . From example 4 we write at once, by symmetry,

$$(a + b + c)^4 = a^4 + 4a^3b + 6a^2b^2 + R + b^4 + 4a^3c + 6a^2c^2 + c^4 + 4b^3a + 6b^2c^2 + 4b^3c + 4c^3a + 4c^3b$$

where  $R$  is the series of remaining terms denoting the three following forms,  $a^2bc, b^2ac, c^2ab$ . Now when  $a, b, c$  are each unity, there are 81 terms (viz.  $3^4$ ). But the number of terms already written down ( $4a^3b$  being considered as 4 terms, &c.) is 45. The quantity  $R$  must consequently make up the other 36 terms,  $\therefore$  it can be nothing else than  $12a^2bc + 12b^2ac + 12c^2ab$ .

Ex. 2.  $(p + q + r)^2 = p^2 + q^2 + r^2 + 2(pq + qr + rp)$ .  
 Cor. If  $p + q + r = 0$ ; then  $p^2 + q^2 + r^2 + 2(pq + qr + rp) = 0$ .

Case 1.  $a - b + b - c + c - a = 0$ , gives  
 $(a - b)^2 + (b - c)^2 + (c - a)^2 + 2\{(a - b)(b - c) + (b - c)(c - a) + (c - a)(a - b)\} = 0$ .

Case 2.  $a(b - c) + b(c - a) + c(a - b) = 0$ , gives  
 $a^2(b - c)^2 + b^2(c - a)^2 + c^2(a - b)^2 + 2\{ab(b - c)(c - a) + bc(c - a)(a - b) + ca(a - b)(b - c)\} = 0$ .

Ex. 3. Prove that  $(x^2 - yz)^3 + (y^2 - xz)^3 + (z^2 - xy)^3 - 3(x^2 - yz)(y^2 - xz)(z^2 - xy)$  is a complete square.

The expression will assume symmetry if  $(x^2 - yz)(y^2 - xz)(z^2 - xy)$ , instead of being multiplied by 3, be repeated three times, each being connected with one of the cubes in turn; this gives—

$$(x^2 - yz)\{(x^2 - yz)^2 - (y^2 - xz)(z^2 - xy)\} + (y^2 - xz)\{(y^2 - xz)^2 - (x^2 - yz)(z^2 - xy)\} + (z^2 - xy)\{(z^2 - xy)^2 - (x^2 - yz)(y^2 - xz)\} = (x^2 - yz)x\{x^3 + y^3 + z^3 - 3xyz\} + \&c., \&c. = (x^3 + y^3 + z^3 - 3xyz)(x^3 + y^3 + z^3 - 3xyz).$$

Ex. 4. Prove that  $(a^2 + b^2 + c^2)^3 + 2(ab + bc + ca)^3 - 3(a^2 + b^2 + c^2)(ab + bc + ca)^2 = (a^3 + b^3 + c^3 - 3abc)^2$ .

Combine each of the cubes with each of the products in succession, and reduce, as in the last example.

Ex. 5. To find the condition that  $px^2 + 2qxy + ry^2$  may be incapable of changing its sign through any change of sign or value of  $x$  and  $y$ . It is evident that  $p$  and  $r$  must have the same sign. Suppose it positive. By multiplying by  $p$ , the quantity may be thrown into the form  $(px + qy)^2 + (pr - q^2)y^2$ , which is the sum of two positive quantities provided  $pr > q^2$ . The condition required is, therefore,  $pr > q^2$ ; or as a particular case  $pr = q^2$ .

Ex. 6. To find the condition that  $ax^2 + by^2 + cz^2 + 2Pyz + 2Qxz + 2Rxy$  may be incapable of changing its sign through any change of sign or value of  $x, y, z$ .

We will suppose  $a, b, c$  to be all positive, in which case the whole result is also positive.

If we multiply the whole by  $a$ , we may write it under the form of a square and a supplement,

$$\text{viz., } (ax + Qz + Ry)^2 + (ac - Q^2)z^2 + (ab - R^2)y^2 + 2(aP - QR)yz.$$

Now as the first term of this expression is a square, it is essentially positive. Hence the required condition can be satisfied only by rendering the remainder positive.

It follows that  $ac > Q^2, ab > R^2$ , and

$$(\text{Example 5}) \quad (ac - Q^2)(ab - R^2) > (aP - QR)^2, \text{ i.e., } abc + 2PQR > aP^2 + bQ^2 + cR^2.$$

If we had begun by throwing the expression into the form of  $(by + Pz + Rx)^2 + \&c.$ , a resulting condition would have been  $bc > P^2$ . The four conditions are consequently

$$ab > R^2, ac > Q^2, bc > P^2, \\ abc + 2PQR > aP^2 + bQ^2 + cR^2.$$

Results of this kind are of the utmost value in the higher analysis.

*Evolution.*

23. Evolution is the reverse of involution, or it is the method of finding the root of any quantity, whether simple or compound, which is considered as a power of that root: hence it follows that its operations, generally speaking, must be the reverse of those of involution.

To denote that the root of any quantity is to be taken, the sign  $\sqrt{\quad}$  (called the *radical sign*) is placed before it, and a small number placed over the sign to express the denomination of the root. Thus  $\sqrt{a}$  denotes the square root of  $a$ ,  $\sqrt[3]{a}$  its cube root,  $\sqrt[4]{a}$  its fourth root, and in general,  $\sqrt[n]{a}$  its  $n$ th root. The number placed over the radical sign is called the *index* or *exponent* of the root, and is usually omitted in expressing the square root: thus, either  $\sqrt[2]{a}$  or  $\sqrt{a}$  denotes the square root of  $a$ .

Case 1. When roots of simple quantities are to be found.

*Rule.* Divide the exponents of the letters by the index of the root required, and prefix the root of the numeral coefficient; the result will be the root required.

*Note 1.* The root of any positive quantity may be either positive or negative, if the index of the root be an even number; but if it be an odd number, the root can be positive only.

2. The root of a negative quantity is also negative when the index of the root is an odd number.

3. But if the quantity be negative, and the index of the root even, then no root can be assigned.

*Ex.* Required the cube root of  $125a^6x^9$ .

Here the index of the root is 3, and the root of the coefficient 5, therefore  $\sqrt[3]{125a^6x^9} = 5a^2x^3$ , the root required; and in like manner the cube root of  $-125a^6x^9$  is found to be  $-5a^2x^3$ .

The root of a fraction is found by extracting the root of both numerator and denominator. Thus the square root of  $\frac{4a^2x^4}{9b^2y^6}$  is  $\frac{2ax^2}{3by^3}$ .

Case 2. When the quantity of which the root is to be extracted is compound.

I. To extract the square root.

Range the terms of the quantity according to the powers of one of the letters, as in division.

Find the square root of the first term for the first part of the root sought, subtract its square from the given quantity, and divide the remainder by double the part already found, and the quotient is the second term of the root.

Add the second part to double the first, and multiply their sum by the second part; subtract the product from the remainder, and if nothing remain, the square root is obtained. But if there is a remainder, it must be divided by the double of the parts already found, and the quotient will give the third term of the root, and so on.

*Ex.* Required the square root of  $x^4 - 2x^3 + \frac{3}{2}x^2 - \frac{x}{2} + \frac{1}{16}$ .

$$\begin{array}{r} x^4 - 2x^3 + \frac{3}{2}x^2 - \frac{x}{2} + \frac{1}{16} \\ \underline{x^4} \\ 2x^2 - x - \frac{1}{16} \\ \underline{2x^2 - 2x + \frac{1}{4}} \\ x - \frac{1}{16} \\ \underline{x - \frac{1}{2}} \\ \frac{3}{2}x^2 - \frac{x}{2} + \frac{1}{16} \\ \underline{\frac{3}{2}x^2 - 3x + \frac{3}{4}} \\ \frac{5}{2}x - \frac{1}{2} \\ \underline{\frac{5}{2}x - \frac{5}{4}} \\ \frac{1}{4} \end{array}$$

To understand the reason of the rule for finding the square root of a compound quantity, it is only necessary to involve any quantity, as  $a + b + c$ , to the second power, and observe the composition of its square; for we have  $(a + b + c)^2 = a^2 + 2ab + b^2 + 2ac + 2bc + c^2$ ; but  $2ab + b^2 = (2a + b)b$  and  $2ac + 2bc + c^2 = (2a + 2b + c)c$ , therefore,

$$(a + b + c)^2 = a^2 + (2a + b)b + (2a + 2b + c)c;$$

and from this expression the manner of deriving the rule is obvious.

As an illustration of the common rule for extracting the square root of any proposed number, we shall suppose that the root of 59049 is required.

Accordingly we have  $(a + b + c)^2 = 59049$ , and from hence we are to find the values of  $a$ ,  $b$ , and  $c$ .

$$a^2 = 200 \times 200 = 40000 \quad \left. \begin{array}{l} 59049(200 = a) \\ 40 = b \\ 3 = c \end{array} \right\} \text{Hence } 243 \text{ is the root required.}$$

$$\begin{array}{r} 2a = 400 \quad 19049 \\ b = 40 \\ \underline{2a + b = 440} \quad 17600 = (2a + b)b \\ 2a + 2b = 480 \quad 1449 \\ c = 3 \\ \underline{2a + 2b + c = 483} \quad 1449 = (2a + 2b + c)c \end{array}$$

II. To extract the cube root.

Cube root

Range the terms of the quantity according to the powers of some one of the letters.

Find the root of the first term, for the first part of the root sought; subtract its cube from the whole quantity, and divide the remainder by three times the square of the part already found, and the quotient is the second part of the root.

Add together three times the square of the part of the root already found, three times the product of that part and the second part of the root, and the square of the second part; multiply the sum by the second part, and subtract the product from the first remainder, and if nothing remain, the root is obtained; but if there is a remainder, it must be divided by three times the square of the sum of the parts already found, and the quotient is a third term of the root, and so on, till the whole root is obtained.

*Ex.* Required the cube root of  $a^3 + 3a^2x + 3ax^2 + x^3$ .

$$\begin{array}{r} a^3 + 3a^2x + 3ax^2 + x^3 \\ \underline{a^3} \\ 3a^2x + 3ax^2 + x^3 \\ \underline{3a^2x + 3ax^2 + x^3} \\ * \quad * \quad * \end{array}$$

The reason of the preceding rule is evident from the composition of a cube; for if any quantity, as  $a + b + c$ , be raised to the third power, we have  $(a + b + c)^3 = a^3 + (3a^2 + 3ab + b^2)b + \{3(a + b)^2 + 3(a + b)c + c^2\}c$ , and by consider-

ing in what manner the terms  $a$ ,  $b$ , and  $c$  are deduced from this expression for the cube of their sum, we also see the reason for the common rule for extracting the cube root in numbers. Let it be required to find the cube root

of 13312053, where the root will evidently consist of three figures; let us suppose it to be represented by  $a + b + c$ , and the operation for finding the numerical values of these quantities may stand as follows:—

$$\begin{array}{r}
 13312053(200 = a) \\
 x^3 = 8000000 \quad 30 = b \\
 \qquad \qquad \qquad 7 = c \quad \therefore 237 \text{ is the root required.} \\
 \hline
 3a^2 = 120000 \quad 5312053 \\
 3ab = 18000 \\
 b^2 = 900 \\
 \hline
 3a^2 + 3ab + b^2 = 138900 \quad 4167000 = (3a^2 + 3ab + b^2)b \\
 \hline
 3(a+b)^2 = 158700 \quad 1145053 \\
 3(a+b)c = 4830 \\
 c^2 = 49 \\
 \hline
 3(a+b)^2 + 3(a+b)c + c^2 = 163579 \quad 1145053 = [3(a+b)^2 + 3(a+b)c + c^2]c
 \end{array}$$

Any root. III. To extract any other root. Range the quantity of which the root is to be found, according to the powers of one of its letters, and extract the root of the first term; that will be the first member of the root required.

Involve the first member of the root to a power less by unity than the number that denominates the root required, and multiply the power that arises by the number itself; divide the second term of the given quantity by the product, and the quotient shall give the second member of the root required.

Find the remaining members of the root in the same manner by considering those already found as making one term.

24. In the preceding examples, the quantities whose roots were to be found have been all such as could have their roots expressed by a finite number of terms; but it will frequently happen that the root cannot be otherwise assigned than by a series consisting of an infinite number of terms. The preceding rules, however, will serve to determine any number of terms of the series. Thus, the square root of  $a^2 + x^2$  will be found to be  $a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7} + \&c.$ , and the cube root of  $a^3 + x^3$  will stand thus,  $a + \frac{x^3}{3a^2} - \frac{x^6}{9a^5} + \frac{5x^9}{81a^8} - \frac{10x^{12}}{243a^{11}} + \&c.$  But as the extraction of roots in the form of series can be more easily performed by the aid of the binomial theorem, we shall refer the reader to the section where this subject is resumed.

*Additional Examples.*

Ex. 1. Write down the square root of  $x^4 - 2x^3 + \frac{3}{2}x^2 - \frac{1}{2}x + \frac{1}{16}$ , which is given as a perfect square.

Since the square contains 5 terms, the root must contain 3. Of these the first is  $x^2$  on account of  $x^4$ , the second  $-x$  on account of  $2x^3$ , and the third  $\pm \frac{1}{4}$  on account of  $\frac{1}{16}$ . But as the last term but one of the square is  $-$ , and the last term but one of the root also  $-$ , the last term of the root must be  $+$ .

$\therefore x^2 - x + \frac{1}{4}$  is the root required.

Ex. 2. Extract the square root of  $25x^4 + 16y^4 - 6xy(5x^2 + 4y^2) + 49x^2y^2$ . We must first arrange the square in terms of some one quantity (say  $x$ ).

The first term of the square is  $25x^4$ , which gives  $5x^2$  as the first term of the root. The second term of the square,

$-30x^2y$  gives  $-3xy$  as the second term of the root. The last term  $16y^4$  gives  $\pm 4y^2$ ; which, since the last term but one is  $-$ , leads to the root  $5x^2 - 3xy + 4y^2$ .

Ex. 3. Extract the cube root of

$$8x^6 - 36x^5 + 66x^4 - 63x^3 + 33x^2 - 9x + 1.$$

Since there are seven terms in the cube, there must be three terms in the root. The first is  $2x^2$ , the second  $-3x$ , the third 1, as will be seen at once by examining the cube of  $p - q + 1$ , viz.,  $p^3 - 3p^2q + \dots - 3q + 1$ .

These examples have been solved by the assumption that the root is capable of extraction without leaving a remainder. When this is not the case, or when there is no certainty that it is so, the only resource is to work the example through, abbreviating the process by the aid of detached coefficients.

Ex. 4. Extract the square root of  $4x^6 + 12x^5y + 5x^4y^2 - 2x^3y^3 + 7x^2y^4 - 2xy^5 + y^6$ . The work is written thus:

$$\begin{array}{r}
 4 + 12 + 5 - 2 + 7 - 2 + 1(2x^3 + 3x^2 - xy^2 + y^3) \\
 \underline{4} \\
 4 + 3) \quad 12 + 5 \\
 \qquad \qquad \underline{12 + 9} \\
 4 + 6 - 1) \quad -4 - 2 + 7 \\
 \qquad \qquad \qquad \underline{-4 - 6 + 1} \\
 4 + 6 - 2 + 1) \quad 4 + 6 - 2 + 1
 \end{array}$$

Ex. 5. Extract the cube root of

$$27x^6 - 27x^5y - 45x^4y^2 + 35x^3y^3 + 30x^2y^4 - 12xy^5 - 8y^6.$$

We have

$$\begin{array}{r}
 27 - 27 - 45 + 35 + 30 - 12 - 8(3x^2 - xy - 2y^2) \\
 \underline{27} \\
 27) \quad -27 - 45 + 35 \\
 \qquad \qquad \underline{-27 + 9 - 1} \\
 27 - 18 + 3) \quad -54 + 36 + 30 - 12 - 8 \\
 \qquad \qquad \qquad \underline{-54 + 36 - 6} \\
 \qquad \qquad \qquad \qquad \underline{+36 - 12} \\
 \qquad \qquad \qquad \qquad \qquad \underline{-8}
 \end{array}$$

SECT. III.—FRACTIONS.

25. In the operation of division, the divisor may be sometimes greater than the dividend, or may not be contained in it an exact number of times: in either case the quotient is expressed by means of a fraction. There can be no difficulty, however, in estimating the magnitude of such a quotient; if, for example, it were the fraction  $\frac{5}{7}$ , we may consider it as denoting either that some unit is divided into 7 equal parts, and that 5 of these are taken, or that

5 times the same unit is dividet into 7 equal parts, and one of them taken.

In any fraction the upper number, or the dividend, is called the *numerator*, and the lower number or divisor is called the *denominator*. Thus, in the fraction  $\frac{a}{b}$ ,  $a$  is the numerator, and  $b$  the denominator.

If the numerator be less than the denominator, such a fraction is called a *proper* fraction; but if the numerator be either equal to or greater than the denominator, it is called an *improper* fraction; and if a quantity be made up of an integer and a fraction, it is called a *mixed* quantity.

Thus,  $\frac{a}{a+x}$  is a proper fraction;  $\frac{a}{a}$  and  $\frac{a+x}{a}$  are both improper fractions; and  $b + \frac{x}{a}$  is a mixed quantity.

The *reciprocal* of a fraction is another fraction, having its numerator and denominator respectively equal to the denominator and numerator of the former.

Thus,  $\frac{b}{a}$  is the reciprocal of the fraction  $\frac{a}{b}$ .

26. The following proposition is the foundation of the operations relating to fractions.

If the numerator and denominator of a fraction be either both multiplied or both divided by the same quantity, the value of the resulting fraction is the same as before.

To demonstrate this proposition we shall throw the definition of a fraction into a categorical form. We shall accordingly define the fraction  $\frac{a}{b}$  as such a magnitude, that when it is multiplied by  $b$ , the product is  $a$ .

Then since  $\frac{a}{b} \times b = a$ .

$$n \times \frac{a}{b} \times b = na$$

i.e. (Art. 9, Law 3),  $\frac{a}{b} \times nb = na$

But  $\frac{na}{nb} \times nb = na$  (Def.)

$$\therefore \frac{a}{b} = \frac{na}{nb}$$

From this proposition, it is obvious that a fraction may be very differently expressed without changing its value, and that any integer may be reduced to the form of a fraction, by placing the product arising from its multiplication by any assumed quantity as the numerator, and the assumed quantity as the denominator of the fraction. It also appears that a fraction very complex in its form may often be reduced to another of the same value, but more simple, by finding a quantity which will divide both the numerator and denominator, without leaving a remainder. Such a common divisor, or common measure, may be either simple or compound; if it be simple, it is readily found by inspection, but if it be compound, it may be found as in the following problem.

27. PROB. I.—To find the greatest common Measure of two Quantities.

Rule 1. Range the quantities according to the power of some one of the letters, as in division, leaving out the simple divisors of each quantity.

2. Divide that quantity which is of most dimensions by the other one, and if there be a remainder, divide it by its greatest simple divisor; and then divide the last compound divisor by the resulting quantity, and if anything yet remain, divide it also by its greatest simple divisor, and the last compound divisor by the resulting quantity. Proceed in this way till nothing remain,

and the last divisor shall be the common measure required.

Note.—It will sometimes be necessary to multiply the dividends by simple quantities in order to make the divisions succeed.

The demonstration of this proposition depends on the AXIOM, that whatever divides a number divides any multiple of the number; and whatever divides two numbers divides their sum or difference. It was given by Euclid in Prop. 2, Book vii., very much as follows:—

Let  $a, b$  be the quantities, the smaller of which is  $b$ .

Let  $a$  be divided by  $b$ , with a remainder  $c$ ,

$b$  by  $c$ , with a remainder  $d$ ,

$c$  by  $d$ , with no remainder,

$d$  is the greatest common measure of  $a$  and  $b$ .

We have  $a - pb = c, b - qc = d, c = rd$ .

Now, (1.)  $d$  is a common measure of  $a$  and  $b$ ; for  $d$  divides  $c \therefore qc \therefore qc + d \therefore b \therefore pb \therefore pb + c \therefore a$ ; i.e.,  $d$  divides  $a$  and  $b$ .

(2.) It is the greatest common divisor. For if not, let  $e$  be the greatest; then, since  $e$  divides  $a$  and  $b$ , it divides  $a$  and  $pb, \therefore a - pb \therefore c \therefore qc \therefore b - qc \therefore d$ ; i.e.,  $e$  is less than  $d$ , and not greater.

Cor. Every other divisor of  $a$  and  $b$  divides their greatest common measure.

Observe that no fraction is in a form to be interpreted until it is reduced to its lowest terms.

Ex. 1. Required the greatest common measure of the quantities  $a^2x - x^3$  and  $a^3 - 2a^2x + ax^2$ . The simple divisor  $x$  being taken out of the former of these quantities, and  $a$  out of the latter, they are reduced to  $a^2 - x^2$  and  $a^2 - 2ax + x^2$ ; and as the quantity  $a$  rises to the same dimensions in both, we may take either of them as the first divisor: let us take that which consists of fewest terms, and the operation will stand thus:

$$\begin{array}{r} a^2 - x^2 \overline{) a^2 - 2ax + x^2} \\ \underline{a^2 - x^2} \phantom{+} \\ -2ax + 2x^2 \text{ remainder,} \end{array}$$

which, divided by  $-2x$ , is  $a - x$

$$\begin{array}{r} a^2 - x^2 \\ + ax - x^2 \\ \hline + ax - x^2 \\ \hline * \quad * \end{array}$$

Hence it appears that  $a - x$  is the greatest common measure required.

Ex. 2. Required the greatest common measure of  $8a^2b^2 - 10ab^3 + 2b^4$ , and  $9a^4b - 9a^3b^2 + 3a^2b^3 - 3ab^4$ .

It is evident, from inspection, that  $b$  is a simple divisor of both quantities; it will therefore be a factor of the common measure required. Let the simple divisors be now left out of both quantities, and they are reduced to  $4a^2 - 5ab + b^2$ , and  $3a^3 - 3a^2b + ab^2 - b^3$ ; but as the second of these is to be divided by the first, it must be multiplied by 4 to make the division succeed, and the operation will stand thus:

$$\begin{array}{r} 4a^2 - 5ab + b^2 \overline{) 12a^3 - 12a^2b + 4ab^2 - 4b^3} \\ \underline{12a^3 - 15a^2b + 3ab^2} \phantom{-} \\ + 3a^2b + ab^2 - 4b^3 \end{array}$$

This remainder is to be divided by  $b$ , and the new dividend multiplied by 3, to make the division again succeed, and the work will stand thus:

$$\begin{array}{r} 3a^2 + ab - 4b^2 \overline{) 12a^2 - 15ab + 3b^2} \\ \underline{12a^2 + 4ab - 16b^2} \phantom{+} \\ -19ab + 19b^2 \end{array}$$

This remainder is to be divided by  $-19b$ , which being done, and the last divisor taken as a dividend as before, the rest of the operation will be as follows:—

$$\begin{array}{r} a-b \quad 3a^2 + ab - 4b^2(3a+4b) \\ \underline{3a^2 - 3ab} \\ + 4ab - 4b^2 \\ \underline{+ 4ab - 4b^2} \\ * \quad * \end{array}$$

from which it appears that the common divisor sought is  $a-b$ , and remarking that the quantities proposed have also a simple divisor  $b$ , the greatest common measure which is required will be  $b(a-b)$ .

It will be seen that the examples we have given are not on numbers, but on algebraic quantities. In fact, the axiom and the demonstration founded on it apply, with some restrictions and modifications, to such quantities. The most important of the modifications is this: that the divisor, instead of being a whole number, is an expression of the form  $x+m$ , where  $m$  is of the nature of a numerical quantity, and does not depend on  $x$ .

The application of this modified form of the axiom has a wide range in the higher analysis. We offer two additional examples for advanced students.

*Ex. 1.* If  $ax^2+bx+c$ ,  $a'x^2+b'x+c'$  have a common divisor of the form  $x+m$ , prove that

$$(a'b - ab')(b'c - bc') = (a'c - ac')^2.$$

Multiply the first expression by  $a'$ , and the second by  $a$ , and subtract the products, the difference  $(a'b - ab')x + a'c - ac'$ , is by the axiom divisible by  $x+m$ ,

$$\therefore x + \frac{a'c - ac'}{a'b - ab'} \text{ is } x + m.$$

Again, multiply the first expression by  $c'$ , and the second by  $c$ , and subtract them; the difference  $(a'c - ac')x^2 + (b'c - bc')x$  is divisible by  $x+m$ ,  $\therefore x + \frac{b'c - bc'}{a'c - ac'} \text{ is } x + m$ .

Consequently, 
$$\frac{b'c - bc'}{a'c - ac'} = \frac{a'c - ac'}{a'b - ab'},$$

the condition required.

*Ex. 2.* If  $ax^3+3bx^2+d$ ,  $bx^3+3dx+e$ , have a common divisor; then

$$(4bd - ae)^3 + 27(ad^2 + b^2e)^2 = 0.$$

Treating this question exactly as the last, viz., multiplying first by  $b$  and  $a$ , and then by  $e$  and  $d$ , and subtracting, it appears (if  $u$  be written instead of  $bd - ae$  for brevity) that the two following expressions have a common divisor,

$$3b^2x^2 - 3adx + u \text{ and } ux^2 - 3bex + 3d^2,$$

whence, by the last example, the condition is

$$(3beu - 9ad^3)(3adu - 9b^3e) = (u^2 - 9b^2d^2)^2,$$

from which  $u$  divides out as a common factor, and the result reduces to that enunciated.

28. PROB. II.—*To Reduce a Fraction to its Lowest Terms.*

*Rule.* Divide both numerator and denominator by their greatest common measure, which may be found by Prob. I.

*Ex. 1.* Reduce  $\frac{a^2x-x^3}{a^3-2a^2x+ax^2}$  to its lowest terms.

We have already found in the first example of Prob. I. that the greatest common measure of the numerator and denominator is  $a-x$ ; and dividing both by this quantity,

we have 
$$\frac{a^2x-x^3}{a^3-2a^2x+ax^2} = \frac{ax+x^2}{a^2-ax}.$$

In like manner we find

$$\frac{9a^4b - 9a^3b^2 + 3a^2b^3 - 3ab^4}{8a^2b^2 - 10ab^3 + 2b^4} = \frac{9a^3 + 3ab^2}{8ab - 2b^2},$$

the common measure being  $b(a-b)$ , as was shown in Example 2, Problem I.

*Ex. 2.* Reduce  $\frac{a^2-b^2-c^2+2bc}{a^2+b^2-c^2+2ab}$  to its lowest terms.

$$\frac{a^2-b^2-c^2+2bc}{a^2+b^2-c^2+2ab} = \frac{a^2-(b-c)^2}{(a+b)^2-c^2} = \frac{(a+b-c)(a-b-c)}{(a+b+c)(a+b-c)} = \frac{a-b+c}{a+b+c}.$$

*Ex. 3.* To find the value of  $\frac{(x+1)^2-3x-3}{x^2-2x}$  when  $x=2$ .

Here the substitution of 2 in place of  $x$  renders the numerator and denominator separately equal to 0. This shows (Art. 20) that  $x-2$  is a divisor of each of them. We get, therefore,

$$\frac{(x+1)^2-3x-3}{x^2-2x} = \frac{x+1}{x}, \text{ which when } x=2 \text{ becomes } \frac{3}{2}.$$

*Ex. 4.* Find the value of  $\frac{x^3-4x^2+2x+1}{x^4-4x^3+6x^2-4x+1}$  when  $x=1$ .

Dividing numerator and denominator by  $x-1$ , the result is  $\frac{x^2-3x-1}{x^3-3x^2+3x-1}$ , which, when 1 is written in place of  $x$ , becomes  $\frac{3}{0}$ , or infinity.

29. PROB. III.—*To Reduce a Mixed Quantity to an Improper Fraction.*

*Rule.* Multiply the integer by the denominator of the fraction, and to the product add the numerator; and the denominator being placed under this sum, the result will be the improper fraction required.

*Ex. 1.* Reduce  $a-x + \frac{x^2}{a+x}$  to an improper fraction.

$$a-x + \frac{x^2}{a+x} = \frac{(a+x)(a-x)+x^2}{a+x} = \frac{a^2}{a+x}, \text{ Ans.}$$

30. PROB. IV.—*To Reduce an Improper Fraction to a Whole or Mixed Number.*

*Rule.* Divide the numerator by the denominator for the integral part, and place the remainder, if any, over the denominator; it will be the mixed quantity required.

*Ex. 1.* Reduce  $\frac{ax+2x^2}{a+x}$  and  $\frac{x^2-y^2}{x-y}$  to whole or mixed quantities.

First  $\frac{ax+2x^2}{a+x} = x + \frac{x^2}{a+x}$ , the answer.

And  $\frac{x^2-y^2}{x-y} = x+y$  a whole quantity, which is the answer.

31. PROB. V.—*To Reduce Fractions having different Denominators to others of the same value which shall have a common Denominator.*

*Rule.* Multiply each numerator separately into all the denominators except its own for the new numerators, and all the denominators together for the common denominator.

*Ex. 1.* Reduce  $\frac{ax}{a-x}$  and  $\frac{a^2-x^2}{a+x}$  to fractions of equal value, having a common denominator.

$$\left. \begin{array}{l} ax(a+x) = a^2x + ax^2 \\ (a^2-x^2)(a-x) = a^3 - a^2x - ax^2 + x^3 \end{array} \right\} \text{the new numerators.}$$

( $a-x$ )( $a+x$ ) =  $a^2-x^2$ , the common denominator.

Hence  $\frac{ax}{a-x} = \frac{a^2x+ax^2}{a^2-x^2}$  and  $\frac{a^2-x^2}{a+x} = \frac{a^3-a^2x-ax^2+x^3}{a^2-x^2}$ .

32. PROB. VI.—To Add or Subtract Fractions.

*Rule.* Reduce the fractions to a common denominator, and add or subtract their numerators; and the sum or difference placed over the common denominator is the sum or remainder required.

In practice, however, it is generally better to separate the process into two or more parts analogous to the addition or subtraction of sums of money, where the pounds are added to the pounds, the shillings to the shillings, &c., and the result afterwards combined.

*Ex.* 1. Add together  $\frac{a}{a-b}$  and  $\frac{b}{b-a}$ .

The latter fraction is  $-\frac{b}{a-b}$ .

$\therefore$  the sum required is  $\frac{a}{a-b} - \frac{b}{a-b} = \frac{a-b}{a-b} = 1$ .

Similarly,  $\frac{1}{a^n-1} + \frac{1}{a^{-n}-1} = \frac{1}{a^n-1} + \frac{a^n}{1-a^n} = \frac{1-a^n}{a^n-1} = -1$ .

*Ex.* 2. Collect into a single fraction

$$\frac{1}{a-b} - \frac{1}{a+b} + \frac{2a}{a^2-b^2}$$

Since  $\frac{1}{a-b} - \frac{1}{a+b} = \frac{2b}{a^2-b^2}$

$\therefore \frac{1}{a-b} - \frac{1}{a+b} + \frac{2a}{a^2-b^2} = \frac{2(b+a)}{a^2-b^2} = \frac{2}{a-b}$ .

*Ex.* 3. Collect  $\frac{1}{4x-8} + \frac{1}{3x-6} + \frac{7}{24-12x}$ .

We observe that  $x-2$  is common to all the denominators; the question may therefore be written,

$$\frac{1}{x-2} + \frac{1}{x-2} - \frac{7}{x-2} = 0.$$

*Ex.* 4. Collect  $\frac{1}{3x+2y} + \frac{1}{x-4y} + \frac{1}{3x-2y} - \frac{25x+4y}{x^2-16y^2}$ .

Here we commence by adding the 1st and 3d together, and the 2d and 4th together; which results in

$$\frac{6x}{9x^2-4y^2} - \frac{24x}{x^2-16y^2}$$

$$= 6x \left( \frac{1}{9x^2-4y^2} - \frac{4}{x^2-16y^2} \right) = 6x \frac{-35x^2}{(9x^2-4y^2)(x^2-16y^2)}$$

$$= -\frac{210x^3}{(9x^2-4y^2)(x^2-16y^2)}$$

*Ex.* 5. Find the sum of  $\frac{1+x+x^2+x^3}{1-x+x^2-x^3} + \frac{1-x+x^2-x^3}{1+x+x^2+x^3}$ .

The numerator will consist of the sum of two products, the one containing  $+x$ , exactly in the same way that the other contains  $-x$ . If, then, we write down one of these products, and double the even powers of  $x$  in it, omitting the odd powers, we shall obtain the required result. The product of the denominators again may be readily obtained by regarding it as that of the difference and sum of  $1+x^2$  and  $x+x^3$ . As such processes are of constant occurrence, we will indicate the work in full.

Numerator,	$\begin{array}{r} 1+1+1+1 \\ 1+1+1+1 \\ 1+1+1+1 \\ +1+1+1+1 \\ +1+1+1+1 \\ +1+1+1+1 \end{array}$
Double of	$\begin{array}{r} 1 \\ +3x^2 \\ +3x^4 \\ +1 \end{array}$

Denominator,  $\{1+x^2-(x+x^3)\} \{1+x^2+(x+x^3)\} = (1+x^2)^2 - (x+x^3)^2 = 1+2x^2+x^4-x^2-2x^4-x^6 = 1+x^2-x^4-x^6$ .

And the result is  $\frac{2+6x^2+6x^4+2x^6}{1+x^2-x^4-x^6}$ .

*Ex.* 6. Collect into one fraction  $\frac{1}{1+x^{m-n}+x^{n-p}} + \frac{1}{1+x^{n-m}+x^{p-n}}$ .

Multiply numerator and denominator of the first fraction by  $x^{-m}$ , &c., and the given quantity becomes

$$\frac{x^{-m}}{x^{-m}+x^{-n}+x^{-p}} + \frac{x^{-n}}{x^{-m}+x^{-n}+x^{-p}} + \frac{x^{-p}}{x^{-m}+x^{-n}+x^{-p}} = 1$$

*Ex.* 7. If  $\frac{1}{1+l+ln} + \frac{m}{1+m+ml} + \frac{nm}{1+n+nm} = 1$ , and  $\frac{l}{1+l+ln} + \frac{ml}{1+m+ml} + \frac{1}{1+n+nm} = 1$ ,

none of the denominators being zero, then  $l=m=n$ .

Multiply the first quantity by  $l$ , and subtract, there results  $l = \frac{1+m}{1+n}n$ , which, when substituted in the first quantity, gives  $m=n$ , whence the proposition.

33. The converse problem to collecting many fractions Partial into one is frequently as important as the direct—the pro-fraction-blem, namely, of resolving a compound fraction into its components or *partial fractions*. For a first example, if it be required to find what simple fractions make up the compound fraction  $\frac{2x}{x^2-a^2}$ , we commence by observing that the denominator  $x^2-a^2$  is the product of  $x+a$  and  $x-a$ . Hence,  $\frac{2x}{x^2-a^2}$  is the sum of the fractions whose denomina-tors are  $x+a$  and  $x-a$ .

Let  $\frac{2x}{x^2-a^2} = \frac{A}{x+a} + \frac{B}{x-a}$ , where  $A$  and  $B$  are quantities which involve  $a$  only, not  $x$ , since  $x^2$  does not appear in the numerator of the sum.

By addition,  $\frac{2x}{x^2-a^2} = \frac{A(x-a)+B(x+a)}{x^2-a^2}$ .

$\therefore 2x = A(x-a) + B(x+a)$ .

To obtain  $A$  and  $B$  from this equality, we remark that the equality is an identity, as in Art. 20. We may, therefore, deal with it in either of two ways: 1. Make the  $x$ 's on the left hand side to coincide with the  $x$ 's on the right, and the  $a$ 's in like manner. 2. As in Art. 20, write anything we please in place of  $x$  on both sides. We will in this example take the first method, and illustrate the second method by the subsequent examples. We get  $2 = A+B$ ,  $0 = A-B$ ;  $\therefore A=B=1$ , and the result is

$$\frac{2x}{x^2-a^2} = \frac{1}{x-a} + \frac{1}{x-a}$$

*Ex.* 2.  $\frac{1}{(x-a)(x-b)} = \frac{A}{x-a} + \frac{B}{x-b}$ .

$\therefore 1 = A(x-b) + B(x-a)$ .

Write  $a$  for  $x$ , then  $1 = A(a-b) \therefore A = \frac{1}{a-b}$ .

Write  $b$  for  $x$ , then  $1 = B(b-a) = -(a-b) \therefore B = -\frac{1}{a-b}$ ;

hence,  $\frac{1}{(x-a)(x-b)} = \frac{1}{a-b} \left( \frac{1}{x-a} - \frac{1}{x-b} \right)$ .

The reader will observe that we have treated  $\frac{1}{a-b}$  as if it were not itself a fraction. In fact, in the application of the subject before us, the letters  $a$  and  $b$  stand for arith-metical quantities, and the fraction  $\frac{1}{a-b}$  is simply an arith-metical fraction, as contradistinguished from an algebraical fraction like  $\frac{1}{x-a}$ .

Ex. 3.  $\frac{px+q}{(x-a)(x-b)(x-c)} = \frac{A}{x-a} + \frac{B}{x-b} + \frac{C}{x-c}$   
 gives  $px+q = A(x-b)(x-c) + B(x-a)(x-c) + C(x-a)(x-b)$ ,  
 $\therefore pa+q = A(a-b)(a-c)$ , &c.,  
 and  $\frac{px+q}{(x-a)(x-b)(x-c)} = \frac{pa+q}{(a-b)(a-c)} \cdot \frac{1}{x-a} + \frac{pb+q}{(b-a)(b-c)} \cdot \frac{1}{x-b} + \frac{pc+q}{(c-a)(c-b)} \cdot \frac{1}{x-c}$ .

Ex. 4. Find the sum of  $\frac{a+b}{(b-c)(c-a)} + \frac{b+c}{(c-a)(a-b)} + \frac{c+a}{(a-b)(b-c)}$ .  
 Let  $a+b+c=s$ ; and write in alphabetical order; it gives

$$\frac{a-s}{(a-b)(a-c)} + \frac{b-s}{(b-a)(b-c)} + \frac{c-s}{(c-a)(a-b)},$$

i.e. (Ex. 3), the A, B, C of the resolved fraction,

$$\frac{x-s}{(x-a)(x-b)(x-c)} = \frac{A}{x-a} + \frac{B}{x-b} + \frac{C}{x-c},$$

and since  $x-s = A(x-b)(x-c) + B(x-a)(x-c) + C(x-a)(x-b)$ , the sum required, being the coefficient of  $x^2$ , is equal to 0.

The reader will easily extend this process to other cases, as, for instance, to prove

Ex. 5.  $\frac{bcd}{(a-b)(a-c)(a-d)} + \frac{cda}{(b-c)(b-d)(b-a)} + \frac{dab}{(c-d)(c-a)(c-b)} + \frac{abc}{(d-a)(d-b)(d-c)} = 1$ .

34. PROB. VII.—To Multiply Fractions.

Rule. Multiply the numerators of the fractions for the numerator of the product, and the denominators for the denominator of the product.

The demonstration follows at once from the definition of a fraction given in Art. 26; thus since  $\frac{a}{b} \times b = a$ ,  $\frac{c}{d} \times d = c$ , we have  $\frac{a}{b} \times b \times \frac{c}{d} \times d = ac$ , i.e., by the commutative law  $\frac{a}{b} \times \frac{c}{d} \times bd = ac$ .

But  $\frac{ac}{bd} \times bd = ac$   
 $\therefore \frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$ .

35. PROB. VIII.—To Divide Fractions.

Rule. Multiply the dividend by the reciprocal of the divisor, the product will be the quotient required.

This rule requires no demonstration.

Examples in Multiplication and Division of Fractions.

Ex. 1. Multiply  $\frac{a}{b} - \frac{b}{a}$  by  $\frac{a^2}{a^2-b^2}$ . Since  $\frac{a}{b} - \frac{b}{a} = \frac{a^2-b^2}{ab}$ ,  
 $\therefore$  the product is  $\frac{a^2-b^2}{ab} \times \frac{a^2}{a^2-b^2} = \frac{a^2}{ab} = \frac{a}{b}$ .

Ex. 2. Multiply  $\frac{x^3-3x+2}{x^3+2x^2+2x+1}$  by  $\frac{x^2+2x+1}{x^2-5x+4}$ .

Because the numerator of the first fraction, and the denominator of the second both become 0, when 1 is written for  $x$ , each is divisible by  $x-1$  (Art. 20). In the same way the denominator of the first fraction, and the

numerator of the second are both divisible by  $x+1$ . Hence,

$$\frac{x^3-3x+2}{x^3+2x^2+2x+1} \times \frac{x^2+2x+1}{x^2-5x+4} = \frac{x^3-3x+2}{x^2-5x+4} \times \frac{x^2+2x+1}{x^3+2x^2+2x+1}$$

$$= \frac{x^2+x-2}{x-4} \times \frac{x+1}{x^2+x+1} = \frac{x^3+2x^2-x-2}{x^3-3x^2-3x-4}$$

Ex. 3. Divide  $\frac{a}{b} - \frac{b}{a}$  by  $\frac{a^2}{b^2} - \frac{b^2}{a^2}$ .

The quotient is  $\frac{a^2-b^2}{ab} \times \frac{a^2b^2}{a^4-b^4} = \frac{ab}{a^2+b^2}$ .

Ex. 4. Reduce  $1 - \left(\frac{b^2+c^2-a^2}{2bc}\right)^2$  to factorials.

$$1 - \left(\frac{b^2+c^2-a^2}{2bc}\right)^2 = \left(1 + \frac{b^2+c^2-a^2}{2bc}\right) \left(1 - \frac{b^2+c^2-a^2}{2bc}\right)$$

$$= \frac{(b+c)^2-a^2}{2bc} \times \frac{a^2-(b-c)^2}{2bc}$$

$$= \frac{(b+c+a)(b+c-a)(a+b-c)(a-b+c)}{4b^2c^2}$$

Ex. 5. Reduce  $1 - \left(\frac{a^2+b^2-c^2-d^2}{2(ab+cd)}\right)^2$  to factorials.

$$1 - \left(\frac{a^2+b^2-c^2-d^2}{2(ab+cd)}\right)^2 = \left\{1 + \frac{a^2+b^2-c^2-d^2}{2(ab+cd)}\right\} \times \left\{1 - \frac{a^2+b^2-c^2-d^2}{2(ab+cd)}\right\}$$

$$= \frac{(a+b+c-d)(a+b-c+d)(c+d+a-b)(c+d-a+b)}{4(ab+cd)^2}$$

Miscellaneous Examples in Fractions.

Ex. 1. Find the value of  $\frac{1}{ab-ax} - \frac{1}{bx-ab} + \frac{x}{(x-a)(bc-cx)}$ , when  $x = \frac{2abc}{ab+ac+bc}$ . Writing down every term with  $x$  first, there results—

$$-\frac{1}{a(x-b)} - \frac{1}{b(x-a)} - \frac{x}{c(x-a)(x-b)} = -\frac{\frac{x}{a} + \frac{x}{b} + \frac{x}{c} - 2}{(x-a)(x-b)} = 0.$$

Ex. 2. Find the value of  $\frac{1}{x-3a} + \frac{1}{x-3b} + \frac{1}{x+3c}$ , when  $\frac{1}{a} + \frac{1}{b} = \frac{1}{c}$  and  $x = 2(a+b-c)$ .

Restore symmetry by writing  $-c$  for  $c$ ; the numerator of the sum is  $(x-3b)(x-3c) + (x-3a)(x-3c) + (x-3a)(x-3b) = 3\{x^2 - 2(a+b+c)x + 3(ab+ac+bc)\}$ . But  $x = 2(a+b+c)$ , whence the first and second terms make up 0; and  $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 0$ , is the third term divided by  $abc$ ,  $\therefore$  the sum required is 0.

Ex. 3. Given that  $(a^2+bc)(b^2+ac)(c^2+ab) + (a^2-bc)(b^2-ac)(c^2-ab) = 0$ , when multiplied out and reduced, may be written  $a^3+b^3+c^3+abc = 0$ , prove that  $(a^2+bc)(b^2+ac)(c^2+ab) - (a^2-bc)(b^2-ac)(c^2-ab) = 0$ , may be reduced to  $\frac{1}{a^3} + \frac{1}{b^3} + \frac{1}{c^3} + \frac{1}{abc} = 0$ . The latter given equality, by dividing it by  $a^2bc \times b^2ac \times c^2ab$ , becomes

$$\left(\frac{1}{bc} + \frac{1}{a^2}\right) \left(\frac{1}{ac} + \frac{1}{b^2}\right) \left(\frac{1}{ab} + \frac{1}{c^2}\right) - \left(\frac{1}{bc} - \frac{1}{a^2}\right) \left(\frac{1}{ac} - \frac{1}{b^2}\right) \left(\frac{1}{ab} - \frac{1}{c^2}\right) = 0$$

i.e.  $\left(\frac{1}{bc} + \frac{1}{a^2}\right) \left(\frac{1}{ac} + \frac{1}{b^2}\right) \left(\frac{1}{ab} + \frac{1}{c^2}\right) + \left(\frac{1}{a^2} - \frac{1}{bc}\right) \left(\frac{1}{b^2} - \frac{1}{ac}\right) \left(\frac{1}{c^2} - \frac{1}{ab}\right) = 0$ ,

which is identical with the first given equality, but with  $\frac{1}{a}, \frac{1}{b}, \frac{1}{c}$ , written in place of  $a, b, c$ . The result therefore of

reducing the second equality will be identical with that of reducing the first, when  $\frac{1}{a}, \frac{1}{b}, \frac{1}{c}$ , are written in place of  $a, b, c$ . Now the former result is  $a^3 + b^3 + c^3 + abc = 0, \therefore$  the latter is  $\frac{1}{a^3} + \frac{1}{b^3} + \frac{1}{c^3} + \frac{1}{abc} = 0$ .

Ex. 4. Prove that  $\frac{a_1^{m-1}}{(a_1 - a_2)(a_1 - a_3) \dots (a_1 - a_n)} + \frac{a_2^{m-1}}{(a_2 - a_1)(a_2 - a_3) \dots (a_2 - a_n)} + \dots$ , is equal to 0 if  $m > n$ , and equal to 1 if  $m = n$ . This is easily proved by resolving  $\frac{x^{m-1}}{(x - a_1)(x - a_2) \dots (x - a_n)}$  into partial fractions (Art. 33).

We have

$$\frac{x^{m-1}}{(x - a_1) \dots (x - a_n)} = \frac{A_1}{x - a_1} + \frac{A_2}{x - a_2} + \dots \&c.,$$

$$\therefore x^{m-1} = A_1(x - a_2) \dots (x - a_n) + \dots \&c. \dots (1),$$

whence, writing  $a_1, a_2, \dots$ , successively for  $x$ , we get  $A_1, A_2, \dots$ , &c.

The given quantity is  $A_1 + A_2 + \dots + A_n$ , and the equation marked (1), gives, by equating coefficients of like powers of  $x$ , the result required.

Ex. 5. If  $\frac{p}{q} = \frac{r}{s}$ , then  $\frac{p+q}{p-q} = \frac{r+s}{r-s}$ .

For  $\frac{p}{q} + 1 = \frac{r}{s} + 1$  gives  $\frac{p+q}{q} = \frac{r+s}{s}$ , and  $\frac{p}{q} - 1 = \frac{r}{s} - 1$  gives  $\frac{p-q}{q} = \frac{r-s}{s}$ . Divide the former by the latter.

Ex. 6. If  $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} = \frac{1}{a+b+c}$ , then  $a^2 = b^2 = c^2$ .

For  $\frac{a+b}{ab} = \frac{1}{a} + \frac{1}{b} = \frac{1}{a+b+c} - \frac{1}{c} = -\frac{a+b}{c(a+b+c)}$ ,  
 $\therefore$  either  $a+b=0$ , or  $\frac{1}{ab} = -\frac{1}{ac} - \frac{1}{bc} - \frac{1}{c^2}$ .

In the latter case,  $\frac{1}{c^2} = \frac{1}{ab} + \frac{1}{ac} + \frac{1}{bc}$ ,

which is not changed by interchanging  $c$  and  $b$  or  $c$  and  $a$ ,

$$\therefore \frac{1}{c^2} = \frac{1}{b^2} = \frac{1}{a^2},$$

so that on either alternative the proposition is true.

Ex. 7. Given that  $\frac{ad-bc}{a-b-c+d} = \frac{ac-bd}{a-b+c-d}$ , and  $a$  not equal to  $b$ , nor  $c$  equal to  $d$ ; to prove that  $a+b=c+d$ ; and that either of the fractions equals  $\frac{a+b+c+d}{4}$ .

Write the equality thus,—

$$\frac{ac-bd}{ad-bc} = \frac{a-b+(c-d)}{a-b-(c-d)}.$$

Apply Example 5, and there results,

$$\frac{ac-bd+ad-bc}{ac-bd-ad+bc} = \frac{a-b}{c-d},$$

i.e.  $\frac{(a-b)(c+d)}{(c-d)(a+b)} = \frac{a-b}{c-d}$ , whence  $a+b=c+d$

If now  $a-c$  or  $d-b$  be written by a single symbol  $x$ , the first fraction becomes

$$\frac{(c+x)(b+x)-cb}{2x} = \frac{b+c+x}{2} = \frac{a+b}{2} = \frac{a+b+c+d}{4}.$$

Ex. 8. If  $x = \frac{1}{\sqrt{b} + \sqrt{c} - \sqrt{a}}, y = \frac{1}{\sqrt{c} + \sqrt{a} - \sqrt{b}}$ ,

$$z = \frac{1}{\sqrt{a} + \sqrt{b} - \sqrt{c}}, u = \frac{1}{\sqrt{a} + \sqrt{b} + \sqrt{c}};$$

prove that

$$\frac{(y+z-x+u)(z+x-y+u)(x+y-z+u)}{(x+y+z-u)^3} = \frac{(b+c-a)(c+a-b)(a+b-c)}{8abc}.$$

Deal with the reciprocals of  $x, y, z, u$ ; thus,

$$\begin{aligned} y+z-x+u &= y+z-(x-u) \\ &= yz\left(\frac{1}{z} + \frac{1}{y}\right) - xu\left(\frac{1}{u} - \frac{1}{x}\right) = 2\sqrt{a}(yz-xu) \\ &= 2\sqrt{a}yzxu\left(\frac{1}{xu} - \frac{1}{yz}\right) \\ &= 4\sqrt{a}yzxu(c+b-a). \end{aligned}$$

Hence, by symmetry, the numerator of the left hand fraction becomes

$$64\sqrt{abc}y^2z^2x^2u^2(b+c-a)(c+a-b)(a+b-c).$$

$$\begin{aligned} \text{Also, } x+y+z-u &= xy\left(\frac{1}{y} + \frac{1}{x}\right) + zu\left(\frac{1}{u} - \frac{1}{z}\right) \\ &= 2\sqrt{c}(xy+zu) = 2\sqrt{c}xyzu\left(\frac{1}{zu} + \frac{1}{xy}\right) \\ &= 8\sqrt{abc}xyzu, \end{aligned}$$

Hence the result.

SECT. IV.—SURDS.

36. It has been already observed (Art. 23), that the root of any proposed quantity is found by dividing the exponent of the quantity by the index of the root; and the rule has been illustrated by examples, in all of which, however, the quotient expressing the exponent of the result is a whole number; but there may be cases in which the quotient is a fraction. Thus, if the cube root of  $a^2$  were required, it might be expressed, agreeably to the method of notation already explained, either thus,  $\sqrt[3]{a^2}$ , or thus,  $a^{\frac{2}{3}}$ .

Quantities which have fractional exponents are called *surds*, or imperfect powers, and are said to be *irrational*, in opposition to others with integral exponents, which are called *rational*.

Surds may be denoted by means of the radical sign, but it will be often more convenient to use the notation of fractional exponents. The following examples will show how they may be expressed either way.

$$\begin{aligned} \sqrt[3]{a} &= a^{\frac{1}{3}}, & \sqrt{4ab^2} &= 2ba^{\frac{1}{2}}, & \sqrt[4]{a^3b^2} &= a^{\frac{3}{4}}b^{\frac{1}{2}}, \\ \sqrt{a^2+b^2} &= (a^2+b^2)^{\frac{1}{2}}, & \sqrt{(a-b)^2} &= (a-b)^{\frac{1}{2}}, \\ \frac{\sqrt{a+b}}{\sqrt{ab}} &= (a+b)^{\frac{1}{2}}a^{-\frac{1}{2}}b^{-\frac{1}{2}}. \end{aligned}$$

The operations concerning surds depend on the following principles:—

1. If the numerator and denominator of a fractional exponent be either both multiplied or both divided by the same quantity, the value of the power is the same. Thus,

$$a^{\frac{m}{n}} = a^{\frac{cm}{cn}}.$$

2. The product of like powers (integral or fractional) is the same power of the product. Thus,  $a^{\frac{1}{2}}b^{\frac{1}{2}} = (ab)^{\frac{1}{2}}$ .

37. I.—Reduction of a Rational Quantity to the form of a Surd of any given denomination.

Rule. Reduce the exponent of the quantity to the form of a fraction of the same denomination as the given surd.

Ex. Reduce  $a^2$  to the form of the cube root.

Here the exponent 2 must be reduced to the form of a

fraction having 3 for a denominator, which will be the fraction  $\frac{2}{3}$ ; therefore  $a^2 = a^{\frac{6}{3}} = \sqrt[3]{a^6}$ .

38. II.—*Reduction of Surds of different denominations to others of the same value and of the same denomination.*

*Rule.* Reduce the fractional exponents to others of the same value, and having the same common denominator.

*Ex.* Reduce  $\sqrt{a}$  and  $\sqrt[3]{b^2}$ , or  $a^{\frac{1}{2}}$  and  $b^{\frac{2}{3}}$  to other equivalent surds of the same denomination.

The exponents  $\frac{1}{2}$ ,  $\frac{2}{3}$ , when reduced to a common denominator, are  $\frac{3}{6}$  and  $\frac{4}{6}$ ; therefore the surds required are  $a^{\frac{3}{6}}$  and  $b^{\frac{4}{6}}$ , or  $\sqrt[6]{a^3}$  and  $\sqrt[6]{b^4}$ .

39. III.—*Reduction of Surds to their most simple terms.*

*Rule.* Reduce the surd into two factors, so that one of them may be a complete power, having its exponent divisible by the index of the surd. Extract the root of that power, and place it before the remaining quantities, with the proper radical sign between them.

*Ex. 1.* Reduce  $\sqrt{48}$  to its most simple terms.

The number 48 may be resolved into the two factors 16 and 3, of which the first is a complete square; therefore  $\sqrt{48} = (4^2 \times 3)^{\frac{1}{2}} = 4 \times 3^{\frac{1}{2}} = 4\sqrt{3}$ .

*Ex. 2.* Reduce  $\sqrt{98a^4x}$ , and  $\sqrt[3]{24a^3x + 40a^3x^2}$ , each to its most simple terms.

First,  $\sqrt{98a^4x} = (7^2a^4 \times 2x)^{\frac{1}{2}} = 7a^2 \times (2x)^{\frac{1}{2}} = 7a^2\sqrt{2x}$ .

Also  $\sqrt[3]{24a^3x + 40a^3x^2} = (2^3a^3(3x + 5x^2))^{\frac{1}{3}} = 2a\sqrt[3]{3x + 5x^2}$ .

40. IV.—*Addition and Subtraction of Surds.*

*Rule.* If the surds are of different denominations, reduce them to others of the same denomination, by prob. 2, and then reduce them to their simplest terms by last problem. Then, if the surd part be the same in them all, annex it to the sum or difference of the rational parts, with the sign of multiplication, and it will give the sum or difference required. But if the surd part be not the same in all the quantities, they can only be added or subtracted by placing the signs + or - between them.

*Ex. 1.* Required the sum of  $\sqrt{27}$  and  $\sqrt{48}$ .

By prob. 3 we find  $\sqrt{27} = 3\sqrt{3}$  and  $\sqrt{48} = 4\sqrt{3}$ , therefore  $\sqrt{27} + \sqrt{48} = 3\sqrt{3} + 4\sqrt{3} = 7\sqrt{3}$ .

*Ex. 2.* Required the sum of  $3\sqrt[3]{\frac{1}{4}}$  and  $5\sqrt[3]{\frac{1}{32}}$ .

$3\sqrt[3]{\frac{1}{4}} = 3\sqrt[3]{\frac{3}{12}} = \frac{3}{2}\sqrt[3]{2}$  and  $5\sqrt[3]{\frac{1}{32}} = 5\sqrt[3]{\frac{2}{64}} = \frac{5}{4}\sqrt[3]{2}$ ,

therefore  $3\sqrt[3]{\frac{1}{4}} + 5\sqrt[3]{\frac{1}{32}} = \frac{3}{2}\sqrt[3]{2} + \frac{5}{4}\sqrt[3]{2} = \frac{11}{4}\sqrt[3]{2}$ .

*Ex. 3.* Required the difference between  $\sqrt{80a^4x}$  and  $\sqrt{20a^2x^3}$ .

$\sqrt{80a^4x} = (4^2a^4 \times 5x)^{\frac{1}{2}} = 4a^2\sqrt{5x}$ , and  $\sqrt{20a^2x^3} =$

$(2^2a^2x^2 \times 5x)^{\frac{1}{2}} = 2ax\sqrt{5x}$ ; therefore  $\sqrt{80a^4x} -$

$\sqrt{20a^2x^3} = (4a^2 - 2ax)\sqrt{5x}$ .

41. V.—*Multiplication and Division of Surds.*

*Rule.* If they are surds of the same rational quantity, add or subtract their exponents.

But if they are surds of different rational quantities, let them be brought to others of the same denomination, by prob. 2. Then, by multiplying or dividing these rational quantities, their product or quotient may be set under the common radical sign.

*Note.* If the surds have any rational coefficients, their product or quotient must be prefixed.

*Ex. 1.* Required the product of  $\sqrt[3]{a^2}$  and  $\sqrt[5]{a^3}$ .

$\sqrt[3]{a^2} \times \sqrt[5]{a^3} = a^{\frac{2}{3}} \times a^{\frac{3}{5}} = a^{\frac{2}{3} + \frac{3}{5}} = a^{\frac{10}{15} + \frac{9}{15}} = a^{\frac{19}{15}} = \sqrt[15]{a^{19}}$ , Ans.

*Ex. 2.* Divide  $\sqrt{a^2 - b^2}$  by  $\sqrt[3]{a + b}$ .

These surds, when reduced to the same denomination, are  $(a^2 - b^2)^{\frac{2}{3}}$  and  $(a + b)^{\frac{1}{3}}$ . Hence  $\frac{\sqrt{a^2 - b^2}}{\sqrt[3]{a + b}} = \frac{(a^2 - b^2)^{\frac{2}{3}}}{(a + b)^{\frac{1}{3}}} = \frac{((a + b)^3(a - b)^2)^{\frac{1}{3}}}{(a + b)^{\frac{1}{3}}} = \frac{(a + b)(a - b)^2}{\sqrt{(a + b)(a - b)^3}}$ .

42. VI.—*Involution and Evolution of Surds.*

The powers and roots of surds are found in the same manner as any other quantities, namely, by multiplying or dividing their exponents by the index of the power or root required. Thus, the square of  $3\sqrt[3]{3}$  is  $3 \times 3 \times (3)^{\frac{2}{3}} = 9\sqrt[3]{9}$ . The  $n$ th power of  $x^{\frac{1}{m}}$  is  $x^{\frac{n}{m}}$ . The cube root of  $\frac{1}{8}\sqrt{2}$  is  $\frac{1}{2}(2)^{\frac{1}{6}} = \frac{1}{2}\sqrt[6]{2}$ , and the  $n$ th root of  $x^{\frac{1}{m}}$  is  $x^{\frac{1}{mn}}$ .

43. The reduction of quadratic surds is facilitated by the following considerations, which appear hardly to require demonstration :

1.  $\sqrt{a}$  cannot =  $b + \sqrt{c}$ , when  $\sqrt{c}$  is a surd.
2.  $a + \sqrt{b}$  cannot =  $c + \sqrt{d}$  when  $\sqrt{b}$ ,  $\sqrt{d}$  are unequal surds.
3.  $a$  cannot =  $\sqrt{b}\sqrt{c}$  when  $\sqrt{b}$ ,  $\sqrt{c}$  are surds not involving the same irrational part,  $\sqrt{2}$  and  $\sqrt{3}$  for example.
4.  $\sqrt{a}$  cannot equal  $\sqrt{b} + \sqrt{c}$  when all are surds not involving the same irrational part.

*Note.* The irrational part of  $\sqrt{8}$ , for instance, is  $\sqrt{2}$ , for  $\sqrt{8} = 2\sqrt{2}$ .

44. For example, we extract the square root of a binomial surd such as  $28 + 10\sqrt{3}$  in the following way :

Let  $\sqrt{28 + 10\sqrt{3}} = x + y$ , where one or both of  $x$  and  $y$  must be a surd.

Then  $28 + 10\sqrt{3} = x^2 + y^2 + 2xy$ ,

$\therefore 28 = x^2 + y^2$ ,

$10\sqrt{3} = 2xy$ ,

or No. 2 above would be violated.

Hence  $\sqrt{28 - 10\sqrt{3}} = \sqrt{x^2 + y^2 - 2xy} = x - y$ .

And  $\sqrt{784 - 300} = x^2 - y^2$ ,

or  $x^2 + y^2 = 28$

$x^2 - y^2 = 22$

$x = 5, y = \sqrt{3}$

and  $5 + \sqrt{3}$  is the root required.

*Additional Examples in Surds.*

*Ex. 1.* Add together  $\frac{1}{1 + \sqrt{2}}$ ,  $\frac{1}{1 - \sqrt{2}}$ ,  $\frac{1}{\sqrt{3} + 1}$ , and  $\frac{1}{\sqrt{3} - 1}$ ,

$\frac{1}{1 + \sqrt{2}} + \frac{1}{1 - \sqrt{2}} = \frac{2}{1 - 2} = -2$

$\frac{1}{\sqrt{3} + 1} + \frac{1}{\sqrt{3} - 1} = \frac{2\sqrt{3}}{3 - 1} = \sqrt{3}$ ,

$\therefore \sqrt{3} - 2$  is the sum required.

*Ex. 2.* Find the difference between

$\frac{a + x + \sqrt{(a+x)}}{(a+x) + \sqrt{(a+x)^3}}$  and  $\sqrt{\frac{(a+x) - \sqrt{(a+x)}}{(a+x)^2 - \sqrt{(a+x)^3}}}$

The former is  $\frac{1}{\sqrt{(a+x)}} \cdot \frac{\sqrt{(a+x)} + 1}{1 + \sqrt{(a+x)}} = \frac{1}{\sqrt{(a+x)}}$ .

The latter is the square root of

$\frac{1}{a+x} \cdot \frac{\sqrt{(a+x)} - 1}{\sqrt{(a+x)} - 1}$ , i.e., of  $\frac{1}{a+x}$ ,

$\therefore$  the difference required is 0.

Ex. 3. Find the value of  $\frac{\sqrt{(a^2+x^2)+x}}{\sqrt{(a^2+x^2)-x}}$ ,

when

$$x = \frac{(b-c)a}{2\sqrt{bc}}.$$

At the first reduction  $a$  divides out, and the fraction is reduced to

$$\frac{\sqrt{\left(1 + \frac{(b-c)^2}{4bc}\right) + \frac{b-c}{2\sqrt{bc}}}}{\sqrt{\left(1 + \frac{(b-c)^2}{4bc}\right) - \frac{b-c}{2\sqrt{bc}}}} = \frac{b+c+(b-c)}{b+c-(b-c)} = \frac{b}{c}.$$

Ex. 4. Find the value of  $\frac{x+\sqrt{(2a-x)}}{x-\sqrt{(2a-x)}}$ ,

when

$$x = \sqrt{(b^2 + 4ab)} - b.$$

By the process explained in this article

$$\sqrt{2a-x} = \sqrt{(2a+b - \sqrt{b^2+4ab})} = \sqrt{\frac{4a+b}{2}} - \sqrt{\frac{b}{2}},$$

whence the fraction reduces to  $\frac{\sqrt{2b+1}}{\sqrt{2b-1}}$ .

45. In arithmetic the square root of a number is another number, which, when multiplied by itself, shall produce the first number. In algebra, where quantity takes the place of number, the definition leads to a less limited result than in arithmetic. In the latter science there cannot be two square roots of the same thing; in the former, there will necessarily be two. For both  $+2 \times +2$  gives 4, and  $-2 \times -2$  gives 4; hence the square root of 4 is  $-2$  as well as  $+2$ .

And, further, as in algebra,  $-2$  is a quantity subject to all the operations and definitions of the science, it is clearly competent to express, in some form or other, the result of extracting its square root. That form must of necessity be something very different in character from  $\sqrt{2}$ , whether  $\sqrt{2}$  be  $+$  or  $-$ . For the definition requires that the square root of  $-2$  shall be such a quantity as when multiplied by itself shall produce  $-2$ . It is then clearly no arithmetical quantity either  $+$  or  $-$ , but some quantity connected with numerical quantities by its properties, but not by its nature. It is termed an impossible or imaginary quantity, and may be written  $\sqrt{-2}$  or  $\sqrt{2} \sqrt{-1}$ , and the same notation applies to the square roots of all negative quantities.

The properties of imaginary quantities are almost identical with those of surds, and we need not stop to consider them. One example of their application will suffice. It affords strong confirmation of the safety of assuming the commutative law to exist in every branch of pure algebra.

Ex. The product of the sum of two squares by the sum of two squares can always be represented under the form of the sum of two squares.

$$\begin{aligned} \text{For } (a^2 + b^2)(c^2 + d^2) &= (a+b\sqrt{-1})(a-b\sqrt{-1}) \\ &\quad \times (c+d\sqrt{-1})(c-d\sqrt{-1}) \\ &= (a+b\sqrt{-1})(c+d\sqrt{-1}) \times (a-b\sqrt{-1})(c-d\sqrt{-1}) \\ &= (ac-bd + ad+bc\sqrt{-1})(ac-bd - ad+bc\sqrt{-1}) \\ &= (ac-bd)^2 + (ad+bc)^2. \end{aligned}$$

Cor.  $(a^2 + b^2)(c^2 + d^2) = (ac + bd)^2 + (ad - bc)^2$ , or the product may be represented in two different ways, under the form of the sum of two squares.

#### SECT. V.—PROPORTION AND PROGRESSION.

46. In comparing together any two quantities of the same kind in respect of magnitude, we may consider how much the one is greater than the other, or else how many times the one contains either the whole or some part of the other; or, which is the same thing, we may consider either

what is the difference between the quantities, or what is the quotient arising from the division of the one quantity by the other: the former of these is called their *arithmetical ratio*, and the latter their *geometrical ratio*. These denominations, however, have been assumed arbitrarily, and have little or no connection with the relations they are intended to express.

#### I. Arithmetical Proportion and Progression.

47. When of four quantities the difference between the first and second is equal to the difference between the third and fourth, the quantities are called *arithmetical proportionals*. Such, for example, are the numbers 2, 5, 9, 12; and, in general, the quantities  $a, a+d, b, b+d$ .

48. The principal property of four arithmetical proportionals is this:—If four quantities be arithmetically proportional, the sum of the extreme terms is equal to the sum of the means. Let the quantities be  $a, a+d, b, b+d$ ; where  $d$  is the difference between the first and second, and also between the third and fourth, the sum of the extremes is  $a+b+d$ , and that of the means  $a+d+b$ ; so that the truth of the proposition is evident.

49. If a series of quantities be such, that the difference between any two adjacent terms is always the same, these terms form an *arithmetical progression*. Thus, the numbers 2, 4, 6, 8, 10, &c., form a series in arithmetical progression, and, in general, such a series may be represented thus:

$a, a+d, a+2d, a+3d, a+4d, a+5d, a+6d$ , &c., where  $a$  denotes the first term, and  $d$  the common difference.

By a little attention to this series, we readily discover that it has the following properties:

1. The last term of the series is equal to the first term, together with the common difference taken as often as there are terms *after* the first. Thus, when the number of terms is 7, the last term is  $a+6d$ ; and so on. Hence if  $z$  denote the last term,  $n$  the number of terms, and  $a$  and  $d$  express the first term and common difference, we have  $z = a + (n-1)d$ .

2. The sum of the first and last term is equal to the sum of any two terms at the same distance from them. Thus, suppose the number of terms to be 7, then the last term is  $a+6d$ , and the sum of the first and last  $2a+6d$ ; but the same is also the sum of the second and last but one, of the third and last but two, and so on till we come to the middle term, which, because it is equally distant from the extremes, must be added to itself.

3. To find the sum of the series, it is only necessary to observe that, if the progression is written down twice,  $1^\circ$  from the beginning,  $2^\circ$  from the end, the terms of the former increase by the same amount as that by which the terms of the latter diminish; so that the sum of any two terms which stand under each other is always the same, viz., the same as the sum of the first and last terms; hence the double series converts addition into multiplication; so that if  $s$  denote the sum of the series, we have  $2s = n(a+z)$ , and  $s = \frac{n}{2}(a+z)$ .

Ex. The sum of the odd numbers 1, 3, 5, 7, 9, &c., continued to  $n$  terms, is equal to the square of the number of terms. For in this case  $a=1, d=2, z=1+(n-1)d=2n-1$ , therefore  $s = \frac{n}{2} \times 2n = n^2$ .

#### II. Geometrical Proportion and Progression.

50. When, of four quantities, the quotient arising from the division of the first by the second is equal to that arising from the division of the third by the fourth, these quantities are said to be in *geometrical proportion*, or are

called simply *proportionals*. Thus, 12, 4, 15, 5, are four numbers in geometrical proportion; and, in general,  $na, a, nb, b$ , may express any four proportionals, for  $\frac{na}{a} = n$ , and also  $\frac{nb}{b} = n$ .

To denote that any four quantities  $a, b, c, d$ , are proportionals, it is common to place them thus,  $a : b :: c : d$ ; or thus,  $a : b = c : d$ ; which notation, when expressed in words, is read thus,  $a$  is to  $b$  as  $c$  to  $d$ , or the ratio of  $a$  to  $b$  is equal to the ratio of  $c$  to  $d$ .

The first and third terms of a proportion are called the *antecedents*, and the second and fourth the *consequents*.

When the two middle terms of a proportion are the same, the remaining terms, and that quantity, constitute three geometrical proportionals; such as 4, 6, 9, and in general  $na, a, \frac{a}{n}$ . In this case the middle quantity is called a mean proportional between the other two.

51. The principal properties of four proportionals are the following:

1. If four quantities be proportionals, the product of the extremes is equal to the product of the means. Let  $a, b, c, d$ , be four quantities, such that  $a : b :: c : d$ ; then, from the nature of proportionals,  $\frac{a}{b} = \frac{c}{d}$ : let these equal quotients be multiplied by  $b d$ , and we have  $ad = bc$ . It follows, that if any three of four proportionals be given, the remaining one may be found. Thus, let  $a, b, c$ , the first three, be given, and let it be required to find  $x$ , the fourth term; because  $a : b :: c : x$ ,  $ax = bc$ , and dividing by  $a$ ,  $x = \frac{bc}{a}$ .

The converse is obviously true, viz., if four quantities be such that the product of two of them is equal to the product of the other two, these quantities are proportionals.

2. If four quantities are proportional, that is, if  $a : b :: c : d$ , then will each of the following combinations or arrangements of the quantities be also four proportionals.

1st, By inversion,  $b : a :: d : c$ .

2d, By alternation,  $a : c :: b : d$ .

Note.—The quantities in the second case must be all of the same kind.

3d, By composition,  $a + b : a :: c + d : c$ ,  
or,  $a + b : b :: c + d : d$ .

4th, By division,  $a - b : a :: c - d : c$ ,  
or,  $a - b : b :: c - d : d$ .

5th, By mixing,  $a + b : a - b :: c + d : c - d$ .

6th, By taking any equimultiples of the antecedents, and also any equimultiples of the consequents,  
 $na : pb :: nc : pd$ .

7th, Or, by taking any parts of the antecedents and consequents,  
 $\frac{a}{n} : \frac{b}{p} :: \frac{c}{n} : \frac{d}{p}$ .

That the preceding combinations of the quantities  $a, b, c, d$ , are proportionals, may be readily proved, by taking the products of the extremes and means; for from each of them we derive this conclusion, that  $ad = bc$ , which is known to be true, from the original assumption of the quantities.

8th, If four quantities be proportional, and also other four, the product of the corresponding terms will be proportional.

Let  $a : b :: c : d$ ,

And  $e : f :: g : h$ ;

Then  $ae : bf :: cg : dh$ .

For  $ad = bc$ , and  $eh = fg$ , as before, therefore, multiplying together these equal quantities,  $adeh = bcfy$ , or  $ae \times dh = bf \times cg$ ; therefore, by the converse of the first property,  $ae : bf :: cg : dh$ .

Hence it follows, that if there be any number of proportions whatever, the products of the corresponding terms will still be proportional.

52. If a series of quantities be so related to each other, that the quotient arising from the division of any term by that which precedes it is always the same quantity, these are said to be in *geometrical progression*; such are the numbers 2, 4, 8, 16, 32, &c., also  $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}$ , &c., and in general, a series of such quantities may be represented thus,  $a, ar, ar^2, ar^3, ar^4, ar^5$ , &c. Here  $a$  is the first term, and  $r$  the quotient of any two adjoining terms, which is also called the *common ratio*.

By inspecting this series, we find that it has the following properties:

1. The last term is equal to the first, multiplied by the common ratio raised to a power, the index of which is one less than the number of terms. Therefore, if  $z$  denote the last term, and  $n$  the number of terms,  $z = ar^{n-1}$ .

2. The product of the first and last term is equal to the product of any two terms equally distant from them: thus, supposing  $ar^5$  the last term, it is evident that  $a \times ar^5 = ar \times ar^4 = ar^2 \times ar^3$ , &c.

The sum of  $n$  terms of a geometrical series may be found thus:

$$\begin{aligned} \text{Let} & s = a + ar + ar^2 + ar^3 \dots + ar^{n-1}. \\ \text{Then} & rs = ar + ar^2 + ar^3 \dots + ar^{n-1} + ar^n. \\ \text{Subtract,} & rs - s = ar^n - a. \\ \text{That is,} & (r - 1)s = a(r^n - 1). \\ \text{Hence} & s = \frac{r^n - 1}{r - 1}a, \text{ or } \frac{1 - r^n}{1 - r}a. \end{aligned}$$

Cor. The sum to infinity =  $\frac{a}{1 - r}$ .

*Additional Examples in Proportion and Progression.*

Ex. 1. How many strokes does a clock strike in twelve hours?

If  $s$  denote the number

$$\begin{aligned} s &= 1 + 2 + \dots + 12 \\ s &= 12 + 11 + \dots + 1 \\ \therefore 2s &= 13 + 13 + \dots + 13 = 13 \times 12; s = 78. \end{aligned}$$

Ex. 2. Find the number of shot lying close together in the shape of an equilateral triangle.

Let  $n$  be the number of shot in a side of the triangle. Counting from one angle, and taking in successive rows parallel to the opposite side, we get as the number required

$$1 + 2 + \dots + n = \frac{n(n+1)}{2}.$$

Ex. 3. To find the number of shot in a pile of the form of a triangular pyramid.

As each shot lies in the hollow formed by those below it, the number of shot in the successive sides from the base upwards will evidently be

$$n - 1, n - 2, \dots, 1.$$

Hence the number of shot in the pile will be

$$\frac{n(n+1)}{2} + \frac{(n-1)n}{2} + \frac{(n-2)(n-1)}{2} + \dots + \frac{1 \cdot 2}{2}.$$

To sum this series induction may be employed. The result is

$$\frac{n(n+1)(n+2)}{6}.$$

Ex. 4. A ratio of greater inequality is diminished, and of less inequality increased, by adding the same quantity to each of its terms.

Let  $a > b$ ; then  $\frac{a+x}{b+x} < \frac{a}{b}$ .

By multiplying out, this is evident.

Ex. 5. Find the vulgar fraction which is equivalent to the recurring decimal.

$$\begin{aligned} & \cdot 314\dot{2} \\ \text{Let } x &= \cdot 314\dot{2}, \\ \text{then } 10x &= 3\cdot 14\dot{2} \\ & 10,000x = 3142\cdot 14\dot{2} \\ \therefore \text{ subtracting} & \qquad 9990x = 3139 \\ & \qquad \qquad \qquad x = \frac{3139}{9990} \end{aligned}$$

Ex. 6. A sum of money doubles itself in fifteen years at a rate a little below 5 per cent. A noble Scotch family have retained in their possession gold coins of the value of £500 since the days of Mary Stuart (300 years); what have they lost by not allowing the money to accumulate at the above rate?

Every pound would have amounted to £2<sup>20</sup>; ∴ £500 (2<sup>20</sup> - 1) is the loss. It amounts to upwards of £524,000,000.

Ex. 7. The sum of the mixed series

$$\begin{aligned} & a + (a+b)r + (a+2b)r^2 + \dots \\ \text{is } \frac{a}{1-r} + \frac{br(1-r^{n-1})}{(1-r)^2} - \frac{(a+n-1b)r^n}{1-r} \end{aligned}$$

SECT. VI.—RESOLUTION OF EQUATIONS INVOLVING ONE UNKNOWN QUANTITY.

53. The primary object of algebraic investigation is to discover certain unknown quantities, by comparing them with other quantities which are given, or supposed to be known. The relation between the known and unknown quantities is either that of equality, or else such as may be reduced to equality; and a proposition which affirms that certain combinations of quantities are equal to one another is called an *equation*. Such are the following:—

$$\begin{aligned} \frac{x}{2} + \frac{x}{3} &= \frac{24}{x}, \\ 2x + 3y &= xy. \end{aligned}$$

The first of these equations expresses the relation between an unknown quantity *x* and certain known numbers; and the second expresses the relation which the two indefinite quantities *x* and *y* have to each other.

The conditions of a problem may be such as to require several equations and symbols of unknown quantities for their complete expression. These, however, by rules hereafter to be explained, may be reduced to one equation, involving only one unknown quantity and its powers, besides the known quantities; and the method of expressing that quantity by means of the known quantities constitutes the theory of equations, one of the most important as well as most intricate branches of algebraic analysis.

An equation is said to be *resolved* when the unknown quantity is made to stand alone on one side, and only known quantities on the other side; and the value of the unknown quantity is called a *root* of the equation. The general definition of a root of an equation is, that it is a *numerical quantity* (i.e., some combination of numbers) which, when written in place of the unknown quantity, renders the equation a numerical identity; thus 1 is the root of the equation  $x = 1$ , 1 and -1 are both roots of the equation  $x^2 = 1$ ; 1,  $\sqrt{-1}$ ,  $-\sqrt{-1}$  and -1 are all roots of the equation  $x^4 = 1$ .

54. Equations containing only one unknown quantity and its powers, are divided into different *orders*, according to the highest power of that quantity contained in any one of its terms. The equation, however, is supposed to be reduced to such a form that the unknown quantity is found only in the numerators of the terms, and that the exponents of its powers are expressed by positive integers.

If an equation contains only the first power of the unknown quantity, it is called a *simple equation*, or an equation of the first order. Such is  $ax + b = c$ , where *x* denotes an unknown, and *a*, *b*, *c*, known quantities.

If the equation contains the second power of the unknown quantity, it is said to be of the second degree, or is called a *quadratic equation*; such is  $4x^2 + 3x = 12$ , and in general  $ax^2 + bx = c$ . If it contains the third power of the unknown quantity, it is of the third degree, or is a *cubic equation*; such are  $x^3 + 2x^2 + 4x = 10$ , and  $ax^3 + bx^2 + cx = d$ ; and so on with respect to equations of the higher orders. A simple equation is sometimes said to be *linear*, or of one *dimension*. In like manner, quadratic equations are said to be of two dimensions, and cubic equations of three dimensions.

When in the course of an algebraic investigation we arrive at an equation involving only one unknown quantity, that quantity will often be so entangled in the different terms as to render several previous reductions necessary before the equation can be expressed under its characteristic form, so as to be resolved by the rules which belong to that form.

These reductions depend upon the operations which have been explained in the former part of this treatise, and the application of a few self-evident principles, namely, that if equal quantities be added to or subtracted from equal quantities, the sums or remainders will be equal; if equal quantities be multiplied or divided by the same quantity, the products or quotients will be equal; and, lastly, if equal quantities be raised to the same power, or have the same root extracted out of each, the results will still be equal.

From these considerations are derived the following rules, which apply alike to equations of all orders, and are alone sufficient for the resolution of simple equations.

55. *Rule 1.* Any quantity may be transposed from one side of an equation to the other, by changing its sign.

$$\begin{aligned} \text{Thus,} & \quad \text{if } 3x - 10 = 2x + 5, \\ \text{Then} & \quad 3x - 2x = 5 + 10, \\ \text{Or} & \quad x = 15. \\ \text{Again,} & \quad \text{if } ax + b = cx - dx + e, \\ \text{Then} & \quad ax - cx + dx = e - b, \\ \text{Or} & \quad (a - c + d)x = e - b. \end{aligned}$$

The reason of this rule is evident, for the transposing of a quantity from one side of an equation to the other is nothing more than adding the same quantity to each side of the equation, if the sign of the quantity transposed was -; or subtracting it, if the sign was +.

From this rule we may infer, that if any quantity be found on each side of the equation with the same sign, it may be left out of both. Also, that the signs of all the terms of an equation may be changed into the contrary, without affecting the truth of the equation.

$$\begin{aligned} \text{Thus, if} & \quad a + x = b + a + c, \\ \text{Then} & \quad x = b + c; \\ \text{And if} & \quad a - x = b - d, \\ \text{Then} & \quad x - a = d - b. \end{aligned}$$

56. *Rule 2.* If the unknown quantity in an equation be multiplied by any quantity, that quantity may be taken away, by dividing all the other terms of the equation by it.

$$\begin{aligned} \text{If} & \quad 3x = 24, \\ \text{Then} & \quad x = \frac{24}{3} = 8. \\ \text{If} & \quad ax = b - c, \\ \text{Then} & \quad x = \frac{b - c}{a} = \frac{b}{a} - \frac{c}{a}. \end{aligned}$$

Here equal quantities are divided by the same quantity, and therefore the quotients are equal.

57. *Rule 3.* If any term of an equation be a fraction, its denominator may be taken away, by multiplying all the other terms of the equation by that denominator.

$$\text{If } \frac{x}{5} = 7,$$

$$\text{Then } x = 35.$$

$$\text{If } \frac{x}{a} = b - c + d,$$

$$\text{Then } x = ab - ac + ad.$$

$$\text{If } a - \frac{b}{x} = c,$$

$$\text{We have } ax - b = cx \text{ and } x = \frac{b}{a-c}.$$

In these examples, equal quantities are multiplied by the same quantity, and therefore the products are equal.

58. *Rule 4.* If the unknown quantity is found in any term which is a surd, let that surd be made to stand alone on one side of the equation, and the remaining terms on the opposite side; then involve each side to a power denoted by the index of the surd, and thus the unknown quantity shall be freed from the surd expression.

$$\text{If } \sqrt{x+6} = 10,$$

$$\text{Then, by transposition, } \sqrt{x} = 10 - 6 = 4;$$

$$\text{And, squaring both sides, } \sqrt{x} \times \sqrt{x} = 4 \times 4,$$

$$\text{Or } x = 16.$$

$$\text{Also, if } \sqrt{a^2 + x^2} - b = x,$$

$$\text{By trans. } \sqrt{a^2 + x^2} = b + x,$$

$$\text{And, squaring, } a^2 + x^2 = (b+x)^2 = b^2 + 2bx + x^2,$$

$$\text{Hence } a^2 = b^2 + 2bx, \quad x = \frac{a^2 - b^2}{2b}.$$

59. *Rule 5.* If the side of the equation which contains the unknown quantity be a perfect power, the equation may be reduced to another of a lower order, by extracting the root of that power out of each side of the equation.

$$\text{Thus, if } x^3 = 64a^3,$$

$$\text{Then, by extracting the cube root, } x = 4a;$$

$$\text{And if } (a+x)^2 = b^2 - a^2,$$

$$\text{Then } a+x = \sqrt{b^2 - a^2}.$$

60. In these examples we have been able to determine the value of the unknown quantity by the rules already delivered, because in every case the first, or at most the second power of that quantity, has been made to stand alone on one side of the equation, while the other consisted only of known quantities; but the same methods of reduction serve to bring equations of all degrees to a proper form for solution. Thus, if  $\frac{1-p+q+r}{x+1} = 1-p-x+\frac{r}{x}$ ; by proper reduction, we have  $x^3 + px^2 + qx = r$ , a cubic equation which may be resolved by rules to be afterwards explained.

#### SECT. VII.—REDUCTION OF EQUATIONS INVOLVING MORE THAN ONE UNKNOWN QUANTITY.

61. Having shown in the last section in what manner an equation involving one unknown quantity may be resolved, or at least fitted for a final solution, we are next to explain the methods by which two or more equations, involving as many unknown quantities, may at last be reduced to one equation and one unknown quantity.

As the unknown quantities may be combined together in very different ways, so as to constitute an equation, the methods most proper for their elimination must therefore be various. The three following, however, are of general application, and the last of them may be used with

advantage, not only when the unknown quantity to be eliminated rises to the same power in all the equations, but also when the equations contain different powers of that quantity.

62. *Method 1.* Observe which of the unknown quantities is the least involved, and let its value be found from each equation, by the rules of last section.

Let the values thus found be put equal to each other, and hence new equations will arise, from which that quantity is wholly excluded. Let this operation be now repeated with these equations, thus eliminating the unknown quantities one by one, till at last an equation be found which contains only one unknown quantity.

*Ex.* Let it be required to determine  $x$  and  $y$  from these two equations.

$$2x + 3y = 23,$$

$$5x - 2y = 10.$$

$$\text{From the first equation, } x = \frac{23-3y}{2}.$$

$$\text{From the second equation, } x = \frac{10+2y}{5}.$$

Let these values of  $x$  be now put equal to each other,

$$\text{And we have } \frac{10+2y}{5} = \frac{23-3y}{2},$$

$$\text{Or } 20 + 4y = 115 - 15y;$$

$$\therefore 19y = 95,$$

$$\text{And } y = 5;$$

$$\text{And since } x = \frac{23-3y}{2}, \text{ or } x = \frac{10+2y}{5}, \text{ from either of}$$

these values we find  $x = 4$ .

63. *Method 2.* Let the value of the unknown quantity which is to be eliminated be found from that equation wherein it is least involved. Let this value and its powers be substituted for that quantity, and its respective powers in the other equations; and with the new equations thus arising, let the operation be repeated till there remain only one equation and one unknown quantity.

*Ex.* Let the given equations, as in last method, be

$$2x + 3y = 23,$$

$$5x - 2y = 10.$$

$$\text{From the first equation, } x = \frac{23-3y}{2};$$

And this value of  $x$  being substituted in the second equation, we have  $5 \times \frac{23-3y}{2} - 2y = 10$ ,

$$\text{Or } 115 - 15y - 4y = 20;$$

$$\therefore 95 = 19y,$$

$$\text{And } y = 5$$

$$\text{And hence } x = \frac{23-3y}{2} = 4, \text{ as before.}$$

64. *Method 3.* Let the given equations be multiplied or divided by such numbers or quantities, whether known or unknown, that the term which involves the highest power of the unknown quantity may be the same in each equation.

Then, by adding or subtracting the equations, as occasion may require, that term will vanish, and a new equation emerge, wherein the number of dimensions of the unknown quantity in some cases, and in others the number of unknown quantities will be diminished; and by a repetition of the same or similar operations, a final equation may be at last obtained, involving only one unknown quantity.

*Ex.* Let the same example be taken, as in the illustration of the former methods, namely,

$$2x + 3y = 23,$$

$$5x - 2y = 10.$$

To eliminate  $x$ , let the first equation be multiplied by 5, and the second by 2; thus we have

$$\begin{aligned} 10x + 15y &= 115, \\ 10x - 4y &= 20. \end{aligned}$$

Here the term involving  $x$  is the same in both equations; and it is obvious, that by subtracting the one from the other, the resulting equation will contain only  $y$ , and known numbers; for by such subtraction we find  $19y = 95$ , and therefore  $y = 5$ .

Having got the value of  $y$ , it is easy to see how  $x$  may be found from either of the given equations; but it may also be found in the same manner as we found  $y$ . For let the first of the given equations be multiplied by 2, and the second by 3, we have

$$\begin{aligned} 4x + 6y &= 46, \\ 15x - 6y &= 30. \end{aligned}$$

By adding these equations, we find

$$19x = 76, \text{ and } x = 4.$$

65. The following examples will serve further to illustrate these different methods of eliminating the unknown quantities from equations.

*Ex. 1.* Given  $\begin{cases} ax + by = c \\ dx + fy = g \end{cases}$  to determine  $x$  and  $y$ .

To eliminate  $y$ , let the first equation be multiplied by  $f$ , and the second by  $b$ , and we have

$$\begin{aligned} afx + bfy &= cf, \\ bdx + bfy &= bg. \end{aligned}$$

Taking now the difference between these equations,

$$\begin{aligned} afx - bdx &= cf - bg, \\ (af - bd)x &= cf - bg, \end{aligned}$$

Or

And therefore 
$$x = \frac{cf - bg}{af - bd}.$$

In the same manner may  $y$  be determined, by multiplying the first of the given equations by  $d$ , and the second by  $a$ ; for we find

$$\begin{aligned} adx + bdy &= cd, \\ adx + afy &= ag. \end{aligned}$$

And taking the difference as before, we get

$$bdy - afy = cd - ag,$$

And therefore

$$y = \frac{cd - ag}{bd - af}.$$

66. This example may be considered as a general solution of the following problem. Two equations expressing the relation between the first powers of two unknown quantities being given, to determine those quantities; for whatever be the number of terms in each equation, it will readily appear, as in Art. 55, that by proper reduction they may be brought to the same form as those given in the above example.

67. Let us next consider such equations as involve three unknown quantities.

*Ex. 2.* Given  $\left. \begin{aligned} \frac{x}{2} + \frac{y}{3} + \frac{z}{4} &= 62 \\ \frac{x}{3} + \frac{y}{4} + \frac{z}{5} &= 47 \\ \frac{x}{4} + \frac{y}{5} + \frac{z}{6} &= 38 \end{aligned} \right\}$  to find  $x$ ,  $y$ , and  $z$ .

Here the given equations, when cleared from fractions, become

$$\begin{aligned} 12x + 8y + 6z &= 1488, \\ 20x + 15y + 12z &= 2820, \\ 30x + 24y + 20z &= 4560. \end{aligned}$$

To eliminate  $z$  by the third method, let the first equa-

tion be multiplied by 10, the second by 5, and the third by 3, the results will be these:

$$\begin{aligned} 120x + 80y + 60z &= 14880, \\ 100x + 75y + 60z &= 14100, \\ 90x + 72y + 60z &= 13680. \end{aligned}$$

Let the second equation be now subtracted from the first, and the third from the second, and we have

$$\begin{aligned} 20x + 5y &= 780, \\ 10x + 3y &= 420. \end{aligned}$$

Next, to eliminate  $y$ , let the first of these equations be multiplied by 3, and the second by 5; hence,

$$\begin{aligned} 60x + 15y &= 2340, \\ 50x + 15y &= 2100. \end{aligned}$$

Subtracting now the latter equation from the former,

$$10x = 240 \text{ and } x = 24,$$

$$\therefore y = \frac{420 - 10x}{3} = 60,$$

And

$$z = \frac{1448 - 12x - 8y}{6} = 120.$$

*Ex. 3.* Given  $x^2 - yz = a^2$ ,  $y^2 - xz = b^2$ ,  $z^2 - xy = c^2$ , to find  $x$ ,  $y$ , and  $z$ .

By subtraction, we have

$$\begin{aligned} (x - y)(x + y + z) &= a^2 - b^2 \quad (1), \\ (z - x)(x + y + z) &= c^2 - a^2 \quad (2), \\ (y - z)(x + y + z) &= b^2 - c^2. \end{aligned}$$

Squaring, adding, and dividing by 2, we get

$$\frac{(x^2 + y^2 + z^2 - xy - xz - yz)(x + y + z)^2}{a^4 + b^4 + c^4 - a^2b^2 - a^2c^2 - b^2c^2} =$$

But  $x^2 + y^2 + z^2 - xy - xz - yz$  is the sum of the three given expressions, and  $\therefore$  equal to  $a^2 + b^2 + c^2$ .

Hence  $(a^2 + b^2 + c^2)(x + y + z)^2 = a^4 + b^4 + c^4 - a^2b^2 - a^2c^2 - b^2c^2$ , which gives  $x + y + z$ .

Equations (1) and (2) are now two simple equations, which, combined with the value of  $x + y + z$  as determined, give  $x$ ,  $y$ , and  $z$ .

*Ex. 4.* Given  $\sqrt{x} = \sqrt{yz} \left( -\frac{a}{x} + \frac{b}{y} + \frac{c}{z} \right)$

$$\sqrt{y} = \sqrt{xz} \left( \frac{a}{x} - \frac{b}{y} + \frac{c}{z} \right)$$

$$\sqrt{z} = \sqrt{xy} \left( \frac{a}{x} + \frac{b}{y} - \frac{c}{z} \right)$$

Multiply the first by  $\sqrt{x}$ , the second by  $\sqrt{y}$ , and the third by  $\sqrt{z}$ , and add two and two. There results

$$x + y = \sqrt{xyz} \frac{2c}{z}$$

$$x + z = \sqrt{xyz} \frac{2b}{y}$$

$$y + z = \sqrt{xyz} \frac{2a}{x}$$

*i.e.*

$$xz + yz = \sqrt{xyz} 2c$$

$$xy + yz = \sqrt{xyz} 2b$$

$$xy + xz = \sqrt{xyz} 2a$$

$\therefore$

$$yz = \sqrt{xyz} (b + c - a)$$

$$xz = \sqrt{xyz} (a + c - b)$$

$$xy = \sqrt{xyz} (a + b - c)$$

Multiplying any two of these we get one of the unknown quantities:

$$\therefore x = (a + c - b)(a + b - c), \text{ \&c.}$$

SECT. VIII.—QUESTIONS PRODUCING SIMPLE EQUATIONS.

68. When the conditions of a problem have been ex-

pressed by equations, or translated from the common language into that of algebra, we must consider whether the problem be properly limited; for in some cases the conditions may be such as to admit of innumerable solutions, and in others they may involve an absurdity, and thus render the problem altogether impossible.

Now, by considering the examples of last section, it will appear, that to determine any number of unknown quantities, there must be given as many equations as there are unknown quantities. These, however, must be such as cannot be derived from each other, and they must not involve any contradiction; for in the one case the problem would admit of an unlimited number of answers, and in the other case it would be impossible. For example, if it were required to determine  $x$  and  $y$  from these two equations,  $2x - 3y = 13$ ,  $4x - 6y = 26$ ; as the latter equation is a consequence of the former (for each term of the one is the half of the corresponding term of the other), it is evident that innumerable values of  $x$  and  $y$  might be found to satisfy both equations. Again, if  $x$  and  $y$  were to be determined from these equations,  $x + 2y = 8$ ,  $3x + 6y = 26$ , it is easy to see that it is impossible to find such values of  $x$  and  $y$  as will satisfy both; for, from the first, we find  $3x = 24 - 6y$ ; and from the second,  $3x = 26 - 6y$ ; and therefore  $24 - 6y = 26 - 6y$ , or  $24 = 26$ , which is absurd; and so also must have been the conditions from which this conclusion is drawn.

69. But there is yet another case in which a problem may be impossible; and that is, when there are more equations than unknown quantities; for it appears, that in this case, by the rules of last section, we should at last find two equations, each involving the same unknown quantity. Now, unless these happened to agree, the problem would admit of no solution. On the whole, therefore, it appears that a problem is limited when the conditions furnish just as many independent equations as there are unknown quantities to be determined: if there be fewer, the problem is indeterminate; but if there be more, the problem in general admits of no solution whatever.

70. We shall now apply the preceding observations to some examples, which are so chosen as to admit of being resolved by simple equations.

*Ex. 1.* What is that number, to which if there be added its half, its third, and its fourth parts, the sum will be 50?

Let  $x$  denote the number sought; then its half will be  $\frac{x}{2}$ , its third  $\frac{x}{3}$ , and its fourth  $\frac{x}{4}$ ;

$$\therefore x + \frac{x}{2} + \frac{x}{3} + \frac{x}{4} = 50.$$

$$\text{Hence } 24x + 12x + 8x + 6x = 1200,$$

$$\text{Or } 50x = 1200;$$

$$\therefore x = 24.$$

Thus it appears that the number sought is 24, which upon trial will be found to answer the conditions of the question.

*Ex. 2.* A post is  $\frac{1}{4}$  of its length in the mud,  $\frac{1}{3}$  in the water, and 10 feet above the water; what is its whole length?

Let its length be  $x$  feet, then the part in the mud is  $\frac{x}{4}$ , and that in the water  $\frac{x}{3}$ ; therefore, from the nature of the question,

$$\frac{x}{4} + \frac{x}{3} + 10 = x.$$

From this equation we find  $7x + 120 = 12x$ , and  $x = 24$ .

*Ex. 3.* A market-woman bought a certain number of eggs at 2 a penny, and as many at 3 a penny, and sold them all out again at 5 for 2d.; but, instead of getting her own

money for them, as she expected, she lost 4d.: what number of eggs did she buy?

Let  $x$  be the number of eggs of each sort;

Then will  $\frac{x}{2}$  be the price of the first sort;

And  $\frac{x}{3}$  = the price of the second sort.

Now, the whole number being  $2x$ , we have

$$5 : 2x :: 2 : \frac{4x}{5} = \text{price of both sorts at 5 for 2d.}$$

$$\therefore \frac{x}{2} + \frac{x}{3} - \frac{4x}{5} = 4, \text{ by the question.}$$

Hence  $15x + 10x - 24x = 120$ ,

And  $x = 120$ , the number of each sort.

*Ex. 4.* A person at play lost  $\frac{1}{4}$  of his money, and then won 3s.; after which he lost  $\frac{1}{3}$  of what he then had, and then won 2s.; lastly he lost  $\frac{1}{4}$  of what he then had, and, this done, found he had only 12s. left: what had he at first?

Suppose he began to play with  $x$  shillings.

He lost  $\frac{1}{4}$  of his money, or  $\frac{x}{4}$ , and had left  $x - \frac{x}{4} = \frac{3x}{4}$ .

He won 3s. and had then  $\frac{3x}{4} + 3 = \frac{3x + 12}{4}$ .

He lost  $\frac{1}{3}$  of  $\frac{3x + 12}{4}$ , or  $\frac{x + 4}{4}$ , and had left

$$\frac{3x + 12}{4} - \frac{x + 4}{4} = \frac{2x + 8}{4}.$$

He won 2s. and had then  $\frac{2x + 8}{4} + 2 = \frac{2x + 1}{4}$ .

He lost  $\frac{1}{4}$  of  $\frac{2x + 16}{4}$ , or  $\frac{2x + 16}{28}$ , and had left

$$\frac{2x + 16}{4} - \frac{2x + 16}{28} = \frac{12x + 96}{28}.$$

And because he had now 12s. left, we have this equation,

$$\frac{12x + 96}{28} = 12.$$

Hence  $12x = 240$ , and  $x = 20$ .

*Ex. 5.* To divide the number 90 into 4 such parts, that if the first be increased by 2, the second diminished by 2, the third multiplied by 2, and the fourth divided by 2, the sum, difference, product and quotient shall be all equal to each other.

In this question there are four quantities to be determined; but instead of introducing several letters, having put  $x$  to denote the first of them, we may find an expression for each of the remaining ones, as follows

Because  $x + 2$  = second quantity - 2,

$\therefore x + 4$  = the second quantity;

And because  $x + 2$  = third  $\times 2$ ;

$\therefore \frac{x + 2}{2}$  = the third quantity.

And in like manner  $2(x + 2)$  = the fourth quantity.

Now by the question, the sum of all the four = 90;

$$\therefore x + x + 4 + \frac{x + 2}{2} + 2(x + 2) = 90.$$

Hence  $9x = 162$ , and  $x = 18$ ;

Therefore the numbers required are 18, 22, 10, and 40.

*Ex. 6.* A and B together can perform a piece of work in 12 hours, A and C in 20, and B and C in 15 hours; in what time will each be able to perform it when working separately?

That we may have a general solution, let us suppose A and B can perform the work in  $a$  hours, A and C in  $b$  hours, and B and C in  $c$  hours. Let  $x$ ,  $y$ , and  $z$ , denote the times in which A, B, and C, could perform it respectively, if each worked alone; and let the whole work be represented by 1. The question gives at once—

$$\frac{1}{x} + \frac{1}{y} = \frac{1}{a}, \quad \frac{1}{x} + \frac{1}{z} = \frac{1}{b}, \quad \frac{1}{y} + \frac{1}{z} = \frac{1}{c}.$$

If these be added, and their sum divided by 2, we find

$$\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = \frac{1}{2a} + \frac{1}{2b} + \frac{1}{2c}.$$

From this equation let each of the three preceding be subtracted in its turn: thus we get

$$\begin{aligned} \frac{1}{z} &= -\frac{1}{2a} + \frac{1}{2b} + \frac{1}{2c} = \frac{+ab+ac-bc}{2abc}, \\ \frac{1}{y} &= \frac{1}{2a} - \frac{1}{2b} + \frac{1}{2c} = \frac{+ab-ac+bc}{2abc}, \\ \frac{1}{x} &= \frac{1}{2a} + \frac{1}{2b} - \frac{1}{2c} = \frac{-ab+ac+bc}{2abc}, \end{aligned}$$

Hence

$$\begin{aligned} z &= \frac{2abc}{+ab+ac-bc} = \frac{7200}{120} = 60, \\ y &= \frac{2abc}{+ab-ac+bc} = \frac{7200}{360} = 20. \\ x &= \frac{2abc}{-ab+ac+bc} = \frac{7200}{240} = 30. \end{aligned}$$

SECT. IX.—SOLUTION OF QUADRATIC EQUATIONS.

Quadratic Equations.

71. We are next to explain the resolution of equations of the second degree, or quadratic equations. These involve the second power of the unknown quantity, and may be divided into two kinds, *pure* and *adfected*.

I. *Pure* quadratic equations are such as after proper reduction have the square of the unknown quantity in one term, while the remaining terms contain only known quantities. Thus,  $x^2 = 64$ , and  $ax^2 + b = c$ , are examples of pure quadratics.

II. *Adfected* quadratic equations contain the square of the unknown quantity in one term, and its first or simple power in another; the remaining terms consisting entirely of known quantities. Such are the following,  $x^2 + 3x = 28$ ,  $2x^2 = 33 - 5x$ ,  $ax^2 + bx - c = d$ .

The manner of resolving a pure quadratic equation is sufficiently evident. If the unknown quantity be made to stand alone on one side, with unity as a coefficient, while the other side consists entirely of known quantities, and the square root of each side be taken, we immediately obtain the value of the simple power of the unknown quantity as directed by rule 5th of Sect. VI.

In extracting the square root of any quantity, it is necessary to observe, that the sign of the root may be either + or -, and that consequently a quadratic method always have two solutions.

72. When an adfected quadratic equation is to be resolved, it may always, by proper reduction, be brought to the following form:

$$x^2 + px = q;$$

where  $p$  and  $q$  are numerical quantities, + or -.

Let us compare the side of it which involves the unknown quantity  $x$  with the square of a binomial  $x + a$ ; that is, let us compare  $x^2 + px$  with  $x^2 + 2ax + a^2 = (x + a)^2$ , and it will presently appear, that if we suppose  $p = 2a$ , or  $\frac{p}{2} = a$ , the quantities  $x^2 + px$  and  $x^2 + 2ax$  will be equal; and as  $x^2 + 2ax$  is rendered a complete square, by adding to it  $a^2$ , so also may  $x^2 + px$  be completed into a square by adding to it  $\frac{p^2}{4}$ , which is equal to  $a^2$ ; therefore, let  $\frac{p^2}{4}$  be added to both sides of the equation  $x^2 + px = q$ , and we have

$$x^2 + px + \frac{p^2}{4} = \frac{p^2}{4} + q, \text{ or } \left(x + \frac{p}{2}\right)^2 = \frac{p^2}{4} + q;$$

and, extracting the square root of each side,

$$x + \frac{p}{2} = \pm \sqrt{\frac{p^2}{4} + q}; \text{ hence } x = -\frac{p}{2} \pm \sqrt{\frac{p^2}{4} + q}.$$

73. From these observations we derive the following general rules for resolving adfected quadratic equations.

1. Bring all the terms involving the unknown quantity to one side, and the known quantities to the other side, and so that the term involving the square of the unknown quantity may be positive.

2. If the square of the unknown quantity be multiplied by a coefficient, let the other terms be divided by it, so that the coefficient of the square of the unknown quantity may be 1.

3. Add to both sides the square of half the coefficient of the unknown quantity itself, and the side of the equation involving the unknown quantity will now be a complete square.

4. Extract the square root of both sides of the equation, by which it becomes simple with respect to the unknown quantity; and, by transposition, that quantity may be made to stand alone on one side of the equation, while the other side consists of known quantities; and therefore the equation is resolved.

*Ex.* 1. Given  $x^2 + 2x = 35$ , to determine  $x$ .

Here the coefficient of the second term is 2; therefore, adding the square of its half to each side, we have

$$x^2 + 2x + 1 = 35 + 1 = 36,$$

And, extracting the square root,  $x + 1 = \sqrt{36} = \pm 6$ .

Hence  $x = \pm 6 - 1$ , that is,  $x = +5$ , or  $x = -7$ , and either of these numbers will be found to satisfy the equation, for  $5 \times 5 + 2 \times 5 = 35$ , also  $-7 \times -7 + 2 \times -7 = 35$ .

*Ex.* 2. Given  $\frac{x^2}{6} - 12 = x$ , to find  $x$ .

This equation, when reduced, becomes  $x^2 - 6x = 72$ ,

And, by completing the square,  $x^2 - 6x + 9 = 72 + 9 = 81$ . Hence, by extracting the square root,  $x - 3 = \pm 9$ , and  $x = \pm 9 + 3$ ;

Therefore  $x = +12$ , or  $x = -6$ ; and upon trial we find that each of these values satisfies the original equation, for

$$\frac{12 \times 12}{6} - 12 = 12, \text{ also } \frac{-6 \times -6}{6} - 12 = -6.$$

*Ex.* 3. Given  $x^2 + 28 = 11x$ , to find  $x$ .

Then  $x^2 - 11x = -28$ .

And, by completing the square,

$$x^2 - 11x + \frac{121}{4} = \frac{121}{4} - 28 = \frac{9}{4}.$$

Therefore, by extracting the root,  $x - \frac{11}{2} = \pm \frac{3}{2}$ .

Hence  $x = \frac{11}{2} \pm \frac{3}{2}$ ; that is,  $x = +7$ , or  $x = +4$ .

In the first two examples, we found one positive value for  $x$  in each, and also one negative value; but in this example both the values of  $x$  are positive, and, upon trial, each of them is found to satisfy the equation; for  $7 \times 7 + 28 = 11 \times 7$ , also  $4 \times 4 + 28 = 11 \times 4$ .

74. As at first sight it appears remarkable, that in every quadratic equation the unknown quantity admits always of two distinct values or roots, it will be proper to consider a little further the circumstances upon which this peculiarity depends.

To do this, let us re-examine the equation  $x^2 + 2x = 35$ . By bringing all the terms to one side, the equation may be expressed thus,  $x^2 + 2x - 35 = 0$ ; so that we shall have determined  $x$ , when we have found such a number as, when substituted for it in the quantity  $x^2 + 2x - 35$ , will render the result equal to 0. But  $x^2 + 2x - 35$  is the product of these two factors  $x - 5$  and  $x + 7$ , as may be proved by actual multiplication; therefore, to find  $x$ , we have  $(x - 5)(x + 7) = 0$ ; and as a product can only become = 0 when one of its factors is reduced to 0, it follows that either of the two factors  $x - 5$  and  $x + 7$  may be assumed = 0. If

$x - 5 = 0$ , then  $x = 5$ ; but if  $x + 7 = 0$ , then  $x = -7$ ; so that the two values of  $x$ , or two roots of the equation  $x^2 + 2x = 35$ , are  $+5$  and  $-7$ , as we have already found in a different manner.

75. What has been shown in a particular case is true of any quadratic equation whatever; that is, if  $x^2 + px = q$ , or, by bringing all the terms to one side,  $x^2 + px - q = 0$ , it is always possible to find two factors  $x - a$ , and  $x + b$ , such, that

$$x^2 + px - q = (x - a)(x + b),$$

where  $a$  and  $b$  are known quantities, which depend only upon  $p$  and  $q$ , the given numbers in the equation; and since that to have  $(x - a)(x + b) = 0$ , we may either assume  $x - a = 0$  or  $x + b = 0$ , it evidently follows that the conditions of the equation  $x^2 + px - q = 0$ , or  $x^2 + px = q$ , are alike satisfied by taking  $x = +a$  or  $x = -b$ .

From these considerations it follows, that  $x$  can have only two values in a quadratic equation; for if it could be supposed to have three or more values, then it would be possible to resolve  $x^2 + px - q$  into as many factors,  $x - c$ ,  $x - d$ , &c.; but the product of more than two factors must necessarily contain the third or higher powers of  $x$ , and as  $x^2 + px - q$  contains no higher power than the second, therefore no such resolution can take place.

76. *Solution of Questions which produce Quadratic Equations.*

*Ex. 1.* It is required to divide the number 10 into two such parts that the sum of their squares may be 58.

Let  $x$  be the one part;

Then, since their sum is 10, the other is  $10 - x$ ;

$\therefore$  by the question,  $x^2 + (10 - x)^2 = 58$ ;

That is,  $x^2 + 100 - 20x + x^2 = 58$ ,

Or  $2x^2 - 20x = 58 - 100 = -42$ ;

Hence  $x^2 - 10x = -21$ .

And completing the square,  $x^2 - 10x + 25 = 25 - 21 = 4$ ;

Hence, by extracting the root,  $x - 5 = \pm \sqrt{4} = \pm 2$ ,

And  $x = 5 \pm 2$ ,

That is,  $x = 7$ , or  $x = 3$ .

If we take the greater value of  $x$ , viz. 7, the other number  $10 - x$  will be 3; and if we take the less value of  $x$ , viz. 3, then the other number is 7. Thus it appears, that the greater value of the one number corresponds to the less value of the other; and indeed this must necessarily be the case, seeing that both are alike concerned in the question. Hence, the only numbers that will answer the conditions of the question are 7 and 3.

*Ex. 2.* A grazier bought as many sheep as cost him £60, out of which he reserved 15, and sold the remainder for £54, gaining 2s. each upon them. How many sheep did he buy, and what did each cost him?

Suppose that he bought  $x$  sheep.

Then each would cost him  $\frac{1200}{x}$  shillings.

Therefore, since after reserving 15, he sold each of the remaining  $x - 15$  for  $\frac{1200}{x} + 2$  shillings, he would receive for them  $(x - 15)\left(\frac{1200}{x} + 2\right)$  shillings. And, because £54 = 1080 shillings, we have by the question,

$$(x - 15)\left(\frac{1200}{x} + 2\right) = 1080;$$

which, by proper reduction, becomes  $x^2 + 45x = 9000$ ;

whence  $x = \pm \frac{195}{2} - \frac{45}{2}$ . And, taking the positive root,

$x = 75$ , the number of sheep; and consequently  $\frac{1200}{75} = 16$  shillings, the price of each.

*Ex. 3.* It is required to find two numbers, of which the product shall be 6, and the sum of their cubes 35.

Let  $x$  be the one number; then  $\frac{6}{x}$  will be the other.

Therefore, by the question,  $x^3 + \frac{216}{x^3} = 35$ ;

$$\begin{aligned} \text{Hence} & \quad x^6 + 216 = 35x^3, \\ \text{Or} & \quad x^6 - 35x^3 = -216. \end{aligned}$$

This equation, by putting  $x^3 = y$ , becomes

$$y^2 - 35y = -216;$$

Hence we find  $y = 27$ , or  $y = 8$ .

And since  $x^3 = y$ ,  $\therefore x = 3$ , or  $x = 2$ .

If  $x = 3$ , then the other number is 2, and if  $x = 2$ , the other number is 3; so that 2 and 3 are the numbers required.

In general, if it be required to find two numbers which are exactly alike concerned in a question that produces a quadratic equation, they will be the roots of that equation. A similar observation applies to any number of quantities which require for their determination the resolution of an equation of any degree whatever.

77. *On some Anomalies in the Solution of a Problem which results in an Equation.*

From what has preceded, it will be evident that a root of an equation may be a very different thing from the solution of the problem on which the equation is based. It will be proper to give a few illustrations of this difference before passing on to consider equations in general.

(1.) A solution may be *inapplicable* to the problem as a problem of arithmetic, applying only to the algebraic problem.

*Ex.* Find a number such that if it be first increased by 10, and then diminished by 10, the difference of the square roots of the results shall be equal to 10.

Let  $x$  be the number; then the problem requires that

$$\sqrt{x + 10} - \sqrt{x - 10} = 10.$$

Transposing and squaring, we get

$$x + 10 = 100 + 20\sqrt{x - 10} + x - 10.$$

Transposing and squaring again, there results  $x - 10 = 16$ ,  $x = 26$ .

Now, it is obvious that 26 does not satisfy the conditions of the problem, but that it is the solution of another problem, viz. that which substitutes "sum" for "difference" in the enunciation. Generally we may remark that an algebraic statement is not definite like an arithmetical one. The algebraic square root of a quantity being  $+$  or  $-$ , algebra cannot, as arithmetic does, distinguish between the two. The equation  $\sqrt{x + 10} - \sqrt{x - 10} = 10$  is algebraically the same as  $\sqrt{x + 10} + \sqrt{x - 10} = 10$ , &c.

(2.) A solution may be inverted, or rather may invert the statement.

*Ex.* Divide 15 into two such parts that the greater shall exceed three times the less by as much as half the less exceeds 3.

Let  $x$  be the greater, and  $\therefore 15 - x$  the less. The statement produces the equation,

$$x - 3(15 - x) = \frac{1}{2}(15 - x) - 3,$$

which gives at once  $x = 11$ , so that 11 is the greater, 4 the less part. But, on trying the solution, we find it is not that of the problem given, but of another problem, in which "exceeds" is replaced by "falls short of." Algebra cannot, in every case, as arithmetic does, distinguish the order of subtraction in stating a *difference*.

*Ex. 2.* Find a number such that the square root of the difference between its fourth power and its square being

found and increased by 1, the square root of the sum shall be equal to the given number diminished by 1.

Let  $x$  be the number, then

$$\sqrt{1 + \sqrt{x^4 - x^2}} = x - 1,$$

$$\therefore \sqrt{x^4 - x^2} = x^2 - 2x, \text{ whence } x = 0, x = \frac{5}{4},$$

neither of which solves the problem as stated.

(3.) A solution may be illusory—that is, it may assume the form  $\frac{0}{0}$ .

*Ex. 1.* There are two pieces of cloth of  $a$  and  $a'$  yards respectively. The owner sells the same number of yards of each at  $b$  and  $b'$  shillings per yard respectively, he then sells the remainder at  $c$  and  $c'$  shillings a yard, and finds that the prices received for both pieces are the same. Required the number of yards first sold.

The number is 
$$\frac{ac - a'c'}{b' - b + c - c'}.$$

As a particular case, if  $a$  and  $a'$  are 60 and 80;  $b$  and  $b'$  10 shillings and 9 shillings; and  $c$  and  $c'$  4 shillings and 3 shillings, the answer assumes the form  $\frac{0}{0}$ .

The answer is in this case indeterminate; in other words, the conditions of the problem are satisfied independently of the number of yards first sold; any number will do.

It is not, however, a necessary interpretation of the form  $\frac{0}{0}$ , that it may be replaced by any number whatever. Most frequently this form results from the fact that some fraction is not in its lowest terms. Solutions of this kind frequently occur—in ordinary equations they may be avoided; and we offer an example simply to show the method applicable to cases in which they cannot be avoided.

*Ex. 2.* Find two numbers such that the sum of their products by  $a$  and  $b$  respectively is  $c$ , and the difference of their squares  $d$ .

We have

$$ax + by = c$$

$$x^2 - y^2 = d$$

*i.e.*

$$x^2 - \left(\frac{c - ax}{b}\right)^2 = d$$

$\therefore$

$$(a^2 - b^2)x^2 - 2acx = -(c^2 + b^2d)$$

$$x = \frac{ac \pm \sqrt{a^2c^2 - (a^2 - b^2)(c^2 + b^2d)}}{a^2 - b^2}.$$

To find the solution when  $a = b$ , we observe that (taking the negative sign of the square root)  $x = \frac{0}{0}$ .

This arises from the fact that some power or root of  $a - b$  is common to the numerator and denominator of the fraction.

To divide this out, we may put  $a^2 - b^2 = pa^2$ , and we shall get

$$x = \frac{ac - ac\sqrt{1 - p\frac{c^2 + b^2d}{c^2}}}{pa^2}$$

$$= \frac{ac - ac + \frac{1}{2}pac\frac{c^2 + b^2d}{c^2} + \&c.}{pa^2}$$

$$= \frac{1}{2} \frac{c^2 + b^2d}{ac} = \frac{1}{2} \frac{c^2 + a^2d}{ac},$$

when  $a$  is written for  $b$ , and 0 for  $p$ .

(4.) A solution may be introduced by the operation.

In the example last given, the positive sign presents us with a solution introduced by the operation, which, when  $a = b$ , is not a solution of the problem at all.

For in that case the two equations become  $x + y = \frac{c}{a}$ ,  $x^2 - y^2 = d$ ; the latter of which is at once reduced to the

simple equation  $x - y = \frac{ac}{c}$  by means of the former. Accordingly, both equations are in this case simple equations, and can admit of only one solution.

(5.) As a solution may be introduced by the operation, so may it be *dropped out*, even when the operation is a perfectly legitimate one.

*Ex.*  $\sqrt{(2x+1)} - \sqrt{(x+4)} = \sqrt{(4x+4)} - \sqrt{(3x+7)}$ . Taking reciprocals, we have

$$\frac{1}{\sqrt{(2x+1)} - \sqrt{(x+4)}} = \frac{1}{\sqrt{(4x+4)} - \sqrt{(3x+7)}}$$

$$\therefore \frac{\sqrt{(2x+1)} + \sqrt{(x+4)}}{x-3} = \frac{\sqrt{(4x+4)} + \sqrt{(3x+7)}}{x-3}$$

$$\text{or } \sqrt{(2x+1)} + \sqrt{(x+4)} = \sqrt{(4x+4)} + \sqrt{(3x+7)},$$

which either added to the original equation, or subtracted from it, produces  $x = -\frac{3}{2}$ .

But  $x = 3$  is a solution of the equation which has been dropped out by the omission of the common denominator  $x - 3$ .

It is not necessary to point out that a solution may appear under the form  $\sqrt{-a}$  or  $\infty$ .

In neither case can the problem be solved arithmetically.

SECT. X.—EQUATIONS IN GENERAL.

78. Before we proceed to the resolution of cubic and the higher orders of equations, it will be proper to explain some general properties which belong to equations of every degree, and also certain transformations which must frequently be performed upon equations in order to prepare them for solution.

In treating of equations in general, we shall suppose all the terms brought to one side, and put equal to 0; so that an equation of the fourth degree will stand thus:

$$x^4 + px^3 + qx^2 + rx + s = 0,$$

where  $x$  denotes an unknown quantity, and  $p, q, r, s$ , numbers or fractions, either positive or negative. Here the coefficient of the highest power of  $x$  is unity, but had it been any other quantity, that quantity might have been taken away, and the equation reduced to the above form by rules already explained (Sect. VI).

The terms being thus arranged, if such a quantity be found as, when substituted for  $x$ , will render both sides = 0, and therefore satisfy the equation, that quantity, whether it be positive or negative, or even imaginary, is defined to be a root of the equation. Definit of root

But we have seen that every quadratic equation has always two roots, real or imaginary; we may therefore assume that a similar diversity will take place in all equations of a higher degree; and this assumption appears to be well founded, by the following proposition, which is of great importance in the theory of equations.

If a root of any equation, as  $x^4 + px^3 + qx^2 + rx + s = 0$ , be represented by  $a$ , the first side of that equation is divisible by  $x - a$ ;

For since  $x^4 + px^3 + qx^2 + rx + s = 0$ ,

And also  $a^4 + pa^3 + qa^2 + ra + s = 0$ ;

Therefore, by subtraction,

$$x^4 - a^4 + p(x^3 - a^3) + q(x^2 - a^2) + r(x - a) = 0.$$

But any quantity of this form  $x^n - a^n$ , where  $n$  denotes a whole positive number, is divisible by  $x - a$  (Art. 20, *Ex. 1*).

Hence, since every term contains a factor of this form, the equation may be written under the form

$$(x - a)(x^3 + p'x^2 + q'x + r') = 0.$$

*i.e.*, the expression  $x^4 + px^3 + qx^2 + rx + s$  is divisible by

$x - a$ ; and since the same mode of reasoning will apply to any equation whatever, the truth of the proposition is evident.

We have found that  $(x - a)(x^2 + p'x^2 + qx + r) = 0$ ; and as a product becomes  $= 0$  when any one of its factors  $= 0$ , therefore the equation will have its conditions fulfilled, not only when  $x - a = 0$ , but also when  $x^2 + p'x^2 + qx + r = 0$ .

Let us now suppose that  $b$  is a root of this equation; then, by reasoning exactly as before,

$$x^3 + p'x^2 + qx + r = (x - b)(x^2 + p''x + q'').$$

By proceeding in the same manner with the quadratic equation  $x^2 + p''x + q'' = 0$ , we shall find that if  $c$  denote one of its roots, then

$$x^2 + p''x + q'' = (x - c)(x + c + p''').$$

So that if we put  $d = -(c + p''')$ , we at last find  $x^4 + px^3 + qx^2 + rx + s = (x - a)(x - b)(x - c)(x - d)$ ;  $a, b, c, d$ , being the roots of the equation,  $x^4 + px^3 + qx^2 + rx + s = 0$ .

The mode of reasoning which has been just now employed in a particular case, may be applied to an equation of any order whatever; we may therefore conclude, that every equation may be considered as the product of as many simple factors as the number denoting its order contains unity, and therefore, that the number of roots in any equation is precisely equal to the exponent of the highest power of the unknown quantity contained in that equation.

79. By considering equations of all degrees as formed from the products of factors  $x - a, x - b, x - c, \&c.$ , we discover certain relations subsisting between the roots of any equation and its coefficients. Thus, if we limit the number of factors to four, and suppose that  $a, b, c, d$ , are the roots of this equation of the fourth degree,

$$x^4 + px^3 + qx^2 + rx + s = 0,$$

we shall also have  $(x - a)(x - b)(x - c)(x - d) = 0$ ; and therefore, by actual multiplication,

$$\left. \begin{array}{l} x^4 - a \\ - b \\ - c \\ - d \end{array} \right\} x^3 \left\{ \begin{array}{l} + ab \\ + ac \\ + ad \\ + bc \\ + bd \\ + cd \end{array} \right. \left. \begin{array}{l} x^2 - abc \\ - abd \\ - acd \\ - bcd \end{array} \right\} x + abcd = 0.$$

If we compare together the coefficients of the same powers of  $x$ , we find the following series of equations:

$$\begin{aligned} a + b + c + d &= -p, \\ ab + ac + ad + bc + bd + cd &= +q, \\ abc + abd + acd + bcd &= -r, \\ abcd &= +s; \end{aligned}$$

and as similar results will be obtained for equations of all degrees, we hence derive the following propositions, which are of great importance in the theory of equations.

1. The coefficient of the second term of any equation, taken with a contrary sign, is equal to the sum of all the roots.

2. The coefficient of the third term is equal to the sum of the products of the roots multiplied together two and two.

3. The coefficient of the fourth term, taken with a contrary sign, is equal to the sum of the roots multiplied together three and three; and so on for the remaining coefficients, till we come to the last term of the equation, which is equal to the product of all the roots having their signs changed.

Instead of supposing an equation to be produced by multiplying together simple equations, we may consider it as formed by the product of equations of any degree, provided that the sum of their dimensions be equal to that of the proposed equation. Thus, an equation of the fourth degree may be formed either from a simple and cubic equation, or from two quadratic equations.

80. When the roots of an equation are all positive, its simple factors will have this form,  $x - a, x - b, x - c, \&c.$ , and if, for the sake of brevity, we take only these three, the cubic equation which results from their product will have this form,

$$x^3 - px^2 + qx - r = 0,$$

$$\text{where } p = a + b + c, q = ab + ac + bc, r = abc;$$

and here it appears that the signs of the terms are + and - alternately.

Hence we infer, that when the roots of an equation are all positive, the signs of its terms are positive and negative alternately.

If again the roots of the equation be all negative, and therefore its factors  $x + a, x + b, x + c$ , then  $p, q$ , and  $r$  being as before, the resulting equation will stand thus:

$$x^3 + px^2 + qx + r = 0.$$

And hence we conclude, that when the roots are all negative, there is no change whatever in the signs.

In general, if the roots of an equation be all real, that equation will have as many positive roots as there are changes of the signs from + to -, or from - to +; and the remaining roots are negative. This rule, however, does not apply when the equation has impossible roots, unless such roots be considered as either positive or negative.

The connection between the signs of the roots and the signs of the terms of an equation can be deduced from the proposition, that the introduction of a new positive root introduces a new change of signs amongst the terms of the equation.

The demonstration of this proposition depends on the Rule of fact already established, that an equation may be resolved into the product of simple factors, so that, for example,

every equation of the fifth degree may be derived from some equation of the fourth, by multiplying the latter by  $x - a$  where  $a$  is the additional root. We shall show that the introduction of a new *positive* root produces an equation with at least one more change of signs than the original, and the introduction of a new *negative* root produces an equation with at least one more continuation of the same sign. To save space, it will suffice if we write the signs without the letters; thus,  $x^2 + px - q$  may be written + + -. Let, then, any equation be written down (of the sixth degree, for instance), + + - - + - +; multiply by  $x - a$ , and write the multiplication in the usual form,

$$\begin{array}{r} + + - - + - + \\ - - + + - - + \\ \hline + ? - ? + - - \end{array}$$

The signs of the product are all determinate except two, which we have marked with a (?). Now the changes of sign in the original equation are three—one between the 1st and 3d terms, one between the 3d and 5th, and one between the 5th and 6th; and it is evident that whatever be the signs marked (?), the produced equation has as many changes of sign as the original between the same limits, and one change beyond those limits, viz., between the 7th and 8th terms. This proposition is perfectly general, that the introduction of a positive root causes the introduction of at least all the original changes of sign within their limits, and one more change beyond those limits. In the same manner we may prove that the introduction of a negative root introduces at least one more continuation of the same sign. Hence the conclusion, that an equation cannot have more positive roots than it has changes of sign, nor more negative roots than it has continuations of the same sign. This proposition is known as Descartes' Rule of Signs.

81. Surd and impossible roots enter equations by pairs.

Let  $a + \sqrt{b}$  be a root, where  $b$  is a positive or negative number or fraction; then  $a - \sqrt{b}$  is also a root.

If  $a + \sqrt{b}$  be written for  $x$  in the quantity  $x^n + px^{n-1} + \&c.$ , the result is composed of a series of powers of  $a$  and  $\sqrt{b}$ . Of these all but the odd powers of  $\sqrt{b}$  are numerical, whilst odd powers of  $\sqrt{b}$  may be written as numerical products of  $\sqrt{b}$  itself. The result of the substitution is therefore of the form  $A + B\sqrt{b}$ . But since  $a + \sqrt{b}$  is a root of the equation  $x^n + px^{n-1} + \&c. = 0$ , we must have  $A + B\sqrt{b} = 0$ , and  $\therefore A = 0, B = 0$ .

Now if  $a - \sqrt{b}$  be substituted for  $x$ , the result will be  $A - B\sqrt{b}$ , because even powers of  $-\sqrt{b}$  are the same as those of  $+\sqrt{b}$ . But  $A = 0, B = 0 \therefore A - B\sqrt{b} = 0$ ; consequently  $a - \sqrt{b}$  is a root of the equation.

From this proposition it appears that every equation whose degree is denoted by an odd number, must have at least one real root.

82. We shall now explain some transformations which are frequently necessary to prepare the higher orders of equations for solution.

Any equation may have its positive roots changed into negative roots of the same value, and its negative roots into such as are positive, by changing the signs of the terms alternately, beginning with the second. The truth of this remark will be evident if we take the equation

$$(x - a)(x - b)(x + c) = x^3 + px^2 + qx + r = 0,$$

and write  $-x$  in place of  $x$ , producing

$$-(x + a) \cdot -(x + b) \cdot (-x + c) = -x^3 + px^2 - qx + r = 0,$$

i.e.,  $(x + a)(x + b)(x - c) = x^3 - px^2 + qx - r = 0,$

where it appears that the signs of the first and third terms are the same as in the original equation, but the signs of the second and fourth are the opposite. And this will be found to hold true of all equations, to whatever order they belong.

83. It will sometimes be useful to transform an equation into another that shall have each of its roots greater or less than the corresponding roots of the other equation, by some given quantity.

Let  $(x - a)(x - b)(x + c) = 0$  be any proposed equation which is to be transformed into another, having its roots greater or less than those of the proposed equation by the given quantity  $n$ ; then, because the roots of the transformed equation are to be  $+a \pm n, +b \pm n$ , and  $-c \pm n$ , the equation itself will be

$$(y \mp n - a)(y \mp n - b)(y \mp n + c) = 0.$$

Hence the reason of the following rule is evident.

If the new equation is to have its roots greater than those of the proposed equation, for  $x$  and its powers substitute  $y - n$  and its powers; but if the roots are to be less, then, for  $x$  substitute  $y + n$ ; and, in either case, a new equation will be produced, the roots of which shall have the property required.

84. By the preceding rule, an equation may be changed into another, which has its roots either all positive or all negative; but it is chiefly used in preparing cubic and bi-quadratic equations for solution, by transforming them into others of the same degree, but which want their second term.

Let  $x^3 + px^2 + qx + r = 0$  be any cubic equation; if we substitute  $y + n$  for  $x$ , the equation is changed into the following:

$$\left. \begin{array}{l} y^3 + 3n \\ + p \end{array} \right\} y^2 + 3n^2 \left. \begin{array}{l} + n^3 \\ + pn^2 \end{array} \right\} y + pn^2 \left. \begin{array}{l} + n^3 \\ + qn \\ + r \end{array} \right\} = 0.$$

Now, that this equation may want its second term, it is evident that we have only to suppose  $3n + p = 0$ , or  $n = -\frac{p}{3}$ ; for this assumption being made, and the value of  $n$  substituted in the remaining terms, the equation becomes

$$y^3 + \left(q - \frac{p^2}{3}\right)y + \frac{2p^3}{27} - \frac{pq}{3} + r = 0;$$

or, putting  $-\frac{p^2}{3} + q = q'$ , and  $+\frac{2p^3}{27} - \frac{pq}{3} + r = r'$ , the same equation may stand thus,

$$y^3 + q'y + r' = 0.$$

85. In general, any equation whatever may be transformed into another, which shall want its second term, by the following rule.

Divide the coefficient of the second term of the proposed equation by the exponent of the first term, and add the quotient, with its sign changed, to a new unknown quantity; the sum being substituted for the unknown quantity in the proposed equation, a new equation will be produced, which will want the second term, as required.

By this rule any affected quadratic equation may be readily resolved; for by transforming it into another equation which wants the second term, we thus reduce its solution to that of a pure quadratic. Thus, if the quadratic equation  $x^2 - 5x + 6 = 0$  be proposed; by substituting  $y + \frac{5}{2}$  for  $x$ , we find

$$\left. \begin{array}{l} y^2 + 5y + \frac{25}{4} \\ - 5y - \frac{25}{2} \\ + 6 \end{array} \right\} = 0, \text{ or } y^2 - \frac{1}{4} = 0.$$

Hence  $y = \pm \frac{1}{2}$ , and since  $x = y + \frac{5}{2}$ , therefore  $x = \pm \frac{1}{2} + \frac{5}{2} = +3$ , or  $+2$ .

86. Instead of taking away the second term from an equation, any other term may be made to vanish, by an assumption similar to that which has been employed to take away the second term. Thus, if in Art. 84 we assume  $3n^2 + 2pm + q = 0$ , by resolving this quadratic equation, a value of  $n$  will be found which, when substituted in the equation, will cause the third term to vanish; and, by the resolution of a cubic equation, the fourth term may be taken away; and so on.

87. Another species of transformation, of use in the resolution of equations, is that by which an equation, having the coefficients of some of its terms expressed by fractional quantities, is changed into another, the coefficients of which are all integers.

Let  $x^3 + \frac{p}{a}x^2 + \frac{q}{b}x + \frac{r}{c} = 0$  denote an equation to be so transformed, and let us assume  $y = abcx$ , and therefore  $x = \frac{y}{abc}$ ; then, by substitution, our equation becomes

$$\frac{y^3}{a^3b^3c^3} + \frac{p}{a^2b^2c^2}y^2 + \frac{q}{ab^2c}y + \frac{r}{c} = 0;$$

and multiplying the whole equation by  $a^3b^3c^3$ , we have

$$y^3 + bcpy^2 + a^2b^2cqy + a^3b^3c^2r = 0.$$

Thus we have an equation free from fractions, while at the same time the coefficient of the highest power of the unknown quantity is unity, as before.

*Examples of the Transformation and Solution of Equations when certain relations amongst the roots are known.*

Ex. 1. If  $a, b, c$  are the roots of the equation  $x^3 - x^2 + 2x - 3 = 0$ , to form the equation of which the roots are

$$(1.) \quad a + b, b + c, c + a.$$

Let  $y$  be any one root of the required equation; put  $y = a + b + c - x = 1 - x$  (Art. 79), and the values of  $y$  will be the roots of the equation required, which is therefore

$$(1 - y)^3 - (1 - y)^2 + 2(1 - y) - 3 = 0,$$

or

$$(2.) \quad \frac{a}{b+c-a}, \frac{b}{a+c-b}, \frac{c}{a+b-c}.$$

Let  $y = \frac{x}{a+b+c-2x} = \frac{x}{1-2x}$ ;

$\therefore y^3 + \frac{29}{17}y^2 + \frac{16}{17}y + \frac{3}{17} = 0$

is the equation required.

(3.)  $a^2, b^2, c^2.$

If  $y = x^2$ , the values of  $y$  are  $a^2, b^2, c^2$ . Accordingly we require to throw the given equation into a form which involves no odd powers of  $x$ . This is done as follows:

$x^3 - x^2 + 2x - 3 = x(x^2 + 2) - (x^2 + 3) = 0$ ;

$\therefore x(x^2 + 2) = x^2 + 3.$

squaring,  $x^2(x^2 + 2)^2 = (x^2 + 3)^2,$

or  $y(y + 2)^2 = (y + 3)^2,$

or  $y^3 + 3y^2 - 2y - 9 = 0.$

(4.)  $\frac{a}{bc}, \frac{b}{ac}, \frac{c}{ab}.$

Let  $y = \frac{x^2}{abc} = \frac{x^2}{3}$ , and  $y^3 + y^2 - \frac{2}{9}y - \frac{1}{3} = 0$

is the equation required.

Ex. 2. Two roots of the equation

$x^4 - 16x^3 + 86x^2 - 176x + 105 = 0$

are 1 and 5. Find the other roots.

The quantity on the left hand side of the equation is (Art. 78) divisible by  $(x - 1)(x - 5)$ , or by  $x^2 - 6x + 5$ .

The quotient is  $x^2 - 10x + 21$ , which, being put = 0, gives 3 and 7, the roots required.

Ex. 3. The equation  $x^3 - 4x^2 + x + r = 0$  has one root, 3; find  $r$  and the other roots.

Write 3 for  $x$ , then  $r = 6$ , and the equation may be written

$(x - 3)(x^2 - x - 2) = 0,$   
which gives  $x = 2, x = -1.$

Ex. 4. The equation  $x^3 + x^2 - 16x - 16 = 0$  has two roots of the form  $+a, -a$ ; find them.

If we write  $-x$  for  $x$ , we get the equation

$x^3 - x^2 - 16x + 16 = 0,$

which has also two roots,  $-a, +a$ ,  $\therefore x^2 - a^2$  is a common measure of the two quantities. But  $x^2 - 16$  is easily found to be a common measure of the two quantities,  $\therefore a = 4$ .

Ex. 5. The roots of the equation

$x^3 - 6x^2 + 11x - 6 = 0$

are in arithmetical progression; find them.

If  $a, a + b, a + 2b$  be the roots, their sum is  $3(a + b)$ , i. e., three times the middle root. But (Art. 79) their sum is 6,  $\therefore a + b = 2,$

also  $a(a + b)(a + 2b) = 6,$

i. e.,  $a(4 - a) = 3, a^2 - 4a + 3 = 0,$

$\therefore a = 1, a = 3.$

Ex. 6. The three roots of the equation  $x^3 - 7x^2 + 16x - 8 = 0$  are in geometrical progression; find them.

Let  $a, ar, ar^2$  be the roots; then their product is  $(ar)^3$ ,  $\therefore (ar)^3 = 8$ , and  $ar = 2$ ,  $\therefore$  their sum  $a + ar + ar^2 = 7,$

which gives  $a = 1, r = 2,$

and 1, 2, 4 are the roots.

SECT. XI.—SOLUTION OF CUBIC EQUATIONS.

88. Cubic equations, like all equations above the first degree, are divided into two classes: they are said to be *pure* when they contain only one power of the unknown quantity; and *adfected* when they contain two or more powers of that quantity.

Pure cubic equations are therefore of this form,  $x^3 = 125$ , or  $x^3 = -27$ , or, in general,  $x^3 = r$ ; and hence it appears that a value of the simple power of the unknown quantity may always be found without difficulty, by extracting the cube root of each side of the equation; thus, from the first of the three preceding examples we find  $x = +5$ , from the second  $x = -3$ , and from the third,  $x = \sqrt[3]{r}.$

It would seem at first sight that the only value which  $x$  can have in the cubic equation  $x^3 = r$ , or putting  $r = c^3$ ,  $x^3 - c^3 = 0$ , is this one,  $x = c$ ; but since  $x^3 - c^3$  may be resolved into these two factors,  $x - c$  and  $x^2 + cx + c^2$ , it follows, that besides the value of  $x$  already found, which results from making the factor  $x - c = 0$ , it has yet other two values, which may be found by making the other factor  $x^2 + cx + c^2 = 0$ ; and accordingly, by resolving the quadratic equation  $x^2 + cx = -c^2$ , we find these values to be  $\frac{-c + \sqrt{-3c^2}}{2}$  and  $\frac{-c - \sqrt{-3c^2}}{2}$ , or  $\frac{-1 + \sqrt{-3}}{2}c$  and  $\frac{-1 - \sqrt{-3}}{2}c.$

Thus it appears, that any cubic equation of this form,  $x^3 = c^3$ , or  $x^3 - c^3 = 0$ , has these three roots,

$x = c, x = \frac{-1 + \sqrt{-3}}{2}c, x = \frac{-1 - \sqrt{-3}}{2}c;$

the first of which is real, but the two last are imaginary. If, however, each of the imaginary values of  $x$  be raised to the third power, the same results will be obtained as from the real value of  $x$ ; the original equation  $x^3 - c^3 = 0$  may also be reproduced, by multiplying together the three

factors  $x - c, x - \frac{-1 + \sqrt{-3}}{2}c,$  and  $x - \frac{-1 - \sqrt{-3}}{2}c.$

89. Let us now consider such cubic equations as have all their terms, and which are therefore of this form,

$x^3 + Ax^2 + Bx + C = 0,$

where A, B, and C denote known quantities, either positive or negative.

It has been shown (Art. 84) how an equation having all its terms may be transformed into another which wants the second term; therefore, assume  $x = y - \frac{A}{3}$ , as directed in that article; then, by proper substitution, the above equation will be changed into another of this form,

$y^3 + qy + r = 0,$

where  $q$  and  $r$  denote known quantities, whether positive or negative; now the roots of this equation being found, it is evident that those of the former may be readily obtained by means of the assumed equation  $x = y - \frac{A}{3}.$

Resuming, therefore, the equation  $y^3 + qy + r = 0$ , let us suppose  $y = v + z$ , and it becomes

$$\left. \begin{aligned} v^3 + 3v^2z + 3vz^2 + z^3 \\ + qv + qz \\ + r \end{aligned} \right\} = 0.$$

Thus we have a new equation, which, as it involves two unknown quantities,  $v$  and  $z$ , may be resolved into any two others, which will simplify the determination of those quantities.

Now, it appears, that the only way in which we can divide that equation into two others, so as to simplify the question, is the following:

$3v^2z + 3vz^2 + qv + qz = 0,$   
 $v^3 + z^3 + r = 0.$

The first of these may also be expressed thus,

$(3vz + q)(v + z) = 0.$

Hence, we must either suppose that  $v + z = 0$ , or that  $3vz + q = 0$ ; but the former supposition cannot be admitted without supposing also that  $q = 0$ ; therefore we must adopt the latter. So that to determine  $v$  and  $z$  we have these two equations,

$3vz + q = 0, v^3 + z^3 + r = 0.$

From the first, we find  $vz = -\frac{q}{3}$ , and  $\therefore v^2z^3 = -\frac{q^2}{27}.$  This reduces the second equation to a quadratic in  $v^3$ , viz  $v^6 + rv^3 - \frac{q^3}{27} = 0$ , the solution of which equation is

$$v^3 = -\frac{1}{2}r + \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}; \quad z^3 = -\frac{1}{2}r - \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2};$$

$$v = \sqrt[3]{-\frac{1}{2}r + \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}}; \quad z = \sqrt[3]{-\frac{1}{2}r - \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}};$$

$$\text{and } y = v + z$$

$$= \sqrt[3]{-\frac{1}{2}r + \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}} + \sqrt[3]{-\frac{1}{2}r - \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}}.$$

Thus we have obtained a value of the unknown quantity  $y$ , in terms of the known quantities  $q$  and  $r$ ; therefore the equation is resolved.

90. But this is only one of three values which  $y$  may have. Let us, for the sake of brevity, put

$$A = -\frac{1}{2}r + \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}, \quad B = -\frac{1}{2}r - \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2},$$

$$\text{and put } \begin{cases} \alpha = \frac{-1 + \sqrt{-3}}{2}, \\ \beta = \frac{-1 - \sqrt{-3}}{2} \end{cases}$$

then, from what has been shown (Art. 88), it is evident that  $v$  and  $z$  have each these three values,

$$v = \sqrt[3]{A}, \quad v = \alpha \sqrt[3]{A}, \quad v = \beta \sqrt[3]{A};$$

$$z = \sqrt[3]{B}, \quad z = \alpha \sqrt[3]{B}, \quad z = \beta \sqrt[3]{B}.$$

To determine the corresponding values of  $v$  and  $z$ , we must consider that  $vz = -\frac{q}{3} = \sqrt[3]{AB}$ . Now if we observe that  $\alpha\beta = 1$ , it will immediately appear that  $v + z$  has these three values,

$$v + z = \sqrt[3]{A} + \sqrt[3]{B},$$

$$v + z = \alpha \sqrt[3]{A} + \beta \sqrt[3]{B}$$

$$v + z = \beta \sqrt[3]{A} + \alpha \sqrt[3]{B},$$

which are therefore the three values of  $y$ .

The first of these formulæ is commonly known by the name of Cardan's rule; but it is well known that Cardan was not the inventor, and that it ought to be attributed to Nicholas Tartalea and Scipio Ferreus, who discovered it much about the same time, and independently of each other. (See the *Historical Introduction*.)

The formulæ given above for the roots of a cubic equation may be put under a different form, better adapted to the purposes of arithmetical calculation, as follows:—

Because  $vz = -\frac{q}{3}$ , therefore  $z = -\frac{q}{3} \times \frac{1}{v} = -\frac{\frac{1}{3}q}{\sqrt[3]{A}}$ ; hence  $v + z = \sqrt[3]{A} - \frac{\frac{1}{3}q}{\sqrt[3]{A}}$ : thus it appears that the three values of  $y$  may also be expressed thus:

$$y = \sqrt[3]{A} - \frac{\frac{1}{3}q}{\sqrt[3]{A}}$$

$$y = \alpha \sqrt[3]{A} - \frac{\frac{1}{3}q\beta}{\sqrt[3]{A}}$$

$$y = \beta \sqrt[3]{A} - \frac{\frac{1}{3}q\alpha}{\sqrt[3]{A}}.$$

91. To show the manner of applying these formulæ, let it be required to determine  $x$  from the cubic equation  $x^3 + 3x^2 + 9x - 13 = 0$ .

As this equation has all its terms, the first step towards its resolution is to transform it into another which shall want the second term, by substituting  $y - 1$  for  $x$  as directed (Art. 84). The operation will stand thus:

$$x^3 = y^3 - 3y^2 + 3y - 1$$

$$+ 3x^2 = + 3y^2 - 6y + 3$$

$$+ 9x = + 9y - 9$$

$$- 13 = - 13$$

∴ adding these, the transformed equation is

$$y^3 + 6y - 20 = 0,$$

which being compared with the general equation,

$$y^3 + qy + r = 0,$$

gives  $q = 6$ ,  $r = -20$ ; hence

$$A = \sqrt[3]{-\frac{1}{2}r + \sqrt{\frac{1}{27}q^3 + \frac{1}{4}r^2}} = \sqrt[3]{10 + \sqrt{108}},$$

therefore the second formula of last article gives  $y = \sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}}$ ; but as this expression involves a radical quantity, let the square root of 108 be taken and added to 10, and the cube root of the sum found; thus we have  $\sqrt[3]{10 + \sqrt{108}} = 2.732$  nearly, and therefore  $\frac{2}{\sqrt[3]{10 + \sqrt{108}}} = \frac{2}{2.732} = .732$ ; hence we at last find one of the values of  $y$  to be  $2.732 - .732 = 2$ .

In finding the cube root of the radical quantity  $\sqrt[3]{10 + \sqrt{108}}$ , we have taken only its approximate value, so as to have the expression for the root under a rational form, and in this way we can always find, as near as we please, the cube root of any surd of the form  $a + \sqrt{b}$ , where  $b$  is a positive number. But it will sometimes happen that the cube root of such a surd can be expressed exactly by another surd of the same form; and accordingly, in the present case, it appears that the cube root of  $10 + \sqrt{108}$  is  $1 + \sqrt{3}$ , as may be proved by actually raising  $1 + \sqrt{3}$  to the third power. Hence we find  $\frac{2}{\sqrt[3]{10 + \sqrt{108}}} = \frac{2}{1 + \sqrt{3}} = \frac{2(1 - \sqrt{3})}{(1 - \sqrt{3})(1 + \sqrt{3})} = -(1 - \sqrt{3})$ ; so that  $y = 1 + \sqrt{3} + 1 - \sqrt{3} = 2$ , as before.

The other two values of  $y$  will be had by substituting  $1 + \sqrt{3}$  and  $1 - \sqrt{3}$  for  $\sqrt[3]{A}$  and  $\frac{\frac{1}{3}q}{\sqrt[3]{A}}$  in the second and third formulæ of last article, and restoring the values of  $\alpha$  and  $\beta$ . We thus have

$$y = \frac{-1 + \sqrt{-3}}{2} \times (1 + \sqrt{3}) + \frac{-1 - \sqrt{-3}}{2} \times (1 - \sqrt{3}) = -1 + \sqrt{-9}.$$

$$y = \frac{-1 - \sqrt{-3}}{2} \times (1 + \sqrt{3}) + \frac{-1 + \sqrt{-3}}{2} \times (1 - \sqrt{3}) = -1 - \sqrt{-9}.$$

So that the three values of  $y$  are

$$+ 2, \quad -1 + \sqrt{-9}, \quad -1 - \sqrt{-9};$$

and since  $x = y - 1$ , the corresponding values of  $x$  are

$$+ 1, \quad -2 + \sqrt{-9}, \quad -2 - \sqrt{-9}.$$

Thus it appears that one of the roots of the proposed equation is real, and the other two imaginary.

The two imaginary roots might have been found otherwise, by considering that since one root of the equation is 1, the equation must be divisible by  $x - 1$  (Art. 78). Accordingly, the division being actually performed, and the quotient put  $= 0$ , we have the quadratic equation,

$$x^2 + 4x + 13 = 0;$$

which gives  $x = -2 \pm \sqrt{-9}$ , the same imaginary values as before.

92. In the application of the preceding formulæ to the resolution of the equation  $y^3 + qy + r = 0$ , it is necessary to find the square root of  $\frac{1}{27}q^3 + \frac{1}{4}r^2$ ; now, when that quantity is positive, as in the equation  $y^3 + 6y - 20 = 0$ , which was resolved in last article, no difficulty occurs, for its root may be found either exactly or to as great a degree of accuracy as we please.

As, however, the coefficients  $q$  and  $r$  are independent of each other, it is evident that  $q$  may be negative, and such that  $\frac{1}{27}q^3$  is greater than  $\frac{1}{4}r^2$ . In this case, the expression  $\frac{1}{27}q^3 + \frac{1}{4}r^2$  will be negative, and therefore its square root an imaginary quantity; so that all the roots appear under an imaginary form. But we are certain (Art. 81) that every cubic equation must have at least one real root. The truth is that roots are frequently real, though they appear und

an imaginary form. Take, for instance, the equation  $y^3 - 6y + 4 = 0$ , of which the roots are found to be

$$y = \sqrt[3]{2 + 2\sqrt{-1}} + \sqrt[3]{2 - 2\sqrt{-1}}$$

$$y = \alpha \sqrt[3]{2 + 2\sqrt{-1}} + \beta \sqrt[3]{2 - 2\sqrt{-1}}$$

$$y = \beta \sqrt[3]{2 + 2\sqrt{-1}} + \alpha \sqrt[3]{2 - 2\sqrt{-1}}$$

It will be found by actual involution that the imaginary expressions  $2 + 2\sqrt{-1}$  and  $2 - 2\sqrt{-1}$  are the cubes of  $-1 + \sqrt{-1}$  and  $-1 - \sqrt{-1}$  respectively, whence by substitution we find

$$y = 2, \quad y = 1 + \sqrt{3}, \quad \text{and} \quad y = 1 - \sqrt{3}.$$

93. We shall now prove, that as often as the roots of the equation  $x^3 + qx + r = 0$  are real,  $q$  is negative, and  $\frac{1}{27}q^3$  greater than  $\frac{1}{4}r^2$ ; and, conversely, that if  $\frac{1}{27}q^3$  be greater than  $\frac{1}{4}r^2$ , the roots are all real.

Let us suppose  $a$  to be a real root of the proposed equation.

Then  $x^3 + qx + r = 0,$   
 And  $a^3 + qa + r = 0.$

And therefore, by subtraction,  $x^3 - a^3 + q(x - a) = 0$ ; hence, dividing by  $x - a$ , we have

$$x^2 + ax + a^2 + q = 0.$$

This quadratic equation is formed from the two remaining roots of the proposed equation, and by resolving it we find

$$x = -\frac{1}{2}a \pm \sqrt{-\frac{3}{4}a^2 - q}.$$

And as, by hypothesis, all the roots are real, it is evident that  $q$  must necessarily be negative, and greater than  $\frac{3}{4}a^2$ ; for otherwise the expression  $\sqrt{-\frac{3}{4}a^2 - q}$  would be imaginary. Let us change the sign of  $q$ , and put  $q = \frac{3}{4}a^2 + d$ ; thus the roots of the equation  $x^3 - qx + r = 0$  will be

$$a, \quad -\frac{1}{2}a + \sqrt{d}, \quad -\frac{1}{2}a - \sqrt{d},$$

and here  $d$  is a positive quantity.

To find an expression for  $r$  in terms of  $a$  and  $d$ , let  $\frac{3}{4}a^2 + d$  be substituted for  $q$  in the equation  $x^3 - qx + r = 0$ ; we thence find  $r = -\frac{1}{4}a^3 + ad$ ; so that to compare together the quantities  $q$  and  $r$ , we have these equations,

$$q = \frac{3}{4}a^2 + d, \quad r = -\frac{1}{4}a^3 + ad.$$

In order to make this comparison, let the cube of  $\frac{1}{3}q$  be taken, also the square of  $\frac{1}{2}r$ , the results are

$$\frac{1}{27}q^3 = \frac{1}{64}a^6 + \frac{1}{16}a^4d + \frac{1}{27}a^2d^2 + \frac{1}{27}d^3,$$

$$\frac{1}{4}r^2 = \frac{1}{64}a^6 - \frac{1}{8}a^4d + \frac{1}{4}a^2d^2;$$

and therefore, by subtraction,

$$\frac{1}{27}q^3 - \frac{1}{4}r^2 = \frac{3}{16}a^4d - \frac{1}{6}a^2d^2 + \frac{1}{27}d^3,$$

$$= 3d\left(\frac{1}{16}a^4 - \frac{1}{18}a^2d + \frac{1}{27}d^2\right)$$

$$= 3d\left(\frac{1}{6}a^2 - \frac{1}{9}d\right)^2.$$

Now the square of any real quantity being always positive, it follows that  $3d\left(\frac{1}{6}a^2 - \frac{1}{9}d\right)^2$  will be positive when  $d$  is positive; hence it is evident that in this case  $\frac{1}{27}q^3$  must be greater than  $\frac{1}{4}r^2$ , and that  $\frac{1}{27}q^3$  cannot be less than  $\frac{1}{4}r^2$ , unless  $d$  be negative, that is, unless  $-\frac{1}{2}a + \sqrt{d}$ ,  $-\frac{1}{2}a - \sqrt{d}$ , the two other roots of the equation are imaginary. If we suppose  $d = 0$ , then  $\frac{1}{27}q^3 = \frac{1}{4}r^2$ ; and the roots of the equations, which in this case are also real, two of them being equal.

Upon the whole, therefore, we infer, that since a cubic equation has always one real root, its roots will be all real as often as  $q$  is negative, and  $\frac{1}{27}q^3$  greater than  $\frac{1}{4}r^2$ ; and consequently, that in this case the formulæ for the roots must express real quantities, notwithstanding their imaginary form.

94. Let  $y^3 - qy + r = 0$  denote any equation of the form which has been considered in last article, namely, that which has its roots all real; then, if we put  $a = -\frac{1}{3}r$ ,

$b^2 = \frac{1}{27}q^3 - \frac{1}{4}r^2$ , one of the roots, as expressed by the first formula (Art. 90) will be

$$y = \sqrt[3]{a + b\sqrt{-1}} + \sqrt[3]{a - b\sqrt{-1}}.$$

This expression, although under an imaginary form, must (as we have shown in last article) represent a real quantity, although we cannot obtain it by the ordinary process of arithmetic.

The case of cubic equations, in which the roots are all real, is now called the *irreducible case*.

It is remarkable that the expression

$$\sqrt{a + b\sqrt{-1}} + \sqrt{a - b\sqrt{-1}},$$

and in general,

$$\sqrt[n]{a + b\sqrt{-1}} + \sqrt[n]{a - b\sqrt{-1}},$$

where  $n$  is any power of 2, admits of being reduced to another form, in which no impossible quantity is found.

Thus,  $\sqrt{a + b\sqrt{-1}} + \sqrt{a - b\sqrt{-1}} = \sqrt{2a + 2\sqrt{a^2 + b^2}}$ ,

and 
$$\sqrt[n]{a + b\sqrt{-1}} + \sqrt[n]{a - b\sqrt{-1}} = \sqrt{\left(\sqrt{2a + 2\sqrt{a^2 + b^2}} + 2\sqrt[n]{a^2 + b^2}\right)},$$

as is easily proved by first squaring and then taking the square root of the imaginary formulæ. But when  $n$  is 3, it does not seem that such reduction can possibly take place.

If each of the surds be expanded into an infinite series, and their sum be taken, the imaginary quantity  $\sqrt{-1}$  will vanish, and thus the root may be found by a direct process.

SECT. XII.—SOLUTION OF BICADRATIC EQUATIONS.

95. When a biquadratic equation contains all its terms, it has this form,

$$x^4 + Ax^3 + Bx^2 + Cx + D = 0$$

where A, B, C, D denote any known quantities whatever.

We shall first consider pure biquadratics, or such as contain only the first and last terms, and therefore are of this form,  $x^4 = b^4$ . In this case it is evident that  $x$  may be readily had by two extractions of the square root; by the first we find  $x^2 = b^2$ , and by the second  $x = b$ . This, however, is only one of the values which  $x$  may have; for since  $x^4 = b^4$ , therefore  $x^4 - b^4 = 0$ ; but  $x^4 - b^4$  may be resolved into two factors  $x^2 - b^2$  and  $x^2 + b^2$ , each of which admits of a similar resolution; for  $x^2 - b^2 = (x - b)(x + b)$  and  $x^2 + b^2 = (x - b\sqrt{-1})(x + b\sqrt{-1})$ . Hence it appears that the equation  $x^4 - b^4 = 0$  may also be expressed thus

$$(x - b)(x + b)(x - b\sqrt{-1})(x + b\sqrt{-1}) = 0;$$

so that  $x$  may have these four values,

$$+b, \quad -b, \quad +b\sqrt{-1}, \quad -b\sqrt{-1},$$

two of which are real, and the others imaginary.

96. Next to pure biquadratic equations, in respect of easiness of resolution, are such as want the second and fourth terms, and therefore have this form,

$$x^4 + qx^2 + s = 0.$$

These may be resolved in the manner of quadratic equations; for if we put  $y = x^2$ , we have

$$y^2 + qy + s = 0,$$

from which we find  $y = \frac{-q \pm \sqrt{q^2 - 4s}}{2}$ , and therefore

$$x = \pm \sqrt{\frac{-q \pm \sqrt{q^2 - 4s}}{2}}.$$

97. When a biquadratic equation has all its terms, the manner of resolving it is not so obvious as in the two former cases, but its resolution may be always reduced to that of a cubic equation. There are various methods by which

such a reduction may be effected. The following, which we select as one of the most ingenious, was first given by Euler in the *Petersburg Commentaries*, and afterwards explained more fully in his *Elements of Algebra*.

We have already explained, Art. 92, how an equation which is complete in its terms may be transformed into another of the same degree, but which wants the second term; therefore any biquadratic equation may be reduced to this form,

$$y^4 + py^2 + qy + r = 0,$$

where the second term is wanting, and where  $p, q, r$ , denote any known quantities whatever.

That we may form an equation similar to the above, let us assume  $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$ , and also suppose that the letters  $a, b, c$  denote the roots of the cubic equation

$$z^3 + Pz^2 + Qz - R = 0;$$

then, from the theory of equations we have

$$a + b + c = -P, \quad ab + ac + bc = Q, \quad abc = R.$$

We square the assumed formula

$$y = \sqrt{a} + \sqrt{b} + \sqrt{c},$$

and obtain  $y^2 = a + b + c + 2(\sqrt{ab} + \sqrt{ac} + \sqrt{bc})$ , or, substituting  $-P$  for  $a + b + c$ , and transposing;

$$y^2 + P = 2(\sqrt{ab} + \sqrt{ac} + \sqrt{bc}).$$

Let this equation be also squared, and we have

$$y^4 + 2Py^2 + P^2 = 4(ab + ac + bc) + 8(\sqrt{a^2bc} + \sqrt{ab^2c} + \sqrt{abc^2});$$

and since  $ab + ac + bc = Q$ , and  $\sqrt{a^2bc} + \sqrt{ab^2c} + \sqrt{abc^2} = \sqrt{abc}(\sqrt{a} + \sqrt{b} + \sqrt{c}) = \sqrt{R} \cdot y$ , the same equation may be expressed thus:

$$y^4 + 2Py^2 + P^2 = 4Q + 8\sqrt{R} \cdot y.$$

Thus we have the biquadratic equation

$$y^4 + 2Py^2 - 8\sqrt{R} \cdot y + P^2 - 4Q = 0,$$

one of the roots of which is  $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$ , while  $a, b, c$  are the roots of the cubic equation  $z^3 + Pz^2 + Qz - R = 0$ .

98. In order to apply this resolution to the proposed equation  $y^4 + py^2 + qy + r = 0$ , we must express the assumed coefficients  $P, Q, R$  by means of  $p, q, r$ , the coefficients of that equation. For this purpose, let us compare the equations

$$y^4 + py^2 + qy + r = 0, \\ y^4 + 2Py^2 - 8\sqrt{R} \cdot y + P^2 - 4Q = 0,$$

and it immediately appears that

$$2P = p, \quad -8\sqrt{R} = q, \quad P^2 - 4Q = r$$

and from these equations we find

$$P = \frac{p}{2}, \quad Q = \frac{p^2 - 4r}{16}, \quad R = \frac{q^2}{64}.$$

Hence it follows that the roots of the proposed equation are generally expressed by the formula

$$y = \sqrt{a} + \sqrt{b} + \sqrt{c};$$

where  $a, b, c$  denote the roots of this cubic equation,

$$z^3 + \frac{p}{2}z^2 + \frac{p^2 - 4r}{16}z - \frac{q^2}{64} = 0.$$

But to find each particular root, we must consider, that as the square root of a number may be either positive or negative, so each of the quantities  $\sqrt{a}, \sqrt{b}, \sqrt{c}$  may have either the sign  $+$  or  $-$  prefixed to it; and hence our formula will give eight different expressions for the root. It is, however, to be observed, that as the product of the three quantities  $\sqrt{a}, \sqrt{b}, \sqrt{c}$  must be equal to  $\sqrt{R}$  or to  $-\frac{q}{8}$ ; when  $q$  is positive, their product must be a negative quantity, and this can only be effected by making either one or three of them negative; again, when  $q$  is negative,

their product must be a positive quantity: so that in this case they must either be all positive, or two of them must be negative. These considerations enable us to determine, that four of the eight expressions for the root belong to the case in which  $q$  is positive, and the other four to that in which it is negative.

99. We shall now give the result of the preceding investigation in the form of a practical rule; and as the coefficients of the cubic equation which has been found involve fractions, we shall transform it into another, in which the coefficients are integers, by supposing  $z = \frac{v}{4}$ .

Thus the equation

$$z^3 + \frac{p}{2}z^2 + \frac{p^2 - 4r}{16}z - \frac{q^2}{64} = 0$$

becomes, after reduction,

$$v^3 + 2pv^2 + (p^2 - 4r)v - q^2 = 0,$$

it also follows, that if the roots of the latter equation are  $a, b, c$ , the roots of the former are  $\frac{a}{4}, \frac{b}{4}, \frac{c}{4}$ , so that our rule may now be expressed thus:

Let  $y^4 + py^2 + qy + r = 0$  be any biquadratic equation wanting its second term. Form this cubic equation

$$v^3 + 2pv^2 + (p^2 - 4r)v - q^2 = 0,$$

and find its roots, which, let us denote by  $a, b, c$ .

Then the roots of the proposed biquadratic equation are,

when $q$ is negative,	when $q$ is positive,
$y = \frac{1}{2}(\sqrt{a} + \sqrt{b} + \sqrt{c}),$	$y = \frac{1}{2}(-\sqrt{a} - \sqrt{b} - \sqrt{c}).$
$y = \frac{1}{2}(\sqrt{a} - \sqrt{b} - \sqrt{c}),$	$y = \frac{1}{2}(-\sqrt{a} + \sqrt{b} + \sqrt{c}).$
$y = \frac{1}{2}(-\sqrt{a} + \sqrt{b} - \sqrt{c}),$	$y = \frac{1}{2}(\sqrt{a} - \sqrt{b} + \sqrt{c}).$
$y = \frac{1}{2}(-\sqrt{a} - \sqrt{b} + \sqrt{c}).$	$y = \frac{1}{2}(\sqrt{a} + \sqrt{b} - \sqrt{c}).$

100. As an example of the method of resolving a biquadratic equation, let it be required to determine the roots of the following,

$$x^4 - 25x^2 + 60x - 36 = 0.$$

By comparing this equation with the general formula, we have  $p = -25, q = +60, r = -36$ ; hence

$$2p = -50, \quad p^2 - 4r = 769, \quad q^2 = 3600,$$

and the cubic equation to be resolved is

$$v^3 - 50v^2 + 769v - 3600 = 0;$$

the roots of which are found, by the rules for cubics, to be 9, 16, and 25, so that  $\sqrt{a} = 3, \sqrt{b} = 4, c = 5$ . Now in this case  $q$  is positive, therefore

$$x = \frac{1}{2}(-3 - 4 - 5) = -6, \\ x = \frac{1}{2}(-3 + 4 + 5) = +3, \\ x = \frac{1}{2}(+3 - 4 + 5) = +2, \\ x = \frac{1}{2}(+3 + 4 - 5) = +1.$$

101. We have now explained the particular rules by which the roots of equations belonging to each of the first four orders may be determined; and this is the greatest length mathematicians have been able to go in the direct resolution of equations; for as to those of the fifth, and all higher degrees, no general method has hitherto been found, either for resolving them directly, or reducing them to others of an inferior degree.

It even appears that the formulæ which express the roots of cubic equations are not of universal application; for in one case, that is, when the roots are all real, they become illusory, so that no conclusion can be drawn from them. The same observation will also apply to the formulæ for the roots of biquadratic equations, because, before they can be applied, it is always necessary to find the roots of a cubic equation. But both in cubics and in biquadratic equations, even when the formulæ involve no imaginary quantities, and therefore can be always applied, it is more convenient in practice to employ other methods, which we are hereafter to explain.

SECT. XIII.—SOLUTION OF EQUATIONS IN WHICH CERTAIN RELATIONS ARE KNOWN TO EXIST AMONGST THE ROOTS.

102. When the coefficients of the terms of an equation form the same numerical series, whether taken in a direct or an inverted order, as in this example,

$$x^4 + px^3 + qx^2 + px + 1 = 0,$$

it may always be transformed into another of a degree denoted by half the exponent of the highest power of the unknown quantity, if that exponent be an even number; or half the exponent diminished by unity, if it be an odd number.

The same observation will also apply to any equation of this form,

$$x^4 + pa.x^3 + qa^2.x^2 + pa^3.x + a^4 = 0.$$

103. That we may effect the proposed transformation upon the equation

$$x^4 + px^3 + qx^2 + px + 1 = 0,$$

let every two terms which are equally distant from the extremes be collected into one, and the whole be divided by  $x^2$ , then

$$x^2 + \frac{1}{x^2} + p\left(x + \frac{1}{x}\right) + q = 0.$$

Let us assume 
$$x + \frac{1}{x} = z;$$

then 
$$x^2 + 2 + \frac{1}{x^2} = z^2, \text{ and } x^2 + \frac{1}{x^2} = z^2 - 2.$$

Thus the equation 
$$x^2 + \frac{1}{x^2} + p\left(x + \frac{1}{x}\right) + q = 0,$$

becomes 
$$z^2 + pz + q - 2 = 0$$

and since 
$$x + \frac{1}{x} = z,$$
 therefore 
$$x^2 - zx + 1 = 0.$$

Hence, to determine the roots of the biquadratic equation

$$x^4 + px^3 + qx^2 + px + 1 = 0,$$

we form the quadratic

$$z^2 + pz + q - 2 = 0,$$

and find its roots, which, let us suppose denoted by  $z'$  and  $z''$ ; then the four roots of the proposed equation will be found by resolving two quadratic equations, viz.

$$x^2 - z'x + 1 = 0, \quad x^2 - z''x + 1 = 0.$$

104. It may be observed, respecting these two quadratic equations, that since the last term of each is unity, if we put  $a, a'$  to denote the roots of the one, and  $b, b'$  those of the other, we have from the theory of equations,  $aa' = 1$ ,

and therefore  $a' = \frac{1}{a}$ ; also  $bb' = 1$ , and  $b' = \frac{1}{b}$ : now  $a, a', b, b'$  are also the roots of the equation

$$x^4 + px^3 + qx^2 + px + 1 = 0.$$

Hence it appears that the proposed equation has this property, that one-half of its roots are the reciprocals of the other half; and to that circumstance we are indebted for the simplicity of its resolution.

105. If the greatest exponent of the unknown quantity in a reciprocal equation is an odd number, as in this example,

$$x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0,$$

the equation will always be satisfied by substituting  $-1$  for  $x$ ; hence,  $-1$  must be a root of the equation, and therefore the equation must be divisible by  $x + 1$ . Accordingly, if the division be actually performed, we shall have in the present case

$$x^4 + (p-1)x^3 - (p-q-1)x^2 + (p-1)x + 1 = 0,$$

another reciprocal equation, in which the greatest exponent of  $x$  is an even number, and therefore resolvable in the manner we have already explained.

106. As an application of the theory of reciprocal equations, let it be proposed to find  $x$  from this equation,

$$\frac{x^5 + 1}{(x + 1)^5} = a,$$

where  $a$  denotes a given number.

Every expression of the form  $x^n + 1$  is divisible by  $x + 1$  when  $n$  is an odd number. In the present case, the numerator and denominator being divided by  $x + 1$ , the equation becomes

$$\frac{x^4 - x^3 + x^2 - x + 1}{x^4 + 4x^3 + 6x^2 + 4x + 1} = a;$$

and this again, by proper reduction, becomes

$$(a - 1)x^4 + (4a + 1)x^3 + (6a - 1)x^2 + (4a + 1)x + a - 1 = 0;$$

and, putting 
$$p = \frac{4a + 1}{a - 1}, \quad q = \frac{6a - 1}{a - 1},$$

$$x^4 + px^3 + qx^2 + px + 1 = 0;$$

a reciprocal equation, resolvable into two quadratics.

EQUATIONS WHICH HAVE EQUAL ROOTS.

107. When an equation has two or more equal roots, these may always be discovered, and the equation reduced to another of an inferior degree, by a method of resolution which is peculiar to this class of equations.

Although the method of resolution we are to employ will apply alike to equations of every degree, having equal roots, yet, for the sake of brevity, we shall take a biquadratic equation,

$$x^4 + px^3 + qx^2 + rx + s = 0,$$

the roots of which may be generally denoted by  $a, b, c$ , and  $d$ . Thus we have, from the theory of equations,  $(x - a)(x - b)(x - c)(x - d) = x^4 + px^3 + qx^2 + rx + s$ .

Let us put

$$\Lambda = (x - a)(x - b)(x - c), \quad \Lambda'' = (x - a)(x - c)(x - d),$$

$$\Lambda' = (x - a)(x - b)(x - d), \quad \Lambda''' = (x - b)(x - c)(x - d):$$

then, by actual multiplication, we have

$$\Lambda = \begin{matrix} x^3 - a \\ -b \\ -c \end{matrix} \left. \begin{matrix} +ab \\ +ac \\ +bc \end{matrix} \right\} x^2 + \dots$$

$$\Lambda' = \begin{matrix} x^3 - a \\ -b \\ -d \end{matrix} \left. \begin{matrix} +ab \\ +ad \\ +bd \end{matrix} \right\} x - abd,$$

$$\Lambda'' = \begin{matrix} x^3 - a \\ -c \\ -d \end{matrix} \left. \begin{matrix} +ac \\ +ad \\ +cd \end{matrix} \right\} x - acd,$$

$$\Lambda''' = \begin{matrix} x^3 - b \\ -c \\ -d \end{matrix} \left. \begin{matrix} +bc \\ +bd \\ +cd \end{matrix} \right\} x - bcd;$$

and taking the sum of these four equations;

$$\Lambda + \Lambda' + \Lambda'' + \Lambda''' = 4x^3 - 3a \left. \begin{matrix} +2ab \\ -3b \\ -3c \\ -3d \end{matrix} \right\} x^2 + \dots \left. \begin{matrix} -abc \\ -abd \\ -acd \\ -bcd \end{matrix} \right\} x$$

But since  $a, b, c, d$  are the roots of the equation

$$x^4 + px^3 + qx^2 + rx + s = 0,$$

$$\text{we have } -3(a + b + c + d) = 3p,$$

$$2(ab + ac + ad + bc + bd + cd) = 2q,$$

$$-(abc + abd + acd + bcd) = r;$$

$$\therefore \Lambda + \Lambda' + \Lambda'' + \Lambda''' = 4x^3 + 3px^2 + 2qx + r.$$

This result expressed in its most general form is as follows:—Let  $\Lambda$  represent the product of all the differences  $x - a, \&c.$ , except one,  $\Sigma\Lambda$ , the sum of all such products; then  $\Sigma\Lambda = nx^{n-1} + (n-1)px^{n-2} + (n-2)qx^{n-3} + \&c.$

108. Let us now suppose that the proposed biquadratic equation has two equal roots, or  $a = b$ ; then  $x - a = x - b$ , and since one or other of these equal factors enters each of the four products  $\Lambda, \Lambda', \Lambda'', \Lambda'''$ , it is evident that  $\Lambda + \Lambda' + \Lambda'' + \Lambda'''$ , or  $4x^3 + 3px^2 + 2qx + r$  must be divisible by  $x - a$ , or  $x - b$ . Thus it appears that if the proposed equation

$$x^4 + px^3 + qx^2 + rx + s = 0$$

have two equal roots, each of them must also be a root of this equation,

$$4x^3 + 3px^2 + 2qx + r = 0;$$

for when the first of these equations is divisible by  $(x - a)^2$ , the latter is necessarily divisible by  $x - a$ .

Let us next suppose that the proposed equation has three equal roots, or  $a = b = c$ ; then, two at least of the three equal factors  $x - a, x - b, x - c$ , must enter each of the four products  $A, A', A'', A'''$ , it is evident that  $A + A' + A'' + A'''$ , or  $4x^3 + 3px^2 + 2qx + r$  must be twice divisible by  $x - a$ . Hence it follows that as often as the proposed equation has three equal roots, two of them must also be equal roots of the equation

$$4x^3 + 3px^2 + 2qx + r = 0.$$

109. Proceeding in the same manner, it may be shown, that whatever number of equal roots are in the proposed equation

$$x^4 + px^3 + qx^2 + rx + s = 0,$$

they will remain, except one, in this equation,

$$4x^3 + 3px^2 + 2qx + r = 0,$$

which may be derived from the former, by multiplying each of its terms by the exponent of  $x$  in that term, and then diminishing the exponent by unity.

110. If we suppose that the proposed equation has two equal roots, or  $a = b$ , and also two other equal roots, or  $c = d$ , then, by reasoning as before, it will appear that the equation derived from it must have one root equal to  $a$  or  $b$ , and another equal to  $c$  or  $d$ ; so that when the former is divisible both by  $(x - a)^2$  and  $(x - c)^2$ , the latter will be divisible by  $(x - a)(x - c)$ .

111. As a particular example, let us take this equation,

$$x^5 - 13x^4 + 67x^3 - 171x^2 + 216x - 108 = 0,$$

and apply to it the method we have explained, in order to discover whether it has equal roots, and if so, what they are. We must seek the greatest common measure of the proposed equation and this other equation, which is formed agreeably to what has been shown (Art. 109),

$$5x^4 - 52x^3 + 201x^2 - 342x + 216 = 0;$$

and the operation being performed, we find that they have a common divisor,  $x^3 - 8x^2 + 21x - 18$ , which is of the third degree, and consequently may have several factors. Let us therefore try whether the last equation, and the following,

$$20x^3 - 156x^2 + 402x - 342 = 0,$$

which is derived from it by the same process, have any common divisor; and, by proceeding as before, we find that they admit of this divisor,  $x - 3$ , which is also a factor of the last divisor,  $x^3 - 8x^2 + 21x - 18$ ; and therefore the product of the remaining factors is immediately found by division to be  $x^2 - 5x + 6$ , which is evidently resolvable into  $x - 2$  and  $x - 3$ .

Thus it appears that the common divisor of the original equation, and that which is immediately derived from it, is  $(x - 2)(x - 3)^2$ ; and that the common divisor of the second and third equations is  $x - 3$ . Hence it follows that the proposed equation has  $(x - 2)^2$  for one factor, and  $(x - 3)^3$  for another factor, and may therefore be expressed thus,  $(x - 2)^2(x - 3)^3 = 0$ . The truth of this conclusion may be easily verified by multiplication. The five roots are 2, 2, 3, 3, and 3.

112. The property proved in Art. 107 enables us to establish numerous relations between the coefficients and roots of an equation, in addition to the fundamental one established in Art. 79, such as the following:—

$$\text{Since } x^n + px^{n-1} + qx^{n-2} + \&c. = (x - a)(x - b)(x - c) \&c.$$

$$\text{and } nx^{n-1} + (n - 1)px^{n-2} + (n - 2)qx^{n-3} + \&c. = (x - b)(x - c) \dots + (x - a)(x - c) \dots + \dots,$$

by division

$$\frac{nx^{n-1} + (x - 1)px^{n-2} + (n - 2)qx^{n-3} + \&c.}{x^n + px^{n-1} + qx^{n-2} + \&c.} = \frac{1}{x - a} + \frac{1}{x - b} + \frac{1}{x - c} + \&c. = \frac{1}{x} + \frac{S_1}{x^2} + \frac{S_2}{x^3} + \frac{S_3}{x^4} + \&c.$$

where  $S_1, S_2, S_3, \&c.$ , are the sums of the first, second, third, &c., powers of the roots of the equation.

Multiplying out and equating coefficients, we get—

$$\begin{aligned} (n - 1)p &= S_1 + np \\ (n - 2)q &= S_2 + pS_1 + nq \\ (n - 3)r &= S_3 + pS_2 + qS_1 + \&c. = \&c. \end{aligned}$$

Or

$$\begin{aligned} S_1 + p &= 0 \\ S_2 + pS_1 + 2q &= 0 \\ S_3 + pS_2 + qS_1 + 3r &= 0 \\ \&c. \&c. \end{aligned}$$

*Ex. 1.* As a particular case, take the cubic equation  $x^3 + qx + r = 0$ .

Here

$$\begin{aligned} S_1 &= 0 \\ S_2 + 2q &= 0 \\ S_3 + 3r &= 0 \\ S_4 + qS_2 &= 0 \\ S_5 + qS_3 + rS_2 &= 0 \end{aligned}$$

∴

$$2S_4 = S_2^2, S_5 = 5qr.$$

The last may be written—

$$\frac{S_5}{5} = qr = \frac{S_3}{3} \cdot \frac{S_2}{2}.$$

*i.e.*, if  $a + b + c = 0$ , then will

$$\frac{a^5 + b^5 + c^5}{5} = \frac{a^3 + b^3 + c^3}{3} \cdot \frac{a^2 + b^2 + c^2}{2}.$$

From  $S_7 + qS_5 + rS_4 = 0$ , we get

$$S_7 = S_5 \cdot \frac{S_2}{2} + S_4 \cdot \frac{S_3}{5},$$

Or

$$\frac{S_7}{7} = \frac{S_5}{5} \cdot \frac{S_2}{2}, \&c. \&c.$$

*Ex. 2.* Take the biquadratic equation

$$x^4 + qx^2 + rx + s = 0$$

Here

$$\begin{aligned} S_1 &= 0 \\ S_2 + 2q &= 0 \\ S_3 + 3r &= 0 \\ S_4 + qS_2 + 4s &= 0 \\ S_5 + qS_3 + rS_2 &= 0 \end{aligned}$$

∴

$$S_5 = S_3 \cdot \frac{S_2}{2} + S_2 \cdot \frac{S_3}{3}$$

or

$$\frac{S_5}{5} = \frac{S_3}{3} \cdot \frac{S_2}{2};$$

*i.e.*, if  $a + b + c + d = 0$ ,

$$\text{then } \frac{a^5 + b^5 + c^5 + d^5}{5} = \frac{a^3 + b^3 + c^3 + d^3}{3} \cdot \frac{a^2 + b^2 + c^2 + d^2}{2}.$$

#### EQUATIONS WHOSE ROOTS ARE RATIONAL

113. It has been shown in Art. 79, that the last term of any equation is always the product of its roots taken with contrary signs. Hence, when the roots are rational, they may be discovered by the following rule:

Bring all the terms of the equation to one side; find all the divisors of the last term, and substitute them successively for the unknown quantity. Then each divisor, which produces a result equal to 0, is a root of the equation.

*Ex.* Let  $x^3 - 4x^2 - 7x + 10 = 0$ .

The divisors of 10, the last term, are 1, 2, 5, 10, each of which may be taken either positively or negatively; and these being substituted successively for  $x$  we obtain the following results:

By putting	+1 for $x$ ,	$1 - 4 - 7 + 10 = 0$ ,
	-1,	$-1 - 4 + 7 + 10 = 12$ ,
	+2,	$8 - 16 - 14 + 10 = -12$ ,
	-2,	$-8 - 16 + 14 + 10 = 0$ ,
	+5,	$125 - 100 - 35 + 10 = 0$ .

Here the divisors which produce results equal to 0 are +1, -2, and +5; therefore these are the three roots of the proposed equation

SECT. XIV. SOLUTION OF EQUATIONS BY APPROXIMATION

114. When the roots of an equation cannot be accurately expressed by rational numbers, it is necessary to have recourse to methods of approximation; and by these we can always determine the numerical values of the roots to as great a degree of accuracy as we please.

The application of methods of approximation is rendered easy by means of the following proposition:

If two numbers, either whole or fractional, be found, which, when substituted for the unknown quantity in any equation, produce results with contrary signs, we may conclude that at least one root of the proposed equation is between those numbers, and is consequently real.

Let the proposed equation be

$$x^3 - 5x^2 + 10x - 15 = 0,$$

which, by collecting the positive terms into one sum, and the negative into another, may also be expressed thus,

$$x^3 + 10x - (5x^2 + 15) = 0;$$

then, to determine a root of the equation, we must find such a number as, when substituted for  $x$ , will render

$$x^3 + 10x = 5x^2 + 15.$$

Let us suppose  $x$  to increase and to have every degree of magnitude from 0 upwards in the scale of number; then  $x^3 + 10x$  and  $5x^2 + 15$  will both continually increase, but with different degrees of quickness, as appears from the following table:—

Successive values of $x$ ;	0, 1, 2, 3, 4, 5, 6, &c.
———— of $x^3 + 10x$ ;	0, 11, 28, 57, 104, 175, 276, &c.
———— of $5x^2 + 15$ ;	15, 20, 35, 60, 95, 140, 195, &c.

By inspecting this table, it appears that while  $x$  increases from 0 to a certain numerical value, which exceeds 3, the positive part of the equation, or  $x^3 + 10x$ , is always less than the negative part, or  $5x^2 + 15$ ; so that the expression

$$x^3 + 10x - (5x^2 + 15) \text{ or } x^3 - 5x^2 + 10x - 15$$

must necessarily be negative.

It also appears, that when  $x$  has increased beyond that numerical value, and which is evidently less than 4, the positive part of the equation, instead of being less than the negative part, is now greater, and therefore the expression

$$x^3 - 5x^2 + 10x - 15$$

is changed from a negative to a positive quantity.

Hence we may conclude that there is some real and determinate value of  $x$ , which is greater than 3, but less than 4, and which will render the positive and negative parts of the equation equal to one another; therefore that value of  $x$  must be a root of the proposed equation; and as what has been just now shown in a particular case will readily apply to any equation whatever, the truth of the proposition is obvious.

115. From the preceding proposition it will not be difficult to discover, by means of a few trials, the nearest integers to the roots of any proposed numerical equation;

and those being found, we may approximate to the roots continually, as in the following example:

$$x^4 - 4x^3 - 3x + 27 = 0.$$

To determine the limits of the roots, let 0, 1, 2, 3, 4, be substituted successively for  $x$ ; thus we obtain the following corresponding results:

Substitutions for $x$ ,	0, 1, 2, 3, 4,
Results,	+27, +21, +5, -9, +15.

Hence it appears that the equation has two real roots, one between 2 and 3, and another between 3 and 4.

That we may approximate to the first root, let us suppose  $x = 2 + y$ , where  $y$  is a fraction less than unity, and therefore its second and higher powers small in comparison to its first power: hence, in finding an approximate value of  $y$ , they may be rejected. Thus we have

$$\begin{aligned} x^4 &= +16 + 32y, \text{ \&c.} \\ -4x^3 &= -32 - 48y, \text{ \&c.} \\ -3x &= -6 - 3y \\ +27 &= +27 \end{aligned}$$

$$\text{Hence } 0 = 5 - 19y \text{ nearly,}$$

and  $y = \frac{5}{19} = .26$ ; therefore, for a first approximation we have  $x = 2.26$ .

Let us next suppose  $x = 2.26 + y'$ ; then, rejecting as before the second and higher powers of  $y'$  on account of their smallness, and retaining three decimal places, we have

$$y' = \frac{.135}{18.119} = .0075, \text{ and } x = 2.26 + y' = 2.2675.$$

This value of  $x$  is true to the last figure, but a more accurate value may be obtained by supposing  $x = 2.2675 + y''$ , and proceeding as before.

116. The method we have hitherto employed for approximating to the roots of equations is known by the name of the *method of successive substitutions*, and was first proposed by Newton. It has been since improved by Lagrange, who has given it a form which has the advantage of showing the progress made in the approximation by each operation. This improved form we now proceed to explain.

Let  $a$  denote the whole number next less to the root sought, and  $\frac{1}{y}$  the fraction, which, when added to  $a$ , com-

pletes the root; then  $x = a + \frac{1}{y}$ . If this value of  $x$  be substituted in the proposed equation, a new equation involving  $y$  will be had, which, when cleared of fractions, will necessarily have a root greater than unity.

Let  $b$  be the whole number which is next less than that root; then, for the first approximation, we have  $x = a + \frac{1}{b}$ .

But  $b$  being only an approximate value of  $y$ , in the same manner as  $a$  is an approximate value of  $x$ , we may suppose  $y = b + \frac{1}{y'}$ ; then, by substituting  $b + \frac{1}{y'}$  for  $y$ , we shall have a new equation, involving only  $y'$ , which must be greater than unity.

Putting therefore  $b'$  to denote the next whole number less than the root of the equation involving  $y'$ , we have  $y = b + \frac{1}{y'}$ ; and substituting this value in that of  $x$ , the result is

$$x = a + \frac{1}{b + \frac{1}{b'}}$$

for a second approximate value of  $x$ .

To find a third value, we may take  $y' = b' + \frac{1}{y''}$ , and so on, to obtain more accurate approximations.

SECT. XV.—INDETERMINATE PROBLEMS.

117. When the conditions of a question are such that the number of unknown quantities exceeds the number of equations, that question will admit of innumerable solutions, and is therefore said to be indeterminate. Thus, if it be required to find two numbers subject to no other limitation than that their sum be 10, we have two unknown quantities  $x$  and  $y$ , and only one equation, viz.  $x + y = 10$ , which may evidently be satisfied by innumerable different values of  $x$  and  $y$ , if fractional solutions be admitted. It is, however, usual, in such questions as this, to restrict values of the numbers sought to positive integers, and therefore, in this case, we can have only these nine solutions,

$$\begin{aligned} x &= 1, 2, 3, 4, 5, 6, 7, 8, 9; \\ y &= 9, 8, 7, 6, 5, 4, 3, 2, 1; \end{aligned}$$

which indeed may be reduced to five; for the first four become the same as the last four, by simply changing  $x$  into  $y$ , and the contrary.

118. Indeterminate problems are of different orders, according to the dimensions of the equation which is obtained after all the unknown quantities but two have been eliminated by means of the given equations. Those of the first order lead always to equations of this form,

$$ax + by = c,$$

where  $a, b, c$ , denote given whole numbers, and  $x, y$ , two numbers to be found, so that both may be integers. That this condition may be fulfilled, it is necessary that the coefficients  $a, b$ , have no common divisor which is not also a divisor of  $c$ ; for if  $a = md$  and  $b = me$ , then  $ax + by = mdx + mey = c$ , and  $dx + ey = \frac{c}{m}$ ; but  $d, e, x, y$ , are supposed to

be whole numbers, therefore  $\frac{c}{m}$  is a whole number; hence  $m$  must be a divisor of  $c$ .

We proceed to illustrate the manner of resolving indeterminate equations of the first order, by some numerical examples.

*Ex. 1.* Given  $2x + 3y = 25$ , to determine  $x$  and  $y$  in whole positive numbers.

From the given equation we have  $x = \frac{25 - 3y}{2} = 12 - y -$

$\frac{y-1}{2}$ . Now, since  $x$  must be a whole number, it follows that  $\frac{y-1}{2}$  must be a whole number. Let us assume  $\frac{y-1}{2} = z$ , then  $y = 1 + 2z$ ; and  $x = 11 - 3z$ , where  $z$  might be any whole number whatever, if there were no limitation as to the signs of  $x$  and  $y$ . But since these quantities are required to be positive, it is evident, from the value of  $y$ , that  $z$  must be either 0 or positive, and from the value of  $x$ , that it must be less than 4; hence  $z$  may have these three values, 0, 1, 2, 3.

	If $z = 0,$	$z = 1,$	$z = 2,$	$z = 3;$
Then	$\begin{cases} x = 11, \\ y = 1, \end{cases}$	$\begin{cases} x = 8, \\ y = 3, \end{cases}$	$\begin{cases} x = 5, \\ y = 5, \end{cases}$	$\begin{cases} x = 2, \\ y = 7. \end{cases}$

*Ex. 2.* It is required to find all the possible ways in which £60 can be paid in guineas and moidores only.

Let  $x$  be the number of guineas, and  $y$  the number of moidores. Then the value of the guineas, expressed in shillings, is  $21x$ , and that of the moidores  $27y$ ; therefore, from the nature of the question,  $21x + 27y = 1200$ , or, dividing the equation by 3,  $7x + 9y = 400$ ; hence, proceeding as before, we obtain

$$\begin{aligned} y &= 7v - 3, \\ x &= 61 - 9v. \end{aligned}$$

From the value of  $x$ , it appears that  $v$  cannot exceed 6, and from the value of  $y$ , that it cannot be less than 1.

Hence if  $v = 1, 2, 3, 4, 5, 6,$   
we have  $x = 52, 43, 34, 25, 16, 7.$   
 $y = 4, 11, 18, 25, 32, 39.$

119. In the foregoing examples the unknown quantities  $x$  and  $y$  have each a determinate number of positive values; and this will evidently be the case as often as the proposed equation is of this form,  $ax + by = c$ . If, however,  $b$  be negative, that is, if the equation be of this form,  $ax - by = c$ , or  $ax = by + c$ , we shall have questions of a different kind, admitting each of an infinite number of solutions; these, however, may be resolved in the same manner as the preceding.

120. If an equation were proposed involving three unknown quantities, as  $ax + by + cz = d$ , by transposition we have  $ax + by = d - cz$ , and, putting  $d - cz = c'$ ,  $ax + by = c'$ . From this last equation we may find values of  $x$  and  $y$  of this form,

$$\begin{aligned} x &= mr + nc', \quad y = m'r + n'c', \\ \text{or } x &= mr + n(d - cz), \quad y = m'r + n'(d - cz); \end{aligned}$$

where  $z$  and  $r$  may be taken at pleasure, except in so far as the values of  $x, y, z$ , may be required to be all positive; for from such restriction the values of  $z$  and  $r$  may be confined within certain limits to be determined from the given equation.

121. We proceed to indeterminate problems of the second degree: limiting ourselves to the consideration of the formula  $y^2 = a + bx + cx^2$ , where  $x$  is to be found, so that  $y$  may be a rational quantity. The possibility of rendering the proposed formula a square depends altogether upon the coefficients  $a, b, c$ ; and there are four cases of the problem, the solution of each of which is connected with some peculiarity in its nature.

*Case 1.* Let  $a$  be a square number; then, putting  $g^2$  for  $a$ , we have  $y^2 = g^2 + bx + cx^2$ . Suppose  $\sqrt{g^2 + bx + cx^2} = g + mx$ ; then  $g^2 + bx + cx^2 = g^2 + 2gmx + m^2x^2$ , or  $bx + cx^2 = 2gmx + m^2x^2$ , that is,  $b + cx = 2gm + m^2x$ ; hence

$$x = \frac{2gm - b}{c - m^2}, \quad y = \sqrt{g^2 + bx + cx^2} = \frac{cg - bm + gm^2}{c - m^2}.$$

*Case 2.* Let  $c$  be a square number  $= g^2$ ; then, putting  $\sqrt{a + bx + g^2x^2} = m + gx$ , we find  $a + bx + g^2x^2 = m^2 + 2mgx + g^2x^2$ , or  $a + bx = m^2 + 2mgx$ ; hence we find

$$x = \frac{m^2 - a}{b - 2mg}, \quad y = \sqrt{a + bx + g^2x^2} = \frac{bm - gm^2 - ag}{b - 2mg}.$$

*Case 3.* When neither  $a$  nor  $c$  is a square number, yet if the expression  $a + bx + cx^2$  can be resolved into two simple factors, as  $f + gx$  and  $h + kx$ , the irrationality may be taken away as follows:

Assume  $\sqrt{a + bx + cx^2} = \sqrt{(f + gx)(h + kx)} = m(f + gx)$ , then  $(f + gx)(h + kx) = m^2(f + gx)^2$ , or  $h + kx = m^2(f + gx)$ ; hence we find

$$x = \frac{fm^2 - h}{k - gm^2}, \quad y = \sqrt{(f + gx)(h + kx)} = \frac{(fk - gh)m}{k - gm^2};$$

and in all these formulæ  $m$  may be taken at pleasure.

*Case 4.* The expression  $a + bx + cx^2$  may be transformed into a square as often as it can be resolved into two parts, one of which is a complete square, and the other a product of two simple factors; for then it has this form,  $p^2 + qr$ , where  $p, q$ , and  $r$  are quantities which contain no power of  $x$  higher than the first. Let us assume  $\sqrt{p^2 + qr} = p + mq$ ; thus we have  $p^2 + qr = p^2 + 2mpq + m^2q^2$  and  $r = 2mp + m^2q$ , and as this equation involves only the first power of  $x$ , we may by proper reduction obtain from it rational values of  $x$  and  $y$ , as in the three foregoing cases.

The application of the preceding general methods of resolution to any particular case is very easy; we shall therefore conclude with a single example.

*Ex.* It is required to find two square numbers whose sum is a given square number.

Let  $a^2$  be the given square number, and  $x^2, y^2$ , the numbers required; then, by the question,  $x^2 + y^2 = a^2$ , and  $y = \sqrt{a^2 - x^2}$ . This equation is evidently of such a form as to be resolvable by the method employed in case 1. Accordingly, by comparing  $\sqrt{a^2 - x^2}$  with the general expression  $\sqrt{g^2 + bx + cx^2}$ , we have  $g = a, b = 0, c = -1$ , and substituting these values in the formulæ, and also  $-n$  for  $+m$ , we find

$$x = \frac{2an}{n^2 + 1}, y = \frac{a(n^2 - 1)}{n^2 + 1}.$$

If  $a = n^2 + 1$ ; there results  $x = 2n, y = n^2 - 1, a = n^2 + 1$ . Hence if  $r$  be an even number, the three sides of a rational right-angled triangle are  $r, \left(\frac{r}{2}\right)^2 - 1, \left(\frac{r}{2}\right)^2 + 1$ . If  $r$  be an odd number, they become (dividing by 2)  $r, \frac{r^2 - 1}{2}, \frac{r^2 + 1}{2}$ .

For example, if  $r = 4$ ; 4, 4 - 1, 4 + 1, or 4, 3, 5 are the sides of a right-angled triangle; if  $r = 7$ , 7, 24, 25 are the sides of a right-angled triangle.

SECT. XVI.—THEOREMS OF EXPANSION.

1. *Binomial Theorem.*

122. To demonstrate this theorem, which has for its object the expansion of  $(a + x)^n$  in the form  $P + Qx + Ax^2 + Bx^3 + \&c.$ , we shall first find  $P$  and  $Q$ ; and then determine the other coefficients  $A, B, \&c.$  in terms of  $P$  and  $Q$ .

$$(1.) (a + x)^n = \left\{ a \left( 1 + \frac{x}{a} \right) \right\}^n = a^n \left( 1 + \frac{x}{a} \right)^n,$$

it being assumed that the power of a product is the product of the powers of the factors, whatever be the index.

(2.) Let  $n$  be a whole number. Since

$$\begin{aligned} (1 + x)^1 &= 1 + x \\ (1 + x)^2 &= 1 + 2x + x^2 \\ (1 + x)^3 &= 1 + 3x + \&c.; \end{aligned}$$

if we assume  $(1 + x)^{n-1} = 1 + (n-1)x + \&c.$ , and multiply both sides by  $1 + x$ , we shall obtain  $(1 + x)^n = 1 + nx + \&c.$ ; whence our induction is complete to prove that the numerical of coefficient  $x$  is the same as the index.

(3.) Let  $n$  be a positive fraction  $\frac{p}{q}$ . We may take

$$\begin{aligned} (1 + x)^{\frac{p}{q}} &= 1 + Qx + \&c. \\ \therefore (1 + x)^p &= (1 + Qx + \&c.)^q, \\ \text{or, } 1 + px + \&c. &= 1 + qQx + \&c. \quad (\text{Case 2.}) \\ \therefore Q &= \frac{p}{q}. \end{aligned}$$

(4.) If  $n$  be negative =  $-m$

$$\begin{aligned} (1 + x)^n &= (1 + x)^{-m} = \frac{1}{(1 + x)^m} \\ &= \frac{1}{1 + mx + \&c.} \quad (\text{Case 3.}) \\ &= 1 - mx + \&c. \text{ by division.} \end{aligned}$$

Hence, generally the numerical coefficient of  $x$  is the same as the index.

To obtain  $A, B, \&c.$  in terms of the first and second terms, we break up  $x$  into two parts,  $y, z$ , which enables us to write the expression  $1 + x$  in two different ways: *1st*, retaining the parts of  $x$  in connection; *2d*, dissevering them. In the first form we simply multiply out, and thus exhibit a result not dependent on the properties of an index, except in so far as relates to the first and second terms. In the second form we apply the properties of an

index to every term. The consequence is, that the latter form, bearing a more intimate connection with the property of an index than the former, is more determinate than the other. The comparison of the two results completes the demonstration.

$$\begin{aligned} \text{I. } (1 + x)^n &= (1 + y + z)^n \\ &= 1 + n(y + z) + A(y + z)^2 + B(y + z)^3 + \&c. \\ &= 1 + ny + Ay^2 + Bzy + \&c. \\ &\quad + nz + 2Ayz + 3By^2z + \&c. \\ &\quad + \&c. + \&c. \end{aligned}$$

$$\begin{aligned} \text{II. } (1 + x)^n &= (1 + y + z)^n = (1 + z + y)^n \\ &= (1 + z)^n \left( 1 + \frac{y}{1 + z} \right)^n \\ &= (1 + z)^n \left\{ 1 + \frac{ny}{1 + z} + \frac{A y^2}{(1 + z)^2} + B \frac{y^3}{(1 + z)^3} + \&c. \right\} \\ &= (1 + z)^n + n(1 + z)^{n-1}y + A(1 + z)^{n-2}y^2 + \&c. \\ &= 1 + ny + \&c. + nz + n(n-1)zy + A(n-2)zy^2 + \&c. \\ &\quad + \&c. + \&c. \end{aligned}$$

Now, as these two expansions are the expansions of the same thing in the same form, the coefficients of  $z, zy, zy^2, \&c.$ , must be the same in both. Comparing them, we get

$$\begin{aligned} n &= n, 2A = n(n-1), 3B = A(n-2) \&c. \\ \therefore A &= \frac{n(n-1)}{1 \cdot 2}, B = \frac{A(n-2)}{3} = \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \end{aligned}$$

&c. = &c.; and finally, whatever  $n$  be,

$$(1 + x)^n = 1 + nx + \frac{n(n-1)}{1 \cdot 2} x^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} x^3 + \&c.$$

Cor. 1. If  $n$  is a positive whole number, the series is finite, since every term after the  $(n + 1)$ th will involve  $n - n$  as a factor.

Cor. 2. Since the coefficients, when the index is a whole number, are the results of simple multiplication, they are necessarily whole numbers, *i.e.*, any such expression as  $\frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}$  is a whole number when  $n$  is such

Cor. 3. The sum of the numerical coefficients is  $2^n$ , for it is equal to  $(1 + 1)^n$ , as will appear if we write 1 for  $x$ .

Cor. 4. The sum of the coefficients in the even places is equal to the sum of the coefficients in the odd. This will appear if we write  $-1$  in place of  $x$ .

Cor. 5. If the index is a whole number, the coefficients from the end are the same as those from the beginning; for they occur at the beginning of  $(x + 1)^n$  in the same positions as at the end of  $(1 + x)^n$ .

Cor. 6. The product  $1 \cdot 2 \cdot 3 \dots r$  is sometimes expressed by the abbreviated form  $r!$ . With this notation the coefficient of  $x^r$  in  $(1 + x)^n$  may be written  $\frac{|n}{r \cdot |n-r}$ .

Cor. 7. The sum of the squares of the coefficients of  $(1 + x)^n$  is the coefficient of  $x^n$  in the expansion of  $(1 + x)^{2n}$ , and is equal to  $\frac{|2n}{(|n|)^2}$ .

*Examples.*

$$\begin{aligned} \text{Ex. 1. } (1 + x)^{-2} &= 1 + \frac{-2}{1}x + \frac{-2 \cdot -3}{1 \cdot 2}x^2 + \frac{-2 \cdot -3 \cdot -4}{1 \cdot 2 \cdot 3}x^3 \\ &\quad + \&c. \\ &= 1 - 2x + 3x^2 - 4x^3 + \&c. \end{aligned}$$

generally  $(1 + x)^{-n} = 1 - nx + \frac{n(n+1)}{1 \cdot 2}x^2 - \&c.$

and  $(1 - x)^{-n} = 1 + nx + \frac{n(n+1)}{1 \cdot 2}x^2 + \&c.$

*Ex. 2.* Find the coefficient of  $x^7$  in  $(x + x^2 + x^3 + x^4 + x^5 + x^6)^2$ .

The expression may be written

$$\left\{ x \left( \frac{1-x^6}{1-x} \right) \right\}^2 = x^2(1-x^6)^2(1-x)^{-2}$$

$$= x^2(1-2x^6+x^{12})(1+2x+3x^2+4x^3+\&c.)$$

The coefficient required is therefore that of  $x^5$  in the last factor, viz. 6.

Ex. 3. Find the sum of  $1+2n+3\frac{n(n-1)}{1.2}+4\frac{n(n-1)(n-2)}{1.2.3}+\&c.$

By writing  $1+1$  for  $2$ ,  $1+2$  for  $3$ , &c., this series may be broken up into the sum of  $1+n+\frac{n(n-1)}{1.2}+\&c.$

and  $n+2\frac{n(n-1)}{1.2}+\&c.$

The latter is  $n \left\{ 1 + \frac{n-1}{1} + \frac{(n-1)(n-2)}{1.2} + \&c. \right\}$

$\therefore$  the sum required is  $2^n + n2^{n-1}$ .

Ex. 4. Find the sum of  $1 + \frac{1}{2}n + \frac{1}{3}\frac{n(n-1)}{1.2} + \&c.$

Multiply by  $n+1$ ; the product is

$$n+1 + \frac{(n+1)n}{1.2} + \frac{(n+1)n(n-1)}{1.2.3} + \&c.$$

$\therefore$  the sum required is  $\frac{2^{n+1}-1}{n+1}$ .

Ex. 5. If  $x_r$  denote the product  $x(x-1)(x-2)\dots(x-r+1)$  whatever be  $r$ , and a similar notation be applied to  $y$ , and  $(x+y)$ , then

$$(x+y)_r = x_r + rx_{r-1}y_1 + \frac{r(r-1)}{1.2}x_{r-2}y_2 + \&c.$$

We have  $(1+a)^x = 1 + x_1a + \frac{x_2}{1.2}a^2 + \frac{x_3}{1.2.3}a^3 + \&c.$

$$(1+a)^y = 1 + y_1a + \frac{y_2}{1.2}a^2 + \&c.$$

$\therefore$   $(1+a)^{x+y}$  = their product.

But  $(1+a)^{x+y} = 1 + (x+y)_1a + \frac{(x+y)_2}{1.2}a^2 + \&c.$

Equating coefficients of  $a^n$  in the two expressions for  $(1+a)^{x+y}$ , and multiplying by  $1.2\dots n$ , the required result is obtained.

Ex. 6. If  $x$  and  $n$  be less than 1, then  $(1+x)^n < (1+nx)$ .

For  $(1+x)^n = 1 + nx + \frac{n(n-1)}{1.2}x^2 + \dots$

$$= 1 + nx - \frac{n(1-n)}{1.2}x^2 \left( 1 - \frac{2-n}{3}x \right) - \&c.$$

Ex. 7. On the same hypothesis  $(1+x)^n < \frac{1}{1-nx}$

Prove that  $(1+x)^{-n} > 1 - nx$  exactly as in the last example.

Ex. 8. If  $x < 1$ ;  $n > r < r+1$ ; then  $(1+x)^n >$  the sum of the first  $r+1$  terms of the expansion; and  $<$  the sum of the first  $r+2$  terms.

Ex. 9. The difference between the sums of the squares of the even coefficients of the expansion of  $(1+x)^n$ , when  $n$  is an even whole number, and the sum of the squares

of the odd coefficients is  $(-1)^{\frac{n}{2}} \left( \frac{1^n}{\frac{n}{2}} \right)^2$ .

2. Logarithmic Theorem.

123. The definition of a logarithm is precisely the same as that of an index or exponent (Art. 21) viz.—the logarithm of a product is equal to the sum of the logarithms of the factors. Such being the case, we are at liberty to employ the definition, either in the form first given, or in the algebraic form  $a^x = y$ . In this last form  $x$  is called the logarithm of  $y$  to the index or base  $a$ . The base of the common or tabular logarithms is 10.

124. Before proceeding to the demonstration of the theorem by which a logarithm is expressed in the form of a series, it may be as well to illustrate the definition as applied to common logarithms.

1st, Since 1 is the logarithm of 10, we may inquire what is  $\frac{1}{2}$  the logarithm; if we resume the form  $10^x = y$ , and write  $\frac{1}{2}$  for  $x$ , we have to inquire what is  $y$ .

Since  $10^{\frac{1}{2}} = y, 10^{\frac{1}{2}} \times 10^{\frac{1}{2}} = y^2.$

But  $10^{\frac{1}{2}} \times 10^{\frac{1}{2}} = 10^{\frac{1}{2}+\frac{1}{2}}$  (def.) = 10,

$\therefore y^2 = 10$  and  $y = \sqrt{10} = 3.1622777,$

so that the number of which  $\frac{1}{2}$  is the logarithm is not a whole number, but a fraction lying between 3 and  $3\frac{1}{2}$ .

In the same way, we may, but with great labour, ascertain the numbers of which any given fraction is the logarithm.

2d, The definition will evidently enable us to obtain a large number of logarithms, when a few have become known. For example: Given  $\log 2 = .30103$  to find  $\log 4$  and  $\log 5$ .

$\log 4 = \log (2 \times 2) = \log 2 + \log 2$  (def.)  
 $= 2 \log 2 = .60206;$

$\log 5 = \log \frac{10}{2} = \log 10 - \log 2$   
 $= 1 - \log 2 = .69897.$

If in addition to  $\log 2$ ,  $\log 3$  be known, we can find a vast number of others. For example: Given—

$\log 3 = .47712$  to find  $\log 6$  and  $\log 72$ .

$\log 6 = \log 2 \times 3 = \log 2 + \log 3 = .77815,$

$\log 72 = \log 8 \times 9 = 3 \log 2 + 2 \log 3 = 1.85733.$

125. To expand  $\log (1+x)$  in terms of  $x$ .

Since  $\log 1 = 0$ ; the expansion must commence with the first power of  $x$ , the coefficient of which will depend on the radix or base. This coefficient we shall determine afterwards for the common logarithms. In the meantime we shall denote it by  $A$ .

Let then  $\log (1+x) = Ax + Bx^2 + Cx^3 + \&c.$

Put  $y+z$  for  $x$ ; then

I.  $\log (1+y+z) = A(y+z) + B(y+z)^2 + \&c.$   
 $= Ay + By^2 + Cy^3 + \&c.$   
 $+ Az + 2Byz + 3Cy^2z + \&c.$   
 $+ \&c. + \&c.$

II.  $\log (1+y+z) = \log (1+y) \left( 1 + \frac{z}{1+y} \right)$   
 $= \log (1+y) + \log \left( 1 + \frac{z}{1+y} \right)$   
 $= Ay + By^2 + \&c.$   
 $+ \frac{Az}{1+y}$   
 $+ \&c.$   
 $= Ay + By^2 + \&c.$   
 $+ Az(1-y+y^2-\&c.)$   
 $+ \&c.$

Equating coefficients of  $z, yz, y^2z, \&c.$ , in the two expansions, there results

$A = A, 2B = -A, 3C = -A$

$\therefore \log (1+x) = A \left( x - \frac{x^2}{2} + \frac{x^3}{3} - \&c. \right)$

126. Cor. If  $x = a - 1$ , where  $a$  is the base of the system, we have  $1 = A \left\{ a - 1 - \frac{1}{2}(a-1)^2 + \&c. \right\}$

This expansion of  $\log (1+x)$  is not convergent, i.e., the terms do not diminish as we advance, but the contrary, when  $x$  is any whole number greater than 1. We can, however, readily obtain from it a converging series for the difference between the logarithms of the consecutive numbers.

For  $\log(1+x) = A\left(x - \frac{x^2}{2} + \&c.\right)$

$\log(1-x) = A\left(-x - \frac{x^2}{2} - \&c.\right)$

$\therefore \log(1+x) - \log(1-x) = 2A\left(x + \frac{x^3}{3} + \frac{x^5}{5} + \&c.\right)$

Now  $\log(1+x) - \log(1-x) = \log \frac{1+x}{1-x}$ ,

and  $x$  has to be found, so that  $\frac{1+x}{1-x}$  shall be the quotient of consecutive numbers  $= \frac{1+u}{u}$ .

This gives  $x = \frac{1}{2u+1}$ ,

and  $\log \frac{1+u}{u} = 2A \left\{ \frac{1}{2u+1} + \frac{1}{3} \frac{1}{(2u+1)^3} + \&c. \right\}$

127. To apply this formula to the calculation of common logarithms, we will commence by finding from it a few logarithms of the system for which  $A=1$ . In this system

1. If  $u=1$ ,  $\log 2 = 2 \left\{ \frac{1}{3} + \frac{1}{3} \cdot \frac{1}{3^3} + \&c. \right\}$   
 $= .693, 147, 2.$

2. If  $u=4$ ,  $\log 5 = \log 4 + 2 \left\{ \frac{1}{9} + \frac{1}{3} \cdot \frac{1}{9^3} + \&c. \right\}$   
 $= 1.609, 437, 9.$

Hence  $\log 10 = \log 2 + \log 5$   
 $= 2.302, 585, 1.$

This system, for which  $A=1$  is the so-called Napierian system, which assumes no base, but defines a logarithm to be such that the increment of the number shall be the product of the number by the increment of the logarithm. In this system the number of which the logarithm is 1 is 2.718... and is generally designated by the letter  $e$ .

To pass from Napierian logarithms to common, we observe that if  $e^x = 10^y = n$ ;  $x$  is the logarithm of  $n$  to the base  $e$ , and  $y$  to the base 10. Now, taking the Napierian logarithm of each side of this equation, we obtain  $x = y \text{ Nap. log } 10$ .

Or  $y = \frac{x}{\text{Nap. log } 10} = \frac{x}{2.302, 585, 1}.$   
 $= x \times .4342944819$   
 $= x \times .4343 \text{ very nearly.}$

This multiplier, which was previously denoted by  $A$ , is called the modulus of the common system of logarithms. A celebrated calculator of the last century, Mr A. Sharp, found it to be

$.43429448190325182765112891891660508229439700$   
 $5803666566114454.$

For further details on the construction and use of logarithmic tables, the reader is referred to the Article on LOGARITHMS.

3. Exponential Theorem.

128. It is now required to expand  $a^x$  in terms of  $x$ .

1. Write  $1+a-1$  for  $a$ , and apply the binomial theorem; the result is

$\{1+(a-1)\}^x = 1+x(a-1) + \frac{x(x-1)}{1.2} (a-1)^2 + \&c.$

Here the only term which does not contain  $x$  is 1; and the coefficient of  $x$  being traced through the different terms, is easily seen to be

$a-1 - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \&c.$

This will seem (Art. 126) to be the reciprocal of the

modulus of the system of logarithms whose base is  $a$ : call it  $r$ . We have now to determine  $B, C, \&c.$ , in terms of  $r$ , from the form of expansion

$a^x = 1 + rx + Bx^2 + Cx^3 + \&c.$

Write  $y+z$  is place of  $x$ ; then

I.  $a^{y+z} = 1 + r(y+z) + B(y+z)^2 + \&c.$   
 $= 1 + ry + B y^2 + \&c.$   
 $+ rz + 2B yz + \&c.$   
 $+ \&c.$

II.  $a^{y+z} = a^y \times a^z = (1 + ry + B y^2 + \&c.)$   
 $\times (1 + rz + B z^2 + \&c.)$   
 $= 1 + ry + B y^2 + \&c.$   
 $+ rz + r^2 yz + r B y^2 z + \&c.$   
 $+ \&c.$

Equating coefficients of  $z, yz, y^2z, \&c.$ , in I. and II., we get

$r = r, 2B = r^2, 3C = rB, \&c.$

$\therefore B = \frac{r^2}{1.2}, C = \frac{r^3}{1.2.3}, \&c$

and  $a^x = 1 + rx + \frac{r^2 x^2}{1.2} + \frac{r^3 x^3}{1.2.3} + \&c.$

129. Now, since  $e$  is such (Art. 127) that  $e-1 - \frac{1}{2}(e-1)^2 + \&c. = 1$ , and  $r = a-1 - \frac{1}{2}(a-1)^2 + \&c.$ , whatever  $a$  be, it follows that when  $e$  takes the place of  $a$ ,  $r$  becomes 1.

$\therefore e^x = 1 + x + \frac{x^2}{1.2} + \frac{x^3}{1.2.3} + \&c.$

and putting  $x=1, e = 1 + 1 + \frac{1}{1.2} + \&c.$   
 $= 2.718281828459045\dots$

Again  $e^r = 1 + r + \frac{r^2}{1.2} + \&c.$

but since,  $a^x = 1 + rx + \frac{r^2 x^2}{1.2} + \&c.$

we have  $a = 1 + r + \frac{r^2}{1.2} + \&c.$   
 $= e^r$

From this equation we have  $r = \text{Nap. log } a$ , a result obtained before.

130. We may approximate directly to the value of  $r$  when  $a=10$ , thus

$\left(\frac{1}{a}\right)^x = a^{-x} = 1 - rx + \frac{r^2 x^2}{1.2} - \&c.$

so that the coefficient of  $x$  in  $\left(\frac{1}{a}\right)^x$  is  $-r$ .

Now  $\left(\frac{1}{a}\right)^x = \left(1 + \frac{1}{a} - 1\right)^x$ , whence (Art. 128) the coefficient of  $x$  in  $\left(\frac{1}{a}\right)^x$  is

$\frac{1}{a} - 1 - \frac{1}{2} \left(\frac{1}{a} - 1\right)^2 + \frac{1}{3} \left(\frac{1}{a} - 1\right)^3 - \&c.$

$\therefore r = 1 - \frac{1}{a} + \frac{1}{2} \left(1 - \frac{1}{a}\right)^2 + \frac{1}{3} \left(1 - \frac{1}{a}\right)^3 + \&c.$

$= \frac{9}{10} + \frac{1}{2} \left(\frac{9}{10}\right)^2 + \frac{1}{3} \left(\frac{9}{10}\right)^3 + \&c.$   
 $= 2.302\dots$

Additional Examples.

Ex. 1. To find the value to which  $\left(1 + \frac{x}{m}\right)^m$  approaches as  $m$  becomes larger and larger.

By the binomial theorem

method explained in Art. 116, the value of the unknown quantity is evidently expressed by a continued fraction. For if  $x$  be the root sought, we have  $x = a + \frac{1}{y}$ ,  $y = b + \frac{1}{y'}$ ,  $y' = b' + \frac{1}{y''}$ ,  $y'' = b'' + \frac{1}{y'''}$ , &c. where  $a, b, b', b'',$  &c. denote the whole numbers, which are next less than the true values of  $x, y, y', y'',$  &c. If, therefore, in the value of  $x$  we substitute  $b + \frac{1}{y'}$  for  $y$ , it becomes

$$x = a + \frac{1}{b + \frac{1}{y'}}$$

Again, if in this second value of  $x$  we substitute  $b' + \frac{1}{y''}$  for  $y'$ , it become

$$x = a + \frac{1}{b + \frac{1}{b' + \frac{1}{y''}}}$$

And so on continually,

133. It is easy to see in what manner the inverse of the preceding operation is to be performed, or a continued fraction reduced to a common fraction.

The fractions which result from omitting portions of a continued fraction are termed the *convergents* to that fraction. Thus, if the fraction be  $\frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3}}}$ ;  $\frac{1}{a_1}$  is the first convergent,  $\frac{a_2}{a_1 a_2 + 1}$  the second, &c.

134. The principal practical application of the properties of continued fractions is to approximate to the value of a given fraction. The proposition on which this application depends is the following:—

*No fraction in terms equally low can give so good an approximation to the value of a fraction as a convergent to the continued fraction which expresses it does.*

To demonstrate this proposition, it is requisite to establish three preliminary propositions, which we shall do very briefly.

135. (1.) If  $\frac{p_n}{q_n}$  denote the  $n$ th convergent, or the reduced fraction which results from stopping at  $a_n$ , and reducing, then  $p_{n+1} = a_{n+1}p_n + p_{n-1}$ ,  $q_{n+1} = a_{n+1}q_n + q_{n-1}$ .

Since no denominator can be multiplied by itself, the reduced fraction must give  $p_n = a_n A + B$ .

Now  $p_{n+1}$  is obtained by writing  $a_n + \frac{1}{a_{n+1}}$  for  $a_n$ , and reducing,

$$\therefore p_{n+1} = a_{n+1}(a_n A + B) + A = a_{n+1}p_n + A;$$

i.e., the multiplier of any  $a$  is the previous  $p$ , and the other term is the multiplier of  $a$  in the previous convergent, hence the proposition.

$$136. (2.) p_{n+1}q_n - q_{n+1}p_n = (-1)^n.$$

This is at once obtained by eliminating  $a_{n+1}$  from the two equations of last article.

137. (3.) The successive convergents are alternately greater and less than the complete fraction, and each convergent approaches nearer in value to it than the preceding.

If  $A$  denote the complete denominator  $a_{n+1} + \text{&c.}$ ;  $u$  the complete fraction; then  $u = \frac{Ap_n + p_{n-1}}{Aq_n + q_{n-1}}$ ; and by subtracting successively  $\frac{p_n}{q_n}$  and  $\frac{p_{n-1}}{q_{n-1}}$  from  $u$  in this form, it will be seen at once that the results have different signs, and that the latter difference is the larger.

138. We are now able to prove the proposition enunciated.

Let  $\frac{p}{q}$  be a fraction nearer to  $u$  than  $\frac{p_{n+1}}{q_{n+1}}$ ; then since the convergents are alternately too great and too small;  $\frac{p_{n+1}}{q_{n+1}}, \frac{p}{q}, \frac{p_n}{q_n}$ , must be in order of magnitude.

$\therefore$  If the first be the greatest,

$$\frac{p_{n+1}}{q_{n+1}} - \frac{p_n}{q_n} > \frac{p}{q} - \frac{p_n}{q_n}.$$

Reducing and applying Prop. 2, there results  $q > q_{n+1}$ . Similarly by inverting the fractions, it may be proved that  $p > p_{n+1}$ .

*Ex. 1.* To determine when a transit of Venus may be expected.

The relative sidereal periods of Venus and the earth are 224,700 days and 365,256 days. The continued fraction which expresses the quotient of these numbers is

$$\frac{1}{1} + \frac{1}{1} + \frac{1}{1} + \frac{1}{1} + \frac{1}{2} + \frac{1}{29} + \text{&c.}$$

The fifth convergent is  $\frac{8}{13}$ ; the sixth  $\frac{235}{382}$ .

On account of the smallness of  $\frac{1}{29}$ , the former is a very close approximation, i.e., 8 years and 13 sidereal periods of Venus are very nearly equal.

In consequence of this, a transit occurs after one period of 8 years, and then again not till after 235 years have been completed.

The last pair of transits at the descending node occurred in 1769, 1777; and at the ascending node in 1639, 1647.

The next pair will accordingly occur at the latter node in 1874 and 1882. The days of transit will be December 8 and December 6, respectively.

*Ex. 2.* To find the periods of probable recurrence of eclipses of the sun.

An eclipse of the sun will occur whenever the place of the new moon is within about 13° of the line of nodes. Now, the interval between two new moons is 29.5306 days; and the mean synodic period of the earth and the line of nodes is 346.6196 days. The proportion of the latter of these numbers to the former, reduced to a continued fraction, gives as convergents  $\frac{47}{4}, \frac{223}{19}$ , &c.

Hence, after 47 lunar months, things have come nearly to their original position, and after 223 lunar months, very nearly. This latter period, termed the *saros*, has been known from the remotest antiquity. It enabled the Chaldean shepherds to predict the return of eclipses. It amounts to 18 years and 10 or 11 days. Thus, there was a total eclipse on the 18th July 1860; adding 18 years 11 days, we get for an eclipse 29th July 1878. If we add 47 lunations or 1388 days, we get 6th March 1864, on which day there was an eclipse.

This period of 1388 days, multiplied by 5, makes exactly 19 years—a period which is designated as the cycle of *Meton*, giving eclipses which occur on the same day of the month. Thus, eclipses happened 18th July 1841 and 18th July 1860, and another will happen 18th July 1879.

*Ex. 3.* The fraction given (Art. 131) represents the ratio of the circumference of a circle to its diameter. By taking the first two terms we have  $\pi = 3 + \frac{1}{2} = \frac{7}{2}$  nearly; and this is the proportion which was found by Archimedes.

Again, by taking the first three terms, we have

$$\pi = 3 + \frac{1}{7} + \frac{1}{15} = 3 + \frac{15}{106} = \frac{333}{106},$$

which is nearer the truth than the former.

And, by taking the first four terms, we have

$$\pi = 3 + \frac{1}{7} + \frac{1}{15} + \dots = \frac{355}{113}$$

which is the proportion assigned by Metius.

Ex. 4. The mean tropical year consists of  $365 \cdot 2422642$  days.

The fraction  $\cdot 2422642$ , reduced to a continued fraction, gives as successive convergents

$$\frac{1}{4}, \frac{7}{29}, \frac{8}{33}, \frac{39}{161}, \frac{47}{194}, \frac{321}{1325}, \&c.$$

To make the civil year approximate to the tropical, 1 leap year in 4 (the Julian Calendar) serves but imperfectly. 7 leap years in 29 would be inconvenient. The Gregorian Calendar, now in use, is based on combining the fractions  $\frac{47}{194}$  and  $\frac{1}{4}$ , by doubling the numerator and denominator of the former, and trebling those of the latter, and adding them respectively. The resulting fraction is  $\frac{97}{400}$ , giving 97 leap years in 400 years, instead of 100 as the Julian does. This diminution of 3 leap years in 400 years is produced periodically, by causing years which indicate the completion of centuries not to be leap years unless the number of centuries is divisible by 4. Thus, 1900 will not be a leap year.

#### SECT. XVIII.—PERMUTATIONS, COMBINATIONS, AND PROBABILITIES.

139. Hitherto we have supposed the letters of the alphabet,  $a, b, c, \&c.$ , to stand for arithmetical quantities of some kind or other. Now we have to employ them, as in geometry, to represent magnitudes or objects, such as pens, pencils, &c., and to investigate the numbers of different ways in which a given set of them can be grouped according to a certain law.

*Permutations* are their arrangements in a line, reference being had to the order of sequence; thus  $ab$  and  $ba$  are the two permutations of  $a$  and  $b$ ; *combinations* are their arrangements in groups, without reference to the order of sequence; thus  $abc$  is a combination involving  $a, b$ , and  $c$ ; and  $bac$  is the same combination, both consisting simply of  $a, b$ , and  $c$  grouped together.

Prop. 1. To find the number of permutations of  $n$  things (1), two and two (2), three and three, &c., together.

Set aside  $a$ , and lay down the other things in a line; place  $a$  before each of them in succession, and you obtain  $ab, ac, ad, \&c.$ , *i.e.*,  $n - 1$  arrangements, each containing two things, with  $a$  first.

In the same way you can form  $n - 1$  arrangements, each containing two things, with  $b$  first. The same is true of each of the other letters, and as there are  $n$  of them, the total number of arrangements of the  $n$  things, two together, is  $n(n - 1)$ .

Again, lay aside  $a$ , and group the other  $n - 1$  things, two together; as we have just shown, there are  $(n - 1)(n - 2)$  such groups. Place  $a$  before each of them, and there will be formed  $(n - 1)(n - 2)$  arrangements, each containing three things, with  $a$  first; and there can be no more arrangements with  $a$  first.

Treat  $b, c, \&c.$ , in the same manner, and it will appear that there are  $(n - 1)(n - 2)$  groups of things, three together, in which every separate thing in succession stands first. Hence, the total number of arrangements, three and three, is  $n(n - 1)(n - 2)$ .

By proceeding in the same manner we shall find the total number of permutations of  $n$  things,  $r$  together, to be  $n(n - 1) \dots (n - r + 1)$ .

Cor. The number of permutations of  $n$  things, all together, is  $n(n - 1) \dots 3 \cdot 2 \cdot 1$ .

Prop. 2. To find the number of combinations of  $n$  things,  $r$  together.

Let  $x$  be the number required.

Take any one of the  $x$  groups of  $r$  things. The number of permutations which can be formed with it will be (Prop. 1. Cor.)  $r(r - 1) \dots 1$ , or  $1 \cdot 2 \dots r$ .

Now, since each of the  $x$  groups is different from all the others, if we treat each of the  $x$  groups separately in this way, we shall form  $1 \cdot 2 \dots r \times x$  permutations, all different. Also, since the  $x$  groups contain every possible combination of the  $n$  things,  $r$  together, we shall thus have formed all the permutations which can be formed; and consequently (Prop. 1) the number is  $n(n - 1) \dots (n - r + 1)$ .

$$\therefore x = \frac{n(n - 1) \dots (n - r + 1)}{1 \cdot 2 \dots r}$$

Prop. 3. To find the number of combinations which can be formed of  $n$  sets of things, containing respectively  $r, s, t, \&c.$  things, by taking one from each set to form a combination.

1. Let there be two sets, one containing  $r$  and the other  $s$  things.

Any one (say  $a$ ) of the  $r$  things may be placed successively with each of the  $s$  things, and thus form  $s$  groups, in each of which  $a$  appears. The same is true of  $b, c, \&c.$ ; *i.e.*, each of the  $r$  things gives rise to  $s$  groups,  $\therefore$  the number required is  $rs$ .

2. Any one of the  $t$  things may be placed in succession with each of the groups of two things referred to in Case 1, so that every one of the  $t$  things will give rise to  $rs$  combinations of three things;  $\therefore$  the number required is  $rst$ . The same may be indefinitely extended.

140. The first and most obvious application of the theory of combinations is to the doctrine of chances. As, however, this application will form the subject of a separate article, all that is requisite for us now to do is to indicate the connecting link between the two subjects.

If we agree to designate certainty by unity, then the chance of an event happening, when it is less than certainty, will be designated by a proper fraction. Thus, if the average number of wet days and of dry is the same, the chance of any day named at random turning out wet will be represented by the fraction  $\frac{1}{2}$ ; that is, if the number of days under consideration be 100, the chance is

$\frac{50}{100}$ , or  $\frac{\text{number of wet days}}{\text{total number of days}}$ . Chance is accordingly defined by the fraction  $\frac{\text{number of favourable events}}{\text{total number of events}}$ .

The only proposition by which chances are combined that we shall offer is this.

If there are two events, and the probability of one of them happening to be  $\frac{a}{b}$ , and of the other  $\frac{c}{d}$ ; then the probability that both will happen is  $\frac{ac}{bd}$ .

For  $a$  and  $c$  may be taken to represent the favourable events respectively, and be combined (Art. 139, Prop. 3) so as to give  $ac$  ways in which they may happen together. And in the same way  $b$  and  $d$  may be combined to give the total number of events.

Ex. A bag contains 3 white and 4 black balls. Find the chance of drawing (1) two white balls; (2) a white and a black; (3) one white at least, when two balls are drawn.

The chance of drawing two white balls is the fraction,

$$\frac{\text{Number of combinations of 3 things, 2 together}}{\text{Number of combinations of 7 things, 2 together}}$$

$$= \frac{\frac{3 \cdot 2}{1 \cdot 2}}{\frac{7 \cdot 6}{1 \cdot 2}} = \frac{1}{7}$$

The chance of drawing a white and a black is (Art. 139. Prop 3),

$$\frac{3 \cdot 4}{7 \cdot 6} = \frac{4}{7}.$$

To find the chance of drawing at least a white ball, we may remark that it is the same as the chance of not drawing two black balls, *i.e.*, certainty—the chance of drawing two black balls.

Now the chance of drawing two black balls is

$$\frac{\frac{4 \cdot 3}{1 \cdot 2}}{\frac{7 \cdot 6}{1 \cdot 2}} = \frac{2}{7}$$

∴ the chance of drawing at least one white ball is

$$1 - \frac{2}{7} = \frac{5}{7}.$$

SECT. XIX.—ON SERIES IN GENERAL; THEIR SUMMATION AND CONVERGENCE.

141. Certain series, from their very appearance, indicate that they are really the sums or differences of two other series. From this circumstance their sum may frequently be determined, as in the following examples:—

*Ex. 1.*  $\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \dots + \frac{1}{n(n+1)}$

Let  $x = \frac{1}{1} + \frac{1}{2} + \dots + \frac{1}{n}$

$$x - 1 + \frac{1}{n+1} = \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n+1}$$

∴ by subtraction,

$$1 - \frac{1}{n+1} = \left(\frac{1}{1} - \frac{1}{2}\right) + \left(\frac{1}{2} - \frac{1}{3}\right) + \dots + \left(\frac{1}{n} - \frac{1}{n+1}\right)$$

$$= \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \dots + \frac{1}{n(n+1)}$$

and the sum is  $1 - \frac{1}{n+1}$ , that is,  $\frac{n}{n+1}$ .

142. The sum of a series may often be easily found by the method of *increments* or *differences*, and this method is especially adapted to the summation of integral series, such as the squares of the natural numbers. We shall exhibit one or two illustrations only.

If we write  $S_n = n(n+1)$ , we have

$$S_{n+1} = (n+1)(n+2), \therefore S_{n+1} - S_n = 2(n+1).$$

Hence conversely, and dividing by 2; if

$$S_{n+1} - S_n = n+1,$$

then will

$$S_n = \frac{n(n+1)}{2}.$$

Similarly, if

$$S_{n+1} - S_n = (n+1)(n+2) \dots (n+r-1),$$

then will

$$S_n = \frac{n(n+1) \dots (n+r-1)}{r}.$$

This last conclusion, of course, assumes that  $S_n$  is 0 when  $n$  is 0. If it be otherwise, some numerical constant, easy of determination, will have to be added.

*Ex. 2.*  $1^2 + 2^2 + 3^2 + \dots + n^2.$

Here  $S_{n+1} - S_n = (n+1)^2 = (n+1)(n+2) - (n+1)$ ;

$$\therefore S_n = \frac{n(n+1)(n+2)}{3} - \frac{n(n+1)}{2} = \frac{n(n+1)(2n+1)}{6}.$$

*Ex. 3.*  $1^4 + 2^4 + 3^4 + \dots + n^4.$

$$S_{n+1} - S_n = (n+1)^4$$

Let

$$(n+1)^4 = (n+1)(n+2)(n+3)(n+4) + A(n+1)(n+2)(n+3) + B(n+1)(n+2) + C(n+1).$$

Dividing by  $n+1$ , and proceeding as in Art. 33, we get  $A = -6, B = 7, C = -1$ .

$$\therefore S_n = \frac{1}{5} n(n+1)(n+2)(n+3)(n+4) -$$

$$\frac{3}{2} n(n+1)(n+2)(n+3) + \frac{7}{3} n(n+1)(n+2) - \frac{1}{2} n(n+1)$$

$$= \frac{n(n+1)(2n+1)}{30} \left\{ 3n(n+1) - 1 \right\}.$$

*On the Convergency and Divergency of Infinite Series.*

143. *Def.* If the limit to which the sum of a series approaches, as the number of terms increases, is finite, the series is a converging series; if otherwise, diverging. For example, the sum of the series  $1 + r + r^2 + \dots$  to  $n$  terms is  $\frac{1-r^{n+1}}{1-r}$  (Art. 52), which, when  $r$  is less than 1,

approaches to  $\frac{1}{1-r}$ , in which case the series is a converging series.

*Prop. 1.* It is necessary and sufficient for convergency that the remaining terms after the  $n$ th have zero for their limit, both individually and collectively, as  $n$  increases.

It is obviously necessary and sufficient for convergency that the sum of the series after the  $n$ th term shall have 0 as its limit; and consequently, when all the terms of the series are positive, the same must be true of each individual term. But when the terms are alternately positive and negative, though it is necessary for convergency that the sum of the consecutive terms with their proper signs should have 0 as its limit, this is not sufficient; for, were it so, the sum to  $n$  terms would depend on whether  $n$  is even or odd.

*Ex. 1.*  $1 + \frac{1}{2} + \frac{1}{3} + \dots$  is not a converging series; for although each term after the  $n$ th tends to 0 as its limit—the sum of  $n$  terms after the  $n$ th, *viz.*,  $\frac{1}{n+1} + \frac{1}{n+2} + \dots + \frac{1}{2n}$ , which is greater than  $\frac{1}{2n} + \frac{1}{2n} + \dots + \frac{1}{2n}$  to  $n$  terms, *i.e.*, greater than  $\frac{1}{2}$ , does not tend to 0 as its limit.

*Ex. 2.*  $1 + \frac{1}{1} + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \dots$  the expression for  $e$  (Art. 129), is convergent.

The sum of the terms after the  $n$ th is

$$\frac{1}{|n|} \left( 1 + \frac{1}{n+1} + \&c. \right)$$

$$< \frac{1}{|n|} \left( 1 + \frac{1}{n} + \frac{1}{n^2} + \dots \right)$$

$$< \frac{1}{|n|} \cdot \frac{1}{1 - \frac{1}{n}} < \frac{1}{(n-1)|n-1|}$$

the limit of which as  $n$  increases is 0.

*Prop. 2.* If the limit of the  $n$ th term is 0, and the terms continually diminish; then when the signs of the terms are alternately + and -, the series is convergent.

Let  $u_1 - u_2 + u_3 - \&c.$ , be the series; the terms after the  $n$ th (+ or -) make up the series of positive groups

$$(u_{n+1} - u_{n+2}) + (u_{n+3} - u_{n+4}) + \&c.$$

But these terms may also be written  $u_{n+1} - (u_{n+2} - u_{n+3}) - \&c.$ , which, since the whole group is positive, must

be less than  $u_{n+1}$ , the only positive term in it. But  $u_{n+1}$  has 0 for its limit, therefore the series is convergent.

Ex. 3.  $1 - \frac{1}{2} + \frac{1}{3} - \dots$  is convergent, for the sum of

the series after the  $n$ th term is less than  $\frac{1}{n+1}$ , which has 0 as its limit.

Prop. 3. If the terms of the series are all positive, and the limit of the  $n$ th term is 0; then if the limit of the quotient of the  $(n+1)$ th term by the  $n$ th be less than 1, the series is convergent; but if the limit be greater than 1, the sum is divergent.

1. Let  $k$  be the greatest value of  $\frac{u_{n+1}}{u_n}$ , after a certain value of  $n$ , and  $k < 1$ ; then,

$$u_{n+1} + u_{n+2} + \dots < u_{n+1}(1 + k + k^2 + \dots),$$

$$< \frac{u_{n+1}}{1-k},$$

which has 0 for its limit. Hence the series is convergent (Prop. 1).

2. Let  $k$ , the least value of  $\frac{u_{n+1}}{u_n}$  after a certain finite value of  $n$ , be greater than 1; then

$$u_{n+1} = \text{or } > k u_n$$

$$u_{n+2} = \text{or } > k^2 u_n$$

$$\&c. \qquad \qquad \&c.$$

$$\therefore u_{n+1} + u_{n+2} + \&c. = \text{or } > k u_n (1 + k + k^2 + \&c.),$$

which is infinite. Hence the series is divergent.

Prop. 4. If  $\frac{u_{n+1}}{u_n}$  be less than 1; then the two series

$$u_1 + u_2 + u_3 + u_4 + \dots \quad (1)$$

$$u_1 + 2u_2 + 4u_3 + 8u_4 + \dots \quad (2)$$

are both convergent, or both divergent together.

Series (2)  $+ u_1 = 2(u_1 + u_2 + 2u_3 + 4u_4 + \dots)$ , which is equal to or less than the following, term by term, viz.:—

$$2\{u_1 + u_2 + (u_3 + u_4) + (u_5 + u_6 + u_7 + u_8) + \dots\},$$

i.e., twice series (1).

Hence if the one series be convergent, the other will be also convergent; and if series (2) be divergent, series (1) is also divergent.

Again, series (2) is equal to or greater than the following, term by term,

$$u_1 + (u_2 + u_3) + (u_4 + u_5 + u_6 + u_7) + \dots$$

which is series (1).

Hence if series (1) be divergent, series (2) is also divergent.

Ex. 1. The series  $\frac{1}{1^r} + \frac{1}{2^r} + \frac{1}{3^r} + \dots$  is convergent if  $r > 1$ , but divergent if  $r =$  or  $< 1$ .

The two series (1) and (2) now become

$$\frac{1}{1^r} + \frac{1}{2^r} + \frac{1}{3^r} + \dots$$

$$\frac{1}{1^r} + \frac{2}{2^r} + \frac{4}{4^r} + \dots$$

the latter of which is the geometric series

$$1 + \frac{1}{2^{r-1}} + \frac{1}{4^{r-1}} + \dots,$$

which is convergent or divergent according as  $r > 1$  or the contrary. Hence the same is true of the given series.

Ex. 2. The binomial series  $1 + nx + \&c.$ , is convergent when  $x < 1$ , divergent when  $x > 1$ .

Ex. 3. To find when the binomial series  $1 - n + \frac{n(n-1)}{1 \cdot 2} - \&c.$ , is convergent.

Let  $n < 1$ ; the  $(r+1)$  term may be written

$$\frac{n}{r} \cdot \frac{r-n-1}{r-1} \cdot \frac{r-n-2}{r-2} \dots$$

$$= \frac{n}{r} \left(1 - \frac{n}{r-1}\right) \left(1 - \frac{n}{r-2}\right) \dots$$

$$< \frac{n}{r} \left(1 + \frac{1}{r-1}\right)^{-n} \left(1 + \frac{1}{r-2}\right)^{-n} \dots \quad (\text{Art. 122, Ex. 7})$$

$$< \frac{n}{r} \left(\frac{r}{r-1}\right)^{-n} \left(\frac{r-1}{r-2}\right)^{-n} \dots$$

$$< \frac{n}{r^{n+1}},$$

whence (Prop. 4, Ex. 1) the series is convergent. Similarly in other cases. (P. K.)

ALGECIRAS, or ALGEZIRAS, a seaport of Spain, in the province of Cadiz, 6 miles W. of Gibraltar, on the opposite side of the bay. The town is picturesquely situated, and its name, which signifies in Arabic the *island*, is derived from a small islet which forms one side of the harbour. It is supplied with water by means of a beautiful aqueduct. It has a dilapidated fortress, and also a military hospital. Though the harbour is bad, and the commerce of the town has considerably declined, there is still a good coasting trade; the exports and imports averaging about £60,000 annually. Charcoal and tanned leather are the chief articles of export. Algeciras was the *Portus Albus* of the Romans, and the first place in Spain taken by the Moors. It remained in their possession from 713 till 1344, when it was taken by Alphonso XI. of Castile after a celebrated siege of twenty months, which attracted crusaders from all parts of Europe, among whom was the English earl of Derby, grandson of Edward III. It is said that during this siege gunpowder was first used by the Moors in the wars of Europe. The Moorish city was destroyed by Alphonso, and the modern town was not erected till 1760. During the siege of Gibraltar in 1780-82, Algeciras was the station of the Spanish fleet and floating batteries. Near Algeciras, on 6th July 1801, the English admiral Saumarez attacked a Franco-Spanish fleet, and sustained a

reverse; but on the 12th he again attacked the enemy, whose fleet was double his own strength, and inflicted on them a complete defeat. Population, 14,000.

ALGER OF LIÈGE, known also as ALGER OF CLUGNY and ALGERUS MAGISTER, a learned French priest who lived in the first half of the 12th century. He was first a deacon of the church of St Bartholomew at Liège, his native town, was afterwards translated to the cathedral church of St Lambert, and finally retired to the monastery of Clugny, where he died not later than 1145, though the precise date is uncertain. His *History of the Church of Liège*, and many of his other works are lost. The most important of his still extant works are:—1. *De Misericordia et Justitia*, a collection of extracts from Fathers, with reflections, which is to be found in the *Anecdota* of Martène, vol. v. 2. *De Sacramento Corporis et Sanguinis Domini*; a treatise, in three books, against the Berengarian heresy, highly commended by Peter of Clugny and Erasmus. 3. *De Libero Arbitrio*; given in Pez's *Anecdota*, vol. iv. 4. *De Sacrificio Missæ*; given in the *Collectio Scriptor. Vet.* of Angelo Mai, vol. ix.

ALGERIA, or ALGIERS (French, *L'Algérie*), the largest and most important of the French colonial possessions, is a country of Northern Africa, bounded on the N. by the Mediterranean, W. by the state of Morocco, S. by the

desert of the Sahara, and E. by Tunis. The boundaries, however, are in many parts not accurately determined. It extends for about 550 miles along the coast, and stretches inland from 320 to 380 miles; lying between 2° 10' W. and 8° 50' E. long., and 32° and 37° N. lat. The area is estimated at about 150,500 English square miles.

The country is generally mountainous, being traversed by lofty ranges of the Atlas system, which run nearly parallel to the coast, and rise in some places to the height of upwards of 7000 feet. These are commonly divided into two leading chains, which are distinguished as the Great and Little Atlas. The former, which is the more southern and bordering on the Sahara, contains some of the highest points in the country. The Little Atlas or Maritime Atlas, as it is sometimes called, lies between the sea and the Great Atlas, and is composed of numerous diversified ranges generally of no great elevation. A number of smaller chains lie between these principal ones, and also between the latter and the sea, forming so many ascending steps or degrees. These principal ranges are connected by numerous transverse ones, thus forming extensive table-lands and elevated valleys, with no connection between them but the intervening heights. Occasionally the principal ranges are broken by deep defiles and narrow valleys. The maritime region presents numerous narrow valleys, each carrying down to the sea its mountain stream. In some parts the mountains rise abruptly from the sea, in others a tract of flat land intervenes between the mountains and the coast, and this is usually marshy, but sometimes fertile and well cultivated. There are a number of extensive plains near the coast, one of the most important of which is that of Metidja, commencing on the eastern side of the bay of Algiers, and stretching thence inland to the south and west. It is about 60 miles in length by 10 or 12 in breadth. Another great alluvial plain extends south and west for many miles from the vicinity of Bona. A third similar plain lies to the south-east and south-west of Oran, and south of Mostaganem is the plain of Shellif. The coast is generally steep and rocky, abounding in capes and gulfs, but very deficient in good harbours, and even in secure roadsteads, in consequence of its exposure to the north winds.

The rivers are numerous, but the majority of them have short courses. They mostly rise in the mountains near the coast, and rush down with great impetuosity through deep and rocky channels, presenting the character of mountain torrents. During the rainy season they are much swollen, so as to render communication with different parts of the country extremely difficult. The most important river, both from the length of its course and the volume of its waters, is the Shellif, which, rising in the northern slopes of the Djebel Amur, flows first north and then west till it empties itself into the Mediterranean near Mostaganem after a course of 370 miles, during which it receives numerous tributary streams. The Seybouse is formed by the union of several small streams in the interior of the province of Constantine, south-east of the town of that name, and after a course of about 120 miles falls into the Mediterranean near Bona. The Summam, which contains the greatest body of water after the Shellif, rises in the interior of the province of Algiers near Aumale, and pursues a generally north-east direction to its mouth near Bougie. The Rummel, formed of several small streams south of the town of Constantine, passes that town and pursues a north-west direction to the sea. Among the less important rivers which empty themselves into the Mediterranean are the Harrach, Isser, Mazefran, Tafna, and Macta. Besides these, there are a number of streams in the interior, but they are less known and are generally dry except in the rainy season.

Algeria abounds in extensive lakes and marshes. Of

the lakes in the northern part of the country, near the coast, the principal are,—the Fezara 14 miles south-west of Bona; the two lakes Sebkhah and El Melah south of Oran; the three small lakes in the immediate vicinity of Calle, and several others. In the southern parts of the country are the extensive lakes of Chott-el-Harbi or Western Chott, the Chott-el-Chergui or Eastern Chott; the Zarhez-Gherbi and the Zarhez-Chergui; the Grand Sebkhah-el-Chott, and a number of others. These are mostly dried up in summer, leaving a thick stratum of salt. Many of the marshes, especially in the neighbourhood of the larger towns, have been drained by the French, and the climate has thus been rendered more salubrious. There are also a number of warm mineral springs, containing principally salts of lime, which are used with success by the Arabs in several kinds of disease. Some of these are in the vicinity of Calle Bougie, Milianah, &c.

Algeria is divided by a line running nearly east and west into two distinct zones, called by the natives the *Tell* and *Sahara*. The *Tell* constitutes the zone bordering upon the Mediterranean, and is the cultivated land—the land of corn. It consists of a series of fertile basins, yielding almost exclusively corn of different kinds, especially wheat and barley. Some parts of it are extremely fertile, but at the same time flat and uniform. The chains separating the basins are clothed with timber, and peopled by the Kabyles. The Sahara lies to the south of the *Tell*, and is the region of pastures and of fruits. Hence, while the inhabitants of the *Tell* are agriculturists, those of the Sahara are shepherds and gardeners. The Sahara is sometimes spoken of as a desert, at other times as the country of dates. It may properly be divided into two regions; the northern is mountainous, but at the same time more fertile, better watered, and more populous than the other, which, bordering on the Great Desert, consists chiefly of oases of greater or less extent. The villages of the Sahara are surrounded by belts of fruit trees, of which the palm is the chief, though there are also pomegranate, fig, apricot, peach, and other trees, and vines. On the mountain ranges near the coast are extensive forests of various species of oak, pine, cedar, elm, ash, maple, olive, &c. The cork tree is also very common. The trees, especially the cedars and oaks, are frequently of gigantic size. Great injury is often done to the forests by the people annually burning up the grass of their fields. In this way extensive forests are sometimes consumed. The want of roads and navigable rivers has prevented the French from deriving much benefit as yet from the forests. Besides wheat and barley, the cotton plant, sugar-cane, and tobacco are extensively cultivated.

The animal kingdom presents little calling for notice. Lions, formerly very plentiful, are now extremely rare; leopards, panthers, jackals, and hyænas are still common; and monkeys and apes are numerous. The wild boar is found in the oak forests, and the brown bear in the higher parts of the country. There are also various species of antelope. Of the feathered tribes, eagles, vultures, hawks, and owls are common; snipes, curlews, plovers, storks, and herons frequent the marshy parts; and the ostrich has its habitat in the desert. Among the reptiles are various species of serpents, tortoises, turtles, lizards, &c. Locusts are common, and sometimes do great damage to the crops. One of the severest invasions of these pests ever known occurred in 1866, when the crops were nearly all destroyed, and the loss sustained by the colonists was estimated at £800,000. The coast is rich in coral and sponges, and the obtaining of these forms a considerable branch of industry. The chief wealth of most of the Arab tribes consists in their sheep, of which they frequently possess immense flocks; camels are also common, but the horses and mules are more esteemed, and are noted for their excellence.

From its position, Algeria might be supposed to enjoy a warm climate; but the temperature varies considerably in different parts, according to the elevation and configuration of the country. In the northern districts the climate very much resembles that of the south of Spain, while in the Sahara the heat is often excessive. In the more elevated regions the winter is frequently very severe; but along the coast the temperature is mild, very rarely sinking to the freezing-point even in winter, when heavy rains are of frequent occurrence. Dr Shaw knew the thermometer reach the freezing-point only twice during twelve years' residence at Algiers. The coldest month is January, the hottest August. The rains prevail from December to February; the temperate season continues from March to June, and the hot season lasts from July to November. The mean annual temperature of the town of Algiers is about 66·5° Fahr.; being for the coldest month 48°, and for the hottest 83°. During summer there is a great difference between the day and night temperature, especially in the inland districts. The simoom or hot wind of the desert sweeps at intervals over the country, between May and September, impregnating the air with fine sand from the desert. In general, with the exception of places in the vicinity of the marshes, Algeria possesses a healthy climate. Ophthalmia, however, is very common, and elephantiasis is by no means an unusual disease, owing to the want of cleanliness among the country people.<sup>1</sup>

Besides the Europeans there are eight distinct races of inhabitants in Algeria—(1.) The Kabyles or Berbers, the descendants of the aboriginal inhabitants of the country, constitute a large portion of the entire population. They occupy chiefly the more elevated and mountainous parts, but numbers of them also inhabit the plains and valleys. They are described as an active, industrious race, living in villages, and principally engaged in agriculture and the cultivation of fruit trees. They also make their own agricultural implements, guns, gunpowder, leather, carpets, &c. (2.) The Arabs are a very numerous class, and inhabit principally the southern parts of the country. Some of them are cultivators of the soil, and live in villages in the neighbourhood of the towns; but the majority of them have no fixed habitation, dwelling in tents and moving about from place to place. These are the Bedouins or nomadic Arabs, and are the most unsettled and turbulent of the Algerine population. (3.) The Moors, a mixed race, inhabit the towns and villages chiefly on or near the sea-coast. (4.) The Jews are also to be found in the towns, and are engaged in mercantile pursuits. (5.) The Turks, though long the dominant race, were never very numerous, and since the French conquest they have nearly disappeared. (6.) The Kolongis are the descendants of Turks by native women, and constitute a considerable proportion of the inhabitants of Algiers and other towns. (7.) The Negroes were originally brought from the interior and sold as slaves, but slavery now no longer exists. (8.) The Mozabites are an African race, to be found inhabiting the coast towns, and chiefly engaged in manual labour. They are described as an honest, industrious, and peaceable people.

<sup>1</sup> A Parliamentary Report on the climate of Algeria published in 1867 is of great interest, particularly as investigating the causes of the great reduction in the mortality of the French troops serving there. The death-rate in Algerian hospitals for the first five years succeeding the conquest amounted to nearly 79 per 1000; and for the period from 1831 to 1846 it is given as high as 80 per 1000. In 1860 the death-rate per 1000 was only 17·8; in 1861, 11·3; in 1862, 12·21; in 1863, 12·29; and in 1864, 14·48. The causes of this remarkable difference are stated to be—the former existence of certain unhealthy conditions in the country itself, and in the mode of life of both troops and colonists, which were accompanied by a high death-rate; and the subsequent removal to a certain extent of these conditions, together with the introduction of improved habits and modes of life, accompanied by improved health and lower death-rates.

The European civil population of Algeria amounted to only 45,000 persons in 1840, and in 1845 it had increased to 75,867. In Dec. 1849 it had risen to 112,607, of whom 58,005 were French, 6943 Maltese, 33,659 Spaniards, 6986 Italians, 2515 Germans, 1253 Swiss, and 3246 of other nations. According to the census of 1861 the entire population of Algeria was 2,966,836, of whom 2,374,091 were nomadic native races, 112,229 French, and 80,517 other Europeans. In 1866 the entire population was 2,921,246, of whom 2,434,974 were of indigenous wandering tribes, 217,990 Europeans, and 251,050 natives settled in towns. Of the Europeans, 122,119 were French, 58,510 Spaniards, 16,655 Italians, 10,627 Maltese, and 5636 Germans. In the civil territory the entire population in 1870 is given as 478,342, of which 121,629 were French, 97,913 other Europeans, 33,117 Jews, and 225,693 Mahometans.

When under the dominion of the Turks, this country was governed by a dey, and divided into four provinces—Algiers and Titterie in the centre, Tlemcen in the west, and Constantine in the east. The last three were governed by beys under the dey. At present it is divided into three provinces—Algiers in the centre, Oran in the west, and Constantine in the east. Till 1871 the country was entirely under military rule, but in that year various important reforms were introduced; and in place of the former military governor a civil governor-general was appointed to administer the affairs of the colony, and to direct the action of both civil and military authorities. He is invested with legislative powers in civil matters; but in all important cases he has to take the advice of a colonial council, the members of which are appointed by the French government. The power of the governor-general, however, extends only over the settled districts. In the thinly-populated parts, and the districts where the nomadic tribes are chiefly found, military rule still prevails. The three provinces are subdivided into twelve departments, at the head of each of which is a prefect, and under him are sub-prefects who rule over smaller divisions. By an Act of 14th July 1865, the natives, both Mahometan and Jewish, were declared entitled to the rank and prerogatives of French citizens, on placing themselves completely and absolutely under the civil and political laws of France, and thus were made admissible to all the grades in the army and navy, and to many posts in the civil service of the state.

In 1840 the revenue amounted to 5,610,706 frs. and the expenditure to 7,206,372 frs.; in 1850 these were respectively 19,632,271 frs. and 27,959,358 frs.; in 1860, 38,908,900 frs. and 39,471,372 frs.; and in 1870, 45,360,859 frs. and 51,762,316 frs. or £1,814,434 and £2,070,492. This expenditure does not include the cost of the maintenance of the army, the expenditure for public works, and other large sums disbursed by the home government. In the French financial estimates for 1873 the home expenditure for Algeria was set down at 24,496,109 frs. or £979,844, and the revenue derived from the colony at 19,008,584 frs. or £760,343. According to a statement made in the French legislative assembly in 1864, Algeria had cost the mother country three milliards of francs, or £120,000,000 in money and 150,000 lives. The French army in Algeria numbers about 60,000 men, and consists of two classes, namely, French troops, who remain there for a certain number of years, and then return to France; and native troops, who never quit the country except for fighting purposes.

Algeria in the time of the Romans was noted for its fertility, and this is still the character of the cultivated parts of the country. Many parts only want water to render them fertile, and the government has lately sunk a number of Artesian wells with the most beneficial results. The principal grain crops are wheat and barley. In 1866 there were in the three provinces 4,163,307 acres of land under different kinds of grain, and the produce amounted to 2,802,208 quarters; 28,132 acres of vineyards, 14,266 acres under cotton, 5957 under flax, and 9793 under tobacco. In the province of Algiers the total area of land under cultivation with cereals in 1868 was, in the civil portion, 178,642 acres, of which 120,286 were cultivated by Europeans; and in the military portion, 808,896 acres. The total yield in the former case was 266,578, and in the latter 668,666 quarters. These figures do not include other agricultural produce, such as beans, maize, &c, of which about 277,062 quarters were produced by 99,503 acres. The produce of tobacco throughout the country was estimated at 6,845,000 lb. Olives are grown largely and almost exclusively in the mountains of Kabylia.

In that portion of the district included in the province of Algiers the quantity of fruit gathered is estimated at over 100,000,000 lb. At present not much attention is given to this article of production; but there can be no doubt that with more care and attention Algeria might become one of the best olive-producing countries in the world. Oranges are grown to a considerable extent, and the trade in this article is increasing. The vine is cultivated; but the produce is chiefly for home consumption, and it has scarcely yet become an article of export. In the province of Algiers in 1868 about 1,350,000 gallons of wine were produced. During the same year the exportation of cork from the colony amounted to £63,932. The most important fibre is the *crin vegetal*, or vegetable horse hair, produced from the dwarf palm (*Chamerops humilis*), with which a vast proportion of the uncultivated parts of the country is covered. Throughout the entire colony, fibre to the value of £89,332 was exported in 1868. The alpha fibre or esparto grass of Oran ranks next in importance, and is largely used in the manufacture of paper. During the American war the cultivation of cotton was extensively carried on, but since the close of the war it has very much fallen off. Flax is cultivated to a considerable extent in some parts. The rearing of the silk-worm is also prosecuted.

Although the mineral wealth of Algeria is enormous, mining operations have not hitherto been carried on very extensively. The most important mineral products are iron, copper, lead, mercury, and antimony. During 1868 the iron mines in the province of Constantine turned out about 240,000 tons of ore, valued at £486,672, being an increase of £185,532 as compared with the preceding year. Nearly the whole of this was from the mine of Ain Mokra or Mokhta-el-Hadid, which yields on an average 200,000 tons of ore per annum. The ore contains 65 per cent. of the metal. Lead ore to the value of £125,745 was exported during that year.

The trade of Algeria has very much increased since it became a French colony. The imports, which in 1831 amounted to only £280,000, rose to £1,600,000 in 1844, to £3,249,377 in 1854, and to nearly £4,500,000 in 1863. The exports, however, have not grown in proportion; and during the ten years preceding 1863 they never exceeded from 1½ to 2 millions sterling. In 1865 an Act declared the navigation not only between France and Algeria but also between Algeria and foreign countries open to all nations, and abolished various oppressive taxes affecting foreign shipping. The following year these privileges were extended: the coasting trade was thrown open and free navigation permitted, tonnage duties on foreign shipping were abolished, and raw manufactured goods entering France free of duty had the same advantage conceded to them in Algeria. Algerian products might enter France free of duty, and the same privilege was accorded to French products in Algeria, sugar excepted. In 1868 the imports amounted to £7,706,574, which was an increase of £199,494 over the previous year. The proportions received from the different countries were—France, 75 per cent.; Turkey, 8.44; Russia, 4.29; Spain, 3.99; Great Britain, 3.54; Italy, 2.56; Barbary States, 1.40. The imports from Turkey and Russia are exceptionally high, owing to the necessity of obtaining grain supplies from these countries in consequence of a failure in the crops. The principal ports of import were—Algiers, 40.43 per cent.; Oran, 33.33; Philippeville, 15.04; Bona, 7.01; Mostaganem, 2.33. In 1869 the imports amounted to £7,332,192, and in 1870 to £6,907,628. The principal imports are cotton goods, wines, spirits, sugar, glass, crystal, cheese, salt-fish, soap, &c. The total value of the exports during 1868 amounted to £4,122,772, being an increase of £236,293 as compared with 1867. The proportions sent to the different countries were—France, 79.20 per cent.; Spain, 11.68; Great Britain, 5.84; Italy, 1.80. The principal exports are sheep, oxen, skins, wool, tobacco, flour, fresh and dried vegetables, olive-oil, flax, cotton, ores, *crin vegetal*. In 1869 the total exports amounted to £4,438,045, and in 1870 to £4,978,250. The overland trade between Algeria and its neighbours, Morocco and Tunis, now begins to assume some importance. The number of vessels that entered and left the various ports in 1868 was 8740, of an aggregate burden of 1,664,513 tons, and manned by 16,173 men. This is an increase over the previous year of 18.40 per cent. as regards the number of ships, and of 12.63 per cent. as regards the tonnage. As engaged in the direct trade with Britain, there entered 99 British vessels with an aggregate of 17,940 tons, and cleared 109 British vessels with an aggregate of 12,523 tons. Besides these there were British vessels engaged in the direct or carrying trade with other countries, of which entered 125 with an aggregate burden of 14,972 tons, and cleared 106 with an aggregate of 19,960 tons. The number of British vessels trading at the four principal ports, namely, Algiers, Oran, Bona, and Philippeville in 1872 was as follows:—direct, entered, 171—tonnage, 60,285; left, 251—tonnage, 76,973; indirect, entered, 170—tonnage, 79,454; left, 125—tonnage, 63,645. During that year 1595 vessels of 3,746,130 tons entered, and 1587 vessels of 376,402 tons cleared, at the port of Algiers. The most important articles of export, as far as British trade is concerned, are *crin vegetal* and alpha fibre. During the first nine months of 1872 about 6000 tons of the former were exported from the port of Algiers alone; and about 60,000 tons of

the latter from the whole colony, chiefly from Oran. Some idea of the rapidly advancing commercial prosperity of Algeria may be gathered from the fact that the amount of sums discounted at the Bank of Algeria (which was established in 1851) had risen from £3,900,130 in 1866-7 to £8,131,535 in 1871-2. Much has been done, particularly of late years, in the way of opening up the country and developing its resources. Roads have been formed and bridges built in various parts, harbours have been improved, and lighthouses erected. There are now 374 miles of railway open for traffic, forming a line from Algiers to Oran and one from Philippeville to Constantine.

In early times this country was inhabited by two nations, the Massyli and the Massæsyli. During the struggle between Hannibal and the Romans, Syphax, the prince of the Massæsyli, espoused the cause of the former, and Massinissa, the prince of the Massyli, that of the latter. On the defeat of the Carthaginians the territories of Syphax were annexed to those of Masinissa, who received the title of King of Numidia. During the Roman civil war, Juba, king of Numidia, sided with Pompey, and being defeated by Cæsar, his kingdom became a Roman province. Under the Romans the country enjoyed a great degree of prosperity. Agriculture was encouraged, commerce extended, roads were formed, and towns sprang up. Christianity, too, was early introduced and flourished. This state of things, however, received a severe check when the Romans were driven out of Africa by the Vandals about the middle of the 5th century. These in turn were expelled by Belisarius, Justinian's general, in 533. About the middle of the 7th century the Saracens made themselves masters of the country, which came afterwards to be divided into a number of petty states under independent chiefs, and the people sank into a state of barbarism. About the middle of the 11th century Abdallah-ben-Yazim, a learned Arab, formed a numerous sect of religionists, known as Morabites, who overran the country, subdued many of the petty chiefs, and laid the foundation of the dynasty of the Almoravides. That dynasty reigned for nearly a hundred years, and at one time nearly the whole of Barbary and a great part of Spain were under their government. They were succeeded by the dynasty of the Almohades, who reigned over the region till 1273, when it was again split up into a number of small states. In 1505, Ferdinand, king of Spain, sent a powerful fleet and army against the country, under the Count of Navarre, who soon made himself master of Oran, Bugia, and other towns, and finally, in 1509, took the town of Algiers. The Spanish rule, however, was very distasteful to the Algerines; and on hearing of the death of Ferdinand, in 1516, one of the native princes sent an embassy to Aruch Barbarossa, the famous Turkish pirate, requesting his aid against the invaders. This was readily granted; and no sooner had he established himself in the country than he murdered the prince and caused himself to be proclaimed king in his room. He introduced that system of piracy for which Algeria was afterwards noted down to 1830. By force and treachery he extended his dominion over other parts of the country, till at length the Spaniards marched a large army against him from Oran, and being joined by many of the natives, defeated him in various engagements, took him prisoner, and beheaded him. His brother Hayradin was then chosen sultan; and he feeling himself unable to cope with the Spaniards, sought the assistance of Turkey, and put himself under the protection of the Grand Seignior. Aid was readily granted, and he himself was appointed pasha or viceroy of Algiers. Having thus got rid of his enemies the Spaniards, he turned his attention to the extension of his piratical enterprises; and in order to do this with the greater security, he fortified the port of Algiers and built a strong mole for the protection of his ships. He is said to have employed 30,000 Christian slaves for three years in the construction of the mole. The Algerine pirates soon became dreaded, not

Trade.

only by the Arabs and Moors, but also by the maritime Christian powers, particularly the Spaniards. At length Pope Paul III. induced Charles V. to undertake an expedition to suppress these depredations, and issued a bull offering remission of sins and the crown of martyrdom to all who either fell in battle or were made slaves. The emperor set sail with 120 ships and 20 galleys, having on board 30,000 chosen men. They landed in safety, and were proceeding to attack the town of Algiers when a fearful storm arose, and in one night (28th Oct. 1541) destroyed 86 ships and 15 galleys with all their crews and military stores, so that the army on shore was deprived of the means of subsistence. This was then fallen upon by the Algerines, when many were killed and a great number taken prisoners, Charles himself and the remains of his army escaping with difficulty.

Algiers continued to be governed by viceroys or pashas appointed by the Porte till the beginning of the 17th century, when the janissaries solicited and obtained the right to choose their own dey or governor from among themselves. This subsequently led to frequent altercations between the pashas and the deys, the former seeking to recover their lost power, the latter to reduce it. In 1609, the Moors being expelled from Spain, flocked in great numbers to Algiers, and, as many of them were very able sailors, they contributed to raise the power of the Algerine fleet. In 1616 it consisted of forty sail of ships, of between 200 and 400 tons, their flagship having 500 tons. The Algerine pirates now became so formidable to the European powers, that in 1617 the French sent against them a fleet of fifty sail, under Beaulieu, who defeated their fleet and took two of their vessels. In 1620 the English sent out a squadron under the command of Sir Robert Mansel on the same errand, but it returned without effecting anything. Their depredations becoming still more frequent and troublesome, the Venetians equipped a fleet of twenty-eight sail, under the command of Admiral Capello, with orders to burn, sink, or take all the Barbary corsairs he should meet. In an engagement which speedily took place he signally defeated them, and took and destroyed sixteen of their galleys. They soon, however, regained their former strength; and at length Louis XIV., provoked by the outrages committed by them on the coasts of Provence and Languedoc, ordered, in 1681, a considerable fleet to be fitted out against them, under the command of Vice-admiral Duquesne. He attacked them near the island of Scios, and destroyed fourteen of their ships. This, however, had little effect upon them, and the following year he bombarded the town of Algiers and nearly reduced it to ashes. The Algerines, by way of reprisal, sent a number of galleys to the coast of Provence, where they committed great ravages. In May 1683, Duquesne with his fleet again cast anchor before Algiers, and proceeded to bombard the town. The dey and the people sued for peace; but Mezomorto, the Algerine admiral, who was to have been delivered up as one of the hostages, violently opposed coming to terms, stirred up the soldiery against the dey, and caused him to be murdered, and was himself chosen as his successor. The bombardment was renewed, and Mezomorto, reduced to extremities, caused all the French in the city to be cruelly murdered, and the French consul to be tied to the mouth of a mortar and shot off in the direction of the bombarding fleet. Duquesne was so exasperated by this piece of cruelty that he did not leave Algiers till he had utterly destroyed the fortifications, shipping, almost all the lower, and about two-thirds of the upper part of the town. The Algerines, now thoroughly humbled, sent an embassy to France to sue for peace, which was readily granted them. In 1686 the English concluded a treaty with the Algerines on favourable terms, and this was

several times subsequently renewed; but it was not till the taking of Gibraltar and Port Mahon that England had sufficient check upon them to enforce the observance of treaties. From that time England was treated with greater deference than any other European power. In 1710 the Turkish pasha was expelled and his office united to that of dey. The dey thus became the supreme ruler in the country. He had the charge of the Turkish militia, recruited from Constantinople and Smyrna, because their children by native mothers could not be allowed to enjoy the same privileges as themselves in consequence of former rebellions against the government. Under the dey there was a divan or council of state, chosen from the principal civic functionaries.

Matters continued very much in the same state, and the history of Algiers presents little calling for special notice down to the expedition of Lord Exmouth. The principal States of Europe had had their attention taken up with weightier matters; but on the establishment of the peace of 1815 the English sent a squadron of ships, under Lord Exmouth, to Algiers, to demand the liberation of all slaves then in bondage there, and the entire discontinuance of piratical depredations. Afraid to refuse, the Algerines returned a conciliatory answer, and released a number of their slaves; but no sooner had the ships left than they redoubled their activity and perpetrated every sort of cruelty against the Christians. Among other acts of cruelty, they attacked and massacred a number of Neapolitan fishermen who were engaged in the pearl-fishery at Bona. The news of this excited great indignation in England, and Lord Exmouth was again despatched with five ships of the line and eight smaller vessels, and at Gibraltar he was joined by a Dutch fleet of six frigates, under Admiral Capellen. They anchored in front of Algiers on the 26th August 1816. Certain terms, which were extremely moderate, were proposed to the dey; but these not meeting with acceptance, a fierce bombardment was at once commenced. At first the assailants were subjected to a heavy fire from the enemy's batteries; but after a time these were one by one silenced, and ship after ship caught fire, till the destruction of the Algerine naval force was complete. Next day the terms proposed to the dey were accepted; Christian slaves to the number of 1211 were set at liberty, and a promise was given that piracy and Christian slavery should cease for ever. The Algerines, however, did not long adhere to the terms of the treaty. They lost no time in putting their city in a more formidable state of defence than before, and this done, they considered themselves in a condition to set the great powers of Europe at defiance.

Various injuries had from time to time been inflicted on the French shipping, but that which more directly led to a declaration of war was an insult offered to the French consul by the dey. A debt had been contracted by the French government to two Jewish merchants of Algiers at the time of the expedition to Egypt, and the dey having a direct interest in the matter, had made repeated applications for payment, but without success. Annoyed at this and at what he considered insulting language on the part of the consul, he struck the latter on the face in public. In consequence of this, a French squadron was sent to Algiers which took the consul on board, and for three years maintained an ineffective blockade. At length war on a great scale was resolved on, and a fleet was equipped at Toulon in May 1830 under the command of Admiral Duperré. It had also on board a land force, under the command of General Bourmont, consisting of 37,000 infantry, 4000 cavalry, and a proportionate number of artillery. The troops began to land on the 14th June upon the western side of the peninsula of Sidi Ferruch, in the bay of Torre

Chica. They did not meet with much opposition till the 19th, when a general attack was made upon them by a force of from 40,000 to 50,000 men. These, after a fierce conflict, were completely routed. They renewed their attack on the 24th and 25th, but were on both occasions repulsed. The French then advanced upon Algiers, and on the 29th the trenches were opened. On the morning of the 4th of July the bombardment commenced, and before night a treaty was concluded for the entire surrender of Algiers. The next day the French took possession of the town; and 12 ships of war, 1500 brass cannon, and over £2,000,000 sterling came into their hands as conquerors. The Turkish troops were permitted to go wherever they pleased, provided they left Algiers, and most of them were conveyed to Asia Minor. The dey himself, with his private property and a large body of attendants, retired to Naples.

When the French undertook the expedition against Algiers a pledge was given to the English government that they did not aim at the permanent possession of the country, but only at obtaining satisfaction for the injuries and insults that they had received, and putting down that system of piracy which had so long outraged Europe. The French government engaged that these objects being accomplished, the final settlement and government of the country should be arranged in concert with the other European powers for the general advantage. Notwithstanding this, the French ministry in 1833 publicly declared that it was the intention of their government to retain possession of Algiers and to colonise it. Subsequently, the English government acquiesced in this, on receiving an engagement that the French would not extend their conquests beyond Algeria either on the side of Tunis or of Morocco.

The capture of Algiers was celebrated in France with great demonstrations of joy. General Bourmont was raised to the rank of marshal, and Admiral Duperré was promoted to the peerage. The revolution of 1830 followed, when Bourmont was deposed, and General Clausel appointed to succeed him. The conquerors, instead of attempting to gain the good-will of the natives, destroyed a number of their mosques, seized upon lands set apart for religious purposes, and attempted to introduce their own laws and usages in place of those of the country, the consequence of which was that the natives entertained the greatest abhorrence for their oppressors, whom they regarded as the enemies of God and their prophet. General Clausel incensed them still more by seizing upon the possessions of the dey, the beys, and the expelled Turks in direct opposition to the conditions on which the capital had been surrendered. Bona was taken possession of, and an incursion was made into the southern province of Titterie, when the troops of the bey were defeated and Medial taken. The beys of Titterie and Oran were deposed, and tributary rulers set up in their room. Still the war continued. The French were incessantly harassed by irruptions of hordes of the Arabs, so that no Frenchman was safe, even in the vicinity of the town; and little reliance could be placed on the fidelity of the beys who governed the provinces. Medial was evacuated, and Oran abandoned. In February 1831 General Berthezene was appointed commander-in-chief, and undertook several expeditions into the interior to chastise the hostile tribes, but met with little success. In October Bona was surrounded and taken by the Kabyles. There was now no safety but in the town of Algiers; agriculture was consequently neglected, and it was necessary to send to France for supplies of provisions and for fresh troops. In November 1831 General Savary, Duc de Rovigo, was sent out with an additional force of 16,000 men. The new governor sought to accomplish his ends by the grossest acts of cruelty and treachery. One of his exploits was the massacre of a whole Arab tribe, including old men, women,

and children, during night, on account of a robbery committed by some of them. He also treacherously murdered two Arab chiefs whom he had enticed into his power by a written assurance of safety. These proceedings exasperated the natives still further against the French, and those tribes that had hitherto remained quiet took up arms against them.

About this time Abd-el-Kader first appears upon the field. His father, a Marabout, had collected a few followers, and attacked and taken possession of the town of Oran. On this they wished to elect him as their chief, but he declined the honour on account of his great age; and recommended his son who, he said, was endowed with all the qualities necessary to success. Abd-el-Kader was born about the beginning of 1807, and had early acquired a great reputation among his countrymen for learning and piety, as he was also distinguished among them for skill in horsemanship and other manly exercises. He had made two pilgrimages to Mecca in company with his father, once when a child and again in 1828, by which he obtained the title of *Hadji*. At this time he was living in obscurity, distinguished by the austerity of his manners, his piety, and his zeal in observing the precepts of the Koran. He collected an army of 10,000 horsemen, and, accompanied by his father, marched to attack Oran, which had been taken possession of by the French. They arrived before the town about the middle of May 1832, but after continuing their attack for three days with great bravery they were repulsed with considerable loss. This was followed by a series of conflicts, more or less severe, between the parties, but without any permanent or decided advantage to either side. In March 1833 the Duc de Rovigo was obliged, on account of his health, to return to France, and General Avizard was appointed interim governor; but the latter dying soon after, General Voirol was nominated his successor. Abd-el-Kader was still extending his influence more and more widely among the Arab tribes; and the French at last considered it to be their interest to offer him terms of peace. A treaty was accordingly concluded with him by General Desmichels, governor of Oran, in February 1834, in which he acknowledged the supremacy of France, and was recognised by them as emir of the province of Mascara. One of the conditions of the treaty was that the emir was to have a monopoly of the trade with the French in corn. This part of the treaty was regarded with great dissatisfaction at home, and the general was removed from his post. In July General Drouet d'Erlon was sent out as governor-general of the colony. An intendant or head of the civil department was also appointed, as well as a commissary of justice at the head of the judicature. Tribunals of justice were also established, by which both French and natives were allowed to enjoy their respective laws. From the tranquil state of the country at this time the new governor was enabled to devote his attention to its improvement. The French, however, soon became jealous of the power of the emir, and on the pretence that he had been encroaching on their territory, General Trezel, who had succeeded Desmichels in the governorship of Oran, was sent against him with a considerable force. The armies met at the river Makta, and the French were routed with great slaughter on the 28th of June 1835. On the news of this defeat Marshal Clausel was sent to Algiers to succeed Count d'Erlon. In order effectually to humble the emir, he set out for his capital, Mascara, accompanied by the Duke of Orleans, at the head of 11,000 men. On reaching the town the French found it deserted, and, having set it on fire, they returned without having effected anything of consequence. In January 1836 Marshal Clausel undertook an expedition against Tlemcen, which he took and garrisoned. Soon

after this the emir attacked and put to flight a body of 3000 men under Count d'Arlandes on the Tafna. General Bugeaud, who had succeeded Marshal Clausel, attacked the Arabs under Abd-el-Kader on the Sikak river, 6th July 1836, and gained a complete victory over them. An expedition against the bey of Constantine was next resolved on, and Marshal Clausel, at the head of 8000 men, set out from Bona for this purpose in November 1836. They encountered on their march a severe storm of hail and snow, followed by a sharp frost, so that many of them died; and when they arrived before the walls of the town they were unable to undertake the siege, and effected their retreat with difficulty. The French were now anxious to conclude a peace with Abd-el-Kader, and with this view General Bugeaud arranged a meeting with him on the banks of the Tafna, and a treaty was signed, 30th May 1837. They were then free to turn their strength against the bey of Constantine, and an army of 20,000 men set out from Bona with this object under the command of General Damrémont early in October. The town was, after a very gallant defence, taken by storm on the 12th of that month by General Valée, General Damrémont having been killed by a cannon-ball the previous day. On the capture of the city the neighbouring tribes hastened to make their submission to the conquerors, and a strong garrison being left to defend the town, the army returned to Bona. As a reward for his services, General Valée was made a marshal and appointed governor-general of the colony. Disputes with the emir as to the boundaries of his territory were frequent, and at length war was again declared between the parties. The immediate cause of war on this occasion was the marching of an armed force of French troops through the emir's territory. This the latter looked upon as an infringement of the treaty, and consequently declared war. In October 1839, he suddenly fell upon the French troops in the plain of Metidja, and routed them with great slaughter, destroying and laying waste the European settlements. He surprised and cut to pieces bodies of troops on their march; outposts and encampments were taken by sudden assault; and at length the possessions of the French were reduced to the fortified places which they occupied. On the news of these events reaching France, reinforcements to the amount of 20,000 men were sent out. The spring campaign was vigorously opened on both sides, and numerous skirmishes took place, but without decisive results to either party. The French were, indeed, everywhere successful in the field, but the scattered troops of the enemy would speedily reassemble and sweep the plains, so that there was no safety beyond the camp and the walls of the towns. The fort of Masagran, near Mostaganem, with a garrison of only 123 men, gallantly withstood a fierce attack by 12,000 to 15,000 Arabs, which lasted for three days. Marshal Valée was now recalled, and General Bugeaud appointed to succeed him. The latter arrived at Algiers on the 22d of February 1841, and adopted a new system, which was completely successful. He made use of movable columns radiating from Algiers, Oran, and Constantine, and having from 80,000 to 100,000 troops at his disposal, the result soon told against the emir. Many of the Arab tribes were thus intimidated or brought under subjection, hard pressed garrisons were relieved and victualled, and towns after towns taken. Tekedemt, the principal stronghold of Abd-el-Kader, was destroyed, and the citadel blown up; Mascara was taken; and Saida, the only remaining fortress in the possession of the emir, was entirely demolished. In January 1842 the town of Tlemcen was taken, and ten days afterwards the fort of Tafna, which was demolished. The terrified Arabs submitted on all sides, and now almost the entire country was subdued. The emir himself, driven to extremities, was

compelled to take refuge in Morocco. Here he succeeded in raising a considerable force, and returned to Algeria. He made up for the want of troops by the rapidity of his movements, and would suddenly make an attack on one place when he was supposed to be in quite an opposite quarter. In November 1842 the Duke of Aumale arrived in Algiers to take part in the operations against the emir; and in the spring of the following year he suddenly fell upon the camp of Abd-el-Kader while the great body of his troops were absent, and took several thousand prisoners and a large booty, the emir himself making his escape with difficulty. Not long afterwards the latter again took refuge in Morocco, and so excited the fanatical passions of the people of that country that their ruler was forced into a war with France. The army which was sent into Algeria was attacked and defeated by Bugeaud at the river Isly, 14th August 1844. The emperor of Morocco soon afterwards sued for peace, which was granted him on condition that he should no longer succour or shelter the emir, but aid in pursuing him. Abd-el-Kader was now reduced to great extremities, and obliged to take refuge in the mountain fastnesses, whence he would from time to time come down to annoy the French. In June 1845 a tribe of Arabs, who were being pursued by a body of French troops under General Pelissier, took refuge in a cave. As they refused to surrender, the general ordered a fire to be kindled at the mouth of the cave, and the whole of those within, men, women, and children, to the number of 500, were suffocated. The emir at length was brought to such straits that he agreed to deliver himself up to the French on being allowed to retire to Alexandria or St Jean d'Acre. Notwithstanding this promise, which was given by General Lamoricière, and ratified by the governor-general, he was taken to France, where he arrived on the 29th of January 1848; and was imprisoned first in the castle of Pau, and afterwards in that of Amboise, near Blois. In October 1852 Louis Napoleon, then president of the French Republic, gave him his liberty on condition that he should not return to Algeria, but reside at Brouso in Asia Minor. Here he remained till 1855 when, in consequence of the destruction of that town by an earthquake, he obtained permission to remove to Constantinople, and afterwards to Damascus. At the latter place he rendered valuable aid to the Christians by protecting them during the massacre by the Turks in Syria in 1860.

On the revolution in France of 1848, General Cavaignac was appointed governor-general of the colony; and the National Assembly, wishing to establish a closer connection between the country and France, offered to incorporate it with the republic. This proposal, however, met with considerable opposition, and Algeria was simply declared a permanent possession, with the right to send four deputies to the National Assembly, to be heard on all matters affecting the interests of the colony. Colonists were also sent out to settle there, and other means taken to further its prosperity. Still the republic did not seem to be more successful in the administration of affairs than the monarchy had been. The colonists died off or left in disgust, the natives were not more reconciled to the French yoke, and many of them rose in open rebellion. The Kabyles, in particular, the most intelligent and industrious of the native population, manifested the greatest repugnance to the imposition of taxes and of the usages of civilisation. In 1849 General Pelissier marched against several of the rebellious tribes, and reduced them to subjection. Generals Canrobert and Herbillon were sent into the district of Zaab to quell an insurrection excited by the Marabout Bon-Zian. The latter was driven to take refuge in Zaatcha, which resisted the utmost efforts of the French to take it for fifty-one days, but at last it was carried by storm. In 1850 there

were several expeditions sent out against the natives, and in 1851 General St Arnaud succeeded in reducing to subjection Little Kabylia. In 1852 General M'Mahon set out against Eastern Kabylia, and Pelissier, in the south, took Laghouat by storm. The next few years present us with several expeditions against the Kabyles, but these were not productive of very marked results. In 1854 there was an expedition against certain Arab tribes in the south, who were reduced to subjection. In 1856 a great expedition, under the command of General Randon, was organised against the tribes of Great Kabylia that had not yet submitted to the French; and after many months' fighting they were brought under subjection. The authority of France was now undisputed over the country, and peace for a time was established.

In 1858 the administration of the colony was confided to a special minister, the first nominated being Prince Napoleon; but he only held office for a short time; and soon after, the special ministry was abolished. In October 1859 certain Arab tribes rose in rebellion, but were speedily subdued. In 1860 Marshal Pelissier was made governor-general, with a vice-governor, a director-general of civil affairs, and a council of thirty members. In the beginning of 1863 the emperor promised to Algeria a constitution, with a representative assembly for provincial matters; and said that it was not a colony properly so called, but an Arab kingdom, and that the natives had an equal right to his protection with the colonists. In April 1864 a formidable insurrection of the Arabs broke out in the south, in consequence of an insult offered to one of their chiefs in a court of justice, and they suddenly fell upon and cut to pieces a detachment of French troops. A large force was speedily assembled and sent against them, and after they had been beaten in several encounters the insurrection was at length put down. Marshal Pelissier died in May, and Marshal M'Mahon was appointed to succeed him. A fresh insurrection of the Arabs broke out in October, but after several defeats they were brought to subjection. In May 1865 the Emperor Napoleon visited Algeria, and was everywhere received with the greatest demonstrations of joy. After his return to France he wrote a letter to Marshal M'Mahon respecting the future government of the colony. He particularly pointed out the necessity of seeking to gain the good-will of the natives by permitting them to enjoy their territories unmolested, and to maintain their own customs, and that they should be held as equal with the colonists before the law. He further directed him to seek to stimulate the industry of the colonists, and to strive to develop the resources of the country. In October a fresh insurrection broke out in the province of Oran. It commenced with an attack upon a friendly tribe, but was at length put down by a body of troops under the command of Colonel de Colomb. It again broke out in March 1866, and Colonel de Colomb was a second time sent out against the insurgents. He encountered them on the 16th, and, after a fierce engagement, put them to flight with great loss. In the beginning of 1867 a new expedition was organised against the refractory Arabs in the south, and these being effectually put down, a period of comparative peace followed. The crops in 1866 were almost entirely destroyed by an invasion of locusts, and in January 1867 a violent earthquake destroyed several villages in the vicinity of Blidah. A prolonged drought followed, which dried up the sources of the springs and produced a famine, from which the natives suffered much. A visitation of cholera succeeded, which is estimated to have carried off not less than 50,000 persons. In January 1868 a fresh revolt broke out among the Arabs, instigated by Si-Hamed, who had led on more than one of the previous revolts. They assailed and plundered some of the

friendly tribes, and being pursued and attacked by a body of French troops, a fierce engagement took place, in which Si-Hamed was killed and his followers put to flight. Peace was enjoyed for the rest of that year; but towards the end of January 1869 several large bands of insurgent Arabs in the extreme south marched northward, took by surprise Tagguin, and being joined by others, in a short time they numbered 3000 horse. A body of French troops was sent out against them from Laghouat, under the command of Colonel Sonis, and after two and a half hours' hard fighting the insurgents were put to flight with great slaughter. In 1871 a widespread insurrection of Arab and Kabyle tribes broke out, stimulated no doubt by a knowledge of the weakened condition of France at home. It commenced with El-Mokrani, the hereditary bach-aga of the Medjana, attacking and burning the village of Brody-Bon-Arreredy, destroying isolated houses and posts throughout the district subject to his influence, the colonists who did not succeed in reaching a place of safety being massacred. All his attacks against the fortified places, however, failed; and as soon as the French were able to assume the offensive he was beaten in every engagement, and subsequently killed in action. When this rebellion appeared almost overcome, the whole of Kabylia rose in arms at the command of the sheikh El-Haddad, one of the most powerful chiefs in Kabylia, and head of an influential religious confraternity. The Kabyles, for the first time in history, descended from their mountain fastnesses, and attempted to invade the plains of the Metidja. The most horrible massacres were perpetrated, and all the principal ports on the coast were strictly blockaded on the landward side. It was not till after the fall of the commune in Paris that troops could be spared in sufficient numbers to suppress the insurrection. But this was at length effected, and a war contribution of £1,200,000 imposed upon the rebels, whose lands were also sequestrated, but the owners were permitted to resume possession on comparatively easy terms. The greater part of the sum recovered was distributed among the colonists who had suffered during the insurrection, and a considerable portion of it has been allotted for public works. The sequestration has also opened up much valuable territory for European colonisation. Since the insurrection many new colonists have arrived here, and among them many from Alsace and Lorraine. A law passed by the French Chamber, 15th September 1871, authorises, on certain conditions, the gratuitous concession of 247,000 acres of land to such natives of Alsace and Lorraine as might desire to preserve their French nationality. A more favourable era, it is believed, has now dawned for the colony. Down to 1871 it had continued under military rule, and this, it was thought, had had not a little to do with the frequent insurrections that had broken out in the country. Accordingly, in October of that year, a civil government was established, as has been already noticed, and since that time the colony has continued in a more peaceable and flourishing condition. (D. K.)

ALGHERO, a seaport of Italy, in the province of Sassari, Sardinia, situated on the west coast of the island, 14 miles S.W. of Sassari. It was founded by the Genoese, and was afterwards taken by the Catalonians, whose language is still spoken. Though strongly fortified towards the sea, the landward side of the town is commanded by the overhanging hills. Alghero is an episcopal see, and has a cathedral, erected in 1517, several monasteries, convents, and public schools. Many of the houses are of antique architecture. Near the town are some fine stalactite grottoes. The neighbourhood produces oil and fruit, and the best wine of the island; and the corals of Alghero are the most beautiful found in the Mediterranean.

The other exports include grain, wool, tobacco, bones, skins, and anchovies. Porte Conte, 9 miles to the N.W., is the roadstead frequented by the largest vessels, and is a secure and fortified anchorage, capable of accommodating a large fleet. Population of commune (1865), 8419.

ALGIERS (Fr. *Alger*, Arab. *Al-Jezair*, i.e., The Islands), a city and seaport of Northern Africa, and capital of Algeria, is situated on the west side of a bay of the same name in the Mediterranean. Lat. (of lighthouse), 36° 47' 20" N., long. 3° 4' 32" E. It is built, in the form of an amphitheatre, on the northern slope of a steep hill rising abruptly from the coast. It ascends the side of the hill in the form of an irregular triangle, the apex of which is occupied by the Casbah, or ancient fortress of the deys, which is about 500 feet above the level of the sea. As seen from a distance, the city presents a very imposing and picturesque appearance; and the houses rising one above the other, and being all built of white stone, it has been compared to a ship under sail. It consists of two towns—the new, which is entirely European in its character, and is built on the lower part of the slope and along the shore; and the old town, which occupies the higher region, and is entirely Oriental in its character. The new town consists of handsome streets and squares, and contains the government houses, hotels, warehouses, barracks, &c. In the centre of the new town is the *Place du Gouvernement*, a large and handsome square in the European style, with a fountain, and planted with orange and lime trees. The streets are regular, spacious, and handsome, and adorned with arcades. In the Arab or old town the streets are narrow, winding, and dirty. The houses are square substantial-looking buildings, presenting to the street bare walls, with only a few slits protected by iron gratings in place of windows. Each house has a quadrangle in the centre, into which it looks, and which is entered by a low narrow doorway. Algiers is surrounded by walls and otherwise fortified, but its landward defences are weak and exposed, while the batteries which defend it towards the sea are very strong. It has two handsome suburbs, and numerous elegant villas are scattered over the vicinity. The town is the residence of the governor-general of Algeria, of the prefect of the department of Algiers, and of the chiefs of the different administrative services. It is also the seat of a bishop and of the supreme courts of justice, and has a chamber and tribunal of commerce, a royal college, various schools, a bank, public library, and museum. Among the principal buildings are a cathedral and several Roman Catholic churches, a Protestant church, several synagogues, and a number of mosques. The town is well supplied with water, and there are numerous public and private fountains and baths. Various markets are held here, and horse-racing is a favourite amusement. Algiers has of late come to be noted as a winter residence for invalids. The French have spent large sums of money in the improvement of the port of Algiers. It has an area of 220 acres, and it is calculated that when a rock near the centre, called *Roche Sans Nom*, is removed, it will be capable of accommodating 40 vessels of war and 300 trading vessels. It has two docks, capable of containing the largest vessels. The lighthouse has a revolving light visible at the distance of 15 miles. Population (1866), 52,614. (For the trade and climate of Algiers, see ALGERIA.)

ALGOA BAY, an inlet in Cape Colony, on the S.E. coast of Africa, 425 miles east from the Cape of Good Hope. Lat. of Croix Island, in the bay, 30° 47' N., and long. 25° 46'. Algoa Bay lies between capes Recife and Padrone, on the former of which there is a lighthouse. It receives the rivers Sunday and Baasher. The best anchorage is on the west side of the inlet, near Port Elizabeth, which is the most important seaport on the

south coast of Africa. Here the holding ground is good, and the anchorage is sheltered, except from the south-east winds. Fort Frederick stands on a hill overlooking Port Elizabeth. Algoa Bay was the first landing-place of the British emigrants to the eastern province of the Cape Colony, and as the harbour of that province it enjoys a rapidly increasing trade.

ALHAMA, a city of Spain, in the province of Granada, 24 miles S.W. of Granada. It is very picturesquely situated on the edge of a gorge in the hills of the Sierra de Alhama, the streets rising in terraces one above another. The river Marchan flows through the chasm, and the mountains behind the town reach a height of 8000 feet. The name Alhama signifies in Arabic "the bath," and is derived from the hot mineral springs in the neighbourhood. These springs, which have a temperature of 118° Fahr., are considered beneficial in cases of dyspepsia and rheumatism, and in former times had as many as 14,000 visitors annually. Alhama was a most important fortress while the Moors ruled in Granada, and its capture by the Marquis of Cadiz in 1482 was the most decisive step in the reduction of their power. Remains of the Moorish castle and walls are still to be seen, as well as an aqueduct of Roman or Moorish origin. Many of the houses are of Moorish architecture, and the antiquities of the town, the mineral springs, and the wild scenery of the environs attract numerous visitors. Population, about 7000.

ALHAMA, a town in Spain, in the province of Murcia, 13 miles S.W. of the town of that name. It is celebrated for its sulphur springs, which have a temperature ranging from 91° to 113° Fahr., and attract numerous visitors. The town has a hospital and the ruins of an ancient castle. Population, about 6500.

ALHAMBRA, the ancient fortress and residence of the Moorish monarchs of Granada, lies on a hill overlooking the city of Granada, on the north. The name, signifying in Arabic "the red," is derived from the colour of the sun-dried *tapia*, or bricks made of fine gravel and clay, of which the outer walls are built. This famous Moorish palace was erected at various dates, chiefly between 1248 and 1354, under the reigns of Ibn-I-Ahmar and his successors. The splendid decorations, and in particular the exquisite painting of the interior, are ascribed to Yusuf I., who died in 1354. Immediately after the expulsion of the Moors in 1492, their conquerors began, by innumerable acts of vandalism, to spoil the marvellous beauty of the Alhambra. The open work was filled up with white-wash, the painting and gilding effaced, the furniture soiled, torn, or removed. Charles V. rebuilt portions in the modern style of the period, and destroyed the greater part of the Winter Palace to make room for a modern structure which has never been completed. Philip V. Italianised the rooms, and completed the degradation by running up partitions which blocked up whole apartments, gems of taste and patient ingenuity. In subsequent centuries the carelessness of the Spanish authorities permitted this pearl of Moorish art to be still further defaced; and in 1812 some of the towers were blown up by the French under Sebastiani, while the whole buildings narrowly escaped the same fate. In 1821 the ancient pile was shattered by an earthquake. Directions were given in 1862, by Isabella, then queen of Spain, for the restoration of the Alhambra to its original condition. The work has been carried on with considerable skill, but the sums devoted to it have been too small for its satisfactory accomplishment.

The hill terrace on which the Alhambra stands is about 2430 feet in length by 674 in breadth at the widest part. A strongly-fortified wall, flanked by thirteen square towers, encloses an area of 35 acres, within which the palace is built. Approaching from the city, the visitor passes

through the Gate of Pomegranates and enters the grounds of the Alhambra, which are well wooded, and in spring are covered by sweet-scented wild flowers. The gardens, though weedy and ravined, are a charming resort, adorned by beautiful waterfalls and sparkling fountains, and enlivened by the song of the nightingale. Passing the pillars of Charles V., a steep ascent leads to the chief entrance to the Alhambra, the Gate of Judgment—a massive archway, surmounted by a square tower 62 feet high, which, while serving as an outwork of the fortress and as an entrance-hall to the palace, was principally used as an open-air court of justice, according to the patriarchal custom of the east. The pillars of the gate are of sculptured marble, and the horse-shoe arch is 28 feet high. A narrow passage leads to the *Plaza de los Algibes*, the Place of the Cisterns, so called from the tanks underneath filled with water from the Darro, which foams through the ravine to the north of the hill. The Plaza is about 225 feet long by 187 wide. To the left rises Alcazaba, the ruined fortress of the Alhambra, with the *Torre de la Vela* or Watch Tower, where the Christian flag was first hoisted on the expulsion of the Moors in 1492. It commands a noble prospect. Below lies the city of Granada, with its hundred churches; and above rise overhanging heights, with white houses glancing out from the green foliage, reminding one of the saying of the Arabic poet, that Granada is like a pearl set round with emerald. In the Place of the Cisterns stands an isolated Moorish tower, the *Torre del Vino*, erected in 1345; and to the right lies the palace of Charles V., displacing so much that was curious in Moorish art. It is a majestic but cold-looking structure in the Renaissance style, unfinished and roofless, and presenting a desolate and ruinous aspect. Behind this edifice lies the Moorish palace, the exterior being severe, plain, and almost forbidding in appearance, according to the peculiarity of Moorish architecture, by which they contrived to heighten the splendour of the interior by contrast with the bare and unadorned structure of the outer walls. But within, the palace stands unrivalled in the gorgeous splendour of its halls and the exquisite beauty of its decorations. Everywhere are seen evidences of the delicate taste and the artistic luxury of the Moors. Spacious courts, with marble pillars and fretted ceilings, partitions coloured and gilt like the sides of a Stamboul casket, and filigree stuccos of veil-like transparency, all distinguished by airy lightness and grace, are among the main features of this palace of the voluptuous caliphs of Granada, who held dominion over that sunny land which their poets described as a terrestrial paradise. The colours chiefly employed are blue, red, and a golden yellow. In the hey-day of Moorish prosperity the palace must have been the most delicious of royal residences. Odoriferous gardens, in which the orange and the myrtle bloomed, alternated with sparkling fountains and soft couches, inviting to a luxurious repose. Everything contributed to render the whole the most splendid abode of Oriental magnificence, to which only the fantastic creations of the *Arabian Nights* can be fitly compared.

The present entrance is by a small insignificant door, from which a corridor conducts to the *Patio de la Berkah*, the Court of the Blessing. This court is 140 feet long by 74 broad; and in the centre there is a large pond set in the marble pavement, full of gold-fish, from which some have called this the Court of the Pond. It is also known as the Court of the Myrtles, from the myrtles which grow along its sides. There are galleries on the north and south sides; that on the south 27 feet high, and supported by a marble colonnade. Underneath it, to the right, was the principal entrance, and over it are three elegant windows with arches and miniature pillars. The columns

supporting the galleries are light in structure, and arches, slender and bending gracefully like palms, spring from the capitals and meet overhead. From this court the walls of the *Torre de Comares* are seen rising over the roof to the north, and its tower and colonnades are reflected in the crystal mirror of the pond.

The Hall of Ambassadors (*Sala de Embajadores*) is the largest in the Alhambra, and occupies all the Tower of Comares. It is a square room, the sides being 37 feet in length, while the centre of the dome is 75 feet high. This was the grand reception-room, and the throne of the sultan was placed opposite the entrance. The azulejos are nearly 4 feet high all round, and the colours vary at intervals. Over them is a series of oval medallions with inscriptions, interwoven with flowers and leaves. There are nine windows, three on each façade, and the ceiling is admirably diversified with inlaid work of white, blue, and gold, in the shape of circles, crowns, and stars—a kind of imitation of the vault of heaven. The walls are covered with varied stucco-work of most delicate pattern, surrounding many ancient escutcheons.

Another of the more celebrated courts of the palace is the *Patio de los Leones*, the Court of the Lions. This is an oblong court, 116 feet in length by 66 in breadth, surrounded by a low gallery supported on 124 white marble columns. A pavilion projects into the court at each extremity, with filigree walls and light-domed roof, elaborately ornamented. The square is paved with coloured tiles, and the colonnade with white marble; while the walls are covered 5 feet up from the ground with blue and yellow tiles, with a border above and below enamelled blue and gold. The columns supporting the roof and gallery are irregularly placed, with a view to artistic effect; and the general form of the piers, arches, and pillars is most graceful. They are adorned by varieties of foliage, &c.; about each arch there is a large square of arabesques; and over the pillars is another square of exquisite filigree work. In the centre of the court is the celebrated Fountain of Lions, a magnificent alabaster basin supported by the figures of twelve lions in white marble, not designed with sculptural accuracy, but as emblems of strength and courage. When the fountain was in good order a great volume of water was thrown up, which fell into the basin, passed through the lions, and issued from their mouths.

The Hall of the Abencerrages derives its name from a legend according to which Boabdil, the last king of Granada, having invited the chiefs of that illustrious line to a banquet, massacred them here. This room is a perfect square, with a lofty dome, and trellised windows at its base. The roof is exquisitely decorated in blue, brown, red, and gold, and the columns supporting it spring out into the arch form in a remarkably beautiful manner. Opposite to this hall is the Hall of the Two Sisters, so called from two very beautiful white marble slabs laid as part of the pavement. These slabs measure 15 feet by 7½, and are without flaw or stain. There is a fountain in the middle of this hall, and the roof is composed of stalactites, nearly 5000 pieces entering into its construction. The whole decorations here are of the most exquisite description.

Among the other wonders of the Alhambra are the Hall of Justice; the mosque; the *Mirador de Lindaraja*, or boudoir of the sultana; the *Patio de la Reja*; the *Tocador de la Reina*, or queen's boudoir; and the *Sala de los Banos*, in all which are to be seen the same delicate and beautiful architecture, the same costly and elegant decorations. There must also be noticed the celebrated vase of the Alhambra, a splendid specimen of Moorish ceramic art, dating from 1320, and belonging to the first period of Moorish porcelain. It is 4 feet 3 inches high; the ground is white, and the enamelling is in blue, white, and gold.

A new hall, called the Hall of the Shields or Esecutiveons, has recently been discovered; and the palace contains, besides the more important halls already mentioned, ranges of bed-rooms and summer-rooms, a whispering gallery and labyrinth, and vaulted sepulchres.

The towers of the fortress have also much of the ornamented character of the palace. Separated from the Alhambra by a ravine lies *Generalife*, the Garden of the Architect, probably in the first instance an outwork of the fortress, afterwards the summer villa of the sultans of Granada. It is impossible to conclude the description of the Alhambra without remarking how admirably every thing was planned to render this palace the most voluptuous of all retreats—the numerous fountains which cooled the air, the judicious disposition of doors and windows securing a free ventilation, the shady gardens, and the noble views of the hills and plains around. Some idea of the beauty of the original is afforded by the Alhambra Court in the Crystal Palace at Sydenham, imitating the Moorish palace in gorgeousness of colouring, elaborateness of ornamentation, and quaint grace of architectural style.

One of the most striking features of the Alhambra is the appliance of poetical conceits and passages from the Koran to enhance and form part of the ornamentation. "There is no God but Allah," "There is no conqueror but God," "Glory be given to our Lord," and other similar inscriptions are everywhere to be observed.

(See Mr Owen Jones's *Plans, Elevations, and Sections of the Alhambra*, 2 vols. fol., 1848.)

ALHAZEN (full name, ABU ALI AL-HASAN IBN AL-HASAN), a mathematician of the 11th century, was born at Bassora, and died at Cairo in 1038. He is to be distinguished from another Alhazen who translated Ptolemy's *Almagest* in the 10th century. Alhazen having boasted that he could construct a machine for regulating the inundations of the Nile, was summoned to Egypt by the caliph Hakem; but, aware of the impracticability of his scheme, and fearing the caliph's anger, he feigned madness until Hakem's death in 1021. Alhazen was, nevertheless, a diligent and successful student, being the first great discoverer in optics after the time of Ptolemy. His researches were prosecuted under the greatest disadvantages, as he was compelled to eke out a livelihood by copying his own works and selling them. To him, and not to Ptolemy, is due the explanation of the apparent increase of heavenly bodies near the horizon. He correctly attributed the phenomenon to the fact that the eye compares these bodies with intervening terrestrial objects. He taught, previous to Vitello, that vision does not result from the emission of rays from the eye, and wrote also on the refraction of light, especially on atmospheric refraction, showing, *e.g.*, the cause of morning and evening twilight. He solved the problem of finding the point in a convex mirror at which a ray coming from one given point shall be reflected to another given point. As a writer, Alhazen is remarkable for prolixity and scholastic subtilty. Only two of his works have been printed—his *Treatise on Twilight*, and his *Thesaurus Optice*. (See Casiri, *Bibl. Arab. Hisp. Eскур.*)

ALI, the fourth in order of the caliphs or successors of Mahomet, was born at Mecca, about the year 600 A.D. His father, Abu Taleb, was an uncle of the prophet, and Ali himself was adopted by Mahomet and educated under his care. While he was still a mere boy he distinguished himself by being the first to declare his adhesion to the cause of Mahomet, who in return made him his vicegerent, and some years after gave him his daughter Fatima in marriage. Ali proved himself to be a brave and faithful soldier; and when Mahomet died without male issue, he seemed to have the best claims to become the recognised head of Islamism. Three other companions of

Mahomet, however, Abubekr, Omar, and Othman, occupied this position before him, and it was not until 656, after the murder of Othman, that he assumed the title of caliph. Almost the first act of his reign was the suppression of a rebellion under Telha and Zobeir, who were instigated by Ayesha, the widow of Mahomet, a bitter enemy of Ali, and hitherto one of the chief hindrances to his advancement to the caliphate. The rebel army was defeated at Kharibah, near Bassorah, the two generals being killed, and Ayesha taken prisoner. Ali's next care was to get rid of the opposition of Moawyah, who had established himself in Syria at the head of a numerous army. A bloody battle took place in the plain of Suffein, near the Euphrates, which seemed at first to be going in favour of Ali; when suddenly a number of the enemy, fixing copies of the Koran to the points of their spears, exclaimed that "the matter ought to be settled by reference to this book, which forbids Mussulmans to shed each other's blood." On hearing this the superstitious soldiers of Ali refused to fight any longer, and demanded that the matter should be referred to arbitration. Abu Musa was appointed umpire on the part of Ali, and Amru, one of the shrewdest men in the kingdom, on the part of Moawyah. Amru persuaded Abu Musa that it would be for the advantage of Moslemism that neither candidate should reign; and also, with a pretence of deference, asked him to give his decision first. Abu Musa, falling into the snare, proclaimed that he deposed both Ali and Moawyah; thereupon Amru declared that he also deposed Ali, but that he invested Moawyah with the caliphate. This treacherous decision greatly injured the cause of Ali, which was still further weakened by the loss of Egypt, Syria, and Persia, including the sacred cities of Mecca and Medina. Ali, however, resolved to make a final effort, and collected a large army for that purpose. He was not destined to see the result of his plans. Three of the fanatic sect of the Karigites made an agreement to assassinate Ali, Moawyah, and Amru as the authors of disastrous feuds among the faithful. The only victim of this plot was Ali, who died at Kufa in 661, of the wound inflicted by a poisoned weapon. He had eight wives besides Fatima, and in all, it is said, thirty-three children, one of whom, Hassan, a son of Fatima, succeeded him in the caliphate. Ali is described as a bold, noble, and generous man, "the last and worthiest of the primitive Moslems, who imbibed his religious enthusiasm from companionship with the prophet himself, and who followed to the last the simplicity of his example." He was also remarkable for learning and wisdom, and there are still extant collections of proverbs, verses, &c., which bear his name, especially the *Sentences of Ali*, an English translation of which, by William Yule, was published at Edinburgh in 1832. The question of Ali's right to succeed to the caliphate is an article of faith which divided the Mahometan world into two great sects, the Sunnis and the Shiabs, the former denying and the latter affirming his right. The Turks, consequently, who are usually Sunnis, hold his memory in abhorrence; whereas the Persians, who are generally Shiabs, venerate him as second only to the prophet, and celebrate the anniversary of his martyrdom.

ALI BEY (1728–73), an adventurer, said to have been a native of the Caucasus, and to have been sold about the age of twelve or fourteen for a slave in Cairo. The two Jews who became his masters presented him to Ibrahim, then one of the most influential men in the kingdom. In the family of Ibrahim he received the rudiments of a literary education, and was also instructed in the military art. He gradually gained the affection of his patron to such a degree that he gave him his freedom, permitted him to marry, and promoted him to the rank of governor of a

district. Afterwards he was elected to the elevated station of one of the governors of provinces. Deprived of his protector by death, and engaging in the dangerous intrigues that pave the way to power in an unstable government, he procured his own banishment to Upper Egypt. Here he spent two years in maturing his schemes for future greatness; and in 1766, returning to Cairo, he either slew or expelled the beys, and seized the reigns of government. Emboldened by success, he rescued himself from the power of the Porte, coined money in his own name, and assumed the rank of sultan of Egypt. Occupied in more important concerns, the Porte made no vigorous opposition to his measures, and Ali seized the opportunity to recover a part of the Said, or Upper Egypt, which had been taken possession of by an Arab sheik. He next sent out a fleet from Suez, which, seizing upon Djedda, entered the port of Mecca; while a body of cavalry, commanded by Mahomet Bey, his favourite, took and plundered Mecca itself. Having formed an alliance in 1770 with the Sheik Daher, a rebel against the Porte in Syria, he aimed at the conquest of all Syria and Palestine. He first endeavoured to secure Gaza; then his army, forming a junction with that of Daher at Acre, advanced to Damascus. There, on the 6th of June 1771, a battle was fought with the Turkish pashas, and Mahomet and Daher, Ali's generals, routed them with great slaughter. The latter instantly took possession of Damascus, and the castle itself had also capitulated, when Mahomet unexpectedly hastened back to Egypt with all his Mamelukes. Some ascribe this strange conduct to an impression made upon Mahomet by the Turkish agents, and others to a report of the death of Ali Bey.

Although unsuccessful, Ali never lost sight of his favourite object; and Mahomet, losing his confidence, was forced to save his life by exile. Mahomet, however, quickly returned with an army, and drove Ali Bey from Cairo. In this unfortunate state of affairs Ali fled to Daher, and, combining their forces, they attacked the Turkish commander at Sidon, and came off victorious, although the Turkish army was three times their number. After a siege of eight months, they next took the town of Jaffa. Deceived by letters from Cairo, which were only intended to ensnare him, and stimulated by his recent victories, Ali returned to Cairo. Entering the deserts which divide Gaza from Egypt, he was furiously attacked by a thousand chosen Mamelukes led on by Murad Bey, who was enamoured of Ali's wife, and had obtained the promise of her, provided that he could take Ali captive. Ali was wounded, made prisoner, and carried to Mahomet. He died three days after, from the effects either of poison or of his wounds.

ALI PASHA, surnamed *Arslan* or "The Lion," was born at Tepelini, a village of Albania, on the Voyutza, at the foot of the Klissoura Mountains, in 1741. He belonged to the Toske tribe, and his ancestors had for some years held the title of Bey of Tepelini, this dignity having become hereditary in his family. His grandfather fell in 1716 at the siege of Corfu, which was then held by the Venetians. His father, who died when Ali was in his fourteenth year, is represented by most authorities as a man of amiable character and peaceful habits, who was despoiled of his territories by the chiefs that lived around him; but his mother was a woman of fierce and unyielding disposition. Inciting her son to recover the possessions of his father, she roused in him a spirit of cruelty and aggression, tempered, however, by a considerable amount of cunning and foresight, which bore bitter fruit in his riper years. Many romantic stories are told of Ali's adventures at the outset of his career, but the only facts that are known with certainty are, that after living in the

mountains as a robber for some years, and enduring great privations, he made himself master of his beylik of Tepelini by the aid of his associates. He is said to have then murdered his brother and imprisoned his mother, who died shortly after, on a charge of attempting to poison him. In order to increase and establish his power, he then made overtures to the Turkish government, by whose orders he attacked and defeated the pasha of Scutari, then in rebellion against the sultan, and put to death Selim, pasha of Delvino. For these acts he was rewarded by being placed in possession of the whole of his father's territories, and he was appointed lieutenant to the Derwend-pacha of Rum-ili, an officer who was charged with the suppression of brigandage and highway robbery in the district. Ali, however, by permitting the robbers to go unchecked in return for a share of the spoil, brought his superior to disgrace and death, but escaped himself by sending bribes to the ministers of the sultan. For his services in the field in the war between Prussia and Turkey in 1787 he was appointed pasha of Trikala in Thessaly, and Derwend-pasha of Rum-ili. He soon cleared the country of robbers, mainly by summoning to his standard all who were willing to serve under him, and by their aid he took forcible possession of Joannina in 1788. By means of the powerful body of troops at his command, and the wise measures that he introduced, he wrought considerable amelioration in the districts under his charge, and the Porte seeing this, confirmed him in the pashalik of Joannina. His whole attention was now turned to the aggrandisement of his territory and personal power. He obtained possession of the western part of Northern Greece, or Livadia as it was then called; but was baffled for many years in his attempts to occupy the country of the Suliotes in the south-west of Epirus. These brave and hardy mountaineers at last, in 1803, agreed to evacuate their country, and were treacherously massacred by Ali while on their way to the coast to embark for Corfu. When the French took Venice in 1797, Ali, by pretending admiration for the principles of the revolution, induced Napoleon to send him engineers, by whose aid he fortified Joannina; but failing to obtain from him, as he had hoped, the Venetian ports on the seaboard of Epirus, he took occasion, after the defeat of Napoleon in Egypt, to lay siege to Prevesa, which was surrendered by the French troops. Ali had now a difficult part to play, but he succeeded so well with his master the sultan, that he was confirmed in the possession of the whole of Albania northwards from Epirus to Montenegro, over which he had asserted his authority, partly by intrigue and partly by force of arms. He also held the high position of governor of Rum-ili for a brief period (1799), during which he amassed a large sum of money by his extortions. The cruel massacre of the inhabitants of Gardiki, for an alleged insult to his mother and sister about forty years previously, was perpetrated about this time. He contrived to make his peace with the French in spite of the capture of Prevesa, and in 1807 once more entered into alliance with them, with the view of obtaining Parga, which he had attempted to capture, but without success, in 1800. Napoleon, however, neglected to secure Parga for him at the peace of Tilsit, and the fortress remained in the hands of the French until it was taken in 1814 by the English, who gave it up in 1817, ostensibly to the sultan, but in reality to Ali. Ali was now at the height of his power: he was almost supreme over Albania, Epirus, part of Thessaly, and the western part of Northern Greece; while one of his sons held the pashalik of the Morea. So powerful was he that, though he was nearly eighty years of age, the Porte feared and hated him, and desired his death, but could find no good pretext for taking measures against him until

1820, when Ali procured the assassination of an officer who had left him and taken service under the sultan at Constantinople. For this daring act the sultan proscribed Ali, and ordered all the European pashas to march against him. He resisted every effort to capture him, but was at last induced by Kourschid Pasha to surrender in January 1822 on promise of a pardon from the sultan. On 5th February, on pretence of handing him the necessary document, Kourschid Pasha procured an interview with him, and then produced the firman authorising his execution. The brave old despot defended himself with his usual resolution and courage, but was overpowered by numbers, and his head was struck from his body and sent to Constantinople.

ALIAS, signifying *at another time*, is used in judicial proceedings to connect the several names of a person who attempts to conceal his true name, or to pass under a feigned one; as Smith alias Jones, James alias John.

ALIBI, in *Law*, denotes the absence of the accused from the place where he is charged with having committed a crime; or his being *elsewhere*, as the word imports, at the time specified.

ALICANTE, a province of Spain, bounded on the N. by Valencia, on the W. by Albacete and Murcia, on the S. by Murcia, and on the S.E. and E. by the Mediterranean Sea. It was formed in 1834 of districts taken from the ancient provinces of Valencia and Murcia, the former contributing by far the larger portion. Its length is about 73 miles, its breadth 68 miles, and the area 2090 square miles. The surface of the province is extremely diversified. In the north and west there are extensive mountain ranges of calcareous formation, intersected by deep ravines; while farther south the land is more level, and there are many fertile valleys. On the Mediterranean coast, salt marshes, exhaling an insalubrious miasma, alternate with rich plains and pleasant and productive huertas or gardens, such as those of Alicante and Denia. There is no considerable river in the province, but a few rivulets flow east through the valleys into the Mediterranean. The sky is clear, the climate temperate, and the rainfall very slight. Notwithstanding the want of rivers and of rain, agriculture is in a very flourishing condition. The inhabitants possess a spirit of steady industry uncommon in Spain, and by means of wells and canals they have to a large extent succeeded in overcoming the disadvantages of nature. Many tracts originally rocky and sterile have been levelled, and now present terraces covered with the vine and with useful trees. Cereals are grown, but the inhabitants prefer to raise such articles of produce as are in demand for export, and consequently part of the grain supply of the province has to be imported. Esparto grass, rice, the sugar-cane, and tropical fruits and vegetables are largely produced. Great attention is given to the rearing of bees and silk-worms; and the wine of the province is held in high repute throughout Spain, while some inferior kinds are sent to France to be mixed with claret. Cattle are not extensively reared. The most important minerals of the province are lead, copper, iron, and coal. There are about twenty lead and copper mines; and mineral springs are found at various places. The manufactures consist of fine cloths, silk, cotton, woollen and linen fabrics, girdles and lace, paper, hats, leather, earthenware, and soap. There are numerous oil-mills and brandy distilleries. Many of the inhabitants are engaged in the carrying trade, while the fisheries on the coast are also actively prosecuted, tunny and anchovies being caught in great numbers. Barilla is obtained from the sea-weed on the shores, and some of the saline marshes yield large supplies of salt by spontaneous evaporation. The province is divided into 16 judicial divisions and 206 parishes. Alicante is the

chief town, and the other places of importance are Denia and Villajoyosa on the coast; and Orihuela, Elche, Villena, and Alcoy in the interior. Education is in a low state; of the criminals arrested it is found that 14 in 15 can neither read nor write. The people are of a lively and irascible temperament, and offences against the person are frequent. Population (1870), estimated at 440,000.

ALICANTE, the capital of the above province, and, after Cadiz and Barcelona, the most considerable seaport of Spain. It is situated at the head of the bay of Alicante, in the Mediterranean Sea, in 38° 20' N. lat., and 0° 30' W. long. The city is built on the bay in the form of a half-moon, and is overlooked by a rock 400 feet high, surmounted by a castle, which has been suffered to fall into decay. There is good anchoring-ground in the bay, but only the smaller vessels can come up to the mole or pier. The bay is protected by batteries, and there is a fixed light on the mole, 95 feet high, and visible for a distance of 15 miles. Alicante was the *Lucentum* of the Romans; but notwithstanding its antiquity, the town presents a modern appearance, and has few remains of Roman, mediæval, or Moorish times. It is the seat of a bishop, and has a cathedral and episcopal palace. It has also a good town-house, an orphanage, a lyceum, a public library, and a school of navigation. Cotton, linen, and woollen goods, cigars, and confections are manufactured. There is a considerable trade in the fruit and other produce of the surrounding plain; and the *vino tinto*, or dark red wine, produced in the vicinity, is sent to France for mixing purposes. At the island of Plana, on the coast, very beautiful marble is procured. The foreign trade of the port, though still considerable, has greatly declined on account of the imposition of an excessive import tariff. In 1871, besides coasting traders, 372 Spanish and foreign vessels, with a tonnage of 62,546, entered the port. Of these vessels, 78 were British, measuring 29,021 tons. The value of the imports under foreign and native flags was £542,526, and the duties paid were £90,421, without reckoning duties corresponding to material and fuel for railways, which are admitted free. The chief imports are coals, iron, machinery, and guano; and the chief exports esparto—of which 11,000 tons were shipped in 1871—raisins, almonds, oranges, olive oil, silk, saffron, wine, lead, salt, and soda. There are here English and other European consuls. Alicante was besieged by the Moors in 1331, and again by the French in 1709, when the English commandant and his staff were killed by the explosion of a mine. Population, 31,500.

ALICATA, or LICATA, a seaport of Italy, in the province of Girgenti, Sicily, situated on the south coast, at the mouth of the Salso, the largest river in the island. It is supposed to occupy the site of the ancient *Phintias*, built by Phintias, tyrant of Agrigentum, in 280 B.C., after the destruction of Gela. The neighbourhood was the scene of many of the most memorable events of the Punic wars. On the hill overlooking the modern town there are extensive ancient remains. Alicata is now the most important commercial town on the south coast of Sicily, though the port is only an open shallow roadstead. The larger vessels lie a mile off shore, and are laden and discharged by means of barges. The chief trade is in sulphur, and the other exports include corn, fruit, macaroni, soda, and excellent wine. Population, 16,000.

ALICUDI, one of the Lipari Islands. See LIPARI ISLANDS.

ALIEN, obviously derived from the Latin *alienus*, is the technical term applied by British constitutional law to any one who does not enjoy the privileges of a British subject. The jealousy which has generally existed against communicating the privileges of citizenship to foreigners

has its foundation in mistaken views of political economy. It arose from the impression that the produce of the energy and enterprise of any community is a limited quantity, of which each man's share will be the less the more competitors there are; superseding the just view that the wealth of a state depends on the number and energy of the producers. Thus the skilled workmen who would increase its riches have often been jealously kept out of a country. But, on the other hand, special temptations, including the gift of citizenship, have often been offered to skilled foreigners by states desiring to acquire them as citizens. Britain has occasionally received industrious and valuable citizens, driven forth by the folly or tyranny of other powers, as in the memorable instance of the revocation of the edict of Nantes, which sent the Spitalfields colony and many other Frenchmen to this country. Looking on the full benefit of British citizenship as a transcendent boon, the principle of our older legislation on the subject has been to allow friendly aliens to possess at least a portion of it. There never existed in Britain a law so harsh as the *Droit d'Aubaine* of France, which confiscated to the crown all the property of a deceased alien. The courts of justice have ever been opened to them, and they have thus been entitled to protect themselves from any inequalities which do not apply to them by special law. It seems to be a rule of the general public law that an alien can be sent out of the realm by exercise of the crown's prerogative; but in modern practice, whenever it has seemed necessary to extrude foreigners, a special Act of Parliament has been obtained for the purpose. (See Phillimore's *Internat. Law*, vol. i., p. 133; Forsyth's *Cases and Opinions on Const. Law*, p. 181.)

Our law, save with the special exceptions mentioned afterwards, admits to the privileges of subjects all who are born within the British dominions. In the celebrated question of the *post-nati* in the reign of James I. of England, it was found, after solemn trial, that natives of Scotland born before the union of the crowns were aliens in England, but that those born subsequently enjoyed the privileges of English subjects. A child born abroad, whose father or whose grandfather on the father's side was a British subject, may claim the same privilege, unless at the time of his birth his father was a traitor or felon, or engaged in war against the British empire (4th Geo. II. c. 22). Owing to this exceptional provision, some sons of Jacobite refugees, born abroad, who joined in the rebellion of 1745, were admitted to the privilege of prisoners of war, because, as the conduct of their fathers deprived them of the privileges of citizenship, they were held not to be liable to its burdens.

It has been enacted with regard to the national status of women and children that a married woman is held to be a citizen of the state of which her husband is for the time being a subject; that a natural-born British woman, having become an alien by marriage, and thereafter being a widow, may be rehabilitated by certificate of the Secretary of State; that where a father or a widow becomes an alien, the children in infancy becoming resident in the country where the parent is naturalised, and being naturalised by the local law, are held to be subjects of that country; that those of a father or of a widow readmitted to British nationality become British subjects also; and that the children of a father or of a widow who obtains a certificate of naturalisation, becoming resident with such parent in the United Kingdom, become naturalised (33 and 34 Vict. c. 14, s. 10). The same statute provides that a declaration of alienage before a justice of peace or other competent judge, having the effect of divesting the declarant of the character of a British subject, may be made by a naturalised British subject desiring to resume the nationality

of the country to which he originally belonged, if there be a convention to that effect with that country; by natural-born subjects who were also born subjects of another state according to its law; or by persons born abroad having British fathers.

The main characteristic disabilities to which aliens have been subjected are incompetency to exercise political privileges, such as that of electing or being elected to sit in Parliament, and incapacity to hold landed property. The privilege of sitting on a jury was also counted among the political rights from which they are excluded; but when a foreigner is on trial, he had in England the privilege of the jury *de medietate linguæ*, in which half the panel consisted of foreigners, a privilege which was taken away in 1870, and never existed in Scotland. An alien enemy can neither by himself nor assignee sue for the recovery of a debt due to him in this country, unless by the Queen's special licence. But his right to do so revives when the war is terminated. (See Mr Justice Story's judgment in *Society for Propagation of the Gospel v. Wheeler*, 2 Gallison's Reports, 127, and Phillimore's *International Law*, iii. 121).

Many of the special disabilities to which aliens were subject under the Navigation Act and other laws connected with our old restrictive commercial policy, have been removed or neutralised by the free trade measures of later years; but it is still impossible for an alien to be the owner of a British ship. In other respects the tendency has been to communicate some of the rights of citizenship to aliens, and to widen the definition of subjects.

Most of the acts of Parliament passed with regard to aliens during the last and the present centuries have been repealed by 33 & 34 Vict. c. 14—the Naturalisation Act, 1870. It enables aliens to take, acquire, hold, and dispose of real and personal property of every description (except British ships), and to transmit a title to land, in all respects as natural-born British subjects. But the act expressly declares that this relaxation of the law does not qualify aliens for any office or any municipal, parliamentary, or other franchise, or confer any right of a British subject other than those above expressed in regard to property, nor does it affect interests vested in possession or expectancy under dispositions made before the act, or by devolution of law on the death of any one dying before the act.

The Act 6 & 7 Will. IV. c. 11 has not been repealed by the Act of 1870. It requires masters of vessels to intimate the arrival of all aliens, who are thereby bound to have their names registered and to obtain certificates of registration. It is believed that these conditions have seldom been complied with or enforced.

It may be remarked that the repealed Act of 1864 (7 & 8 Vict. c. 66) was the first considerable relaxation of the alien law. It communicated to the children born abroad of a British mother the privilege of acquiring land by purchase or succession. It gave friendly aliens the privilege of holding leases for any time not exceeding twenty-one years. Before this act the rights of citizenship could only be conferred on aliens by statute; and it was enacted at the commencement of the Hanover succession, that no private naturalisation bill should be brought in unless it contained a clause disqualifying the person it applied to from being a privy councillor or a member of Parliament, and from holding any office, civil or military, and from being a freeholder; but this restriction is repealed by the act of 1844. Limited privileges could formerly be given by the sovereign's letters of denization; but by the act of 1844 an alien intending to reside and settle in Britain was enabled, by application to the Home Secretary, to obtain a certificate giving him all the rights of a natural-born subject, with certain exceptions. Naturalisation,

which is accompanied by political and other rights, privileges, and obligations, may now, under the act of 1870, be obtained by applying to the Home Secretary and producing evidence of having resided for not less than five years in the United Kingdom, or of having been in the service of the crown for not less than five years, and of intention to reside in the United Kingdom or serve under the crown. Such a certificate may be granted by the Secretary of State to one naturalised previously to the passing of the act, or to a British subject as to whose nationality a doubt exists, or to a statutory alien, *i.e.*, one who has become an alien by declaration in pursuance of the act 1870. The laws of a British colony with regard to naturalisation have effect only within the limits of that colony. Naturalisation is also effected by the operation of the law upon the acts of individuals, as a woman by marriage acquires the nationality of her husband. The naturalisation of a father carries with it that of his children in minority; and Felix holds that that of a widow has the same effect upon her minor children. (See Felix, *Traité de Droit Internat. Priv.*, l. i. t. 2, s. 2; Savigny, *Priv. Internat. Law*, translated by Guthrie, pp. 26, 31, 32; Phillimore's *Internat. Law*, vol. i.; Bar, *Das Internat. Privat und Strafrecht*, § 30; Gand, *Code des Etrangers*; Hansard on *Aliens*; Heffter, *Europ. Völkerrecht*, § 59 sqq.; Sir A. E. Cockburn on *Nationality*, Lond. 1869; Cutler on *Naturalisation*, Lond. 1871).

In the United States an alien desiring to be naturalised must declare on oath his intention to become a citizen of the United States; two years afterwards must declare on oath his intention to support the constitution of the United States and renounce allegiance to every foreign power, including that of which he was before a subject; must prove residence in the United States for five years, and in the state where his application is made for one year, as a good citizen; and must renounce any title of nobility. In France an alien desiring naturalisation must obtain permission to establish his domicile in France; three years after (in special cases one year) he is entitled to apply for naturalisation, which involves the renunciation of any existing allegiance. (See further, ALLEGIANCE; LAW OF NATIONS).

ALÍGARH, a district of British India, in the Meerut division, and under the jurisdiction of the Lieutenant-Governor of the North-West Provinces, lies between lat. 27° 29' and 28° 10' 30" N., and between long. 77° 32' 30" and 78° 42' 30" E. It contains an area of 1954 square miles, of which upwards of two-thirds, or 884,060 acres, are under cultivation. Population in 1865 returned at 925,538 souls, and by the census of 1872 ascertained to be 1,073,108. Aligarh is bounded on the N. by the Bulandshahr district and a portion of Budáon; on the E. by Etah district; on the S. by Mathurá district; and on the W. by Gurgáon and Mathurá districts. The district is nearly a level plain, but with a slight elevation in the centre, between the two great rivers, the Ganges and Jamná. The only other important river is the Kálí Nadí, which traverses the entire length of the district from north-west to south-east.

The civil station and principal town is Koel, situated a short distance to the south of Aligarh Fort. The chief products are wheat, barley, joár, bajrá, pulses, oil-seeds, gram, and indigo. There are no manufactures. In 1870-71 the total net revenue of the district was returned at £233,709, and the expenditure at £45,438; the land revenue in the same year amounted to £196,655, or 84 per cent. of the total net revenue. Nine towns are returned as containing a population of upwards of 5000 souls, as follows:—Koel, the civil station and principal city, population within municipal limits, 55,228; Hátrás, population, 33,100; Atraulí, population within municipal limits, 15,895; Sikandra Ráo, population within municipal limits, 11,988; Jaláli, population, 7516; Mursán, population, 6113; Topal, population, 6031; Bijaigarh, population,

5779; and Hardeoganj, population, 5202. There are five municipal towns in the district, the revenue raised being derived from octroi duties. The following was the municipal revenue and its incidence per head in 1871-72:—Koel (Aligarh), municipal revenue, £5467; incidence, 1s. 11½d. per head of the municipal population. Hátrás, municipal revenue, £5221, 16s.; incidence per head, 3s. 1½d. Sikandra Ráo, municipal income, £505, 12s.; incidence, 10d. per head. Atraulí, municipal income, £709; incidence, 10½d. per head. Hardeoganj, municipal income, £462, 18s.; incidence, 1s. 9½d. per head. In 1871-72, the district contained 370 schools, attended by a total of 7939 pupils, of whom 6766 were Hindus and 1173 Mahometans. For the protection of person and property, a regular police force is maintained, consisting of 1056 men of all grades, equal to one man to every 1·85 square mile of area, or one to every 1016 of the population. The Village Watch or rural police numbered 2000 in 1871, equal to one man to every 67 square miles, or one to every 536 inhabitants.

ALÍGARH FORT, in the district of the same name, is situated on the Grand Trunk Road, in lat. 27° 56' N., and long. 78° 8' E. The fort consists of a regular polygon, surrounded by a very broad and deep ditch. It was captured from the Marhattás under the leadership of Perron, a French officer, by Lord Lake's army, in September 1803, since which time it has been much strengthened and improved. In the rebellion of 1857 the troops stationed at Aligarh mutinied, but abstained from murdering their officers, who, with the other residents and ladies and children, succeeded in reaching Hátrás.

ALIMENT, in the *Law of Scotland*, is the sum paid or allowance given in respect of the reciprocal obligation of parents and children, husband and wife, grandparents and grandchildren, to contribute to each other's maintenance. The term is also used in regard to a similar obligation of other parties, as of creditors to imprisoned debtors, the payments by parishes to paupers, &c. Alimentary funds, whether of the kind above mentioned, or set apart as such by the deed of a testator, are intended for the mere support of the recipient, and are not attachable by creditors.

ALIMONY is, in *English Law*, the allowance for maintenance to which a wife is entitled out of her husband's estate on a decree, obtained at the wife's instance, for judicial separation or for the dissolution of the marriage. It is settled by the judge of the Divorce Court on a consideration of all the circumstances of the case.

ALISON, REV. ARCHIBALD, an author of great reputation in his own day, was born on the 13th November 1757 at Edinburgh, of which his father was for a time lord provost. After studying at the university of Glasgow and at Balliol college, Oxford, he took orders in the Church of England, and was appointed in 1778 to the curacy of Brancepeth, near Durham. In 1780 he married Dorothea, youngest daughter of Professor Gregory of Edinburgh. The next twenty years of his life were spent in Shropshire, where he held in succession the livings of High Erall, Roddington, and Kenley. In 1800 he removed to Edinburgh, having been appointed senior incumbent of St Paul's chapel in the Cowgate. For thirty-four years he filled this position with great acceptance, his preaching attracting so many hearers that a new and larger church was built for him. His last years were spent at Colinton, near Edinburgh, where he died on the 17th May 1839. Mr Alison published, besides a Life of Lord Woodhouselee, a volume of sermons, which passed through several editions, and a work entitled *Essays on the Nature and Principles of Taste*, which received a very laudatory criticism from Lord Jeffrey in the *Edinburgh Review* for May 1811. His theory of the beautiful, which is based on the principle of association, is incomplete and unsatisfactory, and his work is now only of historical importance. Two sons of Mr Alison attained distinction. The elder, Dr William Pulteney Alison, born in 1790, was from 1820 until within a few years of his death, in 1859, a prominent member of the medical faculty in the university

of Edinburgh. The younger son is the subject of the following notice.

ALISON, SIR ARCHIBALD, Bart., the celebrated historian, younger son of the preceding, was born at Kenley, Shropshire, on the 29th December 1792. He studied at the university of Edinburgh, distinguishing himself especially in the classes of Greek and mathematics. In 1814 he passed at the Scotch bar, but he did not at once enter on the regular practice of his profession. The close of the war had opened up the Continent, and Alison, sharing with many of his countrymen the desire to witness the scene of the stirring events of the previous twenty years, set out in the autumn of 1814 for a lengthened tour in France. It was during this period, as he tells us in a characteristic passage of the work itself, that he "conceived the first idea" of writing his History, and "inhaled that ardent spirit, that deep enthusiasm," which enabled him to accomplish his self-imposed task. A more immediate result of the tour was his first literary work of any importance, *Travels in France during the Years 1814-15*, which appeared in the latter year. On his return to Edinburgh, Mr Alison practised at the bar for some years with but very moderate success. In 1822, however, he became one of the four advocates-depute for Scotland. The extensive and varied experience gained in this office, which he held until 1830, gave him the necessary qualifications for writing his *Principles of the Criminal Law of Scotland* (1832), and *Practice of the Criminal Law of Scotland* (1833), works that are still of standard authority. It was the acknowledged merit of these treatises that chiefly induced Sir Robert Peel, during his brief administration of 1834, to confer on Mr Alison the important judicial office of sheriff of Lanarkshire, which ranks next in dignity and emolument to a judgeship in the supreme court. The office, though by no means a sinecure, afforded considerable leisure, which Mr Alison employed in not only making frequent contributions to periodical literature, but also writing the long-projected *History of Europe*, for which he had been collecting materials for more than fifteen years. The history of the period from the commencement of the French revolution till the restoration of the Bourbons in 1815 was completed in ten volumes in 1842, and met with a success almost unexampled in works of its class. Within a few years it ran through ten editions, and was translated into most of the languages of Europe, as well as into Arabic and Hindustani. At the time of the author's death it was stated that 108,000 volumes of the library edition and 439,000 volumes of the popular edition had been sold. A popularity so wide-spread must almost of necessity have had some basis of real merit on which to rest, and the good qualities of Mr Alison's work lay upon the surface. It brought together, though not always in a well-arranged form, an immense amount of information that had before been practically inaccessible to the general public. It made an attempt at least to show the organic connection in the policy and progress of the different nations of Europe; and its descriptions of what may be called external history—of battles, sieges, and state pageants—were always spirited and interesting. On the other hand, the faults of the work were so numerous and glaring as to prevent it from ever taking rank as a classic. The general style was prolix, involved, and vicious; inaccurate statements and fallacious arguments were to be found in almost every page; and the constant repetition of trite moral reflections and egotistical references seriously detracted from its dignity. A more grave defect resulted from the author's strong political partisanship, which entirely unfitted him for dealing with the problems of history in a philosophical spirit. In the position of unbending Toryism which he occupied, it was impossible for him to give any

explanation of so complex a fact as the French revolution that would be satisfactory to reflective minds. Accordingly, his treatment of what may be called the inner history of those forces hidden in the French revolution which have made modern Europe what it is, was meagre and incomplete in the last degree.

A continuation of the History, embracing the period from 1815 to 1852, which was completed in four volumes in 1856, did not meet with the same success as the earlier work. The course of events did not afford the same material for the exercise of the author's powers of description, and the period being so near as to be almost contemporary, there was a stronger temptation, which he seems to have found it impossible to resist, to yield to political prejudice. Three great measures of English legislation—the Act restricting the paper currency, the Reform Act of 1832, and the Act abolishing the corn laws—were the object of his special aversion; and, with little regard for consistency, he was in the habit of tracing, now to one and now to another of these measures, all the real and many imaginary evils in the state of the nation. On the currency question, in regard to which he stood from the first almost alone in opinion, he has inserted several tedious dissertations in the continuation of his History, besides publishing a separate pamphlet in 1847. On the two other great measures he clung tenaciously to his opinion long after the more intelligent of his party had admitted the necessity, if not the justice, of the concessions that had been made. The use which Mr Alison made of statistics in the continuation of his History to support his peculiar political and economic theories was little short of astounding. He will be acquitted of intentional unfairness only by those who are aware, not merely how easy it is to make figures yield any result that may be wished, but also how difficult it is to bring out the correct result, even with the most honest purpose, unless there be special aptitude and special training on the part of the investigator.

Mr Alison's successful literary career received from time to time due recognition in the form of public honours. In 1845 he was chosen rector of Marischal College, Aberdeen, and in 1851 he was raised to the same honourable position by the students of Glasgow University. In 1852 the dignity of baronet was conferred upon him by Lord Derby, and in the following year he was made a D.C.L. of Oxford. His literary activity continued till within a short time of his death, the chief works he published in addition to his History being the *Principles of Population* (1840), in answer to Malthus; a *Life of Marlborough* (1847); and the *Lives of Lord Castlereagh and Sir C. Stewart* (1861). Three volumes of his political, historical, and miscellaneous essays were reprinted in 1850. Sir Archibald died at Possil House, Glasgow, on the 23d May 1867.

ALIZARIN, the principal colouring matter of madder, may be obtained by subliming on paper an alcoholic extract of madder, or by exhausting the root with water, precipitating with sulphuric acid, dissolving the moist precipitate in a solution of chloride of alumina, and separating the impure alizarin by the addition of hydrochloric acid. The impure alizarin is dissolved in alcohol, and separated as a lake on treating with hydrate of alumina, which is now boiled with carbonate of soda to separate another colouring matter called purpurin, and is finally treated with hydrochloric acid, which dissolves the alumina and leaves the pure substance.

Alizarin in the anhydrous state forms red prisms, and in the hydrated condition crystals like mosaic gold. It dissolves sparingly in water even at the boiling point, but is soluble in alcohol or ether. Mineral acids do not decompose the colouring matter at ordinary temperatures. Caustic alkalis or alkaline carbonates dissolve alizarin.

forming deep purple solutions, from which acids precipitate in orange-coloured flakes. Alizarin has the atomic composition  $C_{14}H_8O_4$ , and has recently been made synthetically from the hydrocarbon  $C_{14}H_{10}$  called anthracene, which occurs among the products of the destructive distillation of coal. This is the first example of the artificial formation of a natural colouring matter. For further details see CHEMISTRY.

ALKALI, a term originally applied to the ashes of plants, now employed in inorganic chemistry as a generic name given to the group of compounds that have the property of neutralising acids. The use of the term is, however, generally confined to such members of the group as are soluble in water. The most soluble alkaline bodies are the oxides of potassium (potash), sodium (soda), lithium (lithia), and ammonium (aqueous ammonia); and next in order the oxides of calcium (lime), barium (baryta), and strontium (strontia). The solutions of these bodies exert a caustic or corrosive action on vegetable and animal substances, and precipitate the oxides of the heavy metals from solutions of their salts. Many vegetable colouring matters are changed in tint by alkaline solutions—for instance, reddened litmus becomes blue, yellow turmeric brown, and syrup of violets and infusions of red cabbage green.

ALKALOIDS, the name of a group of organic bodies that possess alkaline properties. They are characterised by the property of combining with acids to form salts, and many have the power of giving an alkaline reaction with vegetable colours. All the natural alkaloids contain nitrogen as an essential constituent, and they are especially marked by possessing great medicinal power. Many artificial alkaloids have been made of recent years in which phosphorus, arsenic, and antimony occupy the place of nitrogen. For the individual properties, tests, &c., of different alkaloids, see CHEMISTRY.

ALKANET (*Alkanna tinctoria*, or *Anchusa tinctoria*), a plant of the order *Boraginaceae*, indigenous to the south of France and the shores of the Levant. It is extensively cultivated on the Continent for the sake of the root, which yields a fine colouring matter, imparting a beautiful carmine tint to oils, wines, wax, and all unctuous substances. Being perfectly harmless, alkanet is much used for colouring in pharmacy. Some of the mixtures styled port wine owe their colour to this dye, and it is also employed in staining furniture.

AL-KINDI, ABU YUSUF, &c., styled by pre-eminence "The Philosopher of the Arabs," flourished during the first half of the 10th century, and died at some unknown date posterior to 961. His literary activity was encyclopædic, and spread itself over all the sciences. The titles of his works number nearly 200 in the catalogue of Casiri, and amount to 265 in that of Flügel; but the latter appears in some cases to have enumerated the same works under two divisions, and it is doubtful whether the philosopher has not been confounded with another writer of the same name. His treatises are arranged under the following heads, which throw some light on his classification of the sciences:—Philosophy in general, logic, politics, ethics, arithmetic (under which he discusses the unity of God), spherology, theory of music (which was closely connected with all primitive speculation from its religious character), astronomy, meteorology, geometry, cosmology (the form, &c., of the heavens), astrology, medicine, and on various arts, besides his commentaries and controversial writings. Of all these, none except some treatises on medicine and astrology remain. Others of them must have been known in the Middle Ages, for Al-Kindi is placed by Roger Bacon, along with Alhazen, in the first rank after Ptolemy as a writer on perspective (optics). Some of them were certainly translated by Gerard of Cremona. Whatever his influence may have been

on the Schoolmen, he was undoubtedly a great initiator as regards his countrymen. He was one of the earliest translators and commentators of Aristotle, but he appears to have been, like Al-Farabi, superseded by Avicenna. He marks the first philosophic revolt against Islamism, and his doctrine on the simplicity and unity of the Deity was apparently equally Aristotelian and un-Mahometan. See Flügel, *Abhandlungen für die Kunde des Morgenlandes*, erster Band, 1859.)

ALKMAAR, a town of the Netherlands, in the province of North Holland, situated on the Helder canal and on the railway between Haarlem and the Helder, about 20 miles N.N.W. of Amsterdam. The streets of Alkmaar are extremely neat and regular, and are intersected by canals lined with trees, while the ramparts of the town have been converted into beautiful boulevards. Many of the public buildings are elegant, especially the church of St Lawrence, a Gothic edifice of the 15th century. Alkmaar is the seat of a court of primary jurisdiction and of a tribunal of commerce, and possesses good schools as well as several literary and scientific societies. Its principal article of commerce is cheese, for which it is said to be the chief market in the kingdom, if not in the world. Besides cheese, it has a good trade in butter, corn, and cattle, and manufactures of salt, sailcloth, soap, vinegar, and leather. Alkmaar successfully sustained a siege by the Duke of Alba in 1573, and in 1799 gave its name to a convention signed by the Duke of York and the French general Brune, in accordance with which the Russo-British army evacuated Holland. Population, 12,000.

ALKMAAR, HEINRIK VON, the German translator of the celebrated satirical poem *Reineke de Vos*, flourished in the latter half of the 15th century. In the preface to his work, which is the only source of information as to his life, he states that he was tutor to the Duke of Lorraine, and that he translated the poem from the Welsh. In spite of the latter statement, many have attributed the authorship to him; but it is now known that the story had a much earlier origin. Some have supposed the name Alkmaar to be a pseudonym.

ALL-SAINTS DAY, ALL-HALLOWS, or HALLOWMAS, a festival, first instituted about 610 A.D., on the 1st of May, in memory of the martyrs, and celebrated since 834 on the 1st of November, as a general commemoration of all the saints. As the number of saints increased, it became impossible to dedicate a feast-day to each. Hence it was found expedient to have an annual aggregate commemoration of such as had not special days for themselves. The festival is common to the Roman Catholic, English, and Lutheran churches. See BELTANE.

ALLAH, the Arabic name for the one true God which is employed in the Koran, and has been adopted into the language of all Mahometan nations. It is compounded of *al*, the definite article, and *ilah*, meaning *worthy to be adored*. See MAHOMETANISM.

ALLAHÁBÁD, a division, district, and city of British India, under the jurisdiction of the lieutenant-governor of the North-Western Provinces. The ALLAHÁBAD DIVISION comprises the six districts of Allahábád, Cawnpur, Fathipur, Hamírpur, Bándá, and Jaunpur. It is bounded on the north and east by the Etáwah and Farrakhábád districts and the province of Oudh; on the south by the Benares division and the Rewah state; and on the west by the states of Bandelkhand and the Jhánsí division. Total population (1872), 5,466,116.

ALLAHÁBÁD DISTRICT lies between  $24^{\circ} 49'$  and  $25^{\circ} 44'$  N. lat., and between  $81^{\circ} 14'$  and  $82^{\circ} 26'$  E. long. In shape the district is that of an irregular oblong; and it is difficult accurately to describe its boundaries, as at one extremity it wanders into Oudh, while on the south the villages

of the state of Rewah and those of this district are hopelessly intermingled. Roughly speaking, however, the boundaries may be described as follows:—On the north by the district of Jaunpur and by the Ganges; on the west by the districts of Fathipur and Bándá; on the south by the independent state of Rewah; and on the east by the districts of Mirzápúr and Jaunpur. The settlement of the district is at present undergoing revision; and as the measurements are still incomplete, it is impossible to state the exact area. For practical purposes, it may be estimated at 2802 square miles, or 1,793,906 acres, of which 1,065,990 acres are cultivated, and 727,916 acres are uncultivated; of this latter, however, there are about 250,000 acres capable of being brought under tillage, although not actually cultivated. The census of 1872 returned the population of the district at 1,394,245 souls, of whom 1,211,778 are Hindus, 181,574 Mussulmans, and 893 Christians. There is, however, a manifest error in these figures, as the European and Eurasian population of Allahábád city alone cannot be set at a lower figure than 3500. The census returns are in consequence undergoing revision. Of the Hindu population, 173,916 are returned as Bráhmans.

The Jamná and the Ganges meet at Allahábád city, and enclose within their angle a fertile tract, well irrigated by means of tanks and wells. The East Indian Railway and the Grand Trunk road afford the principal means of land communication. The former enters the district from the east, crosses the Jamná at Allahábád city, and travels westward, leaving the district near Khágá station. The Grand Trunk road enters Allahábád from the north-east, meets the railway at Allahábád city, and thence runs almost parallel with it till it leaves the district. Only three towns are returned as containing a population of over 5000 souls—viz., Allahábád, population 144,464; Manaimá, population 6146; and Chizwá, population 5791. Rice is the principal crop, the area under it being returned at 139,000 acres, and the average produce at 5½ cwt. per acre. A little more than half of the total rice crop is retained for local consumption, and the remainder exported. The average price of common rice in February 1873 was 6s. 9d. per cwt. Pulses are also grown in large quantities, the area under the various sorts being about the same as rice, and the yield also about the same. Joár and bajrá cover as large an area as either rice or pulses, but the yield is neither so large nor of such value. About half the crop is said to be annually exported. Wheat is cultivated to the extent of about 150,000 cwt. per annum, of which about one-half is exported; the average yield is said to be about 6½ cwt. per acre, and the average price from 6s. 2d. to 6s. 9d. per cwt. Mustard, tobacco, opium, linseed, and indigo are also cultivated largely, with cotton and sugar-cane in small quantities. Indigo stands first among the manufactures of the district, and large factories exist at Alamchánd, Saráí Salem, Gadúpur, Kansaridh, Thardái, and Dum-duma. These are generally under the supervision of European managers, and the produce is forwarded direct to the Calcutta market. Next to indigo, the most important industry is stone-cutting. The stone is chiefly quarried from a low range of hills near Shiorápur, whence it is carried in country carts to the Jamná river; and after crossing it in flat-bottomed boats, it is finally landed at Balwá Ghát. Here the stone-masons take it in hand. The gross income of the Balwá Ghát stone traders is estimated at £2000 per annum. A brisk trade is also carried on in hides, the principal mart being the village of Karwá, in Aráíl fiscal division, where it is estimated that the sale of skins amounts to upwards of £10,000 per annum for the Mirzápúr and Calcutta hide markets. Paper is manufactured in the fiscal division of Karrá, and a considerable quantity exported to Oudh. Several villages in the fiscal divisions of Karrá and Chail are noted for the manufacture of brass and copper vessels; and iron vessels are largely manufactured in Khairágarh, Karrá, and Phulpur. The East India Railway Company have a large castor-oil manufactory at the village of Manauri. The total net revenue of the district in 1871-72 is returned at £244,537, and the total net civil expenditure at £51,770. The district passed into the hands of the English in 1801, by a treaty between the Vazír of Oudh and the East India Company.

ALLAHÁBÁD CITY, the capital of the North-Western Provinces, is also the administrative headquarters of the Allahábád division and of the district of the same name. It is situated at the confluence of the Ganges and Jamná rivers, in 25° 26' N. lat., and 81° 55' E. long. Its most conspicuous feature is the fort, which rises directly from the banks of the confluent rivers, and com-

pletely commands the navigation of both streams. Within the fort are the remains of a splendid palace, erected by the Emperor Akbar, and once a favourite residence of his. A great portion of it has been destroyed, and its hall is converted into an arsenal. Outside the fort, the places most of importance are the Saráí and garden of Khasrú, the son of the Emperor Jahángír, and the Jumá Masjid, or great mosque. When the town first came into the hands of the English this mosque was used as a residence by the military officer commanding the station, and afterwards as an assembly-room. Ultimately it was returned to its former owners, but the Mahometans considered it desecrated, and it has never since been used as a place of worship. Allahábád is one of the most noted resorts of Hindu pilgrimage. It owes its sanctity to its being the reputed confluence of three sacred streams—the Ganges, the Jamná, and the Saraswatí. This last stream, however, is not visible. It leaves the Himálayas to the west of the Jamná, passes close to Tháneswar in the Panjáb, and loses itself in the sands of Sirhind, 400 miles north-west of Allahábád. The Hindus, however, assert that the stream joins the other two rivers under ground, and in a subterranean temple below the fort a little moisture trickling from the rocky walls is pointed out as the waters of the Saraswatí. An annual fair is held at Allahábád, at the confluence of the streams, on the occasion of the great bathing festival, at the full moon of the Hindu month of Mágh. Allahábád was taken by the British, in the year 1765, from the Vazír of Oudh, and assigned as a residence for Sháh Alam, the titular Emperor of Dehli. Upon that prince throwing himself into the hands of the Marhattas, the place was resumed by us in 1771, and again transferred to the Nawáb of Oudh, by whom it was finally ceded, together with the district, to the British in 1801, in commutation of the subsidy which the Vazír had agreed to pay for British protection. The population and trade of Allahábád city have rapidly increased of late years. According to the census of 1853, the city and suburbs contained 72,098 inhabitants. Before 1872 the population had exactly doubled, the census returns for that year exhibiting a total population of 144,464. The municipal income and expenditure of Allahábád city in 1871-72 were as follows:—Income—Octroi duties, £13,676, 14s.; tax on professions, £220, 10s.; carriage tax, £1264, 4s.; proceeds of the Hindu fair and ground rents, £5364; total municipal income, £20,525, 8s.; incidence of taxation, 2s. 11d. per head of the population. Expenditure—Establishment, including cost of collection, police, conservancy, and lighting, £9906, 4s.; streetwatering, £1002, 12s.; new works, £7677, 16s.; repairs, £1088, 2s.; vaccination, £20; dispensary, £330; charities, £250; Alfred Park, £800; other items, £223, 2s.: total, £21,297, 16s. Allahábád forms the junction of the great railway system which unites Bengal with Central India and Bombay, and it is rapidly developing into a great centre of inland and export trade.

ALLAMAND, JEAN NICOLAS SEBASTIAN, natural philosopher, born at Lausanne in 1713, was educated for the church, and held for a short time a clerical appointment at Leyden. Here he enjoyed the patronage and friendship of the celebrated S'Gravesende, who made him his literary executor. In 1747 he was appointed professor of philosophy and natural history at Franeker, and two years later he was transferred to a similar chair at Leyden, which he occupied until his death in 1787. Allamand's chief service to science consisted in translating and editing the scientific works of others, but he also made some original discoveries of importance, especially in connection with electricity. He was the first to explain fully the phenomena of the Leyden jar, and he made a near approach to the discovery of negative electricity. He greatly enriched

the botanical garden and natural history museum at Leyden by specimens from all quarters of the globe. His translation of Buffon's works was published at Amsterdam, in thirty-eight quarto volumes, between 1766 and 1779. Allamand was a member of the Royal Society of London and of the Academy of Sciences at Haarlem.

ALLAN, DAVID, a Scottish historical painter of considerable celebrity, was born at Alloa on the 13th February 1744. At a very early age he gave such proofs of natural artistic talent as led to his being placed under the care of the Messrs Foulis, who some time before had instituted an academy in Glasgow for painting and engraving. On leaving the academy (1762), after seven years' successful study, he obtained the patronage of Lord Cathcart and of Erskine of Mar, on whose estate he had been born. The latter furnished him with the means of proceeding to Rome (1764), where he remained for a number of years engaged principally in copying the old masters. Among the original works which he then painted was the "Origin of Portraiture"—representing a Corinthian maid drawing her lover's shadow—well known through Cunego's excellent engraving. This gained for him the gold medal given by the Academy of St Luke in the year 1773 for the best specimen of historical composition. Returning from Rome in 1777, he resided for a time in London, and occupied himself in portrait-painting. In 1780 he removed to Edinburgh, where, on the death of Alexander Runciman in 1786, he was appointed director and master of the Academy of Arts. There he painted and etched in aquatint a variety of works, those by which he is best known—as the *Scotch Wedding*, the *Highland Dance*, the *Repentance Stool*, and his *Illustrations of the Gentle Shepherd*—being remarkable for their comic humour. He has had frequently applied to him the name of the "Scottish Hogarth;" but his drolleries are not to be compared for a moment with the productions of the great English satirist. Allan died at Edinburgh on the 6th August 1796.

ALLAN, SIR WILLIAM, R.A., and president of the Royal Scottish Academy, was born at Edinburgh in 1782. At an early age he was entered as a pupil in the School of Design established in Edinburgh by the Board of Trustees for Arts and Manufactures, where he had as companions, Wilkie, Burnet the engraver, and others who afterwards distinguished themselves as artists. Here Allan and Wilkie were placed at the same table, studied the same designs, and contracted a friendship which terminated only with their lives. Leaving the Edinburgh school, Allan prosecuted his studies for some time in London; but his attempt to establish himself there was unsuccessful, and after exhibiting at the Royal Academy (1805) his first picture, *A Gipsy Boy and Ass*, an imitation in style of Opie, he determined, in spite of his scanty resources, to seek his fortune abroad. He accordingly set out the same year for Russia, but was carried by stress of weather to Memel, where he remained for some time, supporting himself by his pencil. At last, however, he reached St Petersburg, where the kindness of Sir Alexander Crichton, the court physician, and other friends procured him abundant employment. The emoluments of his profession enabled him by and by to make excursions into southern Russia, Turkey, the Crimea, and Circassia, where he filled his portfolio with vivid sketches, of which he made admirable use in his subsequent pictures. In 1814 he returned to Edinburgh, and in the two following years exhibited at the Royal Academy *The Circassian Captives* and *Bashkirs conducting Convicts to Siberia*. The former composition, which united graceful forms and powerful expression with novel and picturesque costumes, established his reputation as a master in the highest walk of art; but the picture remained so long unsold in the studio of the artist, that, thoroughly disheartened, he threatened to retire to Circassia

when, through the kindness of Sir Walter Scott, a subscription of 1000 guineas was obtained for the picture, which fell by lot into the possession of the Earl of Wemyss. About the same time the Grand Duke Nicholas, afterwards emperor of Russia, visited Edinburgh, and purchased his *Siberian Exiles* and *Haslan Gheray crossing the River Kuban*, giving a very favourable turn to the fortunes of the painter, whose pictures were now sought for by collectors. From this time to 1834 we find him pursuing his art in the sphere in which he achieved his greatest success and firmly established his fame, the illustration of Scottish history. His most important works of this class were *Archbishop Sharpe on Magus Moor*; *John Knox admonishing Mary Queen of Scots* (1823), engraved by Burnet; *Mary Queen of Scots signing her Abdication* (1824); and *Regent Murray shot by Hamilton of Bothwellhaugh*. The last procured his election as an associate of the Royal Academy (1825). Later Scottish subjects were *Lord Byron* (1831), portraits of Scott, and *The Orphan* (1834), which represented Anne Scott seated near the chair of her deceased father. In 1830 he was compelled, on account of an attack of ophthalmia, to seek a milder climate, and visited Rome, Naples, and Constantinople. He returned with a rich store of materials, of which he made excellent use in his *Constantinople Slave Market* and other productions. In 1834 he visited Spain and Morocco, and in 1841 went again to St Petersburg, when he undertook, at the request of the Czar, his *Peter the Great teaching his Subjects the Art of Shipbuilding*, exhibited in London in 1845, and now in the Winter Palace of St Petersburg. His *Polish Exiles* and *Moorish Love-letter*, &c., had secured his election as a Royal Academician in 1835; he was appointed president of the Royal Scottish Academy (1838), and limner to Her Majesty for Scotland, after Wilkie's death (1841); and in 1842 received the honour of knighthood. His later years were occupied with battle-pieces, the last he finished being the second of his two companion pictures of the *Battle of Waterloo*. He died on the 22d February 1850, leaving a large picture unfinished—*Bruce at Bannockburn*—which exhibits no traces of impaired power.

ALLEGHANY, ALLEGHENY, or ALLEGANY MOUNTAINS, is the name often given to the Appalachian Mountains in the United States. A more exact use of the name restricts it to the portion of the system that lies west of the Hudson river, and forms the watershed of the Mississippi basin on the south-east. See APPALACHIAN MOUNTAINS.

ALLEGHANY, a river of the United States, which rises in the north of Pennsylvania, and after flowing about 300 miles, first in a northerly, but for the greater part of its course in a westerly direction, during which it passes for a short distance into the state of New York, unites with the Monongahela at Pittsburg to form the Ohio. The country through which it flows is mostly hilly, and large numbers of pines, white oaks, and chestnuts grow upon its banks. It is navigable for small steamers for about 200 miles above Pittsburg.

ALLEGHENY, a large suburb of PITTSBURG (*q.v.*) In 1870 it contained 53,180 inhabitants.

ALLEGIANCE, either derived from the French *allegiance* or taken from the same Latin source, has been used to express that duty which a person possessing the privileges of a citizen owes to the state to which he belongs, and is technically applied in law to the duty which a British subject owes to the sovereign as representing the state. It has been divided by the English legal commentators into natural and local; the latter applying only to the deference which a foreigner must pay to the institutions of the country in which he happens to live; but it is in its wider sense that the word is important, as representing a condition attached to mankind of which it is

very difficult in theory, and still more in practice, to adjust the true character and limits. For a state to decide what persons are bound to it by allegiance may be easy, but for a man to know where his allegiance lies when two or more states claim him—and hence for jurists to decide what is the reasonable extent to which any state ought to make such a claim—is often involved in difficulty. The English doctrine, which was also adopted in the United States, asserted that allegiance was indelible. *Nemo potest exuere patriam* (Forsyth's *Cases and Opinions in Constitutional Law*, pp. 257, *sqq.*, 333, *sq.*) Accordingly, as the law stood before 1870, every person born within the British dominions, though he should be removed in infancy to another country where his family resides, owes an allegiance to the British crown which he could never resign or lose, except by Act of Parliament or by the recognition of the independence or the cession of the portion of British territory in which he resided. By the Naturalisation Act, 1870, 33 & 34 Vict. c. 14 (see ALIEN), it was made possible for British subjects to renounce their nationality and allegiance, and the ways in which that nationality is lost are defined. So British subjects voluntarily naturalised in a foreign state are deemed aliens from the time of such naturalisation, unless, in the case of persons naturalised before the passing of the Act, they have declared their desire to remain British subjects within two years from the passing of the Act. Persons who, from having been born within British territory are British subjects, but who at birth became under the law of any foreign state subjects of such state, and also persons who, though born abroad are British subjects by reason of parentage, may by declarations of alienage get rid of British nationality.

ALLEGIANCE, *Oath of*, an oath of fidelity to the sovereign taken by all persons holding public office. By ancient common law it might be required of all persons above the age of twelve, and it has repeatedly been used as a test for the disqualified. It was first imposed by statute in the reign of Elizabeth (I. c. 1), and its form has more than once been altered since. Up to the time of the Revolution the promise was "to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb and terrene honour, and not to know or hear of any ill or damage intended him without defending him therefrom." This was thought to favour the doctrine of absolute non-resistance, and accordingly the Convention Parliament enacted the form that has been in use since that time—"I do sincerely promise and swear that I will be faithful and bear true allegiance to Her Majesty Queen Victoria." These words are included in the form prescribed by 21 & 22 Vict. c. 48, which substitutes one oath for the oaths of allegiance, supremacy, and abjuration.

ALLEGORY (*ἄλλος*, other, and *ἀγορεύω*, to speak), a figurative representation conveying a meaning *other* than and in addition to the literal. It is generally treated as a figure of rhetoric, but the medium of representation is not necessarily language. An allegory may be addressed to the eye, and is often embodied in painting, sculpture, or some form of mimetic art. The etymological meaning of the word is wider than that which it bears in actual use. An allegory is distinguished from a metaphor by being longer sustained and more fully carried out in its details, and from an analogy by the fact that the one appeals to the imagination and the other to the reason. The fable or parable is a short allegory with one definite moral. The allegory has been a favourite form in the literature of nearly every nation. The Hebrew scriptures present frequent instances of it, one of the most beautiful being the comparison of the history of Israel to the growth of a vine, in the 80th psalm. In classical literature one of the best known allegories is the

story of the stomach and its members in the speech of Menenius Agrippa (Livy, ii. 32); and several occur in Ovid's *Metamorphoses*. Perhaps the most elaborate and the most successful specimens of allegory are to be found in the works of English authors. Spencer's *Faerie Queene*, Swift's *Tale of a Tub*, Addison's *Vision of Mirza*, and, above all, Bunyan's *Pilgrim's Progress*, are examples that it would be impossible to match in elaboration, beauty, and fitness, from the literature of any other nation.

ALLEGRI, ANTONIO. See CORREGGIO.

ALLEGRI, GREGORIO, musical composer, probably of the Correggio family, was born at Rome about 1580. He studied music under Nanini, the intimate friend of Palestrina. Being intended for the church, he obtained a benefice in the cathedral of Fermo. Here he composed a large number of motetts and sacred pieces, which, being brought under the notice of Pope Urban VIII., obtained for him an appointment in the choir of the Sistine chapel at Rome. He held this from Dec. 1629 till his death on the 18th Feb. 1652. His character seems to have been singularly pure and benevolent. Among the musical compositions of Allegri were two volumes of Concerti, published in 1618 and 1619; two volumes of Motetts, published in 1620 and 1621; besides a number of works still in manuscript. He was one of the earliest composers for stringed instruments, and Kircher has given one specimen of this class of his works in the *Musurgia*. But the most celebrated composition of Allegri is the *Miserere*, still annually performed in the Sistine chapel at Rome. It is written for two choirs, the one of five and the other of four voices, and has obtained a celebrity which, if not entirely factitious, is certainly not due to its intrinsic merits alone. The mystery in which the composition was long enshrouded, no single copy being allowed to reach the public, the place and circumstances of the performance, and the added embellishments of the singers, account to a great degree for much of the impressive effect of which all who have heard the music speak. This view is confirmed by the fact, that when the music was performed at Venice by permission of the pope, it produced so little effect that the Emperor Leopold I., at whose request the manuscript had been sent, thought that something else had been substituted. In spite of the precautions of the popes, the *Miserere* has long been public property. In 1769 Mozart was able to write it down after hearing it twice; and in 1771 a copy was procured and published in England by Dr Burney. The entire music performed at Rome in Holy Week, Allegri's *Miserere* included, has been issued at Leipsic by Breitkopf and Härtel. Interesting accounts of the impression produced by the performance at Rome may be found in the first volume of Mendelssohn's letters, and in Miss Taylor's *Letters from Italy*.

ALLEINE, JOSEPH, Nonconformist divine, the author of *An Alarm to the Unconverted*—a book which remains as potential as when first modestly sent forth, scarcely second to Richard Baxter's *Call to the Unconverted*—was otherwise noticeable. Baxter himself wrote a characteristic introduction to his Life fully two centuries ago (1672); while recently (1861) the Rev. Charles Stanford has retold his story and the story of his age with great fulness of knowledge and historical fidelity. The Alleine came out of Suffolk, and as early as 1430 some of them—sprung of Alan, lord of Buckenhall—settled in the neighbourhood of Calne and Devizes, whence descended the immediate ancestors of "worthy Mr Tobie Alleine of Devizes," father of our worthy. Joseph Alleine, fourth of a large family, was born at Devizes early in 1634. 1645 is marked in the title-page of a quaint old tractate, by an eye-witness, as his "*setting forth in the Christian race*." His eldest brother Edward had been a clergyman, but in this year died, in his twenty-

seventh year ; and Joseph entreated his father that he might be educated to succeed his brother in the work of the ministry. His father consented, and he was immediately sent to Poulshot, then under a fellow of Exeter College, Oxford (William Spinage). In April 1649 he set out for Lincoln College, Oxford, in the presidency of Dr Paul Hood, with Dr John Owen as the vice-chancellor of the university. A Wiltshire place becoming vacant in Corpus Christi College, on the 3d Nov. 1651 he was chosen scholar of that house. Of his student life it was written contemporaneously, "*He could toil terribly.*" On 6th July 1653 he took the degree of B.D., and thereupon became a tutor of his college. He became also chaplain of Corpus Christi, preferring this to a fellowship. In 1654 he had offers of high preferment in the state, which he declined. The succeeding year (1655) brought him another offer, which he did not decline. George Newton, of the great church of St Mary Magdalene, Taunton, sought him for assistant ; and putting from him all other things, even forsaking further academical honours within his immediate grasp, he accepted the invitation by proceeding at once to Taunton, undergoing the accustomed probation, and at last being ordained as the associate of one of the most venerable of the later Puritan fathers. The ministry that resulted stands out lustrous and noble in the history of historical Taunton, and in the Life of the junior pastor, as told by Baxter and Stanford. Almost coincident with ordination came the marriage of the associate-pastor with Theodosia Alleine, daughter of Richard Alleine. Friendships among "gentle and simple"—of the former, with Lady Farewell, grand-daughter of Protector Somerset—bear witness to the attraction of Alleine's private life. His public life—in preaching after the intense, awakening, wistful type ; in catechising with all diligence and fidelity ; in visitation among the poor and mean and sad ; in letter-writing, tender and sympathetic ; in devotional intercession through long consecrated hours of day and night—was a model of pastoral devotion. This is all the more remarkable as the pastor continued the student-toil of Corpus Christi, one monument of which was his *Theologia Philosophica*, a lost MS., establishing the harmony between revelation and nature, and whose learning—classical, patristic, and recondite—drew forth the wonder of Baxter. Alleine was no mere scholar or divine, but a man who associated on equal terms with the patriarchs of the Royal Society, then laying those broad and deep foundations on which rests England's present scientific renown. These scientific studies and experiments, nevertheless, were ever kept in subordination to his proper work. The extent of his influence was, in so young a man, unique, resting fundamentally on the earnestness of his nature and the manifest power of his ministry. The year 1662 found senior and junior pastors like-minded, and both were of the Two Thousand. Alleine, when the Ejection blow fell, with John Wesley (grandfather of the celebrated John Wesley) for fellow-labourer, also ejected, carried on a kind of itineracy wherever opportunity was found for preaching the gospel. For this he was cast into prison, indicted at sessions, and suffered as hundreds of England's noblest men have suffered. His *Letters from Prison* were an earlier *Cardiphonia*. He was released on 26th May 1664 ; and spite of the Conventicle Act (Five Mile Act), he returned to his beloved work as a preacher of the gospel. He found himself again in prison, and again and again a sufferer. Tempestuous and troubled were his remaining years. Now in hiding, now in great bodily weakness, now coming to the front in some act of charity or patriotism, now at the waters of Bath, slowly but serenely wearing out. He died November 17, 1668 ; and the mourners, remember-

ing their beloved minister's words while yet with them, "If I should die fifty miles away, let me be buried at Taunton," found a grave for him in St Mary's chancel. Pilgrims from over the sea read with dim eyes the brief Latin inscription on his stone. No Puritan-Nonconformist name is so affectionately cherished as is that of Joseph Alleine. "Being dead he yet speaketh" through his imperishable practical books. (*Life*, edited by Baxter ; *Joseph Alleine: his Companions and Times*, by Charles Stanford, 1861 ; *Wood's Athence* ; *Palmer's Nonc. Mem., s.v.* ; *Harleian MSS.*, and *Williams MSS.*) (A. B. G.)

ALLEINE, RICHARD, M.A., author of *Vindicia Pietatis*, was educated at St Albans Hall, Oxford, where Anthony à Wood states he was entered commoner in 1627, aged sixteen ; and where, having taken the degree of B.A., he transferred himself to New Inn, and continued there until he proceeded M.A. He and the like-minded William Alleine were sons of Richard Alleine, rector for upwards of fifty years of Dichey, Somerset. The younger Richard being ordained, became assistant to his venerable father, and immediately stirred the entire county by his burning eloquence. In March 1641 he succeeded to many-sided Richard Bernard as rector of Batcomb (Somerset). He declared himself on the side of the Puritans by subscribing "The testimony of the ministers in Somersetshire to the truth of Jesus Christ" and "The Solemn League and Covenant." He continued for twenty years rector of Batcomb. On the Act of Uniformity being passed, he cast in his lot with the Two Thousand of the ejected. Upon the Five-Mile Act he removed to Frome Selwood, and preached there and around until his death on December 22, 1681. His works are all of the richest spiritual character, with a wistfulness of appeal that goes right to the heart. His *Vindicia Pietatis* (which appeared successively in 1660, 1663, and 1665) was refused licence by Sheldon, and was published, in common with other Nonconformist books, without it. It was rapidly bought up, and "did much to mend this bad world." Roger Norton, the king's printer, caused a large part of the first impression to be seized, on the ground of not being licensed, and to be sent to the royal kitchen. Glancing over its pages, he was struck with what he read, and on second thoughts it seemed to him a sin that a book so holy—and so saleable—should be destroyed. He therefore bought back the sheets, says Calamy, for an old song, bound them, and sold them in his own shop. This in turn was complained of against him, and the shrewd publisher had to beg pardon on his knees before the council-table ; and the remaining copies were sentenced to be "bisk'd," or rubbed over with an inky brush, and sent back to the kitchen for lighting fires. Such "bisk'd" copies occasionally occur still. The book was not killed. It was reissued, with additions, and a contribution by Joseph Alleine, and went forth on a mission which has endured to our day. (Calamy, *s.v.* ; *Palmer's Nonconf. Mem.* iii. pp. 167-8 ; *C. Stanford's Joseph Alleine; Researches at Batcomb and Frome Selwood; Wood's Athence, s.v.*) (A. B. G.)

ALLEN, BOG OF, the name given to a congeries of morasses in Kildare and King's County, Ireland. Clane Bog, the eastern extremity, is within 17 miles of Dublin, and the morasses extend westward almost to the Shannon. Their total area is about 238,500 acres. They do not form one continuous bog, the tract of the country to which the name is given being intersected by strips of dry cultivated land. The rivers Brosna, Barrow, and Boyne take their rise in these morasses ; and the Grand Canal crosses them. The Bog of Allen has a general elevation of 250 feet above the level of the sea, and the average thickness of the peat of which it consists is 25 feet. It rests on a subsoil of clay and marl

ALLEN, JOHN (1770-1843), was born near Edinburgh, and educated at the university of that city, where he took the degree of M.D. in 1791. With youthful enthusiasm, Allen joined the Scottish movement of that period for parliamentary reform. He was an acute metaphysician, and the prelections on physiology which he delivered in Edinburgh are distinguished by clearness and precise philosophical views. Leaving Edinburgh, he took up his abode at Holland House as the friend and private secretary of the late Lord Holland. In 1811 he was elected warden of Dulwich College; and in 1820 obtained the comfortable sinecure of master of that institution, where he died in 1843. Allen's detached publications, though well written, are not very important, if we except his valuable *Inquiry into the Growth of the Royal Prerogative* (1830), "a learned and luminous work;" but he was an able contributor to the *Edinburgh Review*, to which he is said to have furnished no less than forty articles, chiefly on physiological, metaphysical, and political subjects; and some of his contributions on French and Spanish history are very interesting. For this last department he was peculiarly fitted by his residence with Lord Holland in France and Spain; he had even collected materials for a history of Spain, but was hindered from fulfilling his purpose by his deep interest in politics. The latter portion of his life was divided between politics and the study of the history of the British constitution. Brougham, in his *Eloge of Allen* (*Works*, vol. iv., 1872), has highly commended him for extensive learning and philosophical talent.

ALLEN, or ALLEN, THOMAS (1542-1632), a famous English mathematician, was born at Uttoxeter in Staffordshire, 21st December 1542. He was admitted scholar of Trinity College, Oxford, in 1561; and in 1567 took his degree of master of arts. In 1580 he quitted his college and fellowship, and retired to Gloucester Hall, where he studied very closely, and became famous for his knowledge of antiquity, philosophy, and mathematics. Having received an invitation from Henry, Earl of Northumberland, a great friend and patron of men of science, he spent some time at the earl's house, where he became acquainted with Thomas Harriot, John Dee, and other famous mathematicians. He was also intimate with Cotton, Camden, and their antiquarian associates. Robert, Earl of Leicester, had a particular esteem for Allen, and would have conferred a bishopric upon him, but his love of solitude made him decline the offer. His great skill in mathematics earned him, as was usual in those times, the credit of being a magician; and the author of *Leicester's Commonwealth* accuses him of employing the art of "figuring" to further the Earl of Leicester's unlawful designs, and of endeavouring by the black art to bring about a match between his patron and Queen Elizabeth. Allen was indefatigable in collecting scattered manuscripts relating to history, antiquity, astronomy, philosophy, and mathematics. A considerable part of his collection was presented to the Bodleian library by Sir Kenelm Digby. He published in Latin the second and third books of *Claudius Ptolemy of Pelusium, Concerning the Judgment of the Stars, or, as it is commonly called, of the Quadrupartite Construction, with an exposition*. He wrote also notes on some of Lilly's books, and on Bale's *De Scripturibus M. Britannicæ*.

ALLENTOWN, formerly called NORTHAMPTON, a thriving town of the United States, capital of Lehigh county, Pennsylvania, is pleasantly situated on a height on the western bank of the Lehigh River, 85 miles E.N.E. of Harrisburg. It is a well-built place, and contains a good court-house, a military institute, an academy, and a theological seminary. Most of the inhabitants are of German descent; the German language is commonly spoken, and

is used along with English both in the newspapers and in the courts of law. The valley of the Lehigh is very rich in iron ore and anthracite, and in the town and neighbourhood extensive iron-works and anthracite furnaces are in operation. This trade is being rapidly developed, and is favoured by good railway communication, New York and Philadelphia being both within 100 miles of Allentown by rail. A tenth of the whole iron manufactured in the United States is said to be produced here. Population (1870), 13,884.

ALLESTRY, or ALLESTREE, RICHARD, D.D., was born at Uppington in Shropshire in 1619, and educated in the grammar school of Coventry, and afterwards at Christ Church, Oxford. After passing as bachelor of arts he was made successively moderator in philosophy, canon of Christ Church, doctor of divinity, chaplain in ordinary to the king, and regius professor of divinity. His early studies, however, were interrupted by the hostilities of the times. In the year 1641 he and many other students of Oxford entered the royal service, and gave signal proofs of their courage and loyalty. A short interval of hostilities permitted Allestry to return to his literary pursuits; but soon after, he again took up arms, and was present at the battle of Keintonfield. On his way to Oxford to prepare for the reception of the king he was taken prisoner, but was released by the king's forces. A violent disease which then prevailed in the garrison of Oxford brought Allestry to the brink of the grave; but recovering, he again joined a regiment of volunteers, chiefly consisting of Oxford students. Here he served as a common soldier, and was often seen with the musket in one hand and a book in the other. At the close of the revolutionary struggle he returned to his favourite studies, but still continued true to his party. This occasioned his expulsion from the college; but he was provided with a comfortable retreat in the families of the Honourable Francis Newport and Sir Anthony Cope. Such was the confidence reposed in him that when the friends of Charles II. were secretly preparing the way for his restoration, they entrusted him with personal messages to the king. In returning from one of these interviews he was seized at Dover, and upon examination committed a prisoner to Lambeth House. The Earl of Shaftesbury obtained his release in a few weeks. His valuable library was bequeathed to the university. He died in January 1681. He erected at his own private expense the west side of the outward court of Eton College, and the grammar school in Christ Church College; besides settling several liberal pensions upon individual persons and families. His only extant work is a volume of sermons, printed at Oxford in 1684.

ALLEYN, EDWARD, eminent as a stage-player in the reigns of Elizabeth and James I., but better remembered in after-times as the founder of Dulwich college, was born in London, in the parish of St Botolph, Bishopsgate, on the 1st of September 1566. When he was only four years old, his father, an innkeeper, died, and his mother soon afterwards married an actor named Browne. This change in his domestic surroundings brought young Alleyn into early and close association with the stage, for which he possessed great natural aptitude. Thus it chanced that "he was bred a stage-player," as stated by Fuller (*Worthies*). A tenacious memory, a polished elocution, a stateliness of figure and countenance, and a genial temperament, were among the natural and acquired accomplishments that he brought to bear on his chosen pursuit. He gained distinction in his calling while yet quite a young man, and by common consent was eventually rated as the foremost actor of his time. Several prominent dramatists and other writers of the period have left forcible testimony to his

rare excellence in the histrionic art. Ben Jonson, a critic nowise prone to exalt the merits of men of mark among his contemporaries, but addicted rather to disparagement, and even, as Drummond of Hawthornden tells, to bitterest detraction, bestowed, nevertheless, unstinted praise on Alleyn's acting (see Jonson's *Epigrams*, No. 89). Nash, in *Pierce Penniless, his Supplication to the Devil*, expresses in prose the same eulogy that Jonson renders in verse. Heywood calls Alleyn "inimitable," "the best of actors," and

"Proteus for shapes and Roscius for a tongue."

—(Prologue to Marlowe's *Jew of Malta*.)

Peele's letter to Marlowe, quoted by several of Alleyn's biographers, telling of a merry meeting at which Shakespeare, Ben Jonson, and Alleyn figure in the front rank of a group of choice spirits, has long been numbered among literary forgeries. (See the Life prefixed to Dyce's *Peele's Works*, 1829.)

But ample and clear evidence remains to show his great celebrity as an actor. His professional earnings as a player formed, however, one only, and not the chief, among several sources from which he drew the wealth that afterwards sustained his great foundation; and his fame as an actor must long since have faded into a dim tradition, of little or no concern to present times, but for the association of his name with an institution around which cluster interesting historic reminiscences, and whose future is fraught with high promise. He inherited house property in Bishopsgate from his father. His marriage, in 1592, with Joan Woodward, stepdaughter to Henslowe, a successful speculator in theatrical and kindred enterprises, brought him eventually much wealth. He became successively part owner in Henslowe's ventures, and in the end sole proprietor of sundry play-houses and other resorts for the diversion of pleasure-seekers. Among these were the Rose Theatre at Bankside, in close contiguity to Shakespeare's Globe Theatre; the Paris Garden, in the same vicinage, where were enacted such pastimes as bear-baiting, bull-baiting, and other sports of the period; and the Fortune Theatre in St Luke's. He filled, too, in conjunction with Henslowe, the post of "master of the king's games of bears, bulls, and dogs." He continued to discharge the duties of this office long after he had relinquished his other professional work.

Alleyn's ownership in Dulwich lands began in 1606, and further acquisitions, made in the course of the next five years, during which he was gradually breaking away from the actual practice of the histrionic art, though not from theatrical speculations or kindred enterprises, increased his holding to more than 1300 acres. His residential connection with Dulwich began in 1607. He occupied the manor-house, a mansion even then very ancient, but which is still tenanted, after many additions and alterations. The priors and abbots of Bermondsey owned and occupied it through the four centuries preceding their expulsion in 1537, when Henry VIII. assigned their house and adjacent church lands to Thomas Calton, grandfather to the Calton who sold his heritage to Alleyn. Some details respecting this and other purchases of neighbouring estates are set forth in Alleyn's own writing, in a small thick memorandum-book which, with other Alleyn papers preserved at Dulwich, has been carefully scrutinised by the writer of this notice.

The landed property stretches from the crest of that range of Surrey hills on whose summit rests the Crystal Palace, to the crest of the parallel ridge, three miles nearer London, known in its several portions as Herno Hill, Denmark Hill, and Champion Hill. Alleyn acquired this large suburban property for little more than £10,000, which may be estimated as equivalent to £50,000 in the present day. But the present value of the lands which he

bought for such a price is hardly under a million and a-half sterling, so enormous has been the rise in the value of land in and near London. Alleyn had barely got full possession of this property before the question how to dispose of it began to press upon him. He was still childless, after twenty years of wedded life. Then it was that the prosperous player—the man "so acting to the life that he made any part to become him" (Fuller, *Worthies*)—began "playing the last act of his life so well" (Bacon's Letter to the Marquis of Buckingham, dated 18th August 1618), as to gain the general applause of his own age, and a large measure of admiration in after times. He built and endowed in his own lifetime the College of God's Gift at Dulwich. All was completed in 1617, except the charter or deed of incorporation for setting his lands in mortmain. Tedious delays occurred in the Star Chamber, where Lord Chancellor Bacon was scheming to bring the pressure of kingly authority to bear on Alleyn with the aim of securing a large portion of the proposed endowment for the maintenance of lectureships at Oxford and Cambridge. Alleyn finally carried his point, and the College of God's Gift at Dulwich was founded, and endowed under letters patent of James I. dated 21st of June 1619. The college, as thus incorporated, consisted of twelve "poor scholars" and as many pensioners, the latter comprising equal numbers of men and women—"poor brethren" and "poor sisters,"—together with a teaching and governing staff of six higher officials. These latter included a master and a warden, who were always to be of the founder's surname, and four fellows, all "graduates and divines," among whom were apportioned the ministerial work of the chapel, the instruction of the boys, and the supervision of the almspeople or pensioners. The scholars and pensioners were to be drawn in equal numbers from the four London parishes out of which the founder drew his wealth. A curious legend, dating from the time of the founder, and always current afterwards among the pensioners on his bounty, tells that he was scared into his generous and charitable scheme by an apparition of the devil, *in propria persona*, among some theatrical demons in a drama in which he was acting. In the fright thus occasioned he was said to have made a vow, which he redeemed in the founding of Dulwich College.

Alleyn was never a member of his own foundation, as stated by Heywood, and copied by succeeding writers. The college records clearly set this point at rest. But he continued to the close of his life to guide and control the affairs of his foundation, under powers reserved to himself in the letters patent. His diary shows that he mixed much and intimately in the daily life of the college. Many of the jottings in that curious record of daily doings and incidents favour the inference that he was genial, kind, amiable, and withal a religious man. His fondness for his old professional work is indicated by the fact that he engaged the boys in occasional theatrical performances. At a festive gathering on the 6th of January 1622 "the boyes play'd a playe."

Shakespeare's name is interwoven with local traditions bearing on Alleyn's life at Dulwich, and the links of association between these famous contemporaries afford strong antecedent probability that the tradition sprang from something more solid than "such stuff as dreams are made of." Each began and closed his professional career as a stage-player in nearly the self-same period and in neighbouring theatres. During several years they were near neighbours in their homes at Bankside, then the headquarters of players and play-houses. Leading actors then, as afterwards, came much in contact with the living authors whose creations they personated. Alleyn performed in "Leir," the "Moore of Venis," "Romeo,"

“Pericles,” and “Henry VIII.,” as appears from his inventory of his own theatrical wardrobe. Among the intimate friends of both were Ben Jonson, Michael Drayton, and other members of the goodly company of poets and dramatists whose genius shed a lustre on their day. Shakespeare had not finally betaken himself to the retirement of Stratford-on-Avon until seven years after Alleyn took up his abode at Dulwich. In the face of all these facts, it can hardly be said the local tradition is groundless, though no direct proof has yet been brought to bear on the point.

Alleyn's first wife died in the summer of 1623. In December of the same year he married Constance Donne, who survived him. This lady was a daughter of Dr Donne, dean of St Paul's. Her maiden name was misquoted by an early biographer. This mistake gave rise to the further error which attributes to Alleyn a third wife. He died in November 1626, in the sixty-first year of his age. His gravestone at Dulwich fixes the date of his death on 21st November, but there are grounds for the belief that the true date is the 25th of the same month.

Besides dispensing bounties within the bounds of his college, Alleyn provided, by an after-thought, some years later than his deed of foundation, for certain extensions of the benefits of his endowment. But successive actions at law, carried on at various periods, resulted in the ruling that it was not within the competence of the founder to divert any portion of the revenues of his foundation to the use of others than the members thereof, as specified in the letters patent. Chief among the good intents on the part of the founder that were thus frustrated was his scheme for embracing in the school work within the college as many outsiders as would bring the total number to eighty boys, inclusive of the twelve foundationers. But as this was not within the bond, his successors in the administration of the trust, for more than two centuries after his death, declined the work. In the latter part of that period, decay, and not development, fixed on the time-honoured memorial of Alleyn's high but thwarted purposes the stigma of a public scandal. Then came, in 1842, a grudging and partial, rather than a full and loyal, concession towards the realisation of the founder's aims. Finally, however, an Act of Parliament, in 1857, extinguished the stagnant and unprogressive corporation. Alleyn's College of God's Gift at Dulwich entered thenceforward on that prosperous career which already links its name with the front rank of institutions doing good service in the educational work of the day. (J. GO.)

**ALLIANCE**, a league between independent states for the purpose of combined action, defensive or offensive, or both—a subject which falls to be treated under the heading **LAW OF NATIONS**. The alliances of greatest historical importance are the Triple Alliance (1688) of Great Britain, Sweden, and the Netherlands against France; the Grand Alliance (1689) of the Emperor Leopold I. and Holland, subsequently joined by England, Spain, and Saxony, against Louis XIV.; the Quadruple Alliance (1718) of Great Britain, France, Austria, and Holland, against Spain; the Holy Alliance (1815) of Russia, Austria, and Prussia, for the maintenance of peace and the establishment of the existing dynasties; and the alliance (1854) of Great Britain, France, and Turkey, against Russia.

**ALLIER**, a department in the centre of France, so called from the river of the same name; bounded on the N. by the department of Cher and Nièvre, on the E. by those of Saône-et-Loire and Loire, on the S. by that of Puy de Dôme, and on the W. by those of Creuse and Cher; extending at the widest points 82 miles from E. to W., and 55 from N. to S.; and containing an area of 2821 square miles. Its surface is in general undulating,

rising to considerable elevations among the mountains of Forez on the south-east, and among those of Auvergne towards the west. The river Allier flows northward between these ranges, receiving the Andelot, the Sioule, and the Bioudre, all from the left; east of the Allier is the Bèbre, which joins the Loire within the limits of the department; and on the west the Cher, with its tributary the Aunance. The soil is for the most part fertile, especially in the valleys of the Allier, the Sioule, and the Bèbre, yielding wheat, oats, barley, rye, fruits, and potatoes, in quantities exceeding what is required for home consumption, as well as some red and white wines. Good timber is grown, and cattle, sheep, goats, and horses are reared in large numbers; but agriculture is on the whole in a backward condition, owing to the inhabitants' aversion to change. The mineral wealth of the department is very considerable, including iron, coal, antimony, marble, and manganese—the coal mines of Commentry being among the most important. The chief manufactures are of cutlery, earthenware, glass, cloth, leather, and paper. The climate is healthy, but is liable to sudden variations of temperature. The mineral waters at Vichy, Nèris, and Bourbon l'Archambault, in the department, are in much repute. Allier comprehends the greater portion of the old province of Bourbonnais, and is at present divided into four arrondissements—Moulins, Gannat, La Palisse, and Montluçon, which are subdivided into 28 cantons and 317 communes. Moulins is the capital, and the seat of a bishop whose diocese is co-extensive with the department. The other important towns are La Palisse, Cusset, Vichy, Gannat, Saint Pourçain, Montluçon, and Commentry. Population in 1871, 390,812; of whom 196,831 were males, and 193,981 females. Of the total population, 223,374 could neither read nor write, and 36,786 could read but could not write.

**ALLIER**, the ancient *Elaver*, a river of France, which rises in the department of Lozère, among the Margeride mountains, a few miles east of the town of Mende, and, after traversing Haute Loire, Puy de Dôme, and Allier, forms the boundary between Cher and Nièvre, until it falls into the Loire four miles west of Nevers. Its length is 200 miles, for a considerable portion of which it is navigable, and its chief tributaries are the Dore and the Sioule.

**ALLIGATOR**, (probably derived from the Spanish *el lagarto*, the lizard), an animal so closely allied to the crocodile that some naturalists have classed them together as forming one genus. It differs from the true crocodile principally in having the head broader and shorter, and the snout more obtuse; in having a large canine tooth of the under jaw received, not into an external furrow, but into a pit formed for it within the upper one; in wanting a jagged fringe which appears on the hind legs and feet of the crocodile; and in having the toes of the hind feet webbed not more than half-way to the tips. The principal species, all found in America only, are the common alligator (*Alligator Mississippiensis* or *Crocodilus Lucius*), occurring in the southern United States; the caiman or cayman (*A. palpebrosus*), in Surinam and Guiana; and the spectacled alligator or jacaré (*A. sclerops*), principally in Brazil. The names *alligator* and *crocodile* are often confounded in popular speech; and the structure and habits of the two animals are so similar that both may be conveniently considered under the heading **CROCODILE**.

**ALLITERATION**. As Milton defined rhyme to be “the jingling sound of like endings,” so alliteration is the jingle of like beginnings. All language has a tendency to jingle in both ways, even in prose. Thus in prose we speak of “near and dear,” “high and dry,” “health and wealth.” But the initial form of jingle is much more common—“safe and sound,” “thick and thin,” “weal or

woe," "fair or foul," "spick and span," "fish, flesh, or fowl," "kith and kin." The poets of nearly all times and tongues have not been slow to seize upon the emphasis which could thus be produced. Accordingly we read in Shakespeare:—

"Full fathom five thy father lies;  
Of his bones are corals made."

In Pope:—

"Here files of pins extend their shining rows  
Puffs, powders, patches, bibles, billet-doux

In Gray:—

"Weave the warp and weave the woof,  
The winding-sheet of Edward's race."

In Coleridge:—

"The fair breeze blew, the white foam flew,  
The furrow followed free;  
We were the first that ever burst  
Into that silent sea."

Churchill describes himself as one

"Who often, but without success, had prayed  
For apt alliteration's artful aid,—"

an example which is itself a proof of his failure; for alliteration is never effective unless it runs upon consonants.

As thus far considered, alliteration is a device wholly dependent on the poet's fancy. He may use it or not, or use it much or little, at his pleasure. But there is an extensive range of poetry whose metrical laws are entirely based on alliteration. This, for example, is the principle on which Icelandic verse is founded; and we have a yet nearer interest in it, because it furnishes the key to Anglo-Saxon and a large portion of early English verse. For a specimen take the following lines, the spelling modernised, from the beginning of *Piers the Ploughman*:—

"But in a May morning | on Malvern hills,  
Me befel a ferly | of fairy methought;  
I was weary of wandering | and went me to rest  
Under a broad bank | by a burn-side;  
And as I lay and leaned | and looked on the waters,  
I slumbered in a sleeping | it sounded so merry."

The rule of this verse is indifferent as to the number of syllables it may contain, but imperative as to the number of accented ones. The line is divided in the middle by a pause, and each half ought to contain two accented syllables. Of the four accented syllables, the first three should begin with the same letter; the fourth is free, and may start with any letter. Those who wish for a more minute analysis of the laws of alliterative verse, as practised by the Anglo-Saxon and early English poets, may consult an exhaustive essay on the subject by the Rev. W. W. Skeat, prefixed to vol. iii. of *Bishop Percy's Folio Manuscript*; only the reader must be on his guard against an error which pervades it, and which this able writer seems to have derived from Rask. The question arises—What is the nature of the cadence in alliterative verse? Now all metrical movement is of two kinds, according as the beat or emphasis begins the movement or ends it. If the beat is initial, we say in classical language that the movement is trochaic or dactylic, according to the number of its syllables; and if the beat is final, we in like manner say that the movement is iambic or anapestic. Mr Skeat and many others object with some reason to use the classical terms, and therefore brushing them aside, let us put the question in the simplest form—Has the movement of alliterative verse got the initial or the final beat? In the middle of last century Bishop Percy decided this question with sufficient accuracy, though he mixed up his statement with a blunder which it is not easy to account for. He points out how the poets began to introduce rhyme into alliterative verse, until at length rhyme came to predominate over alliteration, and "thus was this kind of

metre at length swallowed up and lost in our common burlesque Alexandrine or anapestic verse, as

A cobbler there was, and he lived in a stall."

Percy made a serious mistake when he gave the name of Alexandrine to anapestic verse; but he is quite right in his general statement that alliterative verse became lost in a measure, the movement of which had the final beat. Conybeare has stated the fact still more accurately. "In the Saxon poetry a trochaic character is predominant. In *Piers Plowman* there is a prevailing tendency to an anapestic cadence." It is the result of a change in the language—the loss of inflection. Take the word *man*. The genitive in Saxon would be *mannes*, a trochee; in English, *of man*, an iambus. The tendency of the language was thus to pass from a metrical movement, in which the beat was initial, to one in which it was final. It may therefore be quite right to speak of Anglo-Saxon alliterative poetry as trochaic or dactylic, and quite wrong to apply the same terms to the cadence of our later alliterative verse. And this is precisely the error into which Mr Skeat has fallen. He says—"Lines do not always begin with a loud syllable, but often one or two and sometimes (in early English especially) even three soft syllables precede it. These syllables are necessary to the sense, but not to the scansion of the line." That is just the point at issue. By leaving out of account the light syllable or syllables at the beginning of a line, and taking his start from the first syllable that has the alliterative beat, Mr Skeat may certainly prove that all the later alliterative poetry has a movement of initial beat. But English ears will not submit to this rule. It is those light syllables of no account which have altered the rhythm of English descent from one of initial to one of final beat. (E. S. D.)

ALLIX, PIERRE, a distinguished divine of the French Reformed Church, was born at Alençon in 1641. He was pastor first at St Agobile in Champagne, and then at Charenton, near Paris. The revocation of the Edict of Nantes in 1685 compelled him to take refuge in London, where, under the sanction of James II., he opened a church for the French exiles. His reputation for learning was such as to obtain for him, soon after his arrival, the degree of doctor of divinity from both universities, and in 1690 he received from Bishop Burnet the more substantial honour of the treasurership and a canonry in Salisbury cathedral. He died at London in March 1717.

The works of Allix, which are very numerous, are chiefly of a controversial and apologetic character, and, like most works of that class, are not thoroughly trustworthy. At the invitation of a number of English ministers, he is said to have written a history of the councils of the church, which, however, owing to want of support, never was published. In opposition to Bossuet he issued *Some Remarks upon the Ecclesiastical History of the Ancient Churches of Piedmont* (1690), and *Remarks upon the Ecclesiastical History of the Ancient Churches of the Albigenes* (1692), with the view of showing that the Albigenes were not Manichæans, but historically identical with the Waldenses. His *Dissertation on the First Rise of the Trisagium or Doxology* (1674), and *Reflections upon the Books of Holy Scripture* (1688), are of little present value.

ALLOA, a seaport town of Scotland, in the county of Clackmannan, situated on the north side of the Firth of Forth, 25 miles from Edinburgh, and 6 below Stirling, with which it is connected by railway. The town as a whole is irregularly built, although in the modern portions there are several spacious streets, with good shops and houses. The parish church, opened in 1819, is a fine Gothic edifice, with a handsome spire 200 feet high; there are also places of worship belonging to the other denomina-

tions, as well as the county court-house, a corn exchange, and schools of various grades. In the immediate vicinity of the town is an ancient tower, 89 feet high, with walls 11 feet in thickness, said to have been built about the year 1315, formerly the residence of the powerful family of Erskine, descendants of the Earls of Mar. Here many of the Scottish princes received their education as wards of the Lords Erskine and the Earls of Mar, the last of these educated here being Henry, the eldest son of James VI. Among the manufactures of Alloa are ale, whisky, iron goods, glass (especially bottles), bricks, yarns, shawls, and blankets. Shipbuilding is also carried on to some extent, and in the neighbourhood there are several collieries. The harbour is safe and commodious, having a depth of 16 feet at neap, and 22 at spring tides; adjoining it is an excellent dry dock, and a capacious wet dock was constructed in 1863. In 1872, 446 vessels of 49,941 tons entered, and 533 of 70,499 cleared the port of Alloa, in addition to coasting vessels in ballast; and in the same year £453 were derived from customs duties. The chief exports were pig-iron, ale, glass, and coals; the imports, timber, grain, iron, linseed, and flax. There is a ferry here across the Forth. Population in 1871, 9362.

ALLODIUM or ALODIUM denotes lands which are the absolute property of their owner, and not subject to any service or acknowledgement to a superior. It is thus the opposite of *fe-odum* or *fief*. The proper derivation of the word has been much discussed and is still doubtful, though it is probably compounded of *all*, whole or entire, and *odh*, property. Allodial tenure seems to have been common throughout northern Europe. It exists in Orkney and Shetland, where the proprietor of an allodial estate was known until recently as an *udaller*. (See Sir Walter Scott's *Pirate*.) In England allodial tenure is unknown, the feudal system having been made universal by William the Conqueror.

ALLORI, ALESSANDRO, a painter of the Florentine school, was born at Florence in 1535, and died in 1607. Having lost his father in his fifth year, he was brought up and trained in art by his uncle, Angelo Bronzino, whose name he sometimes assumed in his pictures. Visiting Rome in his nineteenth year, he carefully studied the works of Michael Angelo; but having himself little genius and no originality, the influence of that great master can only be traced in the anatomical correctness of his drawing of nude figures. He was very successful as a portrait-painter.

ALLORI, CRISTOFANO, son of the preceding, was born at Florence on the 17th October 1577, and died in 1621. He received his first lessons in painting from his father, but becoming dissatisfied with the hard anatomical drawing and cold colouring of the latter, he entered the studio of Paganì, who was one of the leaders of that later Florentine school which endeavoured to unite the rich colouring of the Venetians with the correct drawing of Michael Angelo's disciples. Allori became one of the foremost of this school. His pictures are distinguished by their close adherence to nature and the delicacy and technical perfection of their execution. His technical skill is proved by the fact that several copies he made after Correggio have been taken to be duplicates by Correggio himself. His extreme fastidiousness limited his power of production, though the number of his works is not so small as is sometimes asserted. Several specimens are to be seen at Florence and elsewhere. The finest of all his works is his "Judith and Holofernes," in the Pitti palace. The model for the Judith was his mistress, the beautiful Mazzafirra, who is also represented in his *Magdalene*; and the head of Holofernes is generally supposed to represent himself, though this is questioned by the best authorities.

ALLOTROPY (from *ἄλλος*, other, and *τρόπος*, manner), a name applied to a property, whereby certain substances, chemically simple, assume different forms and conditions without undergoing chemical change. Sulphur and phosphorus, for instance, occur sometimes in crystals and sometimes in an amorphous state, being in the latter case sometimes translucent and sometimes opaque, and present very different properties under these different conditions. Ozone is an allotropic form of oxygen. The name *isomerism* is given to the similar by no means uncommon property whereby compound bodies, although entirely distinct, are made up of the same chemical elements in precisely the same proportions.

ALLOXAN, a product of the action of oxidising agents on uric acid, obtained by adding slowly, in small quantities, uric acid to strong nitric acid of specific gravity 1.4, kept cool, and stirring constantly. Carbonic acid and nitrogen are evolved during the action, and the alloxan crystallises out on standing. It is purified by recrystallisation from water, and then has the composition  $C_4H_2N_2O_4 + aq$ . The crystals of this compound are large and colourless, and when heated to a temperature of 150° C., lose the water of crystallisation, and acquire a red colour. Alloxan is readily soluble in water and alcohol, and its aqueous solution reddens litmus, has an astringent taste, and colours the skin purple after some time. It produces a great number of derivatives, for which see URIC ACID.

ALLOY, the name given to a combination obtained by fusing metals with each other. Few metals are employed in the pure state, with the exception of iron, copper, lead, tin, zinc, platinum, aluminium; metals are more frequently used in the forms of alloys for technical purposes. Every industrial application necessitates special qualities that may not occur in any isolated metal, but which may be produced by the proper mixture of two or more of these substances. Thus gold and silver, which in their pure state are too soft and flexible for the manufacture of plate, coin, trinkets, &c., are hardened by the addition of a tenth part of copper, while the colour and other valuable qualities are not materially impaired. Similarly copper is rendered hard by mixture with zinc, when we obtain brass, an alloy of a beautiful yellow colour, easier to work than the pure metal. If brass has to be used in turning operations it is found to tear under the action of the chisel, unless a small quantity of lead has been added. These examples are sufficient to show that an alloy is really an industrial metal, often of greater importance than the metals which compose it.

Alloys are equally interesting from a purely scientific point of view. They are not only mixtures of metals having certain particular qualities, but in reality are true chemical compounds, generally dissolved in an excess of one of the constituent metals. In the appearances which accompany the union of the metals, and in the properties of the resulting products, we observe that which characterises the manifestation of affinity, that is, an evolution of heat and light, resulting in the formation of substances having a definite composition, distinct crystalline form, and a variety of properties different from those of the constituents. If a piece of clean sodium is rubbed in a mortar with a quantity of dry mercury, the metal dissolves, producing a harsh sound resembling the immersion of red hot iron in water. This phenomenon is due to the large evolution of heat which accompanies the combination, as the mercury rises rapidly in temperature on the addition of each successive piece of sodium. If the mass is allowed to cool after the action, long needles of a white brilliant alloy of definite composition crystallise from the middle of the liquid, from which the excess of mercury may be separated by decantation. Platinum, iridium, gold, rhodium, ruthenium, and silver unite with tin, producing an evolution of heat; if

the tin is in excess after cooling, a metallic ingot is obtained resembling closely the original substance; but if the mass is treated with strong hydrochloric acid, the excess of tin is dissolved and crystals remain of a definite alloy of tin and the precious metal. These alloys are insoluble in strong hydrochloric acid, which dissolves tin so easily; but they are soluble in aqua regia, even when the precious metal contained therein (rhodium, ruthenium, iridium) is in the free state absolutely insoluble. This is no proof that the industrial alloys are always the result of one definite combination dissolved in excess of one of the metals, as many combinations are able to co-exist in the same alloy. This may be proved by taking an alloy of tin, lead, and bismuth, which melts below the boiling point of water, heating to a temperature of 25° C., and observing the rate of cooling by means of a thermometer. The thermometer falls at first regularly as far as a certain degree, where it remains stationary for some time, after which it descends to a lower temperature, where it is again similarly arrested. These two stoppages in the rate of cooling can only be explained by admitting the production of a less fusible alloy in the fluid mass, which solidifies with an evolution of heat, rendering the thermometer stationary for a time. Each successive arrest will therefore correspond to the formation of more fusible combinations. Thus the metals form amongst themselves true chemical combinations; and alloys are often formed by the mixture of one or more of these compounds with excess of one of the constituents.

Recently hydrogen, which, although a gaseous substance, has chemical properties resembling those of the true metals, has been combined with palladium, sodium, and potassium, producing compounds similar in properties to the recognised alloys.

**PROPERTIES OF ALLOYS.** *Density.*—If the density of any alloy is calculated from that of the components—assuming that there is no condensation of volume—the resulting number is sometimes greater than, equal to, or less than, the experimental result. Thus the alloys of gold and silver are less dense than the theoretical mean density; whereas brass and the alloys of lead and antimony vary in the opposite direction. The former are therefore produced through an expansion, the latter through a condensation of their constituents. In the formation of many alloys there is no alteration of volume, and then the calculated density is correct. *Colour.*—This is generally grey, unless when we have a coloured metal like copper or gold present in sufficient quantity. *Hardness, Ductility, and Tenacity.*—Alloys are for the most part harder and more brittle, and are generally less ductile and possess less tenacity than the constituent metal that has these properties in excess. Aluminium bronze is an exception, as its tenacity is greater than that of either of the components. *Fusibility.*—This is always greater than that of the least fusible metal entering into the composition of the alloy, and is sometimes greater than in any of the components. Thus an alloy, composed of 5 parts of bismuth, 3 of lead, and 2 of tin, melts at 91° C. Alloys of lead and silver, containing a small quantity of the latter, are more fusible than lead, and potassium and sodium form an alloy fluid at the ordinary temperature of the air. *Liquation.*—The constituents of an alloy heated gradually to near its point of liquefaction frequently unite anew in such proportions as to form a mass that is fusible at the given temperature. If the fluid portion is poured off, there remains a solid alloy less fusible than the original. Copper is separated from silver by this process. *Decomposition.*—When the alloy contains a volatile metal like zinc or mercury, heat decomposes it, but the temperature required to expel the last trace of the volatile metal must be considerably higher than that

metal's normal temperature of ebullition. *Temper.*—The alloy of 94 parts of copper and 6 parts of tin forms a bronze so brittle that it may be pulverised with a hammer when it has been slowly cooled; but if, on the contrary, it is cooled rapidly by tempering it in cold water, it becomes malleable. *Influence of the Constituent Metals.*—Mercury, bismuth, tin, and cadmium give fusibility to alloys into which they enter; tin also gives hardness and tenacity if present in considerable quantity; lead and iron give hardness; arsenic and antimony render alloys brittle.

**COMPOSITION OF ALLOYS.**—A statement of the average proportions in which the metals enter into the best known alloys, the composition of which is generally very variable, is given in the following table:—

Coinage of gold, {	Gold, 90.	Specula of tele-	Copper, 67.
	Copper, 10.		scopes,.....
Gold jewellery {	Gold, 75 to 92.	Pinchbeck,.....	Copper, 90.
and plate,.....	Copper, 25 to 8.		Zinc, 10.
Silver coinage,.....	Silver, 90.	Brass,.....	Copper, 67 to 72.
	Copper, 10.		Zinc, 33 to 28.
Silver vessels,.....	Silver, 95.	German silver,.....	Copper, 50.
	Copper, 5.		Zinc, 25.
Silver jewellery,...	Silver, 80.	Type metal,.....	Nickel, 25.
	Copper, 20.		Lead, 80.
Aluminium {	Copper, 90 to 95.	Antimony, 20.	Tin, 100.
Bronze,.....	Aluminium, 10 to 5.		
Bronze.—Coins, {	Copper, 94 to 96.	English metal,.....	Antimony, 8.
Medals,.....	Tin, 4 to 6.		Bismuth, 1.
	Zinc, 1 to 5.	Copper, 4	
Bronze.—Cannon, {	Copper, 90.	Pewter,.....	Tin, 92.
	Tin, 10.		Lead, 8.
Bronze.—Bells,....	Copper, 78.	Liquid measures,.....	Tin, 82.
	Tin, 22.		Lead, 18.
Bronze.—Cymbals,.....	Copper, 80.	Plumbers' solder,.....	Tin, 67.
	Tin, 20.		Lead, 33.

**PREPARATION OF ALLOYS.**—The metals are generally fused together under a layer of charcoal to prevent oxidation, thoroughly mixed by agitating, and the mass left to cool slowly. This process can only be employed when the constituent metals are all non-volatile at the temperature required for combination. If the mixture contains volatile metals, like sodium, potassium, magnesium, or zinc, they are added after the more refractory metal is fused.

ALLSTON, WASHINGTON, an eminent American historical painter and poet, was born 5th November 1779, at Waccamaw, in South Carolina, where his father was a planter. He early displayed a taste for the art to which he afterwards devoted himself. He graduated at Harvard in 1800, and for a short time pursued his artistic studies at Charleston with Malbone and Charles Fraser. He then removed to London, and entered the Royal Academy as a student of Benjamin West, with whom he formed a life-long friendship. In 1804 he repaired to Paris, and from that city, after a few months' residence, to Rome, where he spent the greater part of the next four years studying Italian art and Italian scenery. During this period he became intimate with Coleridge and Thorwaldsen. From 1809 to 1811 he resided in his native country, and from this latter date to 1817 he painted in England. After visiting Paris for a second time, he returned to the United States, and practised his profession at Boston (1818–30), and afterwards at Cambridge, Massachusetts, where he died on the 9th July 1843. He was elected an associate of the Royal Academy in 1819. The paintings of Allston are characterised rather by grandeur of conception than by skilful execution. In colour and the management of light and shade he closely imitated the Venetian school, and he has hence been styled "the American Titian." Many of his pictures have biblical subjects, and Allston himself had a profoundly religious nature. His first great painting, "The Dead Man Revived," executed shortly after his second visit to England, gained a prize of 200 guineas from the British Institution; in England he also prepared his "St Peter Liberated by the Angel," "Uriel in the Sun," "Jacob's Dream," and "Elijah in the Wilderness." To the period of

his residence in America belong "The Prophet Jeremiah," "Saul and the Witch of Endor," "Miriam," "Beatrice," "Rosalie," "Spalatro's Vision of the Bloody Hand," and the vast but unfinished "Belshazzar's Feast," at which he was working at the time of his death. As a writer, Allston shows great facility of expression and imaginative power. His friend Coleridge said of him that he was surpassed by no man of his age in artistic and poetic genius. His literary works are—*The Sylphs of the Seasons and other Poems* (1813), where he displays true sympathy with nature and deep knowledge of the human heart; *Monaldi* (1841), a tragical romance, the scene of which is laid in Italy; and *Lectures on Art*, edited by his brother-in-law, R. H. Dana the novelist (1850).

ALLUVIUM, soil or land made up of the sediment deposited by running water. Rivers act on the rocks in their course both mechanically and chemically, and are in consequence always more or less loaded with detritus, which in its turn again aids the water in abrading other rocks. A great proportion of the matter with which rivers are thus charged is carried out to sea. But in level tracts, where the motion of a river is slow, it frequently overflows its banks, and leaves a sediment of earth, mud, gravel, &c., when it returns to its ordinary channel. The principal alluvial tracts are the deltas or deltoid formations at the mouths of large rivers. These vary in character very considerably. The Delta of the Nile is the best-marked specimen; the waters of the Rhine, Ganges, &c., arrested by the solid matter they have washed down, force their way through it in numerous smaller channels; the Mississippi has carried the solid matter it holds in suspension far into the Gulf of Mexico, forming long spits of land on the banks of the stream. The cognate term *diluvium* (now little used) has been applied to formations produced by extraordinary aqueous agencies.

ALMA, a river of Russia, in the S.W. of the Crimea, which falls into the sea about 16 miles N. of Sebastopol. It gives its name to a battle gained over the Russians, on the 20th September 1854, by the allied British, French, and Turkish armies. The British numbered 25,000 men, with 60 guns, and were commanded by Lord Raglan; the French force consisted of 30,000 men and 68 guns, to which were added 7000 Turkish infantry—all under the command of Marshal St Arnaud. To these were opposed 36,000 Russians, with 122 guns, under Prince Menschikoff, strongly posted on the heights on the left bank of the river. The victory was largely due to the determined advance of the British in face of the Russian fire.

ALMADEN, or ALMADEN DEL AZOQUE (in Arabic, the "Mine of Quicksilver"), a town of Spain, in the province of Ciudad Real, lies in the Sierra Morena, 55 miles S.W. of the town of Ciudad Real. It is the *Sisapon* of the Romans, and is famous for its quicksilver mines, which have been wrought extensively both in ancient and in modern times. They were the richest and most productive in the world until the discovery of quicksilver at New Almaden in California. The annual yield is about 1,400,000 lb, and 4000 workpeople are employed. The principal vein is 25 feet thick; a depth of 1000 feet has been reached, and the ore increases in richness with the depth of the descent. These mines belong to the Spanish Government, and yield a large revenue. At various periods they have been leased to private speculators. The town has a good hospital and mining schools. Population, 9000.

ALMAGEST, compounded of the Arabic *al* and *μεγίστη*, the name applied by the Arabians to their translation of the *Μεγάλη Σύνταξις* of Claudius Ptolemy, which contains a large collection of problems in geometry and astronomy. The translation was made about the year 827 A.D. by order

of the caliph Al-Mamun. The name is also applied to other editions and translations of the work, as well as to other scientific compilations. Thus Riccioli published a book of astronomy, the *New Almagest*, and Plukenet an *Almagestum Botanicum*.

ALMAGRO, a town of Spain, in the province of Ciudad Real, 12 miles E.S.E. of the town of that name. It stands in a fertile plain, and is a well-built town, with spacious streets and a fine square. It was once almost exclusively inhabited by monks and the Knights of Calatrava, and contains several ruined churches, monasteries, and convents. In the town and neighbourhood lace is extensively manufactured, as many as 9000 workmen being employed. Brandy, soap, earthenware, and leather are also made; and the surrounding district is famous for its breed of asses and mules, for the sale of which two great fairs are annually held. Excellent red wine is produced in the district. Population, 14,000.

ALMAGRO, DIEGO DE, a Spanish commander, the companion and rival of Pizarro, was born at Aldea del Rey in 1475. According to another account he was a foundling in the village from which he derived his name. Nothing is known of his life until 1525, when he joined Pizarro and Hernando de Luque at Panama in a scheme for the conquest of Peru. The details of his subsequent career are given at length in the article PERU. He was executed by order of his former associate Pizarro in 1538.

ALMALI, a prosperous town of Asiatic Turkey, situated on the river Myra, 25 miles from its mouth, and 50 miles W.S.W. of Adalia. It lies 5000 feet above the sea, in a valley at the extremity of an extensive plain, the neighbouring mountains rising to a height of 10,000 feet. The town is well built, with handsome houses, several mosques, and a bazaar; and its appearance is rendered very attractive by the lofty trees interspersed through the streets, and by the gardens of the environs. There are numerous mills and factories, tanyards and dyeworks; and the inhabitants are exceedingly industrious. The town is much frequented by merchants from Smyrna and other places, who purchase the produce of the district and send it to the coast for shipment. Population, 8000.

AL-MAMUN (also written AL-MAMOUN, AL-MAMON, and simply MAMUN), one of the most renowned of the Abbasside dynasty of caliphs, was born in 786 A.D. He was the son of Harun-al-Raschid, whose caliphate is the golden age of Mahometan history. Harun, dying in 808, left the supremacy to his son Al-Amin, Al-Mamun being at the time governor of Khorassan, and favourable to the succession of his brother. Irritated, however, by the treatment he received at the hands of Amin, and supported by a portion of the army, Mamun speedily betook himself to arms. The result was a five years' struggle between the two brothers, ending in the death of Amin, 4th October 813, and the proclamation of Al-Mamun as caliph at Baghdad. Various factions and revolts, which disturbed the first years of his reign, were readily quelled by his prudent and energetic measures. But a much more serious rebellion, stirred up by his countenancing the heretical sect of Ali and adopting their colours, soon after threatened his throne. His crown was actually on the head of his uncle Ibrahim ben Mahdi (surnamed Mobarek) for a short time, and a civil war with the orthodox Mussulmans was imminent, when the timely death of Mamun's vizier and of the imam Rizza removed his principal heretical advisers, and restored the people to their allegiance. This inaugurated a period of tranquillity, which Al-Mamun employed in patronising and fostering the cultivation of literature and science throughout his empire. He had already, while governor of Khorassan, founded a college there, and attracted to it the most eminent men of the

day; and now Baghdad became, under his auspices, the seat of academical instruction and the centre of intelligence. At his own expense he caused to be translated into Arabic many valuable books from the Greek, Persian, Chaldean, and Coptic languages; and he was himself an ardent student of mathematics and astronomy. The first Arabic translation of Euclid was dedicated to him in 813. Mamun founded observatories at Baghdad and Kassiun (near Damascus) for astronomical purposes, and he succeeded in determining the inclination of the ecliptic. He also caused a degree of the meridian to be measured on the plain of Shinar; and he constructed astronomical tables, which are said to be wonderfully accurate. The supposed antagonism of orthodoxy and science receives some support from the conduct of Mamun. A lover of philosophy and letters, he did not concern himself about the creed of the professors he appointed to his colleges, or the physicians he employed at his court; and on the occasion of his marriage he distributed largesses to Mussulmans, Jews, and Christians indiscriminately. These liberal measures culminated, however, in his becoming a convert in 827 to the heterodox faith of the Motasali, who asserted the free-will of man and denied the eternity of the Koran. The later years (829–830) of his reign were distracted by hostilities with the Greek emperor Theophilus, occasioned, it is said, by a dispute about an eminent Greek priest whom the caliph wished to attach to his college at Baghdad. A series of revolts in different parts of the Arabian empire betokened the decline of the military glory of the caliphs. Already had Spain and part of Africa asserted their independence, and Egypt and Syria were now inclined to follow. In 833, after quelling Egypt, at least nominally, Mamun marched into Cilicia to prosecute the war with the Greeks; but with this expedition the career of one of the most famous of the caliphs was to terminate. He died near Tarsus, leaving his crown to a younger brother, Motassem. The death of Al-Mamun ended an important epoch in the history of science and letters, and the period of Arabian prosperity which his father's reign had begun. The influence of these two sovereigns is sometimes exaggerated; but there can be no doubt we owe much to their exertions at a time when Europe was sunk in barbarism. Mamun was the author of *Inquiries into the Koran*, of a tract on the *Signs of Prophecy*, and of one on the *Rhetoric of the Priests and Panegyrist of the Caliphs*.

ALMANAC, a book or table, published from year to year, containing a calendar of the days, weeks, and months of the year, a register of ecclesiastical festivals and saints' days, and a record of various astronomical phenomena, particularly the rising and setting of the sun, the changes and phases of the moon, eclipses of the sun and moon, the times of high water at particular ports, &c. In addition to these contents, which may be regarded as essential to the almanac, it generally presents additional information, which is more or less extensive and varied according to the many different special objects contemplated in works of this kind. The derivation of the word is doubtful. The first syllable is the Arabic definite article; the rest of the word has been variously derived from the Greek *μήν*, a month; the Anglo-Saxon *mona*, the moon; and (which appears the most probable derivation) the Arabic *manah*, to reckon.

The CALENDAR will be treated of in a separate article (which see). Here we have to do with the publication which contains the calendar of any particular year, along with other matter, astronomical, statistical, political, &c. The *Ephemeris* again, it is to be observed, is a strict astronomical term, being a register from day to day of the places and motions of the heavenly bodies.

The attention given to astronomy by Eastern nations,

and the practice that prevailed among them of divination by means of the stars, must have led to the early construction of such tables as are comprised in our almanacs. Our information respecting these is extremely scanty; but we are not left in the same ignorance with regard to the practice of the ancient Romans. The peculiar arrangement of their calendar is well known, and their *fasti sacri* or *kalendaræ* were very similar to modern almanacs. Originally knowledge of the calendar was confined to the class of pontifices or priests, whom the people had to consult not only about the dates of the festivals, but also regarding the proper times of instituting various legal proceedings. But about 300 B.C. one Cn. Flavius, the secretary of Appius Claudius, possessed himself of the secret, either by the stealthy use of documents in the possession of his master, or, according to Pliny, by repeatedly consulting the pontifices and jurists, and collating the particulars of the information he obtained from them. It was neither more nor less than publishing an almanac when, as Livy<sup>1</sup> relates, he exhibited the *fasti* on white tablets round the forum. From this time tablets containing the calendar, the festivals, astronomical phenomena, and sometimes historical notices, seem to have been common. The *Fasti* of Ovid is a poetical relation of incidents and traditions connected with the calendar. The researches of antiquaries have brought to light numerous *fasti* or *calendaria* cut on marble and other kinds of stone. Representations of several of these will be found in Gruter's *Inscriptiones*. One figured there, the Farnese rustic calendar, is a cubical block of stone, on each of the four vertical faces of which three columns are engraved, detailing for each different month the number of days, the date of the *nones*, the lengths of the day and night, the sun's place in the zodiac (which is also indicated by a representation of the sign at the top of the column), the tutelary deity of the month, the rural operations of the season, and the chief festivals.

Almanacs of a ruder kind, known as *clogg almanacs*, were in use in some parts of England as late as the end of the 17th century. Dr Robert Plot, keeper of the Ashmolean Museum and professor of chemistry at Oxford, gives a figure of one of these, with a very minute description, in his *Natural History of Staffordshire* (Oxford, 1686); and another is represented in Gough's edition of Camden's *Britannia* (1806, vol. ii. p. 499). The cloggs were square blocks of hard wood, about 8 inches in length, with notches along the four angles corresponding to the days of the year. The accompanying illustration shows the angle

on which is registered the almanac for the months of January, February, and March, taking it from left to right. The marks on the under side in the figure exhibit the primes or golden numbers of a cycle, which is fully described in Plot's work. They generally increase by 8, 19 being struck off when that number is exceeded; and the same number will be found to stand against all the dates (approximately) of new moon throughout the year. The cross mark is for X, and the hook at the end of a line for V. The weeks are indicated by a deeper notch for every seventh day, and a broadening stroke on the upper side in the figure represents the first day of each month.

<sup>1</sup> "Fastos circa forum in albo proposuit, ut quando lege agi posset, sciretur" (ix. 46).

The other characters on the upper side are for saints' days and festivals. Thus Epiphany (Jan. 6) is indicated by a star, St Hilary (Jan. 13) by a bishop's double cross, the conversion of St Paul (Jan. 25) by an axe, St Valentine (Feb. 14) by a true lover's knot, St Matthias (Feb. 24) by a battle-axe, &c. All the feasts of the Virgin, as the Purification (Feb. 2) and the Annunciation (March 25), are denoted by a heart—Dr Plot was greatly puzzled to know why. St Blaise (Feb. 3), St Agatha (Feb. 5), and others were indicated by their initials; and opposite the day (March 1) consecrated to David, the patron saint of Wales, is a symbol which some consider a harp and others a leek.

The earliest almanac regarding which Lalande (whose *Bibliographie Astronomique*, Paris, 1803, is the best authority on publications of this kind) could obtain any definite information belongs to the 12th century. Manuscript almanacs of considerable antiquity are preserved in the British Museum and in the libraries of Oxford and Cambridge. Of these the most remarkable are a calendar ascribed to Roger Bacon (1292), and those of Peter de Dacia (about 1200), Walter de Elvendene (1327), John Somers (1380), &c. It is to be remembered that early calendars (such as the *Kalendarium Lincolnense* of Bishop Robert Grosseteste) frequently bear the names, not of their compilers, but of the writers of the treatises on ecclesiastical computation on which the calendars are based. In 1812 there was printed at Hackney what purported to be a transcription of the greater part of an almanac for 1386. This, if it exists, must be one of the earliest, perhaps the earliest, in the English language that has been preserved. The earliest English calendar in the British Museum is one for the year 1431. The first printed almanac known is one for the year 1457; the first of importance is that of Joannes de Monte-Regio, better known as Regiomontanus, which appears to have been printed at Nuremberg in 1472. In this work the almanacs for the different months embrace three Metonic cycles, or the 57 years from 1475 to 1531 inclusive. The *Ephemerides* of Regiomontanus, which are to be distinguished from his almanac, were sold, it is said, for ten crowns of gold, considerably more than their own weight. The earliest almanac printed in England was *The Kalendar of Sheparden*, a translation from the French, printed by Richard Pynson about 1497.

The exclusive right to sell "almanacs and prognostications," enjoyed in the time of Elizabeth by two members of the Company of Stationers, was extended by James I. to the two universities and the Stationers' Company jointly; but the universities commuted their privilege for an annuity from the company. About a century ago one Thomas Carnan, a bookseller, conceiving that the company had no just title to its monopoly, published an almanac for three successive years, and was thrice imprisoned on that account by the company. In 1775 the case came before the Court of Common Pleas, and was decided in Carnan's favour. The question argued was, "Whether almanacs were such public ordinances, such matters of state, as belonged to the king by his prerogative, so as to enable him to communicate an exclusive right of printing them to a grantee of the crown?" and the judges were unanimously of the opinion that the crown had no such right. The minister, Lord North, made an attempt in 1779 to put the company in possession, by a parliamentary enactment, of what the judges had denied it; but the proposed monopoly was denounced by Erskine and others with such ability and severity that the bill was thrown out by a majority of forty-five. In consequence of this loss to the company of its exclusive right to issue almanacs, the universities lost their title to their annuity, and in lieu of it they received

a parliamentary grant. The company continued, however, virtually to retain its monopoly by buying up as much as possible all the almanacs issued by other publishers, and by means of the great influence it possessed over the book trade. In more recent times the power to control the sale of this class of publications has altogether ceased, but a considerable proportion of the almanacs published in this country still issue from the hall of the Stationers' Company. A lively description of "Almanac Day" at Stationers' Hall will be found in Knight's *Cyclopædia of London* (1851), p. 588.

The influence of the heavenly bodies on the conditions and affairs of men has been believed in, and a superstitious importance has been attached to particular times and seasons by the credulous from the remotest times. As might be imagined, therefore, since the bases on which the whole system of judicial astrology rested all fall within the field of the almanac-makers' labours, great prominence was given to omens and predictions in many of these publications. The early almanacs had commonly the name of "prognostications" in addition, and what they professed to show may be gathered from titles like the following, which is quoted by Mr Halliwell:—"Pronostycacyon of Mayster John Thybault, medycyner and astronomer of the Emperyal Majestie, of the year of our Lorde God mccccxxxiiij., comprehending the iiij. partes of this yere, and of the influence of the mone, of peas and warre, and of the sykenesses of this yere, with the constellacions of them that be under the vij. planettes, and the revolutions of kynges and princes, and of the eclipses and comets." In 1579 Henry III. of France deemed it necessary to prohibit all almanac-makers from indulging in predictions. No such restriction, however, existed in this country; and it was to their prophesyings that the almanacs of the Stationers' Company were long indebted for much of their popularity. Among almanacs of this class published in England, and principally by the Stationers' Company, are Leonard Digges's *Prognostication Everlasting of Right Good Effect*, for 1553, 1555, &c.; William Lilly's *Merlinus Anglicus Junior*, for 1644, &c., and other almanacs and "prognostications;" Booker's *Bloody Almanac* and *Bloody Irish Almanac*, for 1643, 1647, &c.—the last attributed erroneously to Napier; Partridge's *Mercurius Cælestis*, for 1681, *Merlinus Redivivus*, &c. The name of Partridge has been immortalised in Pope's *Rape of the Lock*; and his almanacs were very cleverly burlesqued by Swift, who predicted Partridge's own death, with all details of time and circumstance, in genuine prognosticator's style. The most famous of all the Stationers' Company's predicting almanacs was the *Vox Stellarum* of Francis Moore, dating from about 1680. Of a different but not a better sort was *Poor Robin*, dating from 1663, and published by the company down to 1828, which abounded in coarse, sometimes extremely coarse, humour.

On the 1st of January 1828 the Society for the Diffusion of Useful Knowledge issued the *British Almanac* for that year—a publication greatly superior in every way to the almanacs of the time. To quote the society's *Almanac* for 1829—

"This was almost the first attempt in this country to produce an almanac that should not only be useful to all classes, and of which the information should be wholly of a popular character, but which should be purified from the superstitions, prejudices, and indeencies which have characterised some of the almanacs of which the circulation has been the most extensive. By a parliamentary return of the year 1828 we find that the stamp duty paid upon the almanacs of England exhibits a circulation of 451,593 annually. It may be safely asserted that two-thirds of these publications contain some large portion of the matter just described; and they thus keep alive a spirit of ignorance utterly opposed to the desire for sound and practical information which distinguishes our own times."

The success of the *British Almanac*, with its valuable

supplement, the *Companion to the Almanac*, led to a great improvement in this class of publications. The Stationers' Company issued the *English Almanac*, a work of a similar kind. The entire repeal in 1834, by the 3d and 4th Will. IV., c. 57, of the heavy stamp duty on all almanacs of fifteenpence per copy, gave an additional stimulus to the publication of almanacs of a better class, and from that time the number has greatly increased. It is interesting to remark that the *British Almanac* and *Companion* still exist, and retain their original form and character, and that this has from 1870 been the principal almanac published by the Stationers' Company.

The variety of extraneous matter included in almanacs, corresponding to the very numerous other objects to which the almanac proper is often only secondary, can be merely alluded to here. A number of publications, issued in Germany from the middle of the 18th to the middle of the 19th century, under such titles as *Musenalmanach*, or *Almanach des Muses*, contain some of the best works of some of the most celebrated German poets. The *Almanach de Gotha*, which has existed since 1764, and is published at present both in French and German, gives a particular account of all the royal and princely families of Europe, and ample details, compressed into little space, concerning the administration and the statistics of the different states of the world. As works of general statistical reference, the two national almanacs, *Oliver and Boyd's New Edinburgh Almanac* (from 1837) and *Thom's Irish Almanac* (from 1843), are of very great value.

The *Nautical Almanac* is a publication the object of which is to supply information that is indispensable to the navigator and the astronomer. It gives with the utmost precision the positions of the principal heavenly bodies at short intervals of time, and other important details of celestial phenomena. The moon's exact position is registered for every hour, and also the angular distances at noon and midnight daily of the moon from the sun and several fixed stars. By means of the data thus supplied, in connection with observations of the heavenly bodies, time, latitude, and longitude can be determined. The *Nautical Almanac* has been published regularly since the issue in 1766 of the Almanac for 1767. It was originated by Dr Maskelyne, the astronomer-royal, who conducted it for many years. About 1830 the Lords of the Admiralty were induced by complaints of its defects to bring the subject under the notice of the Royal Astronomical Society. The society appointed a committee to consider what changes seemed necessary, and, on the committee's recommendation, the form was adopted which has continued with little change from 1834 to the present time. During that period the Almanac has been published under the superintendence of the Admiralty. It is issued generally three years at least before it comes into use. The *Connaissance des Temps* (from 1679), the *Berliner Jahrbuch* (from 1776), and the *American Ephemeris and Nautical Almanack* (from 1855) are publications of a similar kind.

(See, in addition to works referred to above, interesting papers by Mr J. O. Halliwell and Professor De Morgan in the *Companion to the Almanac* for 1839, 1840, 1845, 1846.)

ALMANSA, a town of Spain, in the province of Albacete, 35 miles E.S.E. of the town of that name, on the Madrid and Alicante railway. The surrounding plain is very fertile, and irrigated by means of a large reservoir. There are manufactures of linen and cotton fabrics, and also of brandy, leather, and soap. A Moorish castle is to be seen on a hill to the north-west of the town. About a mile from Almansa stands an obelisk commemorating the decisive battle fought here on 25th April 1707, in which the French, under the Duke of Berwick, the natural son

of James II. of England, completely defeated the allied English and Spanish armies. The French greatly outnumbered the opposing force. This battle hastened the conclusion of the war of the Spanish succession. Population of the town, about 8000.

ALMEI, or ALMAI (from *âlim*, wise, learned), the name of a distinct class of singing girls in Egypt. To be received into it, according to M. Savary, it is necessary to have a good voice, to understand the language well, to know the rules of poetry, and be able to compose and sing impromptu couplets adapted to the circumstances. The almai are present at all festivals and entertainments, and also at funerals, where they act the part of hired mourners. They are to be distinguished from the ghawazee, or dancing girls, who perform in the public streets, and are of a lower order.

ALMEIDA, a strongly-fortified town of Portugal, in the province of Beira, situated between the Coa and the Duas Casas, a branch of the Agueda, 95 miles N.E. of Coimbra, and 25 miles from the Spanish fortress of Ciudad Rodrigo. It was taken by the Spaniards in 1762, and again by the French in 1810. The recapture of it by the Duke of Wellington in 1811 was deemed one of the most brilliant exploits of the Peninsular war. It is well fortified, and contains an ancient church and two hospitals. Population, 6580.

ALMEIDA, DON FRANCISCO DE, the first viceroy of Portuguese India, was born at Lisbon about the middle of the 15th century. He was the seventh son of the second Count of Abrantes, and thus belonged to one of the most distinguished families in Portugal. In his youth he took part under Ferdinand of Aragon in the wars against the Moors (1485-92). In March 1505, having received from Emmanuel I. the appointment of viceroy of the newly-conquered territory in India, he set sail from Lisbon in command of a large and powerful fleet, and arrived in July at Quiloa, which yielded to him almost without a struggle. A much more vigorous resistance was offered by the Moors of Mombaza, but the town was taken and destroyed, and its large treasures went to strengthen the resources of Almeida. At other places on his way, such as the island of Anjediva, near Goa, and Cananore, he built forts, and adopted measures to secure the Portuguese supremacy. On his arrival in India he took up his residence at Cochin, where a Portuguese fort had been built by Albuquerque in 1503. The most important events of Almeida's brief but vigorous administration were the conclusion of a commercial treaty with Malacca, and the discoveries made by his son Lorenzo, who acted as his lieutenant. The latter was probably the first Portuguese who visited Ceylon, where he established a settlement, and is also celebrated as the discoverer of Madagascar and the Maldive islands. In 1508 he was killed at Dabul in a naval engagement with the Moors. His father was preparing signally to avenge his death when Albuquerque arrived in Cochin, and presented a commission empowering him to supersede Almeida in the government. It was probably Almeida's unwillingness to be thwarted in his scheme of vengeance that chiefly induced him to refuse to recognise Albuquerque's commission, and to cast him into prison. (See ALBUQUERQUE.) The punishment he inflicted on the Moors was speedy and terrible. Sailing along the coast, he pillaged and burned various ports, including Goa and Dabul, and finally encountering the enemy's combined fleet off Diu early in 1509, he completely destroyed it. Returning immediately to Cochin, he held out for a few months against the claims of Albuquerque, but in November 1509 he was compelled to yield. On the 1st December he set sail for Europe with an escort of three vessels. On the voyage the fleet called at Saldanha Bay, in South Africa, to

procure water, and here Almeida was killed (March 1, 1510) in an unprovoked attack upon the Caffre natives, during which he showed great personal courage. His body was recovered on the following day, frightfully mutilated, and received a hasty burial.

ALMERIA, a modern province of Spain, comprehending the eastern portion of the ancient kingdom of Granada. It is bounded on the N. by Jaen and Murcia, on the E. and S. by Murcia and the Mediterranean, and on the W. by Granada; with an area of about 3300 square miles. The province is traversed by mountain ridges, some of them of considerable elevation, with corresponding valleys and plains of great fertility. The principal sierras are those of Maria, Almahilla, Cabrera, Almagrera, Gata, and Gador, and in the W. some offshoots of the Sierra Nevada. The most considerable rivers are the Almanzora, running from west to east, with a course of about 50 miles; the Almeria, flowing from north-west to south-east; and the Adra from north to south, watering the fertile district between the Sierra de Gador and the Alpujarras. On the S. coast is the Gulf of Almeria, a spacious bay, 25 miles wide at the entrance, and about 10 miles in depth. The climate of the province is mild, except in the interior, where the winter is cold. On the coast rain seldom falls, and south-west winds prevail. The inhabitants are principally engaged in mining and agriculture. Many of the proprietors farm their own land, the number of landed properties being 44,858, while the tenants are only 7365. Of the area of the province, 376,698 acres are arable and pasture land; 13,538 acres vineyards; 5360 acres olive plantations; 30,797 acres cultivated mountain and wood lands; and 1,686,738 acres uncultivated. There are 438,357 head of live stock. All kinds of grain are raised in abundance. The common fruits are plentiful, as well as oranges, lemons, and vines. Much excellent silk is produced in the western districts; cotton is raised to some extent along the coast, and the sugar-cane is also cultivated. Cattle are extensively bred; those of the valley of the Almeria are especially remarkable for their size and beauty. The province is one of the richest in minerals of all Spain, the mountains yielding silver, mercury, lead, antimony, copper, and iron. The silver mines of the Sierra de Almagrera, opened in 1839, produced in 1843 nearly 1,700,000 ounces; while the lead mines of the Sierra de Gador are computed to have yielded, from 1795 to 1841 inclusive, 11,000,000 quintals of lead, and the present annual output is from 30,000 to 40,000 tons of ore. In the Sierra de Gata, jaspers and agates are found; in the Sierra Nevada, to the west, are the celebrated quarries of Macael marble; and the Sierra Cabrera yields antimony, malachite, gypsum, magnetic iron, &c. The manufactures of the province consist chiefly of esparto cordage, white-lead, shot, salt-petre, soap, leather, and earthenware. The principal exports are lead, esparto, barilla, and soap; while the imports include coal and machinery from England, woollen and cotton stuffs from Catalonia, silk from Valencia and Malaga, and linen from Marseilles and Gibraltar. From the want of adequate facilities for communication, the development of the agricultural and mining resources of Almeria has not been so rapid as might have been expected. The disturbances attending the revolution of 1868 have also had a prejudicial effect. Education is in a backward state, the proportion of the population at school being only fifteen in the thousand. Crime, although great, is not excessive, offences against the person forming the greater number of the cases tried. The people generally are simple, sober, and religious. Population in 1870, estimated at 361,553.

ALMERIA, the capital of the above province, lies on the Gulf of Almeria, on the Mediterranean, 72 miles E.S.E.

of Granada. From the strength of the port it was deemed by the Moorish kings of Granada one of the most valuable of their fortresses and their best commercial harbour. Sailing hence, their cruisers overawed the Catalans and Italians, and their merchant ships conveyed the produce of the country to Africa, Egypt, and Syria. In the time of the Moors Almeria was the seat of hordes of pirates. The walls of the town, and the Moorish fortress, or Alcazaba, overlooking it, as well as the architecture of many of the houses, still attest its Moorish origin. It is pretty well built, and has several handsome squares, although the streets are generally narrow. Almeria is the seat of a bishop, and has a cathedral and theological seminaries. Off the port there is good anchorage in 12 and 14 fathoms water; and in addition to its landward defences the place is protected towards the sea by the forts of Trinidad and Tiro. In 1866, 46 vessels, of 21,603 tons, with cargoes, entered and cleared the port; and the annual value of the exports is about £50,000. The manufactures are trifling, but there is a good export trade in wine, soda, esparto, silk, and lead; while the imports consist chiefly of coal and manufactured goods. Here there are also some mineral springs. Population (1857), 27,036.

ALMOHADES (*Almoahedun*, Unitarian), a Mahometan dynasty that flourished in Africa and in Spain during the 12th and 13th centuries. Mohammed-Ibn-Abdallah, the founder of the Almoahedun sect, was the son of a lamp-lighter in the great mosque at Sous-el-Aksa. He studied at Cordova, and afterwards visited Cairo and Baghdad, where he became the disciple of the famous philosopher Algazali. In order to establish his power with his countrymen, he connected himself with Abd-el-Mumen, a young Mussulman of great abilities, whom he sent forth as his apostle to propagate the new doctrine (1116-17); while in his own person he affected an unusual degree of piety and mortification, appearing in tattered garments, and interdicting the use of wine and music and every gratification of the senses. His fame spread rapidly among the mountain tribes of Mahgreb, and the ignorant multitude adopted his opinions with eager zeal. His followers saluted him as the Al-Mehedi on the 28th November 1121. Entering the city of Morocco, this new prophet foretold the downfall of the existing dynasty, and mocked the authority of the reigning prince Ali-Ibn-Yussef. Ali, lulled in security, despised his predictions as the mere ravings of a fanatic; and it was not without some difficulty that he was at length prevailed on to banish him from the city. Mohammed retired to the mountains, and fortified the town of Tinmal, which he defended against every assault of his enemies (1123). His retreat became the rendezvous of a numerous sect, who assumed the title of Almoahedi, or Almohades, and asserted that they alone of all the Mussulmans maintained the religion of Islam in its original purity. Many Arab and Berber tribes acknowledged him as their political chief, and 20,000 soldiers rallied around his standard. Ali only perceived the error he had committed when it was too late: his armies, at each encounter, were panic-struck, and fled. Yet notwithstanding the great success of the Almohades, the vast empire of the Almoravides was not at once subdued: and Mohammed, after an ineffectual attempt to reduce the city of Morocco, died in the year 1130, having failed to accomplish the object of his ambition, the possession of a throne. He was succeeded by Abd-el-Mumen, who assumed the title of *Emir-el-Mumenin*, or Commander of the Faithful. During the thirty years that he reigned, and under his descendants, Yussef and Yakub, called Almanzor-Billah, the dynasty of the Almohades was exceedingly illustrious, and the arts flourished greatly. They rendered themselves masters of

the provinces of Fez, Marocco, Tlemcen, Oran, and Tunis; and passing into Spain, they overran Andalusia, Valencia, and a part of Aragon and Portugal, as far the Ebro on one side and the Tagus on the other. But this vast empire was not of long continuance; for in the year 1212, when the Moslems under Mohammed were defeated by the Christian princes of Spain in the great battle of Las Navas, near Tolosa, the governors of the several provinces took advantage of that disaster to throw off their allegiance, and declared themselves independent—an example that was the signal for a general revolt. The dynasty of the Almohades became extinct in Spain in the year 1257, and in Africa in 1269. The last sovereign of this race, Abu Dabus Edris, who had with difficulty maintained a shadow of power in the city of Marocco, was assassinated by a slave. They were succeeded by the dynasties of the Hassides, the Mevanides, and the Merinides. See ALMORAVIDES.

ALMON, JOHN, a political pamphleteer and publisher of considerable note, was born at Liverpool about 1738. In early life he was apprentice to a printer in his native town, and he subsequently spent two years at sea. He came to London in 1758, and at once commenced a career which, if not important in itself, had a very important influence on the political history of the country. The opposition, hampered and harassed by the government to an extent that threatened the total suppression of independent opinion, were in great need of a channel of communication with the public, and they found what they wanted in Almon. He had become personally known to the leaders through various publications of his own which had a great though transient popularity; the more important of these being *The Conduct of a late Noble Commander* [Lord George Sackville] *Examined* (1759); a *Review of the Reign of George II.*, published on the death of that monarch; a *Review of Mr Pitt's Administration* (1761); and a collection of letters on political subjects. The review of Pitt's administration passed through four editions, and secured for its author the friendship of Lord Temple, to whom it was dedicated. Being thus in the counsels of the party, he was persuaded in 1763 to open a bookseller's shop in Piccadilly, chiefly for the publication and sale of political pamphlets. As he generally received with every pamphlet a sum sufficient to secure him against all contingencies, it cannot be said that he acted entirely from disinterested or patriotic motives. At the same time, he deserves the credit of intrepidity; and it cannot be denied that, whether he knew the full value of the principle for which he was contending or not, he did very much to secure the freedom of the press. The government of course were not unobservant of Almon's proceedings, and, as has often been the case, strengthened his influence by the very measures they took to repress it. In 1765 the Attorney-General moved to have him tried for the publication of the pamphlet entitled *Juries and Libels*, but the prosecution failed; and in 1770, for merely selling a copy of the *London Museum* containing Junius's celebrated "Letter to the King," he was sentenced by Lord Mansfield to pay a fine of ten marks, and give security for his good behaviour. It was this trial that called forth the letter to Lord Mansfield, one of the most bitter of the Junius series. Almon himself published an account of the trial, and of course did not let slip the opportunity of reprinting the matter that had been the ground of indictment, but no further proceedings were taken against him. In 1774 Almon commenced the publication of his *Parliamentary Register*, and he also issued an abstract of the debates from 1742, when Chandler's Reports ceased, to 1774. About the same time, having earned a competency, he retired to Boxmoor in Hertfordshire, though he still continued to write on political subjects. He afterwards became proprietor of the *General Advertiser*,

in the management of which he lost his fortune, and was declared insolvent. To these calamities was added an imprisonment for libel and a sentence of outlawry. Being enabled at last to return to Boxmoor, he continued for some years a career of undiminished literary activity. His last work, a *Life of Wilkes*, in five volumes (1805), was perhaps his worst, being entirely wanting in proportion and arrangement. He died on the 12th December 1805. A complete list of Almon's works, most of which appeared anonymously, is given in Watt's *Bibliotheca Britannica*. Though their literary merit is not great, they are of very considerable value to the student of the political history of the period.

ALMOND. This is the fruit of *Amygdalus communis*, a plant belonging to the natural order Rosaceæ, sub-order Amygdaleæ or Drupiferae. The tree appears to be a native of Asia, Barbary, and Marocco; but it has been extensively distributed over the warm temperate region of the Old World. It is a tree of moderate size; the leaves are oblong-lanceolate, and serrated at the edges; and the flowers, which appear early in spring, are of a pink colour. The fruit is a drupe, having a downy outer coat, called the epicarp, covering a tough portion called the mesocarp, which encloses the reticulated hard stony shell or endocarp. The seed is the kernel which is contained within these coverings. The shell-almonds of trade consist of the endocarps enclosing the seeds. The tree grows in Syria and Palestine; and is referred to in the Bible under the name of *Shaked*, meaning "hasten." The word *Luz*, which occurs in Genesis xxx. 37, and is there translated hazel, appears to be the name of the Almond-tree, while *Shaked* is the name of the fruit.

The Almond-tree (*Amygdalus communis*), the fruit of which is a drupe with a tough mesocarp. The Hebrew word *Shaked* is generally translated Almond (Gen. xliii. 11; Exod. xxv. 33, 34; xxxvii. 19; Numb. xvii. 8). The word *Luz*, which occurs in Genesis xxx. 37, and is there translated hazel, appears to be the name of the Almond-tree, while *Shaked* is the name of the fruit.

The Almond-tree (*Amygdalus communis*), the fruit of which is a drupe with a tough mesocarp. The Hebrew word *Shaked* is generally translated Almond (Gen. xliii. 11; Exod. xxv. 33, 34; xxxvii. 19; Numb. xvii. 8). The word *Luz*, which occurs in Genesis xxx. 37, and is there translated hazel, appears to be the name of the Almond-tree, while *Shaked* is the name of the fruit. The tree grows in Syria and Palestine; and is referred to in the Bible under the name of *Shaked*, meaning "hasten." The word *Luz*, which occurs in Genesis xxx. 37, and which has been translated hazel, is supposed to be another name for the almond. In Palestine the tree flowers in January, and this hastening of the period of flowering seems to be alluded to in Jeremiah i. 11, 12, where the Lord asks the prophet, "What seest thou?" and he replies, "The rod of an almond-tree;" and the Lord says, "Thou hast well seen, for I will hasten my word to perform it." In Ecclesiastes xii. 5 it is said the "almond-tree shall flourish." This has often been supposed to refer to the resemblance of the hoary locks of age to the flowers of the almond; but this exposition is not borne out by the facts of the case, inasmuch as the flowers of the almond are not white but pink. The passage is more probably intended to allude to the hastening or rapid approach of old age. The application of *Shaked* or *hasten* to the almond is similar to the use of the name "May" for the hawthorn, which usually flowers in that month in Britain. The rod of Aaron, mentioned in Numbers xvii., was taken from an almond-tree; and the Jews still carry rods of almond-blossom to the synagogues on great festival days. The fruit of the almond supplied a model for certain kinds of ornamental carved work (Exodus xxv. 33, 34; xxxvii. 19, 20). Dr Tristram remarks: "The blossom of the almond is a very pale pink, but where, as in the

orchards near Nablous (Shechem), the peach and almond trees are intermingled, the almond looks white by comparison. In early spring it forms a beautiful feature in the landscape there, as the lower slopes of Gerizim, as well as the valley, are studded with almonds and peaches, in lively contrast with the deep green foliage of the orange-trees, and rivalling an apple orchard in splendour of colour. There are also many wild almond-trees on Mount Carmel. "The tree seldom exceeds 12 to 16 feet in height." There are two varieties of the plant, the one producing sweet, the other bitter almonds. The kernel of the former contains a fixed oil and emulsin; while that of the latter has in addition a nitrogenous substance called amygdalin, which, by combination with emulsin, produces a volatile oil and prussic acid. The flowers of the bitter almond-tree (*Amygdalus communis*, variety *amara*) are larger and whiter than those of the sweet almond-tree (*Amygdalus communis*, variety *dulcis*). The sweet almond is bland and inodorous. There are numerous commercial varieties, of which the most esteemed is the Jordan almond, imported from Malaga. Valentia almonds are also valued. Fresh sweet almonds are nutritive and demulcent, but as the outer brown skin or epispem sometimes causes irritation of the alimentary canal, they are blanched by removal of this skin when used at dessert. When bitter almonds are pounded in water a ratafia odour is produced, on account of the formation of prussic acid. The essential oil or essence of almonds, so much employed for flavouring dishes, requires to be used with caution, as it possesses marked poisonous qualities. In some cases the oil, even when taken in small quantities, produces nettle-rash. The import of sweet almonds into Britain in 1870 amounted to 36,189 cwt.; of bitter almonds, 7618 cwt.

**ALMONDBURY**, an extensive parish and township of Yorkshire in England, lying to the S.E. of Huddersfield. As the manufactures of Huddersfield have increased, various outlying districts have been built on, so that the parish of Almondbury now includes a considerable part of that important and flourishing town. The parish contains 28,092 acres. The town lies on the river Calder, 2 miles S.E. of Huddersfield, and had formerly a cathedral and a strong castle. By some writers it is supposed to occupy the site of the Roman *Campodunum* mentioned by Antoninus; but whether or not, the place can boast a Roman origin—it was at least a town of importance in Saxon times, and a seat of the kings of Northumbria. It has a free grammar school founded by James I., a good church, and several other public buildings. The inhabitants of the town and parish are chiefly engaged in the manufacture of fine cloths, and woollen, cotton, and silk goods. In 1871 the population of the parish was 46,299; of the township, 11,669.

**ALMONER**, in its primitive sense, denotes an officer in religious houses, to whom belonged the management and distribution of the alms of the house. By the ancient canons, all monasteries were to spend at least a tenth part of their income in alms to the poor, and all bishops were required to keep almoners.

**LORD ALMONER**, or **LORD HIGH ALMONER OF ENGLAND**, is an ecclesiastical officer, generally a bishop, who has a right to the forfeiture of all deadlands and the goods of a *felo de se*, which he is to distribute among the poor. He has also, by virtue of an ancient custom, the power of giving the first dish from the king's table to whatever poor person he pleases, or, instead of it, an alms in money. See **MAUNDAY THURSDAY**.

**ALMORÁ**, the principal town in the British district of Kumáon, within the lieutenant-governorship of the North-Western Provinces, is situated in 29° 35' N. lat., and 79° 42' E. long. The town is built on the crest of a ridge of

the Himálayas, running east and west, and 5337 feet above sea-level. It consists chiefly of a single street, about 50 feet wide and three-quarters of a mile long, closed by a gate at each end. A few detached houses, inhabited by Europeans, are scattered along the face of the mountain below the town. The town was captured by the Gurkhás in 1790, who constructed a fort on the eastern extremity of the ridge. Another citadel, Fort Moira, is situated on the other extremity of the ridge. Almorá is also celebrated as the scene of the British victory which terminated the war with Nepál in April 1815, and which resulted in the evacuation of Kumáon by the Gurkhás, and the annexation of the province by the British. According to the census of 1872, the town contains a population of 5900 souls. It has been constituted a municipality, the revenue and expenditure of which in 1871-72 is returned as follows:—Revenue—Receipts from octroi, £29, 16s.; house-tax, £211, 8s.; other sources of income, £30, 14s.: total, £271, 18s. Expenditure—Establishment, including cost of collection, police, and conservancy, £182; repairs, £90, 16s.; other items, £3, 16s.: total, £276, 12s.

**ALMORAVIDES**, a family of Mahometan princes who reigned in Africa and in Spain between 1073 and 1147 A.D. This appellation was derived from the sect of *Al-Morabethun* (Dedicated to the service of God), which arose about the middle of the 11th century, among a poor ignorant tribe of Berbers inhabiting the mountains of Atlas, on the shores of the Atlantic Ocean. At the request of a sheik of Lamtouna, who had acquired some taste for learning by travelling in the East, Abdallah-ben-Yazim, an Arabian of extraordinary erudition, consented to instruct the people in the truths of Islam. The enthusiasm of Abdallah created a like zeal in the hearts of his ignorant hearers; and by the energy and novelty of his discourses he so inflamed the minds of his disciples that they compelled those whom persuasion could not move to embrace the new religion. Thus Abdallah found himself at the head of a numerous sect, who soon began to regard him as their leader both in temporal and spiritual matters. Under the name of Almorabethun or Almoravides, they overran the country of Daza, lying between the desert of Sahara and the ancient Getulia, and ultimately extended their conquests from the shores of the Mediterranean to the frontiers of Nigritia. Abdallah died on the field of battle in the year 1058. He was succeeded by Abu-Bekr-Ibn-Omar, a man whose abilities were scarcely equal to the difficulties of the position in which he was placed. In 1072 he was supplanted by Yussef-Ibn-Tashfyn, to whom he had entrusted the government on setting out for Atlas to quell an insurrection of the Berbers. Yussef completely established the Almoravide power in Al-Magreb in 1073. On the invitation of Mohammed of Seville, he crossed to Algeciras in 1086, and at once marched against Alphonso VI., the most powerful prince in Christendom. They met in the plains of Zalaca (23d Oct. 1086), and Alphonso was defeated with terrible slaughter. The news of Yussef's success induced many of the Arabs of Spain to enlist under his victorious banner. In a third expedition to Spain (1091), he attacked Mohammed, and after a protracted siege became master of Seville. This conquest was followed by the subjugation of Almeria, Denia, Xativa, and Valencia. The acquisition of the Balearic Isles was the completion of this vast empire, which extended from the Ebro and the Tagus to the frontiers of Soudan. Although Morocco was his capital, he frequently visited his Spanish dominions; and on the last occasion, having assembled the governors of the province at Cordova, he appointed Ali, the youngest of his sons, as his successor. He then returned to Morocco, where he died at a very advanced age, 1106 A.D. (500 of the Hegira), after a reign of forty years.

Few kings have received so noble a heritage as that to which Ali succeeded. The first years of his reign were prosperous, though disturbed by the Almohades, who were preparing the way for the destruction of the Almoravides. Ali was at last obliged to recall from Spain his son Tashfyn, who was using his utmost endeavours to oppose the victorious career of Alphonso of Aragon, surnamed the Fighter. But the valour of Tashfyn was of little avail against the rising power of the Almohades: disaster followed disaster; and when, in 1143, he succeeded to the throne, but a moiety of the kingdom remained. It was in vain that he received succours from Spain, the troops from that soft climate being little fitted for service in the wild regions of Atlas. Driven from Tlemecen, he sought refuge in Oran; but Abd-el-Mumen appeared before its walls, and by threats so intimidated the inhabitants that Tashfyn was compelled to attempt escape on horseback, with his favourite wife behind him; but being closely pursued, he urged his horse over a precipice, and with his wife was dashed to pieces. With Tashfyn expired the domination of the Almoravides; for although they still remained in possession of the city of Marocco, their power was completely broken. Ishak-Ibrahim, the son of Tashfyn, was taken and put to death at Alcazar in 1147, on the surrender of Marocco by treachery, and with him the dynasty of the Almoravides became extinct. The remnant of the sect, driven from Spain, took refuge in the Balearic Islands, but it was finally suppressed in 1208. (For the history of the Arabians in Spain, see the works of Cardonne, Condé, St Hilaire, D'Herbelot, Al-Makkari, and Dozy.)

ALMQVIST, KARL JONAS LUDWIG, one of the most extraordinary figures that the history of literature can produce, was born at Stockholm in 1793. He began life under highly favourable auspices; but becoming tired of a university career, he threw up the position he held in the capital to lead a colony of friends to the wilds of Wernland. This ideal Scandinavian life soon proved a failure; Almqvist found the pen easier to wield than the plough, and in 1829 we find him once more settled in Stockholm. Now began his literary life; and after bringing out several educational works, he made himself suddenly famous by the publication of his great novel, *The Book of the Thorn-Rose*. The career so begun developed with extraordinary rapidity; few writers have equalled Almqvist in productivity and versatility; lyrical, epic, and dramatic poems; romances; lectures; philosophical, æsthetical, moral, political, and educational treatises; works of religious edification, studies in lexicography and history, in mathematics and philology, form the most prominent of his countless contributions to modern Swedish literature. So excellent was his style, that in this respect he has been considered the first of Swedish writers. His life was as varied as his work. Unsettled, unstable in all his doings, he passed from one lucrative post to another, at last subsisting entirely on the proceeds of literary and journalistic labour. More and more vehemently he espoused the cause of socialism in his brilliant novels and pamphlets; friends were beginning to leave him, foes beginning to triumph, when suddenly all minor criticism was silenced by the astounding news that Almqvist, convicted of forgery and charged with murder, had fled from Sweden. This occurred in 1851. For many years no more was heard of him; but it is now known that he went over to America, and under a feigned name succeeded in being appointed secretary to Abraham Lincoln. After Lincoln's death, Almqvist again fell under the ban of the law; his MSS., including several unprinted novels, were confiscated and destroyed, but he himself escaped to Europe, where under another alias he continued to exist a short time longer. His strange and sinister existence came to a close at Bremen in 1866. It is by his romances, un-

doubtedly the best in Swedish, that his literary fame will mainly be supported; but his singular history will always point him out as a remarkable figure even when his works are no longer read. He was another Eugene Aram, but of greater genius, and so far more successful that he escaped the judicial penalty of his crimes. (E. W. G.)

ALMUG or ALGUM TREE. The Hebrew words *Almuggim* or *Algummin* are translated Almug or Algum trees in our version of the Bible (see 1 Kings x. 11, 12; 2 Chron. ii. 8, and ix. 10, 11). The wood of the tree was very precious, and was brought from Ophir (probably some part of India), along with gold and precious stones, by Hiram, and was used in the formation of pillars for the temple at Jerusalem, and for the king's house; also for the inlaying of stairs, as well as for harps and psalteries. It is probably the red sandal-wood of India (*Pterocarpus santalinus*). This tree belongs to the natural order Leguminosæ, sub-order Papilionaceæ. The wood is hard, heavy, close-grained, and of a fine red colour. It is different from the white fragrant sandal-wood, which is the produce of *Santalum album*, a tree belonging to a distinct natural order.

ALMUNECAR, a small seaport town of Spain, in the province of Granada, about 33 miles south of the town of that name. It is a place of Moorish origin, and is tolerably well built. The harbour is fit for small vessels only, and is much exposed to gales from the east. Sugar, cotton, and fruits are the chief products of Almunecar and the surrounding country, which is naturally very fertile, but the trade is small compared with that of former times. Population, 5000.

ALNWICK, the county town of Northumberland, is situated on the south bank of the river Alne, 310 miles N. of London, 34 N. of Newcastle, and 29 S. of Berwick. There are remains of the old wall which surrounded the town, and one of the four gates still exists; but most of the houses are comparatively modern, and are laid out in well-paved spacious streets. In the market-place there is a large town-hall, and a handsome building containing an assembly-room and a reading-room. Besides the parish church, Alnwick possesses a beautiful district church, a Roman Catholic chapel, and several Protestant dissenting places of worship. The chief employments are brewing, tanning, and brickmaking, but these manufactures are here of little importance. A small export trade is carried on through Alnmouth in corn, pork, and eggs, and a market is held every Saturday chiefly for these articles. The local government consists of a bailiff, nominated by the Duke of Northumberland, and twenty-four common councilmen, four of whom are elected annually as chamberlains; the councilmen fill up vacancies in their body from the freemen, who usually are about 300 in number. The ceremony of making freemen is of a very peculiar kind. The candidates, mounted on horseback, assemble in the market-place very early in the morning of St Mark's day—the 25th April—clad in white from head to foot, with swords by their sides, and attended by the bailiff and chamberlains, who are mounted and armed in the same manner. From the market-place they proceed, with music playing before them, to a large pool called *Freeman's Well*, where they dismount and draw up in a body at some distance from the water, and, on a given signal from the bailiff, rush into the pool, and scramble through the mud as fast as they can. As the water is generally very foul, they come out in a dirty condition; but they put on dry clothes, remount their horses, and ride at full gallop round the boundaries of the town. According to tradition, the observance of this custom was enjoined by King John to punish the inhabitants for their carelessness, the king having, it is said, lost his way, and been bemired in a bog, from their neglect of the roads near the town. To the

north west of the town is Alnwick Castle, which has belonged to the Northumberland family since 1310. In early times this fortress was an important defence against the Scotch, and was besieged by them on several occasions, most memorably in 1093, when Malcolm Canmore and his son Edward were slain under its walls; and in 1174, when William the Lion was defeated and taken prisoner. For a long time it was permitted to fall into decay, but it has recently been restored, and to some extent remodelled, and is now one of the most magnificent specimens of a baronial residence in England. The grounds are extensive, and contain the remains of two abbeys, Alnwick and Hulme. The population of Alnwick in 1871 was 5822.

**ALOE.** Aloes is a medicinal substance used as a purgative, and produced from various species of aloe, such as *A. spicata*, *vulgaris*, *socotrina*, *indica*, and *purpurascens*, all belonging to the natural order Liliaceæ. Several kinds of aloes are distinguished in commerce—Barbadoes, socotrine, hepatic, Indian, and Cape aloes. The first two are those commonly used for medicinal purposes. Aloes is the inspissated juice of the leaves of the plant. When the leaves are cut the juice flows out, and is collected and evaporated. After the juice has been obtained, the leaves are sometimes boiled, so as to yield an inferior kind of aloes. The active principle is called aloein. Aloes is used in the form of extract, pill, tincture, and wine. It is irritant, and requires to be used with caution.

The plant called American aloe belongs to a different order, viz., Amaryllidaceæ. The plant is called *Agave Americana*. The juice of the plant, taken immediately before flowering, is used in America for the manufacture of an intoxicating beverage. In Ecuador the spongy substance of the flower stem is used instead of tinder, and in the schools the green leaves serve as paper. A punishment among the Aztecs was introducing the spiny points of the leaves into the skin. The plant often delays flowering for many years, and then pushes up a flowering stalk with great rapidity, sometimes at the rate of 1 foot or even 2 feet in twenty-four hours. The fibrous matter procured from the agave by maceration supplies pita flax.

The aloes or lign aloes of the Bible (Numb. xxiv. 6, and Psalm xlv. 8) is quite different from the medicinal aloes. The Hebrew words *ahalim* and *ahaloth*, and the Greek word *aloe*, are rendered aloes in our version of the Scriptures. The substance is supposed by some to be the fragrant wood of *Aquilaria Agallochum*, a plant belonging to the natural order Aquilariaceæ. There are, however, considerable doubts as to the correctness of this view, more especially as the tree is a native of Cochin China, Silhet, and Northern India, and is not found in Chaldea or Syria. From the allusion made to the trees of lign aloes by Balaam, it seems probable that they were known as growing in Syria. It is quite possible, however, that the precious fragrant substance called aloes, and mentioned in Scripture along with cinnamon, cassia, myrrh, and spices, may have been brought from India. As a perfume it is noted in Psalm xlv. 8; Prov. vii. 17; Song of Sol. iv. 14. The use of aloes in perfuming the coverings of the dead is referred to in John xix. 39, 40.

**ALOIDÆ**, or **ALOIDÆ**, the designation of Otus and Ephialtes, sons of Poseidon by Iphimedeia, wife of Aloeus. They are celebrated for their extraordinary stature, being 27 cubits in height and 9 in breadth when only nine years old. The story of their piling Pelion upon Ossa in their war with the Olympian gods is one of the best known of the early Greek myths. According to Homer's account, they were destroyed by Apollo ere their beards began to grow. (*Odyssey*, xi. 305; *Iliad*, v. 385.)

**ALOMPRA**, **ALOUNG P'HOURA**, founder of the reigning dynasty in Burmah, was born in 1711 at Monchaboo, a

small village 50 miles north-west of Ava. Of humble origin, he had risen to be chief of his native village when the invasion of Birman by the king of Pegu in 1752 gave him the opportunity of attaining to the highest distinction. The whole country had tamely submitted to the invader, and the leading chiefs had taken the oaths of allegiance. Alompra, however, with a more independent spirit, not only contrived to regain possession of his village, but was able to defeat a body of Peguan troops that had been sent to punish him. Upon this the Birmese, to the number of a thousand, rallied to his standard, and marched with him upon Ava, which was recovered from the invaders before the close of 1753. For several years he prosecuted the war with uniform success. In 1754 the Peguans, to avenge themselves for a severe defeat at Keoum-nuoum, slew the king of Birman, who was their prisoner. The son of the latter claimed the throne, and was supported by the tribe of Quois; but Alompra resisted, being determined to maintain his own supremacy. In 1755 Alompra founded the city of Rangoon. In 1757 he had established his position as one of the most powerful monarchs of the East by the invasion and conquest of Pegu. Ere a year clasped the Peguans revolted; but Alompra, with his usual promptitude, at once quelled the insurrection. The Europeans were suspected of having instigated the rising, and the massacre of the English at Negrais in October 1759 is supposed to have been approved by Alompra after the event, though there is no evidence that he ordered it. Against the Siamese, who were also suspected of having abetted the Peguan rebels, he proceeded more openly and severely. Entering their territory, he was just about to invest the capital when he was seized with an illness which proved fatal on the 15th May 1760. Alompra is certainly one of the most remarkable figures in modern Oriental history. To undoubted military genius he added considerable political sagacity, and he deserves particular credit for his efforts to improve the administration of justice. His cruelty and deceitfulness are faults common to all Eastern despots.

**ALOST**, or **AALST**, a town of Belgium, on the eastern frontier of the province of East Flanders, about midway between Ghent and Brussels. The Dender, a navigable tributary of the Scheldt, passes through the town, which is a clean, well-built place, surrounded by a wall with five gates. The church of St Martin, a fine edifice, although unfinished, contains a celebrated picture by Rubens, "St Roche Praying for the Cessation of the Plague." Among the other public buildings are a town-hall, which was founded about 1200 A.D., a college, and an hospital. The trade is extensive, chiefly in corn, oil, hops, and beer; and there are linen, lace, and cotton manufactories, and iron foundries of considerable importance. Alost was formerly the capital of imperial Flanders. The French under Turenne took it in 1667, but were obliged to abandon it after the battle of Ramillies in 1706. Population, 19,000.

**ALPACA** is a name applied generally to several allied South American wool-bearing animals, but more properly restricted to one of the species. It is further used to distinguish the wool obtained from these animals, and the woven textures manufactured from the wool are also known as alpacas. The alpacas or llamas are natives of the lofty table-lands and mountain-range of the Andes in Peru and Chili, and in that region of the globe they long occupied the position held in the Old World by their congeners of larger size, the camels. To the ancient Peruvians the llamas were the only available beasts of burden and wool-bearing creatures, just as to the present day the camel is to the tribes of the Asiatic deserts. The camel (*Camelus*) and the llama (*Auchenia*) form the two existing genera of the family Camelidæ; and thus in a zoological sense also the one

represents the other in different regions of the earth. A great deal of doubt and confusion has existed as to the number of species into which the llamas can be divided—a very common occurrence in dealing with domesticated or semi-domesticated creatures. Most authorities now, however, agree in regarding them as separable into four species, following the classification of Von Tschudi, who has given much careful consideration to the subject. The species, according to that naturalist, are the llama (*Auchenia lama*), the huanaco or guanaco (*A. huanaco*), the alpaca or paco (*A. paco*), and the vicugna (*A. vicugna*.) The two first-named species are, or rather were, more valued as beasts of burden, and for their flesh, than as sources of wool, being able to bear from 120 to 150 lb burden over long distances daily. The guanaco attains a size not much less than our red deer; and is the largest and most widely spread of all the species, being found from the equator southward to Patagonia. The llama is next in size, but its habitat is limited to the loftier mountains of North Peru. Although both species yield a serviceable quality of wool, which is used by the Peruvians and found in commerce, it is chiefly to the alpaca we owe the supply of wool imported into this country under that name. The alpaca is considerably smaller than either the llama or the guanaco, but in general outline all the species resemble each other. In its native condition the alpaca ranges between 10° and 20° S. lat., from the centre of Peru into Bolivia, not coming lower down in vertical distribution than between 8000 and 9000 feet above the sea-level. At and above these heights it lives in herds in a semi-domesticated condition, being only driven into the villages to be shorn. The wool, which varies in length from 2 to 6 inches, is of a very lustrous and fine quality, and is mostly white, black, or gray, shades of brown or fawn being rarer. The vicugna is a much rarer animal than the alpaca, being found sparsely scattered from Ecuador, throughout Peru, into Bolivia, but seldom descending under 13,000 feet above the sea-level. It is about the same size as the alpaca, and yields an exceedingly delicate wool, varying in colour from a reddish yellow to a dull white. It is usually worth about twice as much as alpaca, and is greatly valued for fine felts.

There is evidence of these animals having been held domesticated and used for their wool in their native regions from remote antiquity. Remains of clothing made from alpaca wools have been found in the graves of the Incas; and when, in the early part of the 16th century, Europeans first visited Peru, these animals formed the chief wealth of the natives, being the carriers of their commerce as well as the main source of their food and clothing. Small quantities of the wool were occasionally met with in English commerce; but it was not till 1836 that it became established as a regular trading commodity with Europe. In that year Mr (now Sir) Titus Salt, a wool-broker and manufacturer in Bradford, purchased a quantity he met with in a Liverpool warehouse at 8d. per lb, and set himself to discover its capabilities. The amount and manner of his success will be described in the articles WOOL and WORSTED MANUFACTURES; it need only be remarked here that his experiments have resulted in making alpaca a staple second in importance to wool, and so creating an industry of great and rapidly increasing dimensions. The success of his experiments led to the erection of his great manufacturing establishment of Saltaire, in which upwards of 3000 hands are employed in the alpaca manufacture. The quantity of alpaca imported into England from 1836—the year of Sir Titus Salt's first experimental purchase—to 1840, averaged 560,800 lb yearly, which sold at about 10d. per lb. In 1852 the imports had risen to 2,186,480 lb, and the price advanced to 2s. 6d. per lb. In 1864 the

imports amounted to 2,664,027 lb, and in 1872 they were 3,878,739 lb; the value of average qualities being from 2s. 6d. to 2s. 10d. per lb. The introduction of the various species of llama into Europe has been frequently urged, Geoffroy St Hilaire and other French naturalists having specially pointed out the desirability of their introduction into France, and at one time a herd existed in the Pyrenees; but in Europe the creatures must be still regarded as curiosities of zoological collections. In 1859 systematic and costly attempts were made to acclimatise the alpaca in our Australian colonies by Mr Ledger, a gentleman who had devoted many years to observation of the conditions of life of the animal. At first the experiment presented most encouraging prospects; the herds continued healthy and increased in numbers; but gradually the subtle influences of the loss of their native mountain climate became apparent,—the creatures drooped, their numbers dwindled, and for the present the undertaking must be regarded as a complete failure.

ALP ARSLAN or AXAN, MOHAMMED BEN DAUD, the second sultan of the dynasty of Seljuk, in Persia, and great-grandson of Seljuk, the founder of the dynasty. He was born in the year 1029 A.D., 421 of the Hegira. He assumed the name of Mohammed when he embraced the Mussulman faith; and on account of his military prowess he obtained the surname *Alp Arslan*, which signifies “a valiant lion.” He succeeded his father Daoud as ruler of Khorassan in 1059, and his uncle Togrul Bey as sultan of Oran in 1063, and thus became sole monarch of Persia, from the river Oxus to the Tigris. In consolidating his empire and subduing contending factions he was ably assisted by Nizam-ul-Mulk, his vizier, one of the most eminent statesmen in early Mahometan history. Peace and security being established in his dominions, he convoked an assembly of the states, and declared his son Malik Shah his heir and successor. With the hope of acquiring immense booty in the rich temple of St Basil in Cæsarea, the capital of Cappadocia, he placed himself at the head of the Turkish cavalry, crossed the Euphrates, and entered and plundered that city. He then marched into Armenia and Georgia, which, in the year 1064, he finally subdued. To punish the Georgians for the brave defence which they had made, and as a badge of their humiliating condition, the conqueror obliged them to wear at their ears horse-shoes of iron. In the year 1068 Alp Arslan invaded the Roman empire, the seat of which was then at Constantinople. The Emperor Romanus Diogenes, assuming the command in person, met the invaders in Cilicia. In three several campaigns his arms were victorious, and the Turks were forced to retreat beyond the Euphrates. In the fourth he advanced with an army of 100,000 men into the Armenian territory, for the relief of that country. Here he was met by Alp Arslan; and the sultan having proposed terms of peace, which were insultingly rejected by the emperor, a bloody and decisive engagement took place near Malazkurd, in which the Greeks, after a terrible slaughter, were totally routed. Romanus was taken prisoner and conducted into the presence of Alp Arslan, who treated him with a noble generosity. A ransom of a million and an annual tribute of 3000 pieces of gold, an intermarriage between the families, and the deliverance of all the captive Mussulmans in the power of the Greeks, having been agreed to as the terms of peace and the liberty of the emperor, Romanus was dismissed, loaded with presents and respectfully attended by a military guard. He was unable, however, to fulfil the terms of the treaty, and the war was accordingly renewed. At this time the dominion of Alp Arslan extended over the fairest part of Asia: 1200 princes or sons of princes surrounded his throne, and 200,000 soldiers were ready to execute his commands. He now declared

his purpose of attempting the conquest of Turkestan, the original seat of his ancestors. After great preparations for the expedition, he marched with a powerful army, and arrived at the banks of the Oxus. Before he could pass the river with safety, it was necessary to gain possession of some fortresses in its vicinity, one of which was for several days vigorously defended by the governor, Yussuf Kothual, a Kharizmian. He was, however, obliged to surrender, and was carried a prisoner before the sultan. Being condemned to suffer a cruel death, Yussuf became incensed, rushed upon the sultan, and stabbed him in the breast. The wound proved mortal, and Alp Arslan expired a few hours after he received it, on the 15th Dec. 1072.

ALPES, the name of three departments in the south-east of France,—*Basses Alpes*, *Hautes Alpes*, and *Alpes Maritimes*.

BASSES ALPES is bounded on the N. by the department of Hautes Alpes; on the E. by the kingdom of Italy and the department of Alpes Maritimes; on the S. by the departments of Var and Bouches du Rhône; and on the W. by those of Vaucluse and Drôme. It extends at the widest points 90 miles from N.E. to S.W., and 70 from E. to W., and contains an area of 2680 square miles. Its surface is mountainous, especially on the north-east, where offshoots of the Maritime Alps penetrate into the country, rising near the river Ubaye to an elevation of over 9000 feet above the level of the sea. With the exception of the south-eastern corner, which is drained by the Var, the whole department is in the basin of the Durance, which for a considerable distance separates Basses from Hautes Alpes, but eventually strikes southward through the former. Its chief tributaries are the Buech and the Jabron on the right, and the Ubaye, the Bléone, the Asse, and the Verdon on the left. The climate in the mountainous districts of the north is cold and variable. The soil there is poor, but it is cultivated with great industry—producing rye, oats, barley, potatoes, and timber. In the south and south-west, however, where the country is comparatively flat, the temperature is milder and the soil more fertile; here plums, almonds, apricots, peaches, and other fruits are produced in large quantities, as well as wine of an excellent description, chiefly for home consumption. Considerable numbers of cattle, sheep, goats, and pigs are reared in the Basses Alpes, besides which many flocks of sheep, from Var and Bouches du Rhône, are pastured during summer in the upper valleys of the department. Game is abundant. There are mines of lead and other metals of some value. The manufactures are few and of little importance, the chief being leather, coarse woollen cloths, cutlery, earthenware, and paper. Basses Alpes, one of the departments formed out of ancient Provence, is divided into five arrondissements—Digne, in the centre; Barcelonnette and Castellane, on the east; Sisteron and Forcalquier on the west; which together contain 30 cantons and 251 communes. Digne is the capital and the seat of a bishop, whose diocese is co-extensive with the department; and among the other towns are Barcelonnette, Castellane, Sisteron, Forcalquier, and Manosque. Population (1871), 139,332.

HAUTES ALPES is bounded on the N. by the departments of Isère and Savoie; on the E. by the kingdom of Italy; on the S. by the department of Alpes Basses; and on the W. by that of Drôme. It extends nearly 80 miles from N.E. to S.W., and contains an area of 2158 square miles. Its surface is very mountainous, being traversed in all directions by the Cottian and Dauphiné Alps, which, in Mont Pelvoux and other peaks, rise to an eleva-

tion of about 13,000 feet above the sea, the highest summits in France. The Drac, flowing northwards into the Isère, and the Durance, with its tributaries the Guil and the Buech, are the chief rivers of Hautes Alpes. The climate is cold in winter, and in summer variable; the soil is barren, yielding only oats, barley, potatoes, rye, and timber, except in a few favoured valleys, where wine of a fair quality and fruits of various kinds are produced. Large numbers of sheep and other domestic animals are reared or pastured in the department. Game, both large and small, is found in great abundance. The mines produce lead, copper, iron, and other metals. There are no manufactures of any commercial importance, although some leather, coarse woollen cloth, hats, woodwork, and iron wares are made. Hautes Alpes, a part of the old province of Dauphiné, is divided into three arrondissements: Gap on the west, Embrun on the south-east, and Briançon on the north-east, with 24 cantons and 89 communes. The capital is Gap, the seat of the bishop; Embrun and Briançon being the only other towns of any size. Population, 118,898.

ALPES MARITIMES, bounded on the N. by Basses Alpes and the kingdom of Italy, which also forms its boundary on the E.; on the S. by the Mediterranean Sea; and on the W. by Var and Basses Alpes. It extends at the widest points 55 miles from N. to S., and 50 from E. to W.; and contains an area of 1517 square miles. The surface of this department, like that of the two former, is more or less mountainous, branches of the Maritimes Alps covering the greater part of the territory. It is watered by the Roya, the Paillon, the Var (with its tributaries the Tinéa and the Esteron), the Loup, and the Siagne. The climate is on the whole warm and gentle, except among the higher mountains; while the mildness of the temperature along the shores of the Mediterranean has made that portion of the department a favourite resort for invalids. The upper valleys and mountain slopes are chiefly devoted to pasture for sheep, being ill-suited for cultivation, although a little barley and maize is grown; the richer districts of the south produce fruits of various kinds, tobacco, honey, and flowers, used in the making of perfumes. The other manufactures are of dried fruits, olive-oil, preserved anchovies and sardines, silk, soap, and paper. Alpes Maritimes is divided into three arrondissements—Grasse and Nice on the south, and Puget Théniers on the north, containing 25 cantons and 146 communes. The arrondissements of Nice and Puget Théniers constitute the bishopric of Nice; Grasse belongs to that of Fréjus. Nice is the capital; and among the other towns are Mentone, Villafanche, Grasse, Antibes, Cannes, and Puget Théniers. The Marseilles, Nice, and Ventimille railway, skirting the coast, connects Cannes, Antibes, Nice, and Mentone, and joins an Italian line which affords direct railway communication with Genoa. The department of Alpes Maritimes was formed in 1860 from the territory of Nice, which had been ceded to France, together with Mentone and Roccabruna, purchased from the Prince of Monaco, and the arrondissement of Grasse, transferred from Var. It had a population of 119,037 in 1871.

ALPHA and OMEGA (Α and Ω), the first and last letters of the Greek alphabet, frequently employed to symbolise the idea of completeness or infinity. They are used as a designation of himself by the speaker in Rev. i. 8; xxi. 6; xxii. 13. In the last passage the speaker is undoubtedly Jesus Christ. In the symbolism of the early church Α and Ω, combined with a cross or with the monogram of Χριστός, represented Christianity, or, more specifically, faith in the divinity of Christ.

## ALPHABET

BY an alphabet we mean a list of symbols which represent conventionally to the eye the sounds which are heard in the speech of a nation. An alphabet will therefore be perfect if the number of its symbols exactly corresponds to the number of simple sounds which are commonly distinguishable in the spoken language. But this perfection has probably never yet been reached: all known alphabets have failed, either by defect, *i.e.*, from not representing all the simple sounds; or by redundancy, in having more than one symbol for the same sound. They must also necessarily become imperfect by lapse of time. No nation keeps the sound of its language unaltered through many centuries: sounds change as well as grammatical forms, though they may endure longer, so that the symbols no longer retain their proper values; often, too, several different sounds come to be denoted by the same symbol; and in strictness the alphabet should be changed to correspond to all these changes. But little inconvenience is practically caused by the tacit acceptance of the old symbol to express the new sound; indeed the change in language is so gradual that the variation in the values of the symbols is imperceptible. It is only when we attempt to produce the exact sounds of the English language less than three centuries ago that we realise the fact that if Shakespeare could now stand on our stage he would seem to us to speak in an unknown tongue; though one of his plays, when written, is as perfectly intelligible now as then. Such changes of sound are most developed in countries where many different dialects, through conquest, immigration, or otherwise, exist side by side: they are checked by the increase of education and by facility of locomotion—both of which causes tend to assimilate all dialects to that one which by some lucky chance has become the literary speech of the nation.

The term alphabet has come to us from the Latin *alphabetum*, which, however, occurs in no prose writer before Tertullian. It could not have been used, for metrical reasons, by Juvenal, when he wrote, "Hoc discunt omnes ante alpha et beta puellæ"—their A B C. But there is no reason why it should not have existed earlier: the word was borrowed from the Greek, as seems clear from the compound *αναλφάβητος*, which is as old as the comedian Philyllius (Meineke, *Com. Frag.* ii. 857), and he was alive in 392 B.C. It does not seem likely that this compound adjective would have been coined if the noun itself had not already existed in the same sense which it now bears.

The symbols of our alphabet are nearly those of the Latin; these in their turn were borrowed from a Greek alphabet; and there seems no reasonable ground for doubting the common tradition that the Greeks derived their characters from a Phœnician source. All these borrowings will be fully described hereafter. At this point absolute certainty ends. We cannot prove to demonstration the origin of our alphabet; but positive facts and analogical arguments may be adduced which enable us to attain a very high degree of probability. It is now commonly believed that the characters were originally hieroglyphics, and in that ultimate form were devised in Egypt. There, for convenience of writing, they took a simpler form (called hieratic). In this shape they were borrowed by the Phœnicians; and thus, in their long course down to us, they passed gradually from being the written expression of an idea into the written expression each of a single sound. It is true that the proof is not clear throughout: sometimes the links are feeble, and here we have to employ the analogy of other languages, in which

the particular step which we want to prove has undoubtedly been made under similar circumstances. Still, it may with some truth be said that we can only prove the possibility of such a process, while any given alphabet may have had a perfectly independent origin; the Phœnician alphabet *may* have been developed in Phœnicia itself, and never been hieroglyphic at all. But this is very difficult to conceive. The *a priori* argument for the derivation of phonetic from hieroglyphic characters is strong. Hieroglyphics have unquestionably been the first attempt of many nations in a rude state to record their thoughts in a permanent and universally intelligible form. It is also certain that these hieroglyphics have undergone progressive degradation of shape, so that their visible connection with the thing signified was often lost; they became in many cases the expression of those combinations of sounds by which the things were denoted in the spoken language, though they still generally retained their original value as well. Here, at all events, a certain connection between hieroglyphics and sounds establishes itself; and *a priori* it is more probable that all alphabets should have derived the single sounds of which they consist from hieroglyphics, through the medium of their derived phonetic values, than that any alphabet should have been produced independently of hieroglyphics (which are admitted to have existed), by some arbitrary process of formation for which absolutely no testimony can be adduced. As we have said above, such a process is not impossible, and may be true for any particular alphabet; but the opposite theory has the most internal probability and all the evidence of which the case admits. Against this it seems insufficient to urge (as has been done) that there exist upon earth savages who have never developed any alphabetic writing out of their rude attempts—a fact which may be readily granted; or that civilised men often return to the simple methods employed by uncivilised nations, such as cutting notches on sticks or tying knots in strings—such return being apparently adduced to prove that two totally different methods of expression can co-exist without there being any tendency to pass from one to the other; nay, it is added that in Egypt the hieroglyphic and the common (or demotic) character did certainly exist side by side; and if the latter were borrowed from the former, it would have superseded it, which it did not do. Now, in answer to this, reasons will appear shortly why the hieroglyphic characters lingered so persistently, even when the later phonetic character was in common use—nay, in the very same inscription or document with the hieroglyphic. Still, the argument would have some weight if it were not grounded on the false assumption that the demotic alphabet was a *purely* phonetic one, totally unconnected with its more aged rival. But modern research has proved incontestably that the demotic characters can be traced back to their original hieroglyphic shape through the medium of the hieratic; in fact, that the cumbrous hieroglyphics were successively put into more and more abbreviated shapes, for convenience of writing, as its use increased.

Excluding, then, attempts of savages such as have been mentioned above, which were neither durable nor intelligible enough to make them of service, except for the smallest number of men during the most limited time—excluding these as not deserving the name, we derive all real writing from hieroglyphics, such hieroglyphics being either purely pictorial, the expression of visible objects in the external world; or symbolic, when some external object is conventionally chosen to represent some action or

some abstract idea. These two methods were probably nearly contemporaneous in their origin, because the necessity of writing at all supposes a considerable advance in civilisation, and therefore a considerable development of ideas. To this system as a whole the convenient term *ideography* is now generally applied. From this men have passed to phonetic writing, first, apparently, in the form of *syllabism*, in which each syllable of a word is regarded as an independent whole and represented by a single sign; then from this to *alphabetism*, in which the syllable is no longer denoted by an indivisible symbol, but is resolved into vowel and consonant, each with its own accepted sign.

It seems probable that all known alphabets (with one or two possible exceptions) may be traced back to four or five parents. These have differed much in fruitfulness, but all were originally hieroglyphic. These five systems of writing are the Egyptian, the cuneiform, the Chinese, the Mexican or Aztec, and the curiously cumbrous characters of Yucatan and central America: these last may be seen interspersed with figurative paintings in a facsimile given by M. de Rosny at p. 20 of his very useful little summary, *Les Ecritures Figuratives des Différents Peuples Anciens et Modernes*. Of these, the first three alone can be said to have had any great extension; and the first, if the Phœnician, and by consequence the European alphabets, were derived from it, far exceeds in importance all the rest together. These systems were perfectly independent, and developed themselves, each in the same course, but in its own manner, and each in the main to a different degree. At certain points in their history all but one became crystallised, and remained to show us the steps by which the progress to phonetism can be made. We do not propose to describe here fully any of these systems of hieroglyphics. We are only concerned to point out their relative degrees of development, their deficiencies, and the consequent motives which must have impelled men by degrees to the production of a genuine alphabet.<sup>1</sup>

There are obvious deficiencies even in the most highly developed hieroglyphics. In the first place, they must have been excessively burdensome to the memory. They speedily lost their original form, which was in most cases too cumbrous to be retained when writing became frequent; their pictorial value was therefore lost, and the new form could not generally have been intelligible to a learner, who was thus obliged to acquire by memory an enormous number of symbols, compared with which even the Sanskrit alphabet may be regarded as easy. Secondly, it is impossible by hieroglyphics to express grammatical relations: the order, indeed, in which the symbols are placed may denote the distinction between subject and object; plurality may be expressed by the repetition of a symbol; some even of the relations in space, denoted in more advanced languages by cases, may be pictorially rendered; but all these helps do not go far to remedy this obvious want. Experience, however, shows how much inconvenience a nation will undergo rather than make any radical change in its phonetic system. We have only to look at our own alphabet, with its numerous and universally confessed deficiencies and redundancies, and then

remember the fruitless attempts which have been made to work a reform in it, to be convinced that no people will of its own accord strike out a thoroughly new system of writing. Such revolutions can only be produced by the meeting of two different civilisations, and the reception by the one of the arts and ideas of the other. But such a meeting may, and more commonly does, only stimulate the inferior race to some partial development. For the new ideas new names are required: these may be metaphorically represented out of the old vocabulary, as when the Romans called the unknown elephant the Lucanian ox, and of course wrote it so. But suppose the inferior people to be one which has not yet advanced beyond hieroglyphic writing; their simplest and most obvious plan will be to take the strange name, and express it by those symbols out of their old stock which denote the nearest sounds to that of the name required. Such symbols then cease to represent ideas only, as they used to do; they are consciously employed to represent mere sounds, and thus arise the first beginnings of phonetism. A good example of this process may be found in the Aztec (Lenormant, i. 29; De Rosny, p. 19, who also gives others). When Christianity was introduced into Mexico, the Lord's Prayer was reduced to writing in the following manner:—The Mexican symbols nearest to the two syllables of *pater* were a flag (sounded as *panlli*), and a rock (*tell*): *pater* was therefore represented pictorially by a flag and a rock; we cannot tell whether it was sounded as *pan-tell*, or only as *pa-te*—the nearest possible equivalent in the Mexican language, which has no *r*. Similarly, *noster* was phonetically represented by *noch-tell*, pictorially by the Indian fig (*nochtli*) and the rock as before. Here, then, we have the application of symbols to denote sound without regard to the original sense; just as we might draw the figures of an eye, a saw, and a horse, and convey by them the idea, "I saw a horse." The Aztec would not long have the ideas of a flag, a rock, and a fig presented to his mind when he read these symbols; and so the first conception of phonetism was gained, the first move from hieroglyphic to alphabetic writing. Yet he had not attained the first real step in the progress—*i.e.*, syllabic writing—because if he had decomposed his new words, *pan* would not have represented to his mind merely so much sound—a syllable by itself meaningless: it would have given him only the idea of a flag. And further than this the Aztec language did not pass: probably it only reached this stage incompletely with a small number of words. The great advance to syllabic writing is to be found elsewhere; first in the Chinese, perhaps through the accident of the monosyllabic nature of the language; but with a clearly-developed purpose in the Aramaic cuneiform inscriptions.

In the Chinese written character we find a considerable number of symbols which were unquestionably at first pictorial. Though but very slight vestiges of their original meaning can now be seen in them, yet they can be traced back to older forms which are unmistakable; and their origin is further attested by the name "images," which the Chinese give them, as distinguished from others which they call "letters." These symbols were simple, and denoted very ingeniously natural objects—the sun (by a circle with a dot inside), the moon (by a crescent with a line inside), a mountain (by three peaks side by side), rain

(by drops under an overarching line), a child (thus ) , a mother () , a figure expressing the arms and bosom

effectively enough), &c. These symbols could be combined: thus the symbols for water and eye combined denoted tears, an ear and a door expressed hearing and under-

<sup>1</sup> The authorities referred to chiefly are Endlicher (*Chinesische Grammatik*), Oppert (*Expédition Scientifique en Mésopotamie*, tom. 2), and Bunsen (*Egypt's Place in History*, vol. v.) Frequent use has been made of De Rosny's book mentioned above, and still more of the *Essai sur la Propagation de l'Alphabet Phénicien dans l'Ancien Monde*, by M. François Lenormant, of which the first volume only has yet appeared. It contains an introduction to his special subject, in which the labours of Champollion, Young, Lepsius, Bunsen, De Rougé, in Egyptian hieroglyphics, and of Grotefend, Rawlinson, Hincks, and Oppert, among the cuneiform characters, are ably summarised, and set forth with much clearness.

standing; but such combinations of pure hieroglyphics were rare, as they would have been liable to be confused with combinations of the same kind used in a different way, as will be seen immediately. There were also some hieroglyphs used symbolically; e.g., a hand to denote a workman, the two valves of a shell-fish to denote friends. These also are few in number, and not very ingenious. Last in this class come some symbols which are essentially pictorial, though they represent no visible object; e.g., "above" was expressed by a dot above a horizontal line; "below," by a dot below it; the numerals one, two, three,

by so many horizontal lines; "right," by the symbol 

"left," by , &c. So far, we have simple hieroglyphs,

or ideograms (a more convenient term),—pictorial representations, expressing not merely visible objects, but also abstract ideas, and even actions; but each of these could also have the phonetic value of the name of the object which it depicted.

Distinct from these are the "letters"—in use, though not in origin. These have two parts—one, a symbol which was originally an ideogram, and which could still be used as such, but which in this particular combination lost its ideographic value, and retained only the phonetic value of the name of its object; the other, an ideogram, which laid aside its phonetic value, and only restricted to a particular class the phonetic symbol which it accompanied. Thus, for example, the ideogram of a ship had also the phonetic value *tcheu*—i.e., the name denoting ship in the spoken language; the ideogram of fire had the phonetic value *hwó*: these two symbols combined were still pronounced *tcheu*, and meant the flickering of flame. The second symbol dropped its phonetic value altogether, but kept the generic idea of fire: the ship was lost, but the idea of undulating motion modified that of fire, and the complex symbol combined the two ideas, with the one sound *tcheu*. Similarly, the ideogram ship and speech combined expressed loquacity, and this in the spoken language was also *tcheu*, the phonetic value of the symbol for speech being dropped, just like that of the symbol fire above. In this way there are ten different ideas given by Endlicher (p. 10), all called in the spoken language *tcheu*, and all expressed to the eye by different complex symbols formed on this principle. These symbols, he reckons, form at least  $\frac{2}{3}$ ths of the written language.

This is a very imperfect sketch of the Chinese system of writing, and into the history of the "keys," which indeed belong rather to Chinese lexicography, we do not propose to enter. But it is enough to throw light on some questions connected with our subject. First of all, we see ideography and phonetism existing side by side; and even the same symbol, having in most cases (not in all) either an ideographic or a phonetic value at will. Therefore, in this case the passage from the one system to the other may be considered as certain; but how it was made there is not sufficient evidence to show. It must have been earlier than the combination of pure ideograms mentioned above. It was probably greatly facilitated by the Chinese being a monosyllabic language; each syllable is a complete word in itself, expressing a complete notion: hence the idea of completeness and individuality would attach to such a combination of sound more easily than would be possible in polysyllabic language; and it would seem more natural to give that sound a symbol for itself, quite apart from its ideographic meaning. Further, as the whole number of single syllables of which the language consists is only 450, the effort of remembering the symbols could not be great, and the memory must have been already trained in that

direction, because the symbols (even in their ideographic acceptance) had lost their obviously pictorial character, and must have been kept by the memory, not recognised each time by the eye; just as children, in learning to read, commonly remember short and familiar words as a whole, without analysing them into the component letters.

The explanation of the cumbrous "letters" described above is simple; and it will show us, secondly, how so apparently monstrous a system of writing could be maintained, and has been in its essence maintained, down to the present day. With so few radical sounds in the language, it was inevitable that many different objects must have been expressed, as ideas grew and multiplied, by the same sound, as we saw above that there were eleven different ideas (including the ship itself) all called *tcheu*. These could be distinguished in the spoken language by tone or accent, and actually were so distinguished. But how were they to be distinguished in writing? Now, writing is but the visible exponent of language, and therefore is naturally formed under the same conditions—those conditions which, because the effect is obvious while the reason is often difficult to detect, we vaguely call the genius of the language: and it must accommodate itself to the defects as well as the strength of the language. There is an inherent evil in Chinese speech—inevitable in a monosyllabic language with a limited number of radicals—that the same combination of sound should serve to express many different ideas. A combination, therefore, of symbols is absolutely necessary, which shall represent to the mind through the eye the fact that the sound which is heard has changed its meaning to meet that of another sound which is not heard—that *tcheu* no longer means a ship, but means the flickering of flame, or something else quite different. It would have been easy enough to have had different symbols for the different meanings of *tcheu*; but it would not practically have been so convenient, because it would not have represented so well the facts of the language. If the Chinese had chosen in their speech to do universally what they did occasionally, to form compounds like "ear-dooring" for "hearing" a thing, the native genius for pictorial representation would have produced a symbolism which might have supplied all its wants down to the present day. But that was not the bent of the language; and the writing therefore remains to the present day a mixture of ideography and phonetism, and is perhaps better so. Still, a great deal of confusion is possible. In modern writing, according to Endlicher, each syllable has several symbols, partly because of the extraordinary number of meanings belonging, as we have seen, to each combination of sound, partly from considerations of calligraphy, because it is not every symbol which will combine neatly with every other; and therefore for particular combinations a different symbol with the same phonetic value is required, so that the shapes of the mixed symbols increase in number. Also, the pictorial symbols being comparatively few, and many of these being employed phonetically for the same syllable, it is obvious that, with the growth of ideas, many new symbols must have been required. To meet this want, the mixed symbols so often mentioned were employed purely phonetically, each in new combination on the old principle with an ideogram, whose meaning was disregarded. Generally these symbols kept their phonetic worth, but sometimes in combination with particular ideograms they change. Thus we see a double evil arise in the language. Not only have we several symbols for each combination of sound, but also the same symbol can under certain circumstances have different phonetic values. But the difficulties thus caused seem greater to a stranger than to a native; and the Chinese have never been moved thereby to exchange their

picturesque but unwieldy system. The impure syllabism marked out for them by the genius of their language has been their furthest development. It was reserved for the Japanese to borrow the Chinese characters, and, expelling all ideographic associations, to employ them simply as syllables, thus advancing to a pure syllabic writing. This borrowing and extension of a system by a foreign nation will be more fully dwelt upon hereafter. It should perhaps be added that the expression of many different senses by one symbol, which has so largely modified the Chinese writing, is not peculiar to monosyllabic language. It is found in all languages, though not to the same extent: roots of different sense have been worn down by phonetic decay till they reach the same form, and this cause may have operated to some extent in China, though it cannot have been very important.

The cuneiform writing, so called from the wedge-like shape of the characters,  or , which compose it, was employed by different nationalities. It was first deciphered by Grotefend on inscriptions of Persepolis, and was found to be the exponent of the Aryan spoken by the conquering Persians, which belonged, as is well known, to the Indo-European family of languages. But cuneiform inscriptions in three languages were found on a monument at Behistun: the first was the Persian, and much the simplest in form; the second and third were composed of elements of the same shape in much more unwieldy combinations.<sup>1</sup> It was obvious that the three inscriptions were identical in meaning, but in different languages; and principally by the help afforded by recurring proper names, whose value could be compared with the known values in Persian, the characters of the last two inscriptions were deciphered, and found to belong, one to the language of the Assyrian and Babylonian subjects of Darius, the other to the old Scythian population of Media, who used a Turanian speech. Other languages, the old Armenian and that of Susa, were found afterwards to be represented by the same characters; and to these different systems the collective name *Anarien* (i.e. non-Aryan) has been given by French writers (Oppert, &c.), to distinguish them from the Aryan-Persian, which is a purely phonetic character.

It seems clear that the origin of this system was Turanian, and that it was borrowed by the Semitic races who used it. It was originally hieroglyphic, though the stiff combinations of wedges give but little indication of such an origin. But both in Assyrian and Babylonian there is an older character and a newer one, and the older forms can again be traced back to a still more archaic shape, which was unquestionably the original of both, and which is not cuneiform, but composed of straight lines only.<sup>2</sup> These show little of the brilliancy of invention of the Chinese; they seem to appeal to the reason rather than to the eye; they are obviously intended to recall the image of the object, but they must have been first explained in order to be intelligible at all, and then they might be remembered.

For example, a house was denoted by ; a town by

. Neither of these are symbols which will be intelligible as soon as seen by a person who has not been taught them. This is probably due to the fact that they were produced, not by the hair-pencil of the Chinese, but by the chisel; they were intended to be written on rock, and for this straight lines are more convenient; and the wedge shape which they assumed afterwards may be explained

by the ease with which it can be made by two strokes of the chisel—perhaps no other figure so clear can be produced with such facility.

This system seems to have reached syllabism before it was adopted by the Aramaic peoples. But the syllabism was still mixed up with ideography, just as we have seen was the case in China—that is, the same symbol denoted ideographically the object, and phonetically the sound, of the name of the object; as though in English we should denote by the symbol B both the insect *bee* and the sound *be*. But there is a difference between this idiom and the Chinese; it was polysyllabic, whereas Chinese was syllabic. When, then, the name of the object contained more than one syllable, the first alone was taken to be denoted phonetically by the symbol. The evidence for this is small in quantity, owing to the scanty remains of the language of that Turanian element of the Chaldee nation from which the cuneiform writing was borrowed. To this language the name Accadian has been given by Dr Hincks, and this name seems to be now generally received. But the Medo-Scythic, mentioned above, which is a closely-connected dialect, supplies us with forms sufficiently close to the old Scythian spoken originally by all the Turanian stock in that part of Asia. Thus one symbol in Assyrian denotes ideographically God and phonetically *an*; now the name for God in Medo-Scythic is *Annap*. Another denotes a city and *but*; *batin* is a city in Scythian. Another is a father and *at*; in Scythian a father is *atta*. (Oppert, ii. 79; Lenormant, i. 41.) This evidence will doubtless be strengthened with time, but even now it is conclusive; and the principle thus established, the arbitrary selection of the first part of a name to have a particular phonetic value, seems to be exactly the principle which we should *a priori* have expected to find if we had tried to conceive the possible ways in which ideography could pass into phonetism.

The confusion which was occasioned by the imperfection of Assyrian writing was immensely increased by the fact of their characters being borrowed, not indigenous, as in China. There is first of all the obvious difficulty of adapting Turanian symbols to a Semitic language, in which the short vowels were not written, and the meaning of the radical group of consonants in any particular place had to be determined by the context. Instead of being able to retain the same symbol to express a root in its modified forms, e.g. in the conjugation of a verb, a new symbol would be necessary for each person-form, which could be expressed by mere vowel change in the root, and these symbols might be totally unconnected, so that all sense of the connection of different parts of a verb would be lost. This is had enough, but it is an evil inherent in the borrowing of such a system of writing to express a language whose genius was so essentially different. But there was another evil, much greater, which might have been avoided, and was not. This is polyphony—the expression of many different sounds by the same symbol. When the Assyrians took an Accadian symbol, they should have taken only its phonetic value, or one of them, if it had more than one, and in this way they might have acquired a purely syllabic character, as the people of Susa afterwards actually did. But, as was not unnatural at the time, they took it with all its values, ideographic and phonetic, and added more of their own. A striking example given by Oppert (ii. 85) will make this plain. In Accadian this symbol  was the ideogram for an open hand, doubtless originally in a more elaborate form. In the spoken language a hand was called *kurpi*, and therefore, by the principle mentioned above, this symbol had also the phonetic value *kur*. But by a metaphor the hand symbol had the further ideographic

<sup>1</sup> A part of this trilingual inscription is printed in De Rosny's *Écritures Figuratives*, p. 70.

<sup>2</sup> For specimens, see Oppert, vol. ii., p. 63.

values of seizing, possessing, and understanding. To seize in the spoken language must have been *mat*, or something very like it (*imid* occurs in this sense in the Scythian), for this phonetic value also belonged to one symbol. But further, in Accadian a mountain was called *kur*; sunrise, *kurra*; earth was *mat*; to go was *mit*; and these sounds, identical or nearly identical, were every one expressed by the same symbol, which thus had eight ideographic and two phonetic values, *kur* and *mat*; and in this wretched condition it was taken by the Assyrians, and employed by them in all these different senses. But this was not all. In the Assyrian language *kur* was the name of a furnace, and *mat* meant to die; and as it must have been to obtain a visible exponent for these sounds that the foreign symbol was adopted, both of these ideas were necessarily denoted by it. Again, in Assyrian, "to understand" was pronounced as *nat*, and to "possess" was *nal*; and so were added two more phonetic values by reason of the metaphoric value of *mat* in Accadian. Lastly was added the phonetic value *shat*, because that was the Assyrian name for a mountain, which we saw was denoted in Accadian by *kur*. Thus, when an Assyrian came upon this little plain-looking symbol he had to determine whether it meant the earth, a mountain, sunrise, a furnace, or seizing, possessing, understanding, going, or dying; or whether it had only one of the phonetic values, *kur*, *mat*, *shat*, *nal*, or *nat*. And a large list of other symbols is given by M. Oppert, which, in a similar way, have two, three, four, and even six different phonetic values. It may seem incredible that a people under such difficulties should ever have been able to express what they wished to say, much less to understand what was written. It is a great witness to the strength of the feeling which must have existed in these old people that ideography was the natural and proper method of writing, and phonetics were only a supplement to eke out its deficiencies. To us such a feeling is at first incomprehensible, but after such an example we cannot doubt its existence. With respect, indeed, to the difficulty caused by one symbol having many ideographic values, we have only to think of the many different significations expressed in our own language by the same combination of sound, without any confusion arising, because the particular meaning is marked out by the context; for instance, when the one sound *but* denotes a conjunction, a verb; and a noun with two senses—one original and one derived, but now quite different,—we should therefore only see in the Assyrian an aggravated case of this want of clearness. But the difficulty is much more serious when the same symbol has different phonetic values; and much help cannot have been obtained from the grammatical lists which have actually been dug out under the superintendence of Mr Layard, in which the Assyrian kings state, avowedly for the instruction of their subjects, the different values which each symbol could possess. (See Oppert, ii. 53.) By these lists some limit might undoubtedly be put to the further multiplication of values for the same sign, but it could not help a reader to trace which of all the authorised values he was to give to a symbol at any particular time. It would appear that in the cuneiform, as unquestionably in the Egyptian, conventional phonetic symbols could be used as complements to other symbols, which might represent an idea or a mere syllable, and by these phonetic complements the special sense could be defined with some approach to exactness. But into these remedies of the ills of polyphony we need not further enter.

It is far beyond the scope of the present article to describe fully the development of hieroglyphism in Egypt, the country in which the last step to alphabetism—the separation of the vowel-symbols from those which mark the consonants—was undoubtedly taken, though with much

faltering, and even turning back. According to M. Lenormant, the Egyptians passed through every stage which we have already seen successively reached by different peoples; and at one of which every one of these peoples halted, without ever achieving for themselves the triumph of alphabetic writing. And evidence of each stage, more or less distinct, certainly lingers in the Egyptian, producing an extraordinary medley, little suited for popular or even literary use, but well adapted for the transmission of occult records and rituals, the purpose for which the Greeks not unnaturally supposed the whole hieroglyphic system to have been invented by the priests. As we have already described the phenomena of each stage with some fulness, it is not necessary to do more here than to indicate their occurrence in Egyptian. The hieroglyphs themselves are certainly the finest of their kind. Whether they represent the full contour of the object with all the assistance of vivid colouring, or whether they are simply formed by lines which convey its essential character—a practice which doubtless owed its origin to the increased use of writing—it is impossible not to admire the extraordinary completeness of the representation. Nothing can be more perfectly pictorial than the portraiture of the different emotions, each by the figure of a man affected by it: the position of the body and the gestures of the arms are simply perfect. These belong in the main to the *symbolic* use of the hieroglyphs: this use we saw in Chinese was but slight, but in Egypt it was immense. Thus, the sun, with rays streaming from it, denoted the Egyptian light and clearness; the moon, with its horns turned downward, denoted the month,—in these cases the cause is put for the effect. Sometimes the part is put for the whole: two arms, one holding a shield and one an offensive weapon, express battle; two legs with the feet denote movement, forward or backward according to the direction of the feet,  or

; an arm holding a stick denotes force. Sometimes the symbol is purely metaphorical: as when a king is expressed by a bee; knowledge by a roll of papyrus; or justice by the feather of an ostrich, because all feathers of that bird were supposed to be of equal length. Such symbols are clearly of later origin than the other; they imply the existence of conventional rules, which could acquire currency for meanings quite unintelligible in themselves. These symbolic ideograms were not very often used alone; most commonly they accompanied other symbols used phonetically, merely to determine their special meaning in each place: as such they are commonly called *determinatives*; this practice we also saw in China, less skilfully employed. Thus, for example, on the Rosetta stone—whose trilingual inscription, hieroglyphic, demotic, and Greek, is the basis of all our knowledge of Egyptian writing—the word for a decree is expressed by characters, consonant and vowel, which denote the sounds of which it is composed, just as in any modern writing; but at the end of these, forming part of the word, though adding nothing to its pronunciation, is the figure of a man with his hand raised to his mouth, which adds the idea of passive obedience to the phonetic combination, and limits it to the idea of a decree. In like manner, the arm with the stick, which as we said denotes force, is added as a determinative to express actions which require force; and the ideogram of motion is also very frequent. This seems to us unnecessary and cumbersome; but when a phonetic combination might have two different meanings, they could hardly have been differentiated in a more intelligible manner. A good list of these symbols may be seen in De Rosny, p. 46.

The traces of the *rebus* stage which we saw in the Aztec,

in which a symbol could be transferred from one object to another, because the names of the two had the same sound in the spoken language, are not very distinct, and have not been fully examined; on this point we may hope for more light from M. Lenormant. He points out that the same symbol denotes "holiness" and a "slave." No metaphorical explanation seems possible here; but both are sounded *hen* in the spoken language, and the community of symbol becomes at once intelligible. In such a practice as this we see at once a cause of great confusion, especially when the same symbol was employed to denote two things the names of which were not exact homophones, and yet sufficiently near in sound to allow themselves to be expressed by the same symbol; e.g., when the circle which denoted the sun was also taken to denote the idea of day, the sun was called *ra*, the day *hru*, and so the symbol became a polyphone; it had two not very different sounds. It is true that here the application of the symbol for the sun to denote the day was not caused only by the similarity of sound in the two words—it was probably employed at first metaphorically; but there can be little doubt that it was helped to its double use by the indistinctness of the Egyptian vowel-sounds, which caused the two words to be sounded nearly alike. From this and similar causes arose that polyphony which necessitated the use of the determinatives described above. Vestiges of the syllabic stage in Egyptian exist beyond a doubt, and they point to a slowly-effected transition from the older to the newer form of writing. Thus the symbol of a fish represented at the syllabic stage the syllable *an*; later on, the letter *a* alone came to be denoted by a reed, and *n* by a waving line. Now we find the syllable *an* represented not merely by its own simple exponent, the fish, but also by the reed and fish together, that is, in phonetic value, by *A . an*; by the reed above the waving line ( $\frac{an}{n}$ ); and even by all three ( $A \frac{an}{n}$ ) (Lenormant, ii. 44). This surely points to a stage at which the alphabetic values of the reed and line were not yet so firmly fixed that the writer could dispense with the older and more familiar sign of the fish to specialise the other two. Of Egyptian alphabetism proper it is not necessary to give examples; we are sufficiently acquainted with the use of letters pure and simple, and their use in Egypt is not denied.

To what cause are we to assign the progress of the Egyptian beyond the Assyrian method of writing? What circumstances enabled the one nation to develop at least an imperfect alphabetism, while the other never advanced beyond syllabism? No certain answer can be given; but at least a probable suggestion is made by M. Lenormant. The Egyptian vowel-sounds were indistinct: the consonants were clear and definite. Therefore it was natural (as Lepsius pointed out) that in each syllable the consonant should come to be regarded as the important element, and should finally extrude the following vowel altogether. Thus a large number of symbols, which originally represented syllables beginning with the same consonant but followed by different vowels, would become in time absolutely identical in value, the different representatives of the same consonant. And a great abundance of such homophones is actually found in Egyptian. The method, therefore, which was followed in passing from the syllable to the mere alphabetic sign, was identical with that which we have already pointed out in Assyrian, by which the symbol of a polysyllabic word was taken to have the phonetic value of the first syllable of that word; in each case it denoted the first element of the name—the syllable in Assyrian, the single sound in Egyptian. And in each language the symbol thus applied to a new use still retained for a long time its old value as the hieroglyphic or at least conventional exponent of a

material object or of an idea. Thus in Egypt *nefer* meant good. This word in writing is expressed in two ways: first, by a single symbol—which had originally been the pictorial representation of some material object, but was afterwards the conventional symbol of the idea of goodness; secondly, by this same symbol followed by two others, which had also, from being originally hieroglyphs, acquired the phonetic values of *f* and *r*; that is to say, one symbol could at will express the whole word *nefer* and its initial letter *n*. This is the natural, perhaps the only possible way of eliminating the single sound; but it is obvious that great difficulties would attend it at the outset. There could be at first no convention to restrict the symbol for *n* to that of the particular word *nefer*; any other beginning with *n* would have served. There was no law to prevent a writer taking as many symbols for *n* as took his fancy; and in fact each letter in this way did have several different symbols.

It follows that while Egypt must be credited with having first invented an alphabetic system, and must for ever claim for this the gratitude of the world, yet that system was far too imperfect to become the instrument of a popular literature. It suffered equally from the opposite diseases of homophony and polyphony, from the expression of the same sound by many different symbols, and from the use of one symbol to denote many different syllables. And each of these evils was only aggravated by time. The earlier Egyptian writing is much more simple than the later, wherein homophones increased to a degree to which there was practically no limit except the strength of the memory; and the numerous phonetic devices to unravel the confusions of polyphony must have been equally burdensome. It might have been expected that polyphony at least would have become extinct with time; that the different symbols for the same syllable would all have been worn down into single letters, and thus, though homophony might have multiplied, polyphony would have perished. This might have been the case if these symbols had ever become perfectly clear of their originally pictorial or conventional origin. But this was never the case. To the last, the employment of a symbol to express an object or idea continued side by side with its employment as a single letter. The spirit of hieroglyphism, real if not apparent, could not be vanquished by alphabetism; and in order that ideography may be finally expelled, it would seem that circumstances are needed more favourable than can be often found combined at any period of any nation's history. In fact, a purely phonetic alphabet is most likely to be produced when one nation borrows from another such portion of that nation's symbols as it requires for its own needs, and rejects that superfluity which only leads to confusion. We have already seen indications of this fact.

Many circumstances combine to render it difficult for a nation to reach of itself pure phonetism in writing. There is the strong disinclination to change, of which we have before spoken. It is always easier to put up with difficulties to which we have been accustomed all our life than to make any radical change, especially when that change causes at once serious difficulties at every moment. It was easier for the Egyptians to retain the odd mixture of ideographic, syllabic, and alphabetic writing, and occasionally to add some new key for unlocking the difficulties to the formidable list which was already in use. The ingenuity of these grammatical devices almost surpasses belief. We can only refer the curious to the hieroglyphic grammar in the fifth volume of Bunsen's *Egypt's Place in Universal History*. In the second place, a good deal must be allowed to the restraining influence of religion. It is well known that most of the ancient nations ascribed a divine origin to their systems of writing. It might well

seem to them to be too wonderful a thing for the result of human ingenuity. Thus in one of the Assyrian lists of the different values of syllables, published, as has been already mentioned, by royal authority, Sardanapalus V. states that the god Nebo has revealed to the kings, his ancestors, the cuneiform writing, which he thus endeavours to simplify for the better understanding of his people (Oppert, ii. 53). The Sanskrit character, which is now known to be due to a Phœnician source, was called *Devanāgarī*, "belonging to the city of the gods," unless, as Prof. M. Müller suggests (*Sanskrit Grammar*, p. 1), we are to understand by the gods here only the Brahmans; but whatever the name may mean, their belief in its divine origin is certain enough. And M. Lenormant points out (i. 80) that the native Egyptian term for writing meant "writing heavenly words." Now it is clear that no nation among which this belief lingered in any degree would be likely to alter fundamentally the spirit of their system of writing. Lastly, it is possible, though, as we have suggested above, not very probable, that the obscurities of the existing system may have recommended it to the priests. These reasons may suffice to show that it was not in Egypt that we should expect to find the development of a purely phonetic system. But just as the Japanese took the Chinese characters, and gave them a development which they have never had in the land of their creation—just as the people of Susiana took the cuneiform writing and made it purely phonetic, without any remnant of ideography,—so the work of extracting order out of the chaos of Egyptian writing was reserved for the Phœnicians.

The Phœnicians were peculiarly fitted to perform this inestimable part in the history of human development. An active and enterprising nation, they were early brought into commercial relations with Egypt, and must of necessity have learnt something of their system of writing; they could see its advantages and its perfectly remediable faults; the advantage of one definite symbol for one sound, and the disadvantage of a dozen; the desirability that this symbol should signify that sound only, and the undesirability of its denoting a horse or a man as well. And the religious scruples which may have affected the Egyptians need have no weight for strangers. If the characters were divine for the priests of Isis, they were a convenient instrument to supply every-day wants for the sailors of Tyre.<sup>1</sup>

These considerations do not, of course, amount to a proof that the Phœnician alphabet was derived from Egypt. It is of course possible that it disengaged itself by degrees out of an earlier hieroglyphic system at home. But of such a system no vestiges remain; and the correspondence between the Phœnician characters and those of the earlier Egyptian hieratic is sufficiently striking to warrant us in regarding it as at least provisionally true that what was natural and perfectly possible did actually take place.<sup>2</sup> The general testimony of the early Greek and Roman writers, that the alphabet was invented in Phœnicia, must then be limited to the sense in which Tacitus says that the Phœnicians had this credit—*tanquam repererint, quæ acceperant*.

It cannot be known with certainty whether the Phœnicians took, together with the Egyptian symbols, the phonetic values which they had in Egypt, or whether they totally disregarded those values, and simply assigned to the symbols the value of their own sounds at will. The first view, however, seems clearly the more probable. The Phœnicians could only become acquainted with the Egyptian

symbol and sound together; the one would naturally suggest the other; and we should expect that they would first take the symbols belonging to those sounds which exactly corresponded in Egyptian and Phœnician, then the symbols of other Egyptian sounds which did not exactly correspond to their own, but which seemed in each case the most analogous to them; but that there would never be any violent rupture between the symbol and its old sound. Yet it seems quite certain that there is no connection between the names which the letters bore in Phœnicia and the original object of which the Egyptian character is the debased representation. Thus the first letter of the Phœnician alphabet (corresponding to the Hebrew *aleph*) was named from its fancied resemblance to an ox's head, the second (Hebrew *beth*) to a house, and so on. But the symbol which strangely seemed to the Phœnicians like an ox is only the form, rapidly drawn, of an eagle; *beth*, in like manner, is the quickly-drawn figure of a crane. It would seem, then, that the Phœnicians borrowed sound and symbol, but no name. They cared nothing for the history of the symbols; and when they found it convenient to have a name for each symbol they chose some object whose name began with the letter in question; and we should have said that it was totally impossible that any similarity in form between the letter and the object whose name it borrowed could have helped to give currency to the nomenclature, did we not see evidence of similar and apparently equally impossible fancies in the names of the constellations, let the origin of those names be what it may.

Such, very briefly traced, seems to have been the origin of the Phœnician alphabet, the parent of almost every alphabet, properly so called, existing on the earth. For the main ramifications of this alphabet in subsequent times we cannot do better than translate the summary of an author already often referred to, M. François Lenormant. He distinguishes (p. 110) five main stems. These are—

1. The *Semitic* stem, wherein the values of the letters have remained exactly the same as those of the Phœnicians, except in a few derived alphabets framed in Persia and the countries immediately adjacent, which being employed to write Indo-European languages, turn the soft breathings of the Phœnician into genuine vowels. This stem subdivides itself into two main branches—the Hebrew-Samaritan and the Aramaic.

2. The *Central* stem, whose province includes Greece, Asia Minor, and Italy. The transformation of the symbols of the smooth, and even of the rough, breathings into symbols of vowels is here the invariable rule. This stem contains first the different varieties of the Hellenic alphabet, then the alphabets derived from the Greek, including three families—the Albanian, Asiatic (taking Asia in the same sense as the old Greeks did), and the Italian. In the Asiatic family we distinguish two groups—one for the Phrygian alphabet only, which is made up of elements whose origin is exclusively Greek, the other containing the Lycian and Carian, where these elements are mixed up with Cypriote characters. The Italian family must also be subdivided into an Etruscan group and a Latin group, between which stands the Faliscan alphabet, of a mixed character.

3. The *Western* stem, containing the systems of writing which resulted from the spread of the alphabet by the colonists of Tyre among the indigenous inhabitants of ancient Spain. This stem reckons but one single family. It has, as that which precedes it, for its fundamental character the change of the value of the Phœnician breathings. But the direction in which the forms of the letters vary is signally different. . . .

4. The *Northern* stem, containing only one branch, the runes of the Teutonic and Scandinavian peoples, who were settled at a particular epoch in the north of Europe, but had arrived from Asia, where they still lived during a part of historic time, and where they must have had imparted to them the alphabet produced by the Phœnicians. Some elements in the runic writing seem to point to a direct reception of the writing from the seamen of Canaan; others, on the contrary, bear a certain stamp of Greek influence. . . .

<sup>1</sup> M. Lenormant (p. 83) will have it that the Phœnicians must have been "très peu religieux, et au fond presque athée." They may have been so, but surely not merely in order to borrow an alphabet from Egypt. It is enough that that alphabet could have had no sanctity for them.

<sup>2</sup> For evidence of this, see plate, p. 600.

<sup>3</sup> The only two alphabets, in the strict sense of the term, which M. Lenormant cannot classify as of Phœnician origin are the Cypriote and the Persian cuneiform—the former still imperfectly deciphered, but seemingly to some extent syllabic; the latter perhaps not pure alphabetic, but retaining certain ideograms.

5. The *Indo-Homerite* stem, distinguished by the appearance of a new principle, the expression of vowel sounds by means of conventional adjuncts attached to the symbol of the consonant, and thus sometimes considerably modifying its shape. The place of its origin seems to have been southern Arabia. From thence it has radiated on the one side to Africa, where the Abyssinian and the African systems form a separate family with the Himyaritic, or alphabet of the old inhabitants of Yemen; on the other side to Ariana, where a special form of writing established itself; and to India, whose most ancient alphabet, *Māgadhi*, now referred by A. Weber to a Phœnician origin, has given birth to an enormous list of derivatives, which can be classified among six families—*Devanāgarī*, *Pāli*, *Dravidian*, *Transgangetic*, *Oceanic*, and *Thibetan*—which we here enumerate in their chronological order of descent.

It will of course be observed that this classification of alphabets runs entirely counter to the universally-accepted classification of languages into certain well-recognised groups under three main heads—Indo-European, Semitic, and that family which, rather because its members differ from the two first-named than from any especial bond of union among themselves, is called Turanian. This is in nowise surprising. There is no necessary connection whatever between the sound and the symbol which signifies it—between the language and the alphabet. The languages of nearly all Europe are Indo-European (or Aryan, as they are sometimes called); the alphabets are universally Semitic—that is the fact, explain it as we may. In fact, if we wish to maintain that sound and symbol correspond, so that the second is the only natural exponent of the first, we must form two hypotheses which refute themselves—first, that it was possible that any race of men, when they first felt the need of an alphabet, deliberately set themselves to form their letters so as to represent the different positions of the organs of speech as each sound was produced; secondly, that such forms could have been exactly preserved through long lapse of time, so as to convey to subsequent generations exactly the same idea as they gave to their inventors. But each supposition is clearly impossible. An alphabet so formed would also be an artificial alphabet, such as could never have entered the minds of men who needed to supply just their actual wants as they arose, not to construct a scientific table of signs to denote all possible sounds. But the construction of such a pictorial alphabet as we have supposed is quite possible, and it has actually been formed most ingeniously by Mr Melville Bell. In his system, which he calls “Visible Speech,” consonants are denoted by curved lines, which represent the position of the tongue or lips in their formation. For example, in forming the gutturals *k, g, ng*, the back of the tongue is raised, and this is expressed by the curve **C**; in pronouncing *y*, the front of the tongue is arched, and this is denoted by **∩**; in pronouncing dentals, the point of the tongue is raised, and this is expressed by **∪**; in sounding labials, the lips are closed, and this is denoted by **∩**; where the passage of the mouth is completely closed by the symbolised organ (as in *k, g, t, d, p, b*), the ends of the curve are shut by a connecting line—thus **C** denotes *k*; the consonants which are voice articulations (*i.e.*, in producing which the *chordæ vocales* vibrate, and so produce voice), as *g, d, b, &c.*, are further distinguished by a short straight line within the curve, the physiological sign which is chosen (conventionally, it must be allowed) to represent voice being (1) a straight line; and the other distinguishing marks of the consonants are similarly expressed either by added marks or by slight modifications of the primary curve. Equally ingeniously, the vowels are expressed by the straight line which is the sign of voice, a subordinate symbol, or “definer,” being

added to denote the part of the mouth which modifies the vowel—*e.g.*, a hook or a solid point at the top or bottom of the vowel-line, a bar across the line to express that the lips are contracted or drawn across the aperture of the mouth, &c., &c. We need not enter further into the minutiae of the system; enough has been said to show the principle on which it is formed. It is obvious that there would be no greater difficulty in teaching this alphabet to a child than in teaching it *a, b, c*, except that the number of symbols is greater, because one is provided for every sound in the language, which our alphabet certainly fails to do; still, to learn either our alphabet or “visible speech” must for a child be simply an effort of memory. And one great practical gain which would be derived from the general adoption of such a system is the ease with which foreign languages could be mastered. The great difficulty in learning to speak a foreign language does not consist in the mere mastering so many declensions; it lies in the fact that two alphabets may be composed of exactly the same symbols, and yet many of these symbols may express to the two nations quite different sounds. This is a preliminary difficulty which must be mastered at once; and it would be immensely lessened if such dissimilar sounds—as, *e.g.*, the German, French, and English *u*—were not all presented to the learner under the same symbol. It seems certain that, with the lapse of time and the progress of invention, the intercourse between nations must be largely increased; and the need of some more perfect instrument of speech between them must increase proportionately. But in spite of the obvious gains, it is utopian to suppose that the world will ever be converted to a system of universal writing; and the real and immense gain of such a method is the power which it gives to a linguistic inquirer to denote accurately on paper the exact sounds heard in any dialect spoken in any part of the world, civilised or uncivilised; for it is as competent to register the click of the Hottentot as the most subtle vowel sound of Europe. With our present alphabet it is utterly impossible to represent adequately the strange sounds of some out-of-the-way dialect (which for students of language may be as important as the literary speech) in such a way as to be generally intelligible, because there often is no symbol to correspond exactly, and naturally no two inquirers agree upon the nearest out of the existing symbols. The science of language is therefore greatly indebted to Mr Bell for providing so effective a method for preserving for ever those dialectic peculiarities which are vanishing with startling rapidity in these days of constant communication between different parts of a country. Another system, equally valuable scientifically, has been invented by the eminent philologist, Mr Alexander J. Ellis. In his “Palæotype” only the ordinary symbols are employed, but they are printed in different ways to denote different sounds—sometimes as capitals, sometimes in italics, sometimes turned upside down; so that, despite the familiarity of the letters, a page of palæotype is at least as appalling to the uninitiated as the curves and lines of “visible speech.”

We may proceed to trace the variations from the Phœnician alphabet to our own, down the central stem of Greece and Italy. The Phœnician alphabet consisted of twenty-eight letters, which for convenience we may call by the names of their Hebrew equivalents. These were (1) Aleph, (2) Beth, (3) Gimel, (4) Daleth, (5) He, (6) Vav, (7) Zayin, (8) Cheth, (9) Teth, (10) Yodh, (11) Kaph, (12) Lamedh, (13) Mem, (14) Nun, (15) Samekh, (16) Ayin, (17) Pe, (18) Tsadhe, (19) Koph, (20) Resh, (21) Shin, (22) Tav. None of these were vowel sounds. Aleph was the lightest guttural or rather faucal sound, being pronounced below the guttural point at the very top of the larynx: it can have been barely audible even before a vowel. He corresponded nearly

to our *h*. Cheth was a strongly-marked *ch*, a continuous guttural sound produced at the back of the palate. Ayin represents a faucal sound peculiar to the Semitic race, varying between an evanescent breathing and a *g* rolled in the throat.

The Phœnicians employed hardly any vowel signs: in Hebrew the three principal sounds *a*, *i*, *u* (see article A) were sometimes expressed in writing, and long *i* and *u* were denoted, not by special signs, but by consonants akin to them, *yodh* and *vav*: *a* was regularly omitted except at the end of a word, where it was denoted by He and sometimes by Aleph. In fact, in all Semitic languages the practice was to ignore vowels in writing, leaving it to the reader to fill in, according to the context, the unvarying framework of consonantal sounds: the Hebrew vowel-points were a later invention, rendered necessary when the language had ceased to be spoken.

When the Greeks received the Phœnician alphabet it is obvious that they must have made considerable changes in the values of the symbols. Several of them would be unnecessary, for they had no sounds in their language to correspond to them: while for other most important sounds, *e.g.*, the vowels, no symbol was provided. It is clear how imperfect any previous alphabet of the Greeks must have been when they adopted in its stead another so foreign to the genius of their language, which developed the vowels and marked strongly the momentary consonants and nasals, but rejected as far as possible the continuous consonants, both palatal and labial, and even under many circumstances the dental *s*, the one sibilant they employed. But they ingeniously adopted the strange signs to new ends. Aleph, He, and Ayin were turned without difficulty into *a*, *ε*, and *o*: Yodh became *i*, as it seems that the semi-vowel *y* had totally disappeared from Greece even at that early period: on the same principle Vav might have served to express *v*, although apparently the *w*-sound was still sufficiently common to require the retention of Vav with its consonantal value. But from what source they took their *upsilon* cannot be known with certainty. Professor Key thinks that it is the Hebrew form of Ayin, which differs much in shape from the nearly perfect circle of the old Phœnician. This is possible enough, for the sound of Ayin was not more like *o* than *v*; and if the Greeks knew the two forms, it is not likely that they may have taken both. On the other hand, it is equally possible that *v* may be a remnant of an earlier native alphabet. Among the consonants β, γ, δ, κ, λ, μ, ν, π, ρ, τ were borrowed with little change of form, and probably of value. And these letters (with σ and the vowels already mentioned) are stated by tradition to have been the only ones brought to Greece from Phœnicia by Cadmus, others having been added by Palamedes, Simonides, or Epicharmus; but which were the letters added by each of these is a question on which the different authorities do not agree; and the incorrectness of most of them is proved by the letters being found in Greek inscriptions before the time of their supposed inventor. In fact, all tradition on this point is worthless, unless it is borne out by inscriptions. It is at least probable that the whole alphabet was borrowed at one time, for all, or nearly all, the characters occur on the oldest inscriptions we possess. Thus on inscriptions of Thera dating from Olympiad 40 (see Franz, *Epigraphicæ Græcæ*, pp. 51-59; Kirchhoff, *Studien zur Geschichte des Griechischen Alphabets*, p. 41), we find Cheth in the form , denoting mainly the rough breathing *h*, but also applied to denote *e*, as it afterwards did regularly by the name *Eta*: Teth occurs as , nearly the later *Theta*; and Koph as , *Koppa*, a symbol which was once current throughout Greece, and

remained universally as the numeral 90, though as a letter it was retained only by the Dorians, and passed with the Doric alphabet into Italy as Q. It may be observed that in this alphabet, and in some later ones of Crete, Corinth, and Coreyra, Iota appears not as a straight line, but in many curved shapes, approximating much nearer to the old Phœnician; and the same is true of Pi, which has the top rounded like a crook. We have then left only the four sibilants, Zayin, Samekh, Tsadhe, and Shin. These are believed to have had the values *dz*, *s*, *ts*, *sh* respectively. We have already said that the Greeks had no great affection for sibilants; witness the manner in which σ was constantly dropped, *e.g.*, in γένεος for γένεο-ος. It was therefore not to be expected that they could employ all the wealth of the Phœnicians; and one symbol (Tsadhe) appears in no Greek alphabet. The name, however, recalls

the name *Zeta*; but the shape of Zeta (always ) is unquestionably that of Zayin; and its place in the alphabet agrees to this. It seems, therefore, most probable that the Greeks confounded together the two compound sounds *dz* and *ts*, and kept but one symbol, perhaps with the name of the other (Tsadhe), because it was most like that of the neighbouring letters Eta and Theta. This confusion of the two sounds seems the more probable when we remember that no symbol was required for the compound *ts* at the time when a special symbol for *ps* was added, and that for *ks* (another analogous compound) perhaps revived. There is also much uncertainty with regard to the relations of Samekh and Shin in their Greek dress. Xi (= *ks*) occupies the place of Samekh, *sigma* of Shin. One form of Samekh seems unquestionably to have furnished that of the Greek Σ (see the forms, p. 600); another  is exactly the Greek ξ of all the inscriptions.

Sigma had the sound (*s*) of Samekh, and cannot be shown ever to have had the sound (*sh*) of Shin. Two names were preserved among the Greeks, *sigma* and *san*. Herodotus (i. 139) speaks of the "same letter which the Dorians call σάν, the Ionians σίγμα;" and though *san* was no letter of the Ionic alphabet, the compound *sampi* (= σαν + πι) denoted 900. The name *san* is obviously the Semitic *shin* or *sin*: it is just possible that σίγμα may be an attempt to turn *samekh* into a form which should explain its meaning to Greek ears. The oldest Greek alphabets known to us—those of Thera, Melos, Crete, and the earlier forms of

those of Argos, Corinth, and Coreyra—have the form  to denote *s*,—that is, the equivalent of *Shin*. It seems fair to infer that this was originally the case in the other alphabets also. Then this symbol was dropped by degrees to avoid confusion with *m*, while one form of *samekh*, with the name *sigma*, was introduced into its place: another form was kept in its old place to denote the compound *ks* (*xi*).

We now come to the apparently non-Phœnician letters of the Greek alphabet, φ, χ, ψ, ω. Of *v* we have already spoken: we may add that its sound was not a pure *u*, but modified, perhaps as is the German *u*. This appears from the fact that, when the Romans borrowed Greek words in the later times of the republic (when Roman taste had grown more scrupulous), they did not use their own symbol *u* to denote the Greek *upsilon* (as their forefathers had done), but together with the sound borrowed the symbol also: which clearly shows that the sound of *upsilon* was different from the ordinary *u*. We now take the aspirates φ and χ. It is most probable that the sounds of the Greek aspirates χ, θ, φ, were not those of the German *ch*, and the English *th* and *f*: that is, they were probably not continuous consonants, but momentary

sounds, followed in each case by a slight but distinctly audible breath; so that  $\chi$  might be represented in English characters by  $k'h$ , though the following breath is not so distinct as an English  $h$ ,—if it were, we should have a compound, not a simple sound. Now two of these aspirates were actually written in the oldest alphabets KH and ΠH (*pi* having the right down-stroke much shorter

than the left): for the dental the single symbol  $\theta$ , borrowed from the Phœnician, sufficed. Afterwards the symbols  $\phi$  and  $\chi$  (variants  $\Phi$  and  $\Psi$ ) were taken to supply the place of these compounds, from what source cannot be certainly known; but it is not impossible that they may have been characters of an older Greek alphabet which originally had the values  $p$  and  $k$ . This draws some probability from the history of  $\psi$ . That letter was originally written ΠΞ; and ξ, of which we have already spoken, written ΚΞ (or KM). But each of these also appears as ΦΞ and ΧΞ; so that here at least  $\phi$  and  $\chi$  appear as no more than  $p$  and  $k$ : the compound ΟΞ remained permanently in the Western alphabets. It is to Epicharmus that tradition (here with some probability) ascribes the establishment of  $\psi$  in the alphabet. The history of  $\omega$  is closely connected with that of  $\eta$ . At an early period, certainly before the 40th Olympiad, in the eastern part of Hellas an attempt was made to distinguish the different kinds of  $e$ . The symbol  $\epsilon$  had hitherto denoted both  $\epsilon$  and the diphthong  $\epsilon i$ , where the  $i$  was probably not a much more important sound than the  $y$ —*e.g.*, in our *day*. The habit of writing the two symbols came in late in the Ionic alphabet, and so spread through Greece. But at the earlier time of which we speak the symbol H began to denote some  $e$ . It is commonly supposed that this was long  $e$  as distinguished from epsilon, which, by the way, does not mean *short e*, but “*e* unaccompanied,” perhaps by that after sound of  $i$  mentioned above, though a different reason is commonly given for the name. It seems very strange that the Greeks should have introduced symbols to express long  $e$  and  $o$ , and none to mark the length of the other vowels, which must have been just as urgently needed: surely this would have been done at Athens at the time of the formal introduction of the Ionian alphabet. Again, there are a great many recognisable varieties of sound which border closely on pure  $e$  and  $o$  (but none of importance near  $i$  and  $u$ ), and such varieties are clearly marked in the south of Europe now. For these two separate reasons, it seems at least more probable that  $\eta$  was adopted to express a sound the same, or nearly the same, as the open  $e$  of the Italians. For the same reasons, it seems probable that  $\omega$  was taken not to denote long  $o$ , but a more open sound; perhaps something between open  $o$  and the English *au*. The form  $\Omega$  is of doubtful origin. It is found in an alphabet of Miletus of about Olympiad 60; not earlier. It looks like a conscious modification of  $O$ .

Greek writing in the earliest times was from right to left, following the example of Phœnicia: several specimens of this still exist. The more convenient practice of writing from left to right soon became universal. It was preceded, however, by an intermediate method, in which the direction of the lines was alternately right to left and left to right, so that it was not necessary to carry the eye back, as with us, from the end of one line to the beginning of the next. This was called *βουστροφῆδόν*, because the lines were made in the same way as the furrows by oxen in ploughing.

Kirchhoff distinguishes two main divisions of Greek alphabets—the East and the West; not that this geographical distribution is exact, but it is the most convenient. The eastern includes first the alphabets of the towns of Asia

Minor—Halicarnassus, Ephesus, Teos, Miletus, Colophon, and Rhodes, which, agreeing essentially, became that Ionic alphabet that was adopted at Athens 463 B.C., and is the Greek alphabet with which we are familiar; secondly, those of the Ægean islands—Thera, Melos, Crete, Paros, Siphnos, Thasos, Naxos,—in which  $\Omega$  does not stand for Omega, but occasionally appears as well as  $o$  for Omicron, and there are other minute differences in the shape of the letters; thirdly, some of the alphabets of the mainland of Greece, which have a closer affinity to the Ionic than to their neighbours, viz., the old one of Attica, down to Ol. 94—Argos, Corinth and its colonies, Corcyra, and even Syracuse. The western division includes the remainder of the towns of Greece proper and their Sicilian and Italian colonies; these are marked by peculiar variations of certain characters, especially  $g$ ,  $e$ ,  $h$ ,  $th$ ,  $l$ ,  $r$ , and  $s$ , by the use of  $h$  as the aspirate only, by the absence of *omega*, and by the universal application of the symbol Ψ or ϒ

to denote, not  $ps$ , but  $ch$ , whilst X or Ψ, the symbol of  $ch$  in the eastern alphabets, here denotes  $x$ . Compare with this last variation what we have said above of the use of XΞ to express X: there can be little doubt that it was from the occurrence of X in this collocation, and no other, that this new value for it arose, and Ξ was dropped. It is significant that in the old Latin alphabet XS appear instead of X. The difference in value of Ψ in the eastern and western alphabets is perplexing: it seems that in one or the other the original value must have been consciously changed, but it is not easy to say in which. The most important alphabet of this group for our purpose is that of the Chalcidian colonies of Sicily and the west coast of Italy—Cumæ, Neapolis, &c.—because from this was derived the Latin alphabet, the direct progenitor of our own. It is distinguished from others of the same class by the rounded form of the Gamma Γ, by the peculiar form of the Lambda Λ, by the very old Mu (μ), and by a rounded Sigma Σ, though it has also the two other ordinary forms ς and Ϝ: in common with some other western alphabets, it has a double rho (P and R). (See p. 600.)

From this Chalcidian alphabet it seems clear that all the Italian alphabets were derived. They fall into two families, which differ from each other considerably, but principally in the loss of old letters and the insertion of new—differences which do not militate against their common origin, but show the cause of their separate development. The first family contains the Etruscan, Umbrian, and Oscan alphabets; the second the Latin and Faliscan. Into the peculiarities of the members of the first group we do not propose to enter at length: they agree in the total rejection of O and X, and the addition of a strange symbol

Ϛ to denote the *f* sound, *vau* being retained with a slightly modified form for *v*: the Etruscan retains the symbols Θ and Ϛ which the other two dropped, and the Etruscan and Umbrian agree in rejecting the soft mutes. The Umbrian, however, has a new symbol for a modified *d*, peculiar to itself, and also for a modified *k*; the Oscan has new symbols for a modified *i* and *a*, and in general shows a difference in the shape of its characters from all the other Italian dialects, which does not seem due to any other foreign influence so much as to its own individuality. These three languages are all written from right to left, in which the Faliscan agrees with them: the Latin alone, from the earliest time of which we have any records, was written from left to right; but there can be little doubt that it did not originally differ from its fellows, but changed at a later time, just as the Greek alphabet itself

had done. The fact that X, found in the Latin and Faliscan alphabets, has the value of *x*, and not of *ch*, and that Ψ, as already mentioned, is found with the value of *ch* in Etruscan, shows that the common source of these five alphabets was a western, not an eastern Greek alphabet; and the rounded form of C, and the peculiar L (V, not Λ) limit the choice to the Chalcidian family. The points in which the Latin differs from the Chalcidian alphabet of Cumæ, from which it was probably derived through commercial intercourse, lie—

(1.) In the application of the symbol *vau* (F), to denote not the *v* but the *f* sound, which was probably strange to the Greeks.

(2.) In allowing K to fall almost out of use—it was employed only in abbreviations, such as the first letter of a prænomen, as *Kæso*, or for *Kalendæ*, &c.—and employing C instead, which had of course in the present Greek alphabet the power of *g*. This change may point to a time when the distinction of the sounds *k* and *g* was obliterated, to be afterwards restored.

(3.) In the formation of the new symbol G—*i. e.*, C with a distinguishing line—to mark the soft gutturals, when the want of a distinctive symbol was again felt. This was some time in the 3d century B.C.; but instead of replacing K for the hard guttural sound, they preferred to leave C in its old place, but with a new value, *k* instead of *g*; while the modified form G was inserted into the place of I (Z), which may have been taken by the Romans (as it certainly was found in the other Italian alphabets), but which fell out of use absolutely without any record.

(4.) In absence of the aspirates Ψ, ⊕, and ⊙: these sounds were not natural to the Roman tongue, and therefore the symbols were never regularly received into their alphabet, though they were taken to represent numerals. Their forms, however, were much altered, and so in process of time they became confused with other letters: thus Ψ denoted 50; but it came to be written ⊥, and so naturally passed into the quite meaningless L: ⊕ denoted 10, but being too cumbersome to write, the circle was dropped, and the cross (X) alone remained. A variant form of the same letter (⊙) seems to have originally represented 100, and either to have been shortened into the common form C, or C superseded it as being the first letter of *centum*. ⊙ was taken for 1000, but for convenience of writing it was broken up into CIO, and this was the more easily done because the parts were characters in use; but this symbol also was replaced by M, the first letter of *milie*. It is probable that ⊙ was simply divided, and the half of it (D) then stood for half of 1000, or 500; and half of X, ten, became V, five. Neither D nor V have any other propriety as symbols.

(5.) In the addition, in the 1st century B.C., of the two symbols Y and Z after X (which had long been the last letter of the alphabet), to express the Greek sounds *v* and *z*. In borrowed words these in earlier times had been roughly denoted by *u* and *ss*; but in Cicero's day greater precision was desired; and not being able to compound two characters of their own to denote the strange sound (as they did for the aspirates *kh*, *th*, *ph*, formerly denoted only by *k*, *t*, and *p* or *b*), they took sound and symbol together, so that Φρύγες appeared, not as *Bruges*, but as *Phryges*: τραπεζίτης ceased to be *tarpessita*, and *sona* became *zona*, &c.

The Latin alphabet agrees with the Chalcidian in the retention of koppa (Ψ); the downward stroke became by degrees more oblique. This symbol had a much wider use in Latin than it had in any Greek language: it was needed to express a modified *k*-sound which the Latins liked, wherein a slight *v* sound was heard after the *k*.

This sound was distasteful to the Greeks, and consequently they changed this *kw* (or *qu*) into *p*; so also did the other Italians (compare *eguos*, ἵππος, *Epona*, &c.); but the Romans liked it, and therefore, alone in Italy, kept the Ψ to denote it. It is true that the Q was generally followed by a written *u*, though not always in the older inscriptions; but it was fully recognised that this *u* was not a real letter. It was only a symbol expressing further, and somewhat unnecessarily, the indistinct after-sound which made Q different from K; it would have been more logical to have written Q alone, as was actually attempted under the empire, where we find on inscriptions forms such as *qis*, *qidem*, *qaerella*; but this never became general. The Latin and Chalcidian alphabets are again at one in not having the symbol M for *s*, differing in this respect from the alphabets of South Italy, and also from the Etruscan and Umbrian, which had both forms. Lastly, the Chalcidian (as we saw) had two forms for *r*, P and R; of these the Latin chose the last, and generally employed the first for *p*; though for that letter the genuine Greek form Π also appears rarely.

The Romans did not retain the Greek names for the characters of the alphabet. The vowels were known by their sounds only. The momentary sounds and *h* were denoted by their own sound followed by a vowel, as *be*, *ce*, *de*, *ge*, *pe*, and *te*, but *ka*, *ha*; *g*, as we saw, had sufficient vowel sound to float it; on the other hand, the continuous consonants were preceded by the vowel, as *ef*, *cl*, *em*, *en*, *er*, *es*; *x* was called *ix*. The difference in the names of the consonants obviously was caused by their nature: momentary sounds are produced by a complete closure and opening of the organs required in each case; when this opening is made, the organs are so placed as to form a vowel, which naturally is produced by the remnant of sound required for the consonant; whereas a vowel cannot be produced before any one of these sounds without conscious effort: hence it was simpler to call *k*, *ka*, than to call it *ak*. But the continuous sounds are pronounced when the necessary organs only approximate more or less closely to each other; the channel through which the sound passes from the larynx to the lips is never closed altogether, and by reason of this slightly open position a certain amount of vowel sound tends to escape—just as the organs are drawing together to produce the consonant, and thus is heard before it; but to sound a vowel after one of these consonants the organs must be intentionally put into the proper position. Thus, then, exactly the same principle—the conscious or unconscious striving for ease of articulation—produces exactly opposite results in the case of the momentary and the continuous consonants. The same reason caused a different vowel to be employed for *h* and *k* from that which is used for the other letters. In sounding *a* the organs are in nearly the same position as in sounding these two gutturals, only a little more open; whereas the position of *e* is more nearly that of all the other consonants. It must of course be remembered that a Roman, if he had wished to speak of his A B C, would not have said, as we do, *a-bee-see*, but *ah-bay-kay*.

The arrangement of the letters of the alphabet has caused much ingenious speculation. It has been more than once pointed out (as by Prof. Key, *The Alphabet*, p. 28) that there are certainly traces of regularity of arrangement. The three soft momentary sounds *b*, *g*, *d*, were placed together; and it is possible that *p*, *k*, *t* (if denoted by Pe, Koph, Tau), may have once been together, and separated by later intrusions; *l*, *m*, *n* have an affinity more apparent than real, which was perpetuated by their meaningless designation as “liquids;” still, the appearance is sufficient to justify the idea that they may have been

purposely put together. It has been suggested that the alphabet was at first composed of "four quaternions" of letters, each headed by a vowel, and the scattered position of the vowels lends itself to this arrangement; but it must be remembered that the arrangement of the European alphabets is certainly the same as that of Phœnicia, and in the Phœnician there were breathings but no vowel symbols. Besides, the remaining letters are just as necessary as any sixteen which we might so arrange, and to all appearance just as ancient. The author of the *New Cratylus*, indeed (p. 170, ed. 3), actually drew up his list of fours: the three soft momentaries headed by *aleph*; then came *h*, followed by *vau*, *cheth*, and *teth*, oddly grouped as aspirates; then the three "liquids," with *samekh* behind them; and lastly, *pe*, *koph*, and *tav*, under the care of *ayin*. This, of course, renders it necessary to "omit *caph*, which is only a softened form of *coph*, the liquid *resh*, and the semi-vowel *yodh*, which are of more recent introduction." Also it is "quite certain that at the first there was only one sibilant, *samekh*." In this way Dr Donaldson satisfies himself that the "original Semitic alphabet contained only sixteen letters." We give this futile attempt at arrangement with no wish to sneer at a philologist who did good work in his day, but simply to show the arbitrary nature of all such attempts, resting as they must do simply on internal evidence. If we bear in mind the history of the derivation of the Phœnician alphabet, as we have attempted to give it, from the Egyptian hieratic, we shall conclude that it is hardly probable that symbols borrowed for practical uses should have been arranged upon any scientific method; that chance guided the general arrangement, though a few sounds obviously similar may have been put intentionally together. No argument can be drawn (as by Rödiger in his Hebrew Grammar) from the juxtaposition of two letters meaning a hand (*yodh* and *kaph*), two meaning a head (*koph* and *resh*), &c.; reasons have been given above for believing that these names have no relation to the original import of the signs, but were merely fanciful analogies drawn by the Phœnicians themselves; and it seems as possible that the juxtaposition may have suggested the idea of the names as that the names caused the arrangement. But if the argument be sound, it is valid against the supposition that the order was fixed throughout on scientific grounds.

It is quite certain that the Teutonic tribes of north-western Europe possessed characters of some sort before they received the Greek or Latin alphabets. These characters are generally called *runes*, and have been the subject of some sound scholarship and much baseless speculation. They may be divided into three main classes—the Anglo-Saxon, the German, and the Scandinavian; each of these contain a number of lists of characters, which, however, do not differ from each other more than the Greek alphabets; and there is so much likeness in the whole family that we may infer a common origin for all. The term *rune* is recognised as the name of a German letter by Venantius Fortunatus at the beginning of the seventh century, in the lines—

Barbara fraxineis pingatur rhuna tabellis;  
Quodque papyrus agit, virgula plana valet.

*i.e.*, these characters were cut on smoothed ash-boughs. The meaning of the word *rûn* in Anglo-Saxon is a "secret;" and the verb *rûnan*, which is derived from the same, means "to whisper"—the same verb which appears in the now disused phrase, to "round in the ear." *Rûna* denoted a magician; the word is contained in the German *alruna*, the well-known designation of those prophetesses whom the German tribes venerated, which appears corrupted by Tacitus (*Germ.* c. viii.) into *aurinia*. There is sufficient evidence to show that the knowledge of these runes was

confined to a small class; that they were used as magical characters, and also as means of augury. It was for this reason undoubtedly that they were generally proscribed on the introduction of Christianity; and the reception of the Latin characters by the Anglo-Saxons was regarded as important as their reception of the Christian doctrines.

It is impossible to believe that the barbarous inhabitants of the German forests should have worked out for themselves a genuine alphabet before they came into intercourse with the civilised nations of the south. When we remember the long process through which a pure alphabet was reached by the highly-developed nations which dwelt on the eastern shores of the Mediterranean, it is utterly incredible that such success should have been achieved, as it were, *per saltum*, under so much more unfavourable circumstances in the West. It may be asserted with some confidence that if the runes were genuine alphabets (which there seems no reason to deny), they must have been derived from the Phœnicians in process of commerce. There is quite sufficient similarity in several of the characters to make this view antecedently probable, but any historical proof would be extremely difficult, if not impossible. It is true that even where the characters resemble the Phœnician the names of the letters differ altogether; but this, as we have before seen in the case of the Phœnicians themselves, is nowise unnatural when an alphabet is borrowed; the form is important, the name signifies little, and new names are attached according to the fancy of the borrowers. It is highly probable, both from the meaning of the word *rune* itself and from the evidence of foreign writers, that these symbols were not used by their owners for any of the ordinary ends of an alphabet (except, perhaps, for inscriptions) until the Teutonic nations came into contact with Greek and Roman civilisation; by the mass of the people they were probably looked on simply as charms, the unknown symbols of an occult science. Nay, it might be held that even to the initiated they had merely a sort of hieroglyphic value, and were developed into phonetic significance only by the contact of the Greek and Roman alphabets. For this view, indeed, there is no evidence, and it is not in itself probable. But we should be driven to it if we were to suppose that the runes were the creation of the Teutonic intellect.

These ancient characters occur plentifully on memorial stones, rings, coins, &c., in Scandinavia. In England they have been found principally in Northumbria, Mercia, and East Anglia. It has been suggested (by Mr Haigh) that this may be due to the milder principles of the Irish monks, who restored Christianity to the north of England after its fall with Edwin in 633, and did not pursue that system of eradicating every trace of paganism which had been originally commanded by Gregory. Runic writing was even employed in the service of Christianity. Mr Kemble (*Archæologia*, vol. xxviii. p. 349) interpreted with great ingenuity the mutilated inscription on the famous cross discovered at Ruthwell, and showed that it refers to the Crucifixion. But the Anglo-Saxon alphabet was soon—early in the 7th century—conformed to the Latin type, those letters of the older form alone being retained which were required to denote sounds that had no counterparts in Latin; these were þ (*wên*), and ð (*thorn*), the latter of which expresses the surd breathing heard in "*thin*:" in order to express the corresponding sonant (heard in "*that*," and confusedly denoted by the same compound *th*) a stroke was drawn across the simple *d* ( $\delta$ ), and the new letter was called *edh*. The symbol  $\mathfrak{z}$  is sometimes found instead of *y*. Curious admixtures of runes with Latin characters occasionally occur even to late times. Thus, in the *Codez Exoniensis* (p. 400, ed. Thorpe), an enigma occurs in verse, and the parts apparently of the subject to be guessed are

written in runes; the odd effect is increased by these runes being written in the regular way—(sometimes they were written *βοστροφηδόν*)—from right to left, contrary to the general run of the words. Kemble, in the *Archæologia*, has given an interesting translation of an Anglo-Saxon poem, each stanza of which begins with the name of a runic letter; thus the first stanza begins with Fesh, “money;” the name of *f*, the first runic letter, and goes on to say—

“Money is a consolation  
To every man:  
Yet shall every man  
Liberally distribute it;  
If he will that, before God,  
Honour shall fall to his lot.”

The second stanza is dedicated to the bull, Ur (*u*), the third to thorn (*th*), &c. This poem accordingly gives the order of the alphabet, which agrees in the main with that of all other runic alphabets. Yet the poem is not old, for the name of *s* (Sigel, “the sun”) is treated by the writer as though it had been Segel “a sail”—clearly a mistake of a later time, when the true name had passed out of use. It may be added that the names of this alphabet are sometimes strangely abstract; thus we find “gift;” “hope;” “need;” “war;” which differ much from the very concrete objects which the Phœnicians chose to denote their letters. In consequence of all these old alphabets beginning with the letters *f, u, th, o, r, c*, in the same order, the alphabets are called by some antiquarians “futhores,” just as we commonly speak of the ordinary alphabet as the *A B C*.

The doctrines of Christianity were first presented to a Teutonic people in a written form by Ulfilas, who, though not the first successful missionary to the Goths, has thereby established his claim to be regarded as the apostle of his race; and while the main body of the Goths, spurning the weak control of Rome, poured westward in their fierce career of victory towards Italy and Spain, a remnant was left in Mæsia, to whom Ulfilas gave the gospel in their own tongue. This was at the end of the 4th century of our era. He employed an alphabet of twenty-four or twenty-five letters, some of which are unmistakably Greek in form; others are common (or nearly so) to the Greek and the runic alphabets, and may therefore have been derived from either; but if they were runic, they at least received a more rounded form, it being no longer necessary to retain those angles which (as we saw above in describing the cuneiform characters) were most convenient in days when writing meant cutting on stone or wood. But some of the letters seem to be beyond doubt runic: most clearly so are *f, r, u, y*, and the symbol for the compound sound *hw*; and the reason for all these (except *r*) appears to be the lack of a proper equivalent in Greek. The letter which Ulfilas adopted to denote the surd breath *th* is not runic, so that the Gothic and Anglo-Saxon alphabets here differ: it is apparently the Greek *ϕ*. It would seem, therefore, that this letter still denoted an aspirate (*p'h*) in Greek, and not a breath, otherwise it would surely have been taken for *f*; here, on the contrary, it seems to have been selected at random from a list of symbols which denoted no corresponding sounds in Gothic. On the same lack of principle *⊙* was taken to denote *hw*. *X* was the exponent of the breath *ch*, as heard in German words: here the difference between the true aspirate and the breath is not great. Long *o* formed a symbol which is very like *omega*.

Another alphabet which has had an important influence on Europe, and which may be destined to a yet wider extension as the alphabet (in a modified form) of the great and progressive Russian empire, is the Cyrillic. This was the work of Cyril, a monk of Constantinople, who, together with Methodius preached the gospel among the Slavonic tribes of Bulgaria and Moravia, in the 9th century, long after the Teutons had come under the influ-

ence of Christianity. Cyril held the services of the church among his new converts in the vulgar tongue, into which he also translated certain books of the Scriptures. The alphabet which he employed for this purpose is more thoroughly Greek than that of Ulfilas; but since the Greek alphabet was not nearly sufficient to express all the Slavonic sounds—especially the numerous sibilants—he added further signs, the history of which is not clear. This alphabet has been largely adopted by the eastern branches of the Slavonic race, including the Russians, Bulgarians, and the Illyrian division of the Slaves. The old Bulgarian (commonly called the Ecclesiastical Slavonic) is the language into which Cyril translated the Scriptures; in philology it holds the same rank as the Gothic has among the Teutonic languages: it is the parent, however, only of one of the least important dialects, the modern Bulgarian. The Illyrian family is divided into the Servians on the one hand, and the Croats and Slovenian peoples on the other. These parties are separated by difference of religion: the Servians belong mainly to the Greek Church, while the others are exclusively Roman Catholic; and the members of the Greek Church naturally cling to the Cyrillic characters, while the Catholics have adopted the Latin alphabet. It is not easy to predict which characters will ultimately predominate. The Latin letters are insufficient to express the Slavonic sounds; but this deficiency can be eked out by diacritical signs, and the greatest literary activity is shown by the Latinising party. Lastly, the Cyrillic alphabet has been adopted by the Wallachians, through the influence of their Slavonic neighbours, though it is little adapted to express their essentially Latin speech, derived from the colonists whom Trajan settled in the new Roman province of Dacia. Most of the needless symbols have been dropped in the newest form of the Wallachian alphabet. (See Max Müller, *Survey of Languages*, pp. 39–84.)

Cyril's original alphabet consisted of forty-eight symbols, but some of these are slightly different representations of the same sound; others are tachygraphies for combinations of sound, as *sh*, *ts*, &c. The names were not Greek, with the exception of three—*ksi*, *psi*, and *thita*—which were relegated to the end as unnecessary, but they retained their original Greek place as numerical signs. The alphabet is printed at the end of this article. It will be seen that *B* occupies the third place, while a modified *B* stands second: the reason is, that *B* had come to denote the *v* sound in Greek, and therefore carried this value into the Slavonic. The modified letter denotes the old *b* sound. The 7th letter, which is not Greek, had the sound of English soft *j*, a little softer than the French *j* in *jamaïs*. The 8th and 9th symbols are the Greek *s* and *z*: they are supposed to have had the same sound, that of the soft English *z* (not *dz*)—perhaps one of them may have originally denoted *dz*, a sound which easily passes into *dj*; *dj* had a special symbol both in the Servian and Wallachian, though it had none in the Cyrillic, probably because the sound had not then been produced; if it had, we may conclude, from the exactness which the Cyrillic alphabet everywhere shows, that it would not have been left without a mark. The 8th letter has been expelled from the Russian alphabet as superfluous: the Russians have no *dj* sound. The 10th and 11th letters were sounded alike as *i*; the 10th is the Greek *Eta*, which had therefore become undistinguishable from Iota in Cyril's day, as it is in modern Greek. The 12th letter, *I* pure and simple, denoted the semi-vowel *y*. The 22d was *t*, followed by a parasitic *y*. The 23d and 24th are only different ways of writing the same combination *ou*; the Greeks having changed the *u* sound into *ü*, Cyril was obliged to write *ou* for *u*, as the Greeks themselves did. The Russian has one symbol (*Y*) to denote this sound: it is

probably a tachygraphy of the 24th. The 25th and 26th denoted respectively the breathings *j* and German *ch*. We may recall here the different treatment of  $\phi$  by Ulfilas; it seems a fair inference that the sound of  $\phi$  had changed from an aspirate to a breathing between the times of Ulfilas and Cyril. The 27th and 28th are the Greek Omega in the simple and in a modified form: they denoted the sounds heard in *note* and *not* respectively; these have been dropped in all the derived alphabets, in which the 17th letter does work for both. We now come to a series of letters (29-44) which are not Greek, and denote sounds which were probably unknown, or at least had no separate exponents, in the Greek system. The first four are sibilants, simple or compound. It will be remembered how the Greek dropped the large Phœnician stock of sibilants, through their own disinclination to such sounds. Cyril, however, did not go back to the original types, but had recourse to the inartistic expedient of using two or three upright strokes, with small modifiers below. Letter 29 is the compound *ts*, 30 denotes the fuller compound *tseh* (English *ch* in "church"), 31 is the simple *sh*, 32 is *sh̄t*, which in Russian is said to be expressible only by *schtsch*, unquestionably a very strong sibilant; the newer form of Wallachian used 29 to express *qj*. The letters 33-36 were attempts to express the neutral vowel (heard in English in *fir*, *sun*, &c.), the first two in its aspect nearest to *u*, the last two nearer to *i*. The first and last are important in Russian: they are written, but not pronounced; but the first hardens a preceding letter, or, if it be a continuous consonant, makes it be sounded as though it were double. The 36th, on the contrary, softens a preceding letter, giving it the *mouillé* sound. The 34th letter has been dropped in Russian; the 35th has a peculiar kind of *i* sound. The 37th letter has an *e* sound; it was apparently introduced into the alphabet in consequence of the polyphony of the original *e*, which in Russian does the work of *e*, *o*, and *œ*, and also of each of these preceded by *y*. The combinations seem to us needless, but the Greek had no symbol for *y*; therefore Cyril probably thought it necessary to connect the I-symbol with the following vowel, in order to show that it was only the semi-vowel, not a full vowel, which would have caused another syllable. The first of these symbols has been retained in Russian unchanged; the second is now written

rather like an inverted *r*  $\Omega$ ; the third was suffered to drop—whence arose the confusion respecting *e* which we have just mentioned. Nos. 41 and 42 denote nasalised vowels, *e* and *o*, as heard in the French *en* and *on*: these sounds seem to have fallen out of all Slavonic languages, except the Polish. 43 and 44 denote the same vowels "pre-iotised," like the three 38-40: these also are now unknown. Then came the Greek Ksi and Psi, the characters being very slightly altered: they have fallen out of use altogether. No. 47, Thita, is retained in Russian, but sounded as an *f*, which has thus two exponents,  $\theta$  and  $\phi$ . Lastly came the equivalent of the Greek Upsilon called *ijica*: this is employed in Russian in words borrowed from the Greek.

Fourteen of these letters have been expelled from the Russian alphabet, namely 8, 11, 22, 23, 27, 28, 34, 40-46; their list of 35 letters is made up by the addition of the inverted *e*, which stands in the 31st place of the alphabet. The forms of the letters are more rounded than those of Cyril, as will be seen by a comparison of the two. This reform, among others, was due to Peter the Great, who printed the first Russian periodical at Moscow in 1704. (Max Müller, *Survey*, p. 49.)

The Servian alphabet differs from the Russian chiefly by the insertion of symbols to denote modification of sound caused by a following *y*. Thus we find a character to express *dy* (equivalent to the Hungarian *gy* heard in "Magyar"); another for *ly*, denoting the sound of the Italian *gli*; another for *ny*, the Italian and French *gn*; and one for *ty*, a softer sound than the *tseh*, the symbol for which is common to Russian and Servian.

The Wallachian adopted nearly all the Cyrillic characters, except the superfluous vowel-symbols and the nasalised vowels. The list was soon considerably shortened, as was natural in a language originally non-Slavonic, though in the course of time it has naturally borrowed many words from its neighbours. Since it has been used for literary purposes, it has been further diminished to 27 symbols by the loss of the short sibilant (32), the second *e*, and the iotised *a*; the other iotised vowels had gone before. The forms of the characters have also been much assimilated to the Latin types: instead of the peculiar symbol for *sch*, which the Russian retains, the new Wallachian has a *J* with a wavy stroke through the middle; *n* is written as *N*, not as *H*; and Cyril's combinations of perpendicular lines are more rounded than the Russian. The Wallachian has one special symbol  $\uparrow$  to denote the sound *ün*.

We have thus described the alphabets used in modern Europe. The only others which have any special interest for Englishmen are the different Indian alphabets; but these are too numerous and complicated to be fully described here. (J. P.)

ALPHEUS, (Ἄλφειός), the chief river of Peloponnesus, now called *Rufia* or *Iouphi*. Its sources are in the mountains of Arcadia, to the east of Megalopolis. Being fed by a great number of small streams, it becomes navigable, and traversing Elis, empties itself into the Ionian sea. At several points in its course it runs in a subterranean channel. This fact probably gave rise to the well-known myth which represents Alpheus, the river-god, as passing under the sea to the nymph Arethusa, who had been changed into a fountain in the island of Ortygia. Milton in his *Arcades* thus alludes to the story—

“That renowned flood, so often sung,  
Divine Alphéus, who by secret sluice  
Stole under seas to meet his Arethuse.”

ALPHONSO, ALFONSO, ALONZO, AFFONSO, or ILDEFONSO. This name, so famous in the annals of the Spanish peninsula, has been borne by no fewer than twenty-two of its sovereigns—viz., by ten of the Asturias and Leon, one of Castile when separate from Leon, five of Aragon, and six of Portugal.

*1st, Asturias and Leon.*—ALPHONSO I., surnamed “The Catholic,” King of the Asturias, the son of Pedro, duke of Biscay, was born in the year 693. On the death of Favila, the son of Pelayo, Alphonso, who had married Ormisinda, the daughter of the latter, was proclaimed king of Asturias. During his whole reign he was engaged in almost perpetual conflicts with the Moors, and is said to have wrested Leon, Galicia, and Castile from their hands. His zeal for the church, displayed in endowing and repairing monasteries and churches, gained for him his surname of “The Catholic.” Alphonso died at Cangas in 757, and was succeeded by his son Fruela I.

ALPHONSO II., surnamed “The Chaste,” King of the Asturias, the son of Fruela I., was but a child when his father was assassinated in 768, and consequently his claims to the throne were passed over in favour of Aurelio, who was probably a cousin of Fruela. Alphonso was invested with regal authority by Silo, the successor of Aurelio; on whose death, in 783, he became sole ruler. He was afterwards dethroned by his uncle Mauregato, and was compelled to retire into Biscay. Mauregato, after a reign of about five years, was succeeded by Bermudo, who, in 791, took Alphonso as his partner on the throne. Bermudo reigned for only about four years longer. A rebellion of many of the chief nobles in 802 compelled Alphonso to surrender his throne for the third time; but he was soon afterwards restored, mainly through the assistance of Theudius, one of his most faithful followers. In addition to having to defend himself against these internal dissensions, Alphonso was during the greater part of his reign at war with the Moors, obtaining, among other successes, a signal victory over Mohammed, governor of Merida, in 830. Alphonso died in 843, in the city of Oviedo, which he had greatly adorned and made the capital of his kingdom. He had some years previously abdicated in favour of Ramiro, son of Bermudo. His surname of “The Chaste” has been connected by some with the legend that he refused to pay the Moors their tribute of a hundred Spanish virgins, but is rather to be ascribed to his vow to preserve an absolute continence.

ALPHONSO III., surnamed “The Great,” King of the Asturias, was born in the year 848, and succeeded his father Ordoño I. in 866. In the following year, Fruela, count of Galicia, disputed Alphonso’s right of succession, and forced him to retire to Alava; but Fruela’s tyranny so exasperated the people that he was assassinated before he had been a year in power, and they gladly recalled Alphonso to the throne. Other conspiracies marked the beginning of Alphonso’s reign, but he soon felt himself tolerably secure at home, and turned his arms against the Moors. By 901, the year in which he gained a splendid victory at

Zamora, he had, it is said, extended his empire to the banks of the Guadiana, and had, by founding and fortifying cities, made good his hold over a large part of the conquered territory. But Alphonso’s victories abroad were greatly neutralised by discontent among his own subjects, who found it difficult to bear the heavy war taxes that had been imposed upon them. There was a rising under Ano in 885, and another under Witiza in 894; and in 907 a more formidable insurrection broke out, headed by Garcia, the king’s eldest son. Garcia was defeated and taken prisoner; but as the greater part of the nation sided with the queen in demanding that he should be released, Alphonso, either wishing to prevent a civil war, or thinking that his cause was hopeless, resigned his crown to his son in 901. After his abdication, Alphonso, offering his services to his son in the true spirit of the age, led an expedition against the Moors, in which he gained fresh victories. He died towards the end of the same year (901). He was the last monarch who bore the title King of Asturias, his successors being called kings of Leon, from the new capital of the kingdom. It was in his reign that the counts of Navarre became independent. There is still extant a Latin chronicle, treating of the history of Spain from the Moorish invasion down to the death of Ordoño, which is usually attributed to Alphonso.

ALPHONSO IV., “The Monk,” King of Leon, succeeded Fruela II., his uncle in 924. On the death of his wife, about six years afterwards, he resigned his crown to his brother Ramiro, and retired into a cloister; but soon growing weary of monastic life, he made an attempt to resume the sceptre. He was, however, taken prisoner at Leon, and confined in the monastery of St Julien, where he died, probably about two and a half years after.

ALPHONSO V. succeeded his father Bermudo II. in 999, being then about five years of age. Gonzalez, count of Galicia, and his wife, were, by appointment of Bermudo II., guardians of the young king; and on arriving at manhood he married their daughter Elvira. The regency is remarkable for the defeat and death of the famous Moor Almansur in 1002—a success that led ultimately to the conquest of Cordova by the Christians. Alphonso himself made war upon the Moors, recapturing Leon and other places that had been lost during his minority. Alphonso died at the siege of Viseo in 1028. He was succeeded in the kingdom of Leon by his son Bermudo III., while the hitherto dependent countship of Castile became a separate kingdom under the sovereignty of Sancho el Mayor, king of Navarre, and husband of the eldest daughter of the late count.

ALPHONSO VI. of Leon, and eventually I. of Castile, surnamed “The Valiant,” was born in the year 1030. His father, Fernando the Great, who in his own right was king of Castile only, but succeeded to the throne of Leon in right of his wife, died in 1065, leaving his kingdom divided among his children. Sancho, the eldest son, received as his portion Castile; to Alphonso was given the kingdom of Leon, the territory of Campos, part of Asturias, and some towns in Galicia; and Garcia the youngest brother, received a part of Galicia and of Portugal; while the towns of Toro and Zamora were left to Urraca and Elvira, Fernando’s two daughters. Peace was not long maintained between the three brothers. In 1068 Sancho made war upon Alphonso, and defeated him in a bloody battle at Piantica, on the Pisuerga. In 1071, hostilities, which seem to have been suspended, again commenced, and Alphonso having recruited his army, defeated Sancho at a place called Valpellaga, on the banks of the Carrion; but the latter, being reinforced, it is said by the famous Roderigo Diaz de Bivar, commonly called “The Cid,” made an attack during the night, and almost exterminated the Leonnese army, Alphonso himself being taken prisoner. He

was compelled to abdicate his throne, and was imprisoned in the monastery of Sahagun, probably with the intention of making him become a monk; but escaping from this place of confinement, he sought refuge with Almamun, the Moorish king of Toledo, who received him with great hospitality. Sancho having taken possession of Leon, advanced into Galicia against Garcia. The two brothers met at Santarem, when the Galicians were defeated with great slaughter, and Garcia himself captured and thrown into prison. Sancho was assassinated in 1073, and Alphonso, after making a solemn declaration that he was guiltless of his brother's death, was reinstated in his own dominion, besides receiving his brother's kingdom of Castile. Garcia, who had been liberated on the death of his brother, was preparing to recover his throne, when Alphonso, having treacherously invited him to his court, shut him up in the castle of Luna, where he died ten years afterwards. Being now the undisputed master of nearly all his father's kingdom, Alphonso was at liberty to turn his arms against the Moors. His first expedition, in 1074, was in defence of Almamun of Toledo, who had befriended him in his adversity, and whose kingdom was now invaded by the Cordovans. Some years later, however, disregarding the ties of gratitude, he himself laid waste the territories of Yahia ben Ismail, the son and successor of Almamun, and ended by taking the city of Toledo itself in 1085. Many parts of Spain, hitherto subject to the Moors, were now added to the empire of Alphonso; and it is not improbable that he would have reduced the entire peninsula to his sway, had not a new and formidable power arisen, which threatened to undo all he and his predecessors had accomplished. A large army of Moors from Africa, under Yusef ben Tashfyn, one of the Almoravides, entered Spain, and, with the assistance of Ben Abad, king of Seville, inflicted a terrible defeat upon Alphonso near Zalaca, in the year 1086. Fortunately for the Christian cause, the Moorish chiefs began to quarrel among themselves, and Alphonso was enabled not only to recover his position, but even to extend his conquests in some directions. In 1108, however, the Almoravides made another serious attempt to destroy the power of Alphonso. A bloody battle was fought at Uclès, in which the Leonnese army was completely defeated, and Sancho, Alphonso's only son, who commanded in place of his father, slain. Alphonso died at Toledo in 1109, and was succeeded by his daughter Urraca, whose husband, Alphonso I. of Aragon, is by some historians enumerated among the kings of Leon as Alphonso VII. Through his illegitimate daughter Teresa, whom he gave in marriage to Henry of Burgundy, Alphonso became an ancestor of the kings of Portugal.

ALPHONSO VII., the same as ALPHONSO I. of Aragon (*q.v.*)

ALPHONSO VIII. of Leon (or VII., according to those who do not consider Alphonso of Aragon as properly a king of Leon) and II. (or III.) of Castile, often called Alphonso Raymond and "The Emperor," was born in the year 1106. He was the son of Urraca, daughter of Alphonso VI., and Raymond of Burgundy, her first husband. In 1112 he was proclaimed king of Galicia, by whom it does not clearly appear; in 1122 he was associated with his mother in the government of Leon and Castile; and on her death in 1126 he became sole monarch. Soon after this event he made war upon his stepfather, Alphonso of Aragon, in order to recover the territories, properly belonging to Leon and Castile, which had been lost owing to his mother's misgovernment. The two kings came to an agreement about the year 1129, Alphonso of Leon having regained most of his possessions. In 1135, Alphonso, elated by the homage of the king of Navarre and the counts of Barcelona and Toulouse, caused himself

to be solemnly crowned emperor of Spain. This dignity was, however, little more than a name, for Alphonso Henriquez of Portugal and Garcia Ramiro of Navarre declared war upon the new emperor almost immediately after his elevation. Intestine feuds between the various Christian princes of Spain, which resulted in no very definite gain to any of them, lasted until the advance of large Moorish armies under the Almohades compelled the Christians to turn against their common foe. Alphonso invaded Andalusia in 1150, and gained several victories, which contributed greatly to the extension of Christian territory in Spain. He died in 1157 at Tremada, on his return from an indecisive battle with Cid Yusef at Jaen; and was succeeded by his elder son, Sancho, in the throne of Castile, and by his younger, Fernando, in that of Leon. In 1156 he instituted the order of St Julien, afterwards so celebrated under the name ALCANTARA (*q.v.*)

ALPHONSO IX. (VIII.), King of Leon only, succeeded his father Fernando in 1188. In 1190 he sought to strengthen his position by marrying his cousin Teresa of Portugal. This marriage, being within the forbidden degrees, was pronounced null by the pope (Celestine III.), who excommunicated Alphonso and his queen until 1195, when they agreed to separate. In 1197 Alphonso a second time defied the papal authority by marrying his cousin Berengaria, daughter of Alphonso III. of Castile, with a view of putting a stop to the frequent quarrels between the two kingdoms. As before, the pope (Innocent III.) prevailed, and in 1204 the separation took place, Innocent, however, granting that the children already born should be recognised as legitimate. After the dissolution of the marriage the old chronic state of feud between the two kings returned, and was kept up, although with little actual warfare, until the death of Alphonso of Castile in 1214. In 1217, Fernando, the eldest son of Alphonso and Berengaria, became king of Castile. Alphonso, thinking that his own claims had been unjustly passed over, declared war upon his son; but finding that the people preferred Fernando, he relinquished his claims. The remainder of Alphonso's reign was chiefly spent in campaigns against the Moors. Along with his son, he captured Merida, Badajoz, and other cities; and in 1230 gained a brilliant victory over Mohammed Ibn Hud at Merida. He died in the same year, and was succeeded by his son Fernando, who thus finally united the kingdoms of Leon and Castile.

ALPHONSO X., surnamed *El Sabio*, or "The Wise," King of Leon and Castile, was born in 1221, and succeeded his father Fernando III. in 1252. He ascended the throne with the entire approbation of his subjects, and with every prospect of a happy reign; but, through the ill-directed aims of his ambition, few sovereigns have been more unfortunate. He first attempted to gain possession of Gascony, contending that he had a better right to that province than Henry III. of England. The arms of England, however, proved too formidable; and he agreed to renounce his claim on condition that Henry's son, afterwards Edward I., should marry his sister Eleonora. The marriage was solemnised with great pomp and magnificence towards the end of October 1254. Alphonso's next act was to lay claim to the duchy of Swabia, which he believed to be his in right of his mother Beatrix, daughter of the late duke. This claim was passed over, but when advancing it Alphonso formed a connection with the German princes, and in 1256 became a competitor, against Richard, Earl of Cornwall, for the imperial crown. He was again unsuccessful, the Earl of Cornwall being elected by a small majority. In 1271, on the death of Richard, he a second time attempted to make himself emperor of Germany, and even after Rodolph of Hapsburg had actually been elected, he undertook a fruitless journey to Beaucaire

in order to prevent the pope (Gregory X.) from confirming the election. These repeated attempts to increase his dignity weakened rather than strengthened the power of Alphonso, and forced him to impose heavy taxes upon his subjects, and even to debase the coinage, thus producing much discontent and disturbance, while the Moors were ever ready to take advantage of any misfortunes that might happen to him. From 1261 to 1266 he was engaged in a war with Mohammed of Granada, during which his army suffered several defeats. In 1270 an insurrection broke out, headed by Felipe, brother of the king, who was assisted by Mohammed of Granada; it was only quelled after nearly all their demands had been conceded to the rebels. In 1275, when Alphonso was absent on his fruitless journey to Beaucaire, his eldest son, Fernando de la Cerda, died, an event which, raising as it did the question of the succession to the crown, threatened anew to involve the kingdom in war. Sancho, Alphonso's second son, was, according to the law of the Visigoths, proclaimed heir by the Cortes at Segovia; but Philip of France, uncle of the two young sons of Fernando, declared war with Alphonso on their behalf; actual hostilities were, however, prevented by the intercession of Pope Nicolas III. In 1281, Sancho, irritated probably by some attempt that Alphonso had made to favour the sons of Fernando, raised the standard of revolt against his father. Sancho, who was a favourite with the people, having secured the assistance of Mohammed of Granada, reduced his father to such extremities that the latter solemnly cursed and disinherited his son, an act which he confirmed by his will in 1283, and at the same time solicited aid from the king of Marocco. At the commencement of the following year, however, Alphonso, on receiving intelligence from Salamanca that Sancho was dangerously ill, pardoned him. Alphonso died a few days afterwards, on 4th April 1284. He was a learned prince, and a great encourager of learning, brave and energetic, but at the same time restless and ambitious. He has been charged with impiety, chiefly on account of a well-known saying of his, that "had he been present at the creation, he could have given some useful hints for the better ordering of the universe." To him science is indebted for a set of astronomical observations known as the *Alphonsine Tables*, which were drawn up under his auspices by the best astronomers of the age; and in the palace of Segovia a room is still shown as the observatory of Alphonso. He was also distinguished as a poet and as a legislator. In the Escorial is preserved a curious manuscript containing some hymns of his composition; and he was the principal compiler of a code of laws which is still extant under the name of *Las Siete Partidas*.

ALPHONSO XI., "The Avenger," was an infant when he succeeded his father, Ferdinand IV., in 1312. During his long minority the kingdom was cruelly distracted by intestine warfare. Assuming the reins of government in 1324, he strove to repress the turbulent spirit of the nobility, and to put down that system of brigandage to which it had given rise, acquiring by his inflexible severity the title of "The Avenger." He lost Gibraltar in 1329, but as commander of the allied armies of Catholic Spain, on the 29th Oct. 1340 he gained a complete victory over the kings of Morocco and Granada at the Salado. The slaughter was immense, and the booty so rich that the value of gold is said to have fallen one-sixteenth. In 1342 Alphonso laid siege to Algeciras, where cannon were employed for the first time in Europe by the Moors in defence of their walls. This siege had lasted two years, when the Moors capitulated on condition of a truce between the two nations for ten years; but the king of Castile broke his word a few years after by besieging Gibraltar,

where he died of the plague on the 26th March 1350, aged 40. He was succeeded by his son, Pedro the Cruel. From this reign dates the institution of *regidores* or jurats, to whom was committed the administration of the communes; and these regidores became the exclusive electors of the Cortes, in which the people ceased to have a voice.

2d, *Castile*.—ALPHONSO III. (according to other enumerations, VIII. or IX.), surnamed "The Noble," is the only king of Castile of the name who was not also king of Leon. He was born in 1155, and succeeded his father, Sancho III., in 1158. His minority was disturbed by the contention of the two powerful houses of Lara and Castro for the regency; but after his marriage with Eleanor, daughter of Henry II. of England, he was proclaimed sole ruler. After compelling the kings of Aragon, Navarre, and Leon to surrender the territories they had taken possession of during his minority, he turned his arms against the Moors, and at Alarcos, in 1195, sustained one of the most terrible defeats recorded in the annals of Spain. This disaster encouraged the kings of Leon and Navarre to renew their hostilities, which were carried on for several years with varying success. In 1211 the Moors again threatened Castile; but in the following year, Alphonso, along with Pedro II. of Aragon and Sancho VII. of Navarre, gained a most complete and splendid victory over them at La Navas de Tolosa. Alphonso died at Garci Muños in 1214, and was succeeded by his son, Enrique I. Alphonso was a patron of literature, and in 1208 founded a university at Palencia, the first in Christian Spain. This university was afterwards transferred to Salamanca.

3d, *Aragon*.—ALPHONSO I., surnamed *El Batallador*, "The Fighter," King of Navarre and Aragon, was the second son of Don Sancho Ramirez, and succeeded his brother Pedro I. in 1104. By his marriage in 1109 with Urraca, daughter and heiress of Alphonso VI. of Leon and Castile, he became her associate in the government of these kingdoms, and in the same year assumed the title of "Emperor of all Spain." Misunderstandings soon arose between Alphonso and his wife, and he separated from her shortly after their marriage, an act which was confirmed by the council of Palencia in 1114. Alphonso, however, refused to give up his claims to the kingdoms of Leon and Castile, and maintained a constant struggle with Urraca till her death in 1126. Alphonso's chief victories were gained over the Moors. He laid siege to Saragossa for the first time in 1114, but the city was not captured until 1118, after several bloody battles had been fought in its neighbourhood. In 1120 his territories were menaced by a large force sent against him by Ali; but engaging the enemy near Daroca, he left 20,000 Almoravides dead on the field. Three years afterwards, while the king of Marocco was fully occupied at home by the rise of a dangerous sect of Almohades, Alphonso seized the opportunity to invade Valencia. In 1125 he undertook a new expedition against Granada in aid of the Mozarabes or Christian Moors. The Moors in their reprisals invaded Estremadura, and defeated the Castilians near Badajoz. The king of Aragon, so far from rendering his neighbour any assistance, determined to take advantage of the critical position of Alphonso Raymond, as well as of the troubles which the death of Urraca had occasioned in several parts of his dominions, but when on the point of battle the two kings came to an agreement. Alphonso next crossed the Pyrenees, and captured the cities of Bordeaux in 1130, and Bayonne in 1131. On his return to Spain he took Mequinenza from the Moors in 1133, and invested Fraga in 1134, where, during a sally from the town, he received a wound from which he died a few days after.

ALPHONSO II. was born in 1152, and in 1163 succeeded his father, Raymondo V., as count of Barcelona, his mother, Petronilla, daughter of Ramiro II., king of Aragon, at the same time resigning that kingdom to him. He was frequently at war with Raymondo of Toulouse, and also directed an expedition against the Almohades, from which the invasion of Aragon by Sancho of Navarre recalled him. He assisted Alphonso of Castile against Cuença, for which service he was relieved from doing homage to Castile. He died in 1196. He was a patron of the troubadours, and wrote some poems in the Provençal language.

ALPHONSO III., the son of Pedro III., was born in 1265, and in 1285, on the death of his father, being absent in Majorca on an expedition against his uncle Jayme, assumed the title of king without taking the oaths of adherence to the articles to which his predecessors had subscribed. When he returned in 1286, however, he was compelled to go through the usual coronation ceremony. In 1287 he signed the Privilege of Union, which permitted his subjects to have recourse to arms to defend their liberties, and invested the *justizero* with the power of citing the king himself to appear before the Cortes. Alphonso's chief wars were with Jayme of Majorca, Sancho of Castile, and the pope. He died in 1291.

ALPHONSO IV., son of Jayme II., was born in 1299, and ascended the throne in 1327. During almost the whole of his reign he was occupied in war with the Genoese about the possession of Corsica and Sardinia. He died in 1336.

ALPHONSO V. of Aragon, I. of Sicily and Sardinia, and latterly I. of Naples, was born in 1385, and succeeded his father, Fernando the Just, as king of Aragon and of Sicily and Sardinia, in 1416. In 1420 Joanna I. of Naples offered to make Alphonso her successor if he would assist her against Louis of Anjou. This he did; but, owing to misunderstandings, the queen revoked her adoption of Alphonso in 1423, making Louis of Anjou her heir. Recalled to Spain immediately after by an attack made by the Castilians upon his hereditary kingdom, he left his brother Pedro as his lieutenant at Naples, which he had taken by storm the year before. On his way to Spain he captured, but generously refrained from pillaging, Marseilles, a city belonging to his rival the duke of Anjou. After restoring peace at home, Alphonso again turned his attention to Naples, where his cause now appeared to be hopeless. Louis of Anjou died in 1434, and Queen Joanna the following year, leaving Naples to Louis's brother René, who had in his possession the whole kingdom except a few fortresses which still held out for Alphonso. In the same year (1435) Alphonso laid siege to Gaëta, but the siege was raised, and Alphonso himself taken prisoner by Philippo Maria Visconti, duke of Milan. Visconti, however, being greatly pleased with the high character and noble appearance of Alphonso, soon released him, and even made him his ally. Immediately on recovering his liberty, Alphonso made a third attempt upon the kingdom of Naples. The issue of the war at first was doubtful, but latterly the arms of Alphonso were nearly everywhere victorious. He laid siege to Naples, and after an obstinate resistance captured it in 1442. The States-General were then convoked, and solemnly proclaimed Alphonso king; his election being sanctioned by Pope Eugenius IV., who had previously promised that honour to René. Alphonso now fixed his residence at Naples, and devoted himself chiefly to the improvement of his kingdom; although he was also frequently involved in the wars and disputes of the Italian princes. He died at Naples on the 27th June 1458; and was succeeded in his kingdoms of Aragon and of Sicily and Sardinia by his brother John, and in that of Naples by his natural son Ferdinand. Alphonso was undoubtedly

one of the best monarchs of his name. His bravery and generalship fitted him for the warlike enterprises he had to undertake; and it is evident that, from his generous and humane disposition, as well as from his love of literature and encouragement of law and justice, his rule would have been equally successful had it been his lot to live in more peaceful times.

4th, Portugal.—ALPHONSO I., *Enriquez*, son of Henry of Burgundy, count of Portugal, and Teresa of Castile, was born at Guimaraens in 1094. He succeeded his father in 1112, and was placed under the tutelage of his mother. When he came of age he was obliged to wrest from her by force that power which her vices and incapacity had rendered disastrous to the state. Being proclaimed sole ruler of Portugal in 1128, he defeated his mother's troops near Guimaraens, making her at the same time his prisoner. He also vanquished Alphonso Raymond of Castile, his mother's ally, and thus freed Portugal from dependence on the crown of Leon. Next turning his arms against the Moors, he obtained, on the 26th July 1139, the famous victory of Ourique, and immediately after was proclaimed king by his soldiers. Not satisfied with this, however, he assembled the Cortes of the kingdom at Lamego, where he received the crown from the archbishop of Braganza; the assembly also declaring that Portugal was no longer a dependency of Leon. Alphonso continued to distinguish himself by his exploits against the Moors, from whom he wrested Santarem in 1146, and Lisbon in 1147. Some years later he became involved in a war that had broken out among the kings of Spain; and in 1167, being disabled during an engagement near Badajoz by a fall from his horse, he was made prisoner by the soldiers of the king of Leon, and was obliged to surrender as his ransom almost all the conquests he had made in Galicia. In 1184, in spite of his great age, he had still sufficient energy to relieve his son Sancho, who was besieged in Santarem by the Moors. He died shortly after, in 1185. Alphonso was a man of gigantic stature, being 7 feet high according to some authors. He has long been regarded as a saint by the Portuguese, who reverence him both on account of his personal character and as the founder of their kingdom.

ALPHONSO II., "The Fat," was born in 1185, and succeeded his father, Sancho I., in 1211. He was engaged in war with the Moors, and gained a victory over them at Alcazar do Sal in 1217. He also endeavoured to weaken the power of the clergy, and to apply a portion of their enormous revenues to purposes of national utility. Having been excommunicated for this by the pope (Honorius III.), he promised to make amends to the church; but he died in 1223 before doing anything to fulfil his engagement. Alphonso framed a code which introduced several beneficial changes into the laws of his kingdom.

ALPHONSO III., son of Alphonso II., was born in 1210, and succeeded his brother, Sancho II., in 1248. Besides making war upon the Moors, he was, like his father, frequently embroiled with the church. In his reign Algarve became part of Portugal. Alphonso died in 1279.

ALPHONSO IV. was born in 1290, and in 1325 succeeded his father, Dionis, whose death he had hastened by his intrigues and rebellions. Hostilities with the Castilians and with the Moors occupied many years of his reign, during which he gained some successes; but by consenting to the barbarous murder of Inez de Castro, who was secretly espoused to his son Pedro, he has fixed an indelible stain on his character. Enraged at this barbarous act, Pedro put himself at the head of an army, and devastated the whole of the country between the Douro and the Minho before he was reconciled to his father. Alphonso died almost immediately after, on the 12th May 1357.

ALPHONSO V., *Africano*, was born in 1432, and succeeded

his father Edward in 1433. During his minority he was placed under the regency, first of his mother, and latterly of his uncle, Don Pedro. In 1448 he assumed the reins of government, and at the same time married his cousin Isabella, daughter of Don Pedro. In the following year, being led by what he afterwards discovered to be false representations, he declared Don Pedro a rebel, and defeated his army in a battle at Alfarrobeira, in which his uncle was slain. In 1458, and with more numerous forces in 1471, he invaded the territories of the Moors in Africa, and by his successes there acquired his surname of "The African." On his return to Portugal in 1475 his ambition led him into Castile, where two princesses were disputing the succession to the throne. Having been affianced to the Princess Juana, Alphonso caused himself to be proclaimed king of Castile and Leon; but in the following year he was defeated at Toro by Ferdinand, the husband of Isabella of Castile. Alphonso went to France to obtain the assistance of Louis XI., but finding himself deceived by the French monarch, he abdicated in favour of his son Juan. When he returned to Portugal, however, he was compelled by his son to resume the sceptre, which he continued to wield for two years longer. After that he fell into a deep melancholy, and retired into a monastery at Cintra, where he died in 1481.

ALPHONSO VI., the second king of the house of Braganza, was born in 1643, and succeeded his father in 1656. In 1667 he was compelled by his wife and brother to abdicate the throne, and was banished to the island of Terceira. These acts, which the vicis of Alphonso had rendered necessary, were sanctioned by the Cortes in 1668. Alphonso died at Cintra in 1675.

ALPHONSUS A SANCTA MARIA, or ALPHONSO DE CARTAGENA, a celebrated Spanish historian, was born at Carthagena in 1396, and died on the 12th July 1456. He succeeded his father, Paulus, as bishop of Burgos. In 1431 he was deputed by Juan II. of Castile to attend the council of Basle, in which he made himself conspicuous by his learning. He was the author of several works, the principal of which is a History of Spain from the earliest times down to the year 1496, printed at Granada in 1545, fol.

ALPINI, PROSPERO (in Latin *Prosper Alpinus*), a celebrated physician and botanist, was born at Marostica, in the republic of Venice, on the 23d November 1553. In his youth he served for a time in the Milanese army, but in 1574 he quitted it, and went to Padua to study medicine. He was admitted to the degree of doctor of physic in 1578, soon after which he left the university, and settled as a physician in Campo San Pietro, a small town in the Paduan territory, at the invitation of its citizens. In the course of his studies he had paid particular attention to

botanical science; but the sphere of his present practice was too limited to afford him much opportunity of prosecuting his favourite study. He wished particularly to extend his knowledge of exotic plants, by observing their economy and habits in their native soil. To gratify this laudable curiosity an opportunity presented itself when George Emo or Hemi, the consul for the Venetian republic in Egypt, appointed Alpini his physician. They sailed from Venice in September 1580, and arrived at Grand Cairo in the following year. Alpini spent three years in Egypt, and by his industry and assiduity greatly improved his botanical knowledge, having travelled along the banks of the Nile, visited every place, and consulted every person from whom he expected any new information. From a practice in the management of date-trees which he observed in this country, Alpini seems to have deduced the doctrine of the sexual difference of plants, which was adopted as the foundation of the celebrated system of Linnæus. He says that "the female date-trees or palms do not bear fruit unless the branches of the male and female plants are mixed together; or, as is generally done, unless the dust found in the male sheath or male flowers is sprinkled over the female flowers." His treatise *De Medicina Egyptiorum* contains the first account of the coffee-plant that was published in Europe. When Alpini returned to Venice in 1586 he was appointed physician to Andre Doria, prince of Melfi; and during his residence at Genoa he was esteemed the first physician of his age. The Venetians were unwilling that the Genoese state should number among its citizens a person of such distinguished merit and reputation; and in the year 1593 he was recalled to fill the botanical chair in the university of Padua, with a salary of 200 florins, afterwards increased to 750. He discharged the duties of his professorship for many years with great reputation, till his declining health interrupted his labours. He died of slow fever on the 6th February 1617, in the sixty-fourth year of his age, and was succeeded as botanical professor by one of his sons. The genus *Alpinia*, belonging to the order Zingiberaceæ, is named after him. Alpini wrote the following works in Latin:—1. *De Medicina Egyptiorum Libri iv.*, Venice, 1591, 4to; 2. *De Plantis Egypti Liber*, Venice, 1592, 4to; 3. *De Balsamo Dialogus*, Venice, 1592, 4to; 4. *De Prasagienda Vita et Morte Ægrotantium Libri vii.*, Venice, 1601, 4to; 5. *De Medicina Methodica Libri xiii.*, Padua, 1611, folio; 6. *De Rhapsodico Disputatio*, Padua, 1612, 4to. Of all these works various editions have appeared; and besides these, two posthumous treatises were published by his son—1. *De Plantis Exoticis Libri ii.*, Venice, 1627, 4to; 2. *Historiæ Naturalis Egypti Libri iv.*, Lugd. Bat. 1635, 4to. Several other works of Alpini remain in manuscript.

## A L P S

**T**AKING a general view of the earth's surface, the continent of Europe appears to be no more than a great peninsula extending westward from the much vaster continent of Asia. Its shores are deeply indented by two inland seas connected by narrow straits with the Atlantic Ocean, and these in their turn are divided into gulfs that penetrate still more deeply into the land, and form a number of secondary peninsulas. The Mediterranean Sea, by its branches—the Gulf of Genoa, the Adriatic, and the Ægean Sea—forms the Iberian, the Italian, and the Greek peninsulas; and the Baltic Sea, extending northward into the Gulf of Bothnia, forms on one side the great Scandinavian peninsula, and on the other that of Denmark. Save the last, all these peninsulas of Europe are essentially mountain regions, traversed by lofty chains that occupy

a large portion of their surface. But in height and importance these are much surpassed by a great mountain zone stretching from the south-east of France to the frontiers of Hungary, and between Italy and the plains of southern Germany, which is collectively known as the Alps, and which must be considered as the most important feature in the physical geography of our continent. Of the influence of this mountain system on the climate of the surrounding regions, on the distribution of animal and vegetable life, and, indirectly, on the political condition of Europe, some brief notice will here be given; but it may be well to remark that owing to the peculiar disposition of the greater masses which form this system, the Alps do not present so continuous a barrier as might be expected from a comparison with other great mountain ranges.

Thus if we take the great masses of the Himalaya in Asia, the Andes in South America, or even such lesser ranges as the Pyrenees or the Great Atlas, we find that they interpose a far more absolute limit between the regions lying on their opposite flanks than occurs in respect to the Alps. These are formed of numerous ranges divided by comparatively deep valleys, which, with many local exceptions, tend towards parallelism with the general direction of the entire mass. This, between Dauphiné and the borders of Hungary, forms a broad band convex towards the north, and most of the main valleys lie between the directions west to east and south-west to north-east. But in many parts deep transverse valleys intersect the prevailing direction of the ridges, and facilitate the passage not only for purposes of human intercourse, but also for the migration of animals and plants, and for currents of air which mitigate the contrast that would otherwise be found between the climates of the opposite slopes.

The received opinion is, that the name Alps is derived from a Celtic root—*alp* or *alb*—signifying height. This has been connected by some writers with the Latin *alb*, *albus*, white, referring to the colour of the peaks. Strabo says that the name Ἄλπια was formerly Ἄλβια. *Alp* in south Germany—*alpa* in old High German—is exclusively applied to mountain pastures. For the present the derivation must remain somewhat uncertain.

To define the precise limits of the Alps, as will be seen fully in describing the several groups, is a somewhat arbitrary operation. To the W. they extend through a large portion of the French departments of Savoie, Haute-Savoie, Hautes Alpes, and Basses Alpes, being divided from the mountain district of the Cevennes by the broad and deep valley through which the Rhone flows from Lyons to the Mediterranean. The Jura range, usually regarded as distinct from the Alps, is nevertheless closely connected on one side with the outer ranges of the Alps of western Savoy, and on the other with those of northern Switzerland. On the N. side the Alps are definitely bounded by the lake of Constance, the plain of Bavaria, and the low country extending from Salzburg to the neighbourhood of Vienna. By these they are completely separated from the mountainous districts of central Germany, which extend through western Bohemia and Saxony in one direction to the Hartz mountains, and in the other to the Sudeten, or Riesengebirge, of Silesia. Hence it happens that the drainage of the northern slopes of the Alps flows either to the North Sea through the Rhine, or is diverted through the Danube to the Black Sea, and no portion of it reaches the Baltic. The eastern limit of the Alps is not easily defined with accuracy. The region of high hills, chiefly formed of tertiary strata, that extends from the left bank of the Mur into Hungary is continued by the north side of Lake Balaton to the Danube near Buda; and some geographers see in the hilly district that stretches thence to the northern Carpathians a connection between that range and the Alps. For practical purposes it seems that the line of depression, partly formed by the valley of the Mur, through which the railway is carried from Vienna to Laybach, may be considered as the eastern boundary of the Alpine chain. On the southern side the difficulty of fixing the precise limits of the Alpine chain is still more apparent. For a distance of some 350 miles, from the neighbourhood of Turin to that of Gorizia, the boundary is sufficiently obvious. The mountains subside into the continuous plain which includes the greater part of Piedmont, Lombardy, and Venetia; and their drainage is all borne eastward to the Adriatic. But on the west side of Piedmont the Alpine chain dividing Italy from France extends nearly due southward till it approaches to the Mediterranean in the neighbourhood of Nice. About 40 miles north of this city,

that which, from its superior height and its geological structure, we call the main chain, is bent round from west to east in a curve, slightly convex towards the south, till it becomes parallel to the Mediterranean shore, and is merged in the chain of the Apennines. For reasons hereafter mentioned it would appear that the limits of the Alps in this direction may best be fixed at the Col d'Altare, west of Savona, though the boundary commonly adopted is that of the Col di Tenda, lying considerably farther to the west. At the south-eastern extremity of the Alpine chain the difficulty of fixing its limits arises rather from the vague use of geographical terms by ancient and modern writers than from the physical structure of the region. Taking no account of the arbitrary proceedings of geographers who have included in the Alps the mountains dividing Bosnia from Croatia and Dalmatia, and regarding only the natural features of the country, it seems clear that the south-eastern extremity of the Alps must be looked for in the group of lofty peaks between the head waters of the Isonzo and those of the Save, whose highest summit is the Terglou; and if we are not to include all the mountain ranges of European Turkey and Greece within the same designation, the plateau of the Karst must be held to form the boundary between these and the Alps. Within these limits the Alps extend from about the 44th to the 48th parallel of N. lat., and from about 5° 10' to 18° 10' E. long.

In every mountain system geographers are disposed to regard the watershed, or boundary dividing the waters flowing towards opposite sides of the range, as marking the main chain; and this usage is often justified by the fact that the highest peaks lie on, or very near, the boundary so defined. In applying this term in the case of the Alps, there are, however, difficulties arising from their great extent and the number of their branches and ramifications. Many of the loftiest groups lie altogether on one side of that which we call the main chain, and at the eastern extremity, where all the drainage is ultimately borne to the Black Sea, we must be partly guided by geological considerations in deciding which of several ranges deserves to be considered pre-eminent.

Starting from the pass of Altare or Cadibona, west of Savona, the main chain extends first south-west, then nearly due west, to the Col di Tenda, but nowhere rising beyond the zone of coniferous trees. Beyond that limit the range is more lofty, and includes four peaks exceeding 10,000 feet in height, till the line dividing the waters flowing to the Adriatic, through the Po, from the short streams that flow into the Gulf of Genoa, reaches the Mont Enchastraye. Beyond that point, although the line of watershed is very sinuous, its general direction for a distance of about 75 miles is nearly due north. On the east side the waters run to the Po; on the west they flow through the Durance to join the Rhone near Avignon. The most considerable peaks in the range immediately north of the Mont Enchastraye are the Grand Rioburent and the Aiguille de Chambeyron; but these are much surpassed by the Monte Viso, which is the highest peak in the range dividing Piedmont from Dauphiné. On the north side of Monte Viso the main chain diminishes much in average height, and presents no prominent peaks until we reach the Mont Tabor. That summit forms the apex of a salient angle which the main chain here presents on the side of France. For a distance of about 28 miles this extends eastward to the prominent peak of the Roche Melon, which may be considered as a re-entering angle in the great rampart by which Italy is guarded from her northern neighbours. Here the main chain resumes its northerly direction, and attains a greater average height than it had previously exhibited. Several of the prominent peaks in the range connecting the Roche Melon with Mont

Blanc exceed 11,000 English feet in height, though they are much surpassed by the highest group of the Graian Alps, lying on the side of Piedmont, and that of the Tarentaise Alps in Savoy; while there is in this part of the main range but one considerable depression, which is that crossed by the road of the Little St Bernard. In the range crowned by the summit of Mont Blanc the Alpine chain attains its highest elevation. From thence to the Pass of St Gotthard its general direction varies between east and north-east. To the east of Mont Blanc a comparatively low tract allows of several comparatively easy passes between Switzerland and Piedmont, one of which has long been famous as the Pass of the Great St Bernard; but from that to the Simplon Pass, a distance of about 52 miles in a straight line, or about 75 miles if measured along the watershed, the main chain preserves a greater average height than in any other part. Several peaks lying in the dividing ridge, such as the Grand Combin, Matterhorn, Lyskamm, and Monte Rosa, exceed 14,000 feet in height; and these are rivalled by at least six summits on the north side of the same ridge, which at two points only sinks below the level of 10,000 feet. The Simplon Pass corresponds to what may be called a dislocation of the main chain. From thence to the St Gotthard the dividing ridge runs nearly due north-east, and does not present any dominant summit excepting the Monte Leone. On the east and south-east side of the St Gotthard Pass, as far as that of the Maloya, the line of watershed between the affluents of the Rhine and that of the Po is determined by what may be called accidental conditions. The chief mountain ridges, which culminate in the Cima Camadra, Piz Valrhein, and Tambohorn, instead of being arranged along the parting of the waters, lie in a transverse direction, and hence the natural frontier of Italy is here more broken and irregular than elsewhere; and it is only on the south side of the Maloya Pass that the main chain assumes a tolerably continuous direction from west-south-west to east-north-east, as between Piz Güz and the Bernina Pass it rises into the lofty group whose dominant peaks are Piz Tremoggia, Piz Bernina, and Piz Cambrena. Eastward of the Bernina Pass the same direction is preserved, and in the range including the Corno di Campo, Monte Zembrasca, and Monte Foscagno the level scarcely sinks below 9000 feet; but beyond the last-named summit, in the space lying between the Lower Engadine, the head waters of the Adige, and those of the Adda, the semblance of a continuous ridge forming the watershed between the Inn and the Adriatic altogether disappears. If we adhere to the usage of designating as the main chain the ridges which part the waters flowing in different directions, it must be owned that the disposition of the chief mountain masses has no connection with the direction of that chain. Lying between the great mass of the Ortoles Alps to the south and the considerable group of the Silvretta Alps on the north side of the Inn, the greater part of the mass in question is drained by streams that flow into the latter river; but the arrangement of the valleys seems to be largely due to erosive action. Few summits in this part of the main chain exceed 10,000 feet, the highest being Piz Scesvenna, on the east side of Val Scarla.

The break in the continuity of the Alpine chain marked by the deep valley through which the main branch of the Adige descends, first southward and then eastward from its source to Meran and Botzen, is one of the most remarkable features in the orography of the Alps. The little lake which is regarded as the chief source of the river lies within less than five miles of the Inn, where that river enters the Tyrol, and no apparent barrier divides the lake from the Inn valley. Eastward of this limit the Alpine chain exhibits a degree of order in its general arrange-

ment which it is impossible to trace in its western and central portions. For a distance of some 250 miles a broad zone of crystalline rocks extends from west to east, flanked on the north and south sides by parallel zones of sedimentary rocks, chiefly belonging to the older secondary formations. Two great valley systems on the opposite sides of the central zone closely coincide with those geological boundaries, and mark out in the physical aspect of this region the limits between the central and the secondary zones. In the former are situated all the highest peaks of the eastern Alps. For a distance of about 140 miles, from the Schafkogel, south-east of Nauders, to the Markkahrspitz, the average level of the main chain is nearly as high as in any equally long section of the central or western Alps. There is one very considerable depression which is marked by the Brenner Pass, but elsewhere in that long barrier there are but three points where the range is passable by beasts of burden. Between the two main sources of the Adige, at the Reschen Scheideck and the Brenner Pass, the considerable groups of the Oetzthal and Stubay Alps attain a great average elevation, though two points only—the Wildspitz and the Weisskugel—surpass the level of 12,000 feet. The drainage of these groups is mostly carried to the Inn, and the line of watershed, about 53 miles in length, is much less direct than in the more easterly portion of the chain. This extends nearly due east for about 90 miles from the Brenner Pass, nowhere falling below the level of 8000 feet, and in two prominent peaks—the Gross Venediger and the Gross Glockner—rising considerably above the limit of 12,000 feet. At a point somewhat north of the Markkahrspitz the central chain divides into two parallel ranges, between which lies the upper valley of the Mur. This river flows for a distance of fully 80 miles nearly due east, till at Bruck-an-der-Mur it turns southward to approach the Drave, and ultimately joins that stream. Various reasons combine to induce geographers to regard the more northern of the two ranges above mentioned, which divides the Enns and other minor tributaries of the Danube from those of the Drave, as constituting the eastern extremity of the main chain of the Alps. This extends a little north of due east for more than 110 miles, with a comparatively low mean elevation, from the Arlscharte to the Semmering Pass, which we regard as the eastern limit of the main chain of the Alps.

Measured along the watershed, as above defined, but without taking into account the minor sinuosities, which would considerably increase the total, the length of the main chain is about 790 English miles.

For ages before there existed any correct knowledge of the configuration of the Alpine chain, the needs of war and commerce had urged the people dwelling on the opposite sides of the great barrier to seek out the easiest and most direct routes for traversing it. Hence the chief passes of the Alps have been known and frequented from a period antecedent to authentic history, while until a quite modern period little attention was given to the parts of the chain which did not lie in or near the lines of traffic. It is highly probable that many other passes, affording the easiest means of communication between adjacent valleys, have been known and used by the native population from a very remote period, but only those which served for international purposes of war or peace became known at a distance, and are alluded to by ancient writers. A pass is a depression between two adjacent mountains, and the track is usually carried over the lowest part of that depression; but nevertheless nearly all the passes of the Alps involve a long ascent to reach the summit, and a long descent upon the opposite slopes. Hence the Romans, who were the first semi-civilised people to make extensive

use of the Alpine passes, applied to each of them the term *Mons*. The same names, more or less modified in the middle ages, have been preserved in the dialects of Latin origin that prevail throughout the western half of the Alpine chain, and the modern name for the chief passes are still Mont Genève, Mont Cenis, Mont Iséran, Petit Mont St Bernard, Grand Mont St Bernard, Monte Moro, and Monte San Gottardo. In more recent times, since geographers have attempted to fix the names and positions of the chief summits of the Alps, they have been continually misled by the supposition that a name of high antiquity designating a mountain must belong to some prominent peak. The errors arising from that source have not yet disappeared from geographical works of high repute, but in point of fact each of the names above enumerated belongs solely to the pass, and there is no neighbouring peak entitled to the same designation. The more important passes of the Alps are enumerated in the following description of the chief groups of the Alps; but it may be here remarked that the direction of the main routes for traffic is not exclusively determined by the position of the lowest and easiest passes over the main chain. The configuration of the mountains is such that a traveller proceeding from Italy to France, Switzerland, or Germany, after crossing a comparatively easy pass over the main chain, may find it necessary to traverse a second and loftier pass over a lateral chain, or else follow a circuitous route that may double the length of his journey. Thus a traveller going from Turin to Lyons, who should take what appears to be the direct course over the pass of Mont Genève, the easiest in the whole range of the western Alps, will find on descending to Briançon that he must cross the much higher and more difficult pass of the Col de Lantaret, or else descend along the Durance till it emerges into the lower country near Gap, and thus more than double the length of his journey. Including the Semmering Pass, there are now not less than 60 Alpine passes that are traversed by carriage roads; and besides three lines of railway now open for traffic, several others are in course of construction.

cent  
visions of  
e Alps.

From the time of Julius Cæsar downwards, the Romans, in the prosecution of their policy of universal dominion, or for the purpose of maintaining communication with their military colonies, had become acquainted with all the easiest and most serviceable passes of the Alps, and were thus naturally led to attach names to the chief groups. As their acquaintance with the entire region was very incomplete, the exact boundaries of these groups were imperfectly understood, and the denominations adopted by them were never accurately defined. As might have been expected, the divisions thus roughly established had reference rather to the aspect of the mountains as presented to one travelling from Italy towards the north or west, than to a general view of the physical conformation of the entire region. Hence the ancient divisions are essentially defective, as taking no note of some important groups, or including under a single designation groups entirely distinct. Notwithstanding these defects, the ancient divisions have been adhered to by all but a few modern geographers, and it is therefore desirable to record them separately.

1. *Maritime Alps* (Alpes Maritimæ).—These included the portion of the main chain dividing south-western Piedmont from the coast of the Mediterranean, and extending northward to the neighbourhood of the conspicuous peak of Monte Viso.

2. *Cottian Alps* (Alpes Cottie or Cottiane) included the portion of the main chain dividing Piedmont from Dauphiné and Savoy, and extending from Monte Viso to the neighbourhood of the Mont Cenis. The name appears to be derived from Cottius, the king or chief of a powerful tribe who ruled the greater part of this region when the paramount authority of Augustus was established in Cisalpine Gaul.

3. *Graian Alps* (Alpes Graiæ).—Under this designation was known the great group of mountains between Turin and the upper Val d'Aosta, and the portion of the main chain lying between the Mont Cenis and the Little St Bernard. Pliny and other Latin writers derive the name from the legendary passage of a body of Greeks led by Hercules through this region; but the true derivation is probably from some lost Celtic appellation.

4. *Pennine Alps* (Alpes Penninæ) was the name applied to the

great range including Mont Blanc and Monte Rosa, which, from the time of Julius Cæsar, if not earlier, was recognised as the highest portion of the entire chain. The word Pen or Ben is still in use in the living dialects of the Celtic stock as a common designation for a conspicuous mountain, and was certainly in use in the speech of this part of Cisalpine Gaul, where many other Celtic terms are preserved in the local names. The Roman designation *Jupiter Penninus* was undoubtedly taken from the Celtic root, but the asserted use of the name Pen for a divinity by the native tribes is not established by valid evidence.

5. *Lepontine Alps* (Alpes Lepontinæ).—It would appear that this denomination was originally restricted to the parts of the main chain lying on either side of the pass of St Gotthard, including the sources of the river Ticino, with those of its tributaries, of which the most important is the Tosa or Toccia, draining the range between the neighbourhood of the Simplon Pass and that of the Gries. The name is derived from the Lepontii, a tribe of doubtful extraction (Rhaetian, according to Strabo) who inhabited the main valley of the Tessin or Ticino, the upper part of which is still called Val Leventina. The eastern limit of this group was usually fixed at the pass of San Bernardino.

6. *Rhaetian Alps* (Alpes Rhaeticæ) derived their name from the Rhaeti, a powerful tribe or nation holding a large tract of territory which appears to have extended from the sources of the Rhine and the Ticino on the west, to those of the Adige and the Salza on the east. The area included under this vague heading is at least equal in area to that of the five divisions hitherto enumerated.

7. *Noric Alps* (Alpes Noricæ).—Under this name the entire region lying north of the Drave, and extending thence to the valley of the Danube on the north and the plains of Hungary on the east, was included.

8. *Carnic Alps* (Alpes Carnicæ).—This name was given to the mountain tract lying between the upper Drave and the low country of Friuli. By some writers it has been limited to the ranges that feed the Tagliamento (*Tilaventus*) and its tributaries; by others the range seems to have been held to extend from the sources of the Piave to those of the Save. The name Carnia is still in use in Friuli, but is strictly limited to the basin of the Tagliamento.

7. *Julian Alps* (Alpes Julie).—This designation has been still more vaguely used by ancient and modern geographers than any of the preceding. The lofty group of peaks crowned by the Terglou, and lying between the head waters of the Isonzo and those of the Save, undoubtedly forms the chief nucleus of the group distinguished by this name; but it also appears to have included the ranges of eastern Friuli, which province, as well as the Alps in question, took its name from the Roman Forum Julii, now known as Cividale. By others, and even by contemporary Italian writers, the term Julian Alps is made to extend southward through the district of Karst between Carniola and the shores of the Adriatic, and thence through Croatia to the frontiers of Bosnia. A great part of this district is an undulating plateau, in part not attaining to 2000 feet above the sea-level, to which by no stretch of language can the term Alps be properly applied.

In addition to the groups above mentioned some writers have enumerated the *Dinaric Alps* (Alpes Dinaricæ), and include under that term the mountain range extending along the western frontier of Bosnia. This is a portion of the extensive mountain system of European Turkey, which in one direction includes the Balkan, and in another is continued through Albania into Greece. The Romans probably applied to these the designation Alps as some of their later writers did to the Pyrenees and the mountains of southern Spain; but it can merely cause confusion to speak of them as a portion of the great system to which the name Alps specially applies. For the reasons already mentioned it is impossible to regard the ancient groups above enumerated as affording a satisfactory division of the region under consideration; but so far as they can be made to correspond with the divisions suggested by a more exact knowledge of its physical configuration, it seems desirable to retain the established nomenclature.

Actual observation of the Alpine region through the greater part of its extent, or even the careful study of accurate models, must convince any one who seeks to divide it into groups that it is not possible to do this by adhering rigidly to any single test or rule. In a general way, it is natural and desirable to include under the same name mountain masses that are not divided by a broad and deep opening; but it is sometimes more convenient to include in one group disjoined masses that have some natural connexion with each other, rather than multiply groups to an inconvenient extent. In some cases the geological structure may supply a rational ground for preferring one arrangement to another, when the choice would otherwise be arbitrary; and in a few cases it may be well to yield something to ancient usage, based upon political

Modern  
division  
the Alps  
into  
groups.

or ethnological grounds. Accurate knowledge of the Alps is so recent that few attempts have been made to establish a general division of the entire region, and it cannot be said that any one arrangement has obtained such general recognition as not to be open to future modification; but there is a pretty general agreement as to the main features of that here proposed, to which a few general remarks must be premised.

Whatever may have been the original cause of those disturbances of the earth's crust to which great mountain chains owe their existence, it is generally, though not universally, true that the higher masses (formed of rocks geologically more ancient) are found towards the central part, and that these are flanked by lower ranges, composed of more recent rocks, which surround the central groups very much as an outer line of entrenchment may be seen to surround a fort. In most cases it is not possible to descend continuously in a nearly direct line from the crest of a great mountain chain to the plains on either side, for there are usually intermediate valleys, running more or less parallel to the central range, which separate this from outer secondary ranges. These, in their turn, are often accompanied by external ranges, intermediate between them and the plains, and related to them as they are to the central ranges. The type of arrangement here described is more or less traceable throughout the greater part of the Alps, but is most distinctly exhibited in the eastern portion lying between the Adige and the frontier of Hungary. We have a central range, composed mainly of crystalline rock; a northern range, formed of secondary rocks, separated from the first by the great valleys of the Inn, the Salza, and the Enns; a southern range, somewhat similar to the last in geological structure, divided from the central one by the Rienz, or east branch of the Adige, and the Drave. Flanking the whole, as an external entrenchment on the north side, are the outer ranges of the Bavarian Alps, of the Salzkammergut, and of Upper Austria, to which correspond on the south side the Monti Lessini, near Verona, the mountains of Recoaro, those of the Sette Comuni, and the considerable masses crowned by the summits of the Grappa, the Col Vicentino, the Monte Cavallo, the Monte Matajur, and Monte Nanos. Where, as in the cases above mentioned, the secondary ranges of the Alps rise to a greater altitude, and are completely separated from the neighbouring portions of the central chain, it is impossible not to distinguish them as distinct groups; but the outermost ranges, which rarely rise above the forest zone, are in all cases regarded as appendages of the adjoining groups. These outer ranges are called in German *Voralpen*, and in Italian *Prealpi*, and it is to be desired that equivalents should be introduced in other European languages. A complete catalogue of the peaks and passes of the Alps would exceed the limits of this article, but it seems desirable to append to each of the main groups in the following arrangement the names of the more conspicuous summits, with the height of each above the sea-level in English feet. No limit of absolute height has been fixed in selecting the peaks here enumerated, as the highest summits of the less lofty groups would appear insignificant in those whose average elevation is much greater. The more important passes are also enumerated, distinguishing those traversed — (1) by carriage road, (2) by bridle-path, practicable for beasts of burden, and (3) by footpath; and (4) snow passes, involving the necessity of crossing snow-fields or glacier

MAIN DIVISIONS OF THE ALPS.

1. *Maritime Alps*.—On examining a map of the region where the chain of the Alps approaches the shores of the Mediterranean, it will be seen that, about 50 miles

N.N.W. of Nice, and about 20 S.S.W. of the Monte Viso, several valleys diverge in various directions, disposed, roughly speaking, like the rays of a fan. These are formed by a number of ridges which converge towards, although they do not actually meet at, the *Mont Enchastraye* or *Cima dei Quattro Vescovadi*. On the west side one of these ridges divides the upper valley of the Ubaye from that of the Verdon, and sends out a branch which separates the latter from the Bléone. A third ridge divides the Verdon from the Var, and a fourth separates this from its main affluent, the Tinéa. As already mentioned, the range extending S.E. from Mont Enchastraye is regarded as the main chain of the Maritime Alps, and extends, with numerous diverging secondary ridges, in a curved line, gradually approaching nearer to the coast till it is merged in the chain of the Apennines. To fix the limit between the Alps and the Apennines in this direction is necessarily a somewhat arbitrary process, and different criteria may be applied with different results; but it seems most natural to fix on the depression west of Savona known as the Col d'Altare or Col di Cadibona, over which the road is carried which leads in one direction to Alessandria, and in the other to Mondovi. This is by far the lowest depression in the barrier dividing the Adriatic from the Mediterranean, the summit being only 1608 feet above the sea-level; and during the Miocene epoch it formed a strait connecting those seas. In modern times the project of utilising the same pass for the construction of a canal to connect the Po with the Gulf of Genoa is an illustration of its geographical significance. On the north side of the Mont Enchastraye, a comparatively low pass, *Col de l'Argentière*, divides that mountain from the adjoining portion of the main chain. This might properly be regarded as the northern limit of the Maritime Alps, but ancient usage has included in that group the ranges that enclose the Val Maira, and separate it on one side from the Stura di Demonte, and on the other from the Vraita. Conforming to that practice, we fix the northern limit of the Maritime Alps at the Col de Longet, S.E. of the peak of Monte Viso, connecting the head of Val Vraita in Piedmont with the sources of the Ubaye in France.

2. *Cottian Alps*.—In the well-known panorama presented to an observer who takes his stand on the Superga, or some other eminence near Turin, the most distinct objects are the peaks of the Maritime Alps south of Cuneo and, exactly in the opposite direction, the great mass of Monte Rosa. In the western horizon, subtended by this chord, about 120 miles in length, the eye follows the irregular curve traced out by the main peaks of the western Alps, that separate upper Italy from France. More than any other part of the Alpine chain, this is characterised by extreme irregularity in the disposition of the mountain masses and the chief valleys. On the west side the pre-

vailing direction seems to be from south-west to north-east, while on the east side it is more nearly from west to east; but the valleys and the ridges that enclose them are often curved or irregularly sinuous. Convenience seems to confirm immemorial usage in subdividing this region into two or more groups; but it is not easy to decide how this is to be effected. The great valley of the Dora Riparia, and the low passes connecting it with the valley of the Durance, seem to afford the most natural division. Ancient and modern usage being alike opposed to this, it appears that the valley of the Oreo in Piedmont and that of the Arc in Savoy, with the connecting pass of the Col del Carro, may best be taken as the boundary between the northern and southern portions. The latter is distinguished as the group of the Cottian Alps. This includes a number of secondary ridges that extend from the main chain on the side of Piedmont, with a general direction from west to east; and on the French side one considerable range, stretching south-west from the neighbourhood of Monte Viso, that divides the Ubaye from the Guil, besides a lesser parallel ridge lying between the Guil and the head waters of the Durance.

3. *Dauphiné Alps.*—On the west side of the Cottian Alps, and separated from these by the broad valley of the Durance, rises a group of lofty peaks, surpassing them considerably in height, and almost completely isolated from their neighbours. This group has not usually been included amongst the Cottian Alps by geographers, and it is more natural to regard it as the nucleus of a distinct division constituting the Dauphiné Alps. On the north side of this central mass, and separated by the valley of the Romanche and the Col de Lautaret, is a considerable group, including three principal ridges, whose direction is nearly due north and south, separated from the neighbouring mountains of Savoy by the deep valleys of the Arc and the Isère, which may best be regarded as an outlying portion of this division. On the south side of the main group another outlying mass, which on one side feeds the chief sources of the Drac, and on the other several short tributaries to the Durance, must also be included in this division. The ranges of secondary rocks lying west of the broad valley between Grenoble and Chambéry, which are geologically and orographically a southern extension of the chain of the Jura, are at the same time exactly parallel to the northern ranges of the Dauphiné Alps, and must be regarded as the outer range or "Border Alps" (*Voralpen*) of the group. The only doubt in fixing the limits of the Dauphiné Alps is as to the boundary between their northern group and the adjoining mass of the Cottian Alps. It seems that this may best be fixed at the *Col de Galibier*,

connecting the chief source of the Durance with the valley of Valloires in Savoy.

4. *Graian Alps.*—The lofty group of snowy mountains lying between the plain of Piedmont and Mont Blanc has from a remote period borne the designation Graian Alps. To the north they are bounded by the Val d'Aosta, and to the south by the valley of the Oreo; but on the west side the boundary is not so easily determined. The portion of the main chain dividing Savoy from Piedmont, between the Levana and Mont Blanc, must undoubtedly be included in this division; but it is not so easy to determine the relations of a group of lofty summits that are divided from the rest of the Graian Alps by the upper valley of the Isère, filling the space between the upper course of that river and that of the Arc. This is further geologically distinguished by the fact that the higher summits are chiefly composed of nearly unaltered sedimentary rocks. This group has by some writers been associated with the mountains of Beaufort, lying between the Isère and the Arly, to form, with some subordinate branches, a group of south Savoy Alps; but we prefer to adhere to the older usage of those who have united them with the Graian Alps. The exact boundary between these and the Mont Blanc group may best be fixed at the pass of the Little St Bernard, the lowest in the main chain between the Mont Cenis and the Simplon.

5. *Pennine Alps*.—The portion of the great chain that includes the peaks of Mont Blanc and Monte Rosa has always been recognised as the most important among the divisions of the Alps. This pre-eminence is due not only to its surpassing height, but to the fact that its peaks are so conspicuous. Throughout the plain of Upper Italy, from Turin to Milan, and even as far as the slopes of the Apennines, Monte Rosa, with its attendant peaks, is commonly the most remarkable object in the northern horizon; while in western Switzerland, and as far westward as the heights above Lyons, the dome of Mont Blanc, rising in the distant eastern horizon, attracts the frequent attention alike of natives and strangers. Some doubts may arise as to the precise limits that should be assigned to this group. Towards the north-east it is generally agreed that the Simplon Pass is the most natural limit. In the opposite direction most writers have fixed on the Col de Bonhomme, south-west of Mont Blanc, as the proper boundary; but it seems reasonable in a general arrangement to regard the range extending from the last-named pass to Grand Cœur, in the valley of the Isère, as a south-western prolongation of the range of Mont Blanc. From the portion of the main chain connecting the Mont Combin with Monte Rosa, numerous branches, with peaks that rival these in height, diverge northward. The secondary ranges that extend on the side of Italy, southward and eastward from Monte Rosa, are much inferior in altitude. On the north and west sides of Mont Blanc an extensive mountain district, including the French department of Haute Savoie, must be considered as an appendage to the group of the Pennine Alps. On the south side, the short range extending parallel to that of Mont Blanc, from Courmayeur to the Val de Bellaval, corresponding to the range of the Aiguilles Rouges and the Brévent, on the opposite side, may best be included within the group of the Pennine Alps.

6. *Bernese Alps*.—There is no considerable mass of Alpine summits whose boundaries are better defined than that which is generally known as the group of the Bernese Alps. By the number and height of the peaks, that rise far above the limits of perpetual snow, it ranks next in importance to the Pennine group; and its position with reference to that group has largely contributed to the fame of the region which they occupy for a marvellous and almost unique combination of grandeur and variety. The most characteristic feature in the orography of Switzerland is the great valley system that extends in a nearly direct line from Martigny to Coire—interrupted, it is true, by two passes (the Furka and Oberalp) of small elevation compared to the surrounding heights. On the opposite sides of this great trench the chief groups of the central Alps are arranged in masses that, amid much apparent irregularity, approach to parallelism with the direction of the central valley. Hence the traveller who attains any considerable height on either side sees over against him the dominant summits of the opposite group in constantly varying combination. The highest groups (the Pennine and Bernese) are so placed that the chief peaks on the one side are rarely more than 20 miles apart from their rivals in the opposite chain, and the projecting summits of the secondary ridges between them afford panoramic views of wonderful beauty and grandeur. What may be called the main chain of the Bernese Alps, forming the boundary between the Swiss cantons of Bern and Valais, extends parallel to the course of the Rhone, from the glacier which is the main source of that river, to Martigny, a distance of about 70 miles; and we must regard as a dependency of that chain the mountain district that lies on its northern side, between the upper course of the Aar and the head of the Lake of Geneva. Desiring to adhere to the divisions of the Alps admitted by ancient geographers, many modern writers have included the Bernese group among the Lepontine Alps; but this arrangement is not consistent with any rational criterion that can be applied. The only question admitting of doubt is as to the eastern limit of this group. The Aar issues from its parent glacier at a point very near to the chief source of the Rhone, and separated only by a comparatively deep and broad depression, the Grimsel Pass; and it might appear that the Bernese Alps should be defined as the group enclosed between those rivers. But some ten miles east of the Grimsel Pass the range lying north of the great valley of Switzerland is completely cut through by the valley of the Reuss, where that stream descends towards the Lake of Lucerne through the famous defile of the Devil's Bridge; and as it would be inconvenient to reckon the comparatively small group that lies between the head waters of the Reuss and those of the Aar as a separate division, we prefer to include this as a portion of the Bernese Alps.

7. *North Swiss Alps.*—Attention has already been called to the great line of valley that traverses Switzerland from Martigny to Coire. The range of high peaks lying on the north side of this valley is interrupted at one point only, where the Reuss flows through the deep defile of the Devil's Bridge from Andermatt to Altdorf, and this breach in the continuity of the range has been here regarded as the eastern limit of the Bernese Alps. The range extending eastward from that boundary to the neighbourhood of Coire might perhaps be considered as a prolongation of the range of the Bernese Alps; but independently of the inconvenience of assigning such wide boundaries to a single group, there are geologic as well as orographic grounds for preferring to class this along with the dependent ranges lying further north as a separate division of the Alps. With regard to the latter ranges, those lying between the valley of the Reuss and the Lake of Lucerne, on one side, and the ancient valley of the Rhine, which included the lakes of Wallenstadt and Zurich, on the other, manifestly correspond to the outer ranges of central Switzerland, which we regard as appendages of the Bernese Alps. The case is somewhat different as regards the small detached group culminating in the Hoh Sentis, and lying in the angle between the ancient course of the Rhine and the modern Rhine valley from Sargans to the Lake of Constance. This is so far separated orographically and by geological structure that it might properly rank as a separate division, but it is on the whole more convenient to reckon it as an outlying portion of this group. The Oberalp Pass, a few miles east of Andermatt, forms the watershed between the Reuss and the main branch of the Rhine, and the waters meet again at the confluence with the latter of the united streams of the Aar and the Reuss at Waldshut, so that the entire territory comprehending this division of the Alps is enclosed between the two first-named rivers.

8. *Lepontine Alps.*—The portion of the Alpine chain lying between the Simplon and Splügen passes, and forming the boundary between the tributaries of the Po and those of the Rhine, presents some peculiar orographic characteristics. The line of watershed is pretty nearly parallel to that great line of depression traced across Switzerland by the valley of the Rhone, the Urserenthal, and the valley of the Vorderrhein; and a tendency to parallelism with the same system may be traced in many parts of this group. But the dominant direction of the secondary valleys and ridges is that of the meridian; and on the south side we find a series of long valleys running from north to south, with occasional slight distortions. The most considerable of these are partly occupied by the two famous Lombard lakes—Maggiore and Como—which have from an early period attracted the admiration of strangers to this region. Ancient geographers limited the term Lepontine Alps to the portion of this group that sends its drainage on the south side to the river Ticino; but the ranges between the Splügen and Bernardino passes, and between the lakes Maggiore and Como, evidently belong to the same system, and must be united in any natural arrangement of the Alps. On considering a tolerably correct model, it is impossible not to be struck by the fact that all the valleys that contain the most considerable streams of the central Alps appear to radiate from the neighbourhood of the St Gotthard Pass. If we measure from the summit of that pass to the head valleys of the Rhone, the Aar, the Reuss, the Vorderrhein, the Ticino, and the Toccia, we find that the most distant lies within 9 English miles from that point. This fact has doubtless a significance which we are not yet able fully to appreciate, but scarcely suffices to justify the view of those who regard the St Gotthard Pass as in some special sense the central point of the whole system of the Alps. It is worth remarking that, so far from being distinguished by superior height, the neighbouring peaks are surpassed by all the surrounding groups, and that the valleys are much deeper than in many other districts, and especially than those of eastern Switzerland.

9. *The Rætian Alps.*—The older geographers included under the term Rætian Alps a vast mountain region extending over 6° of long., from the east side of the Lago Maggiore to the left bank of the Salza, and through 2½° of lat., from the neighbourhood of Brescia to the plain of Bavaria. There is no assignable reason for uniting in a single division mountain groups so distinct as many of those included within this wide space—scarcely less than that occupied by all the divisions hitherto enumerated—save the fact that at an early period they received a common designation from writers who had a most imperfect acquaintance with their topography. It might be expedient to discard a term to which it is difficult to assign a limited meaning without incurring the risk of confusion; but general usage has so constantly applied the term Rætia to the mountain region of Switzerland lying east of the Rhine, with the adjoining portion of Tyrol, that it seems best to preserve the ancient name while endeavouring to restrict it within juster limits. With that object it is necessary to take account of one of the most remarkable features in the orography of the Alps—the great breach in the continuity of the main chain shown in the upper valley of the Adige. On a general view of western Tyrol it is apparent that the lakes which feed the head of that stream lie on the northern side of the axis of elevation of the main chain, and in fact several streams draining the northern slopes of the central mass are borne southward to the Adriatic through that opening. This is not the place to take into consideration the important influence that this breach in the line of defence between Italy and the north, and the equally deep opening of the Brenner Pass at the head of the other main branch of the Adige, has had on the history of Europe, nor to discuss the geological significance of the same depression throughout an incalculably longer period; but it is sufficiently clear that this should be taken as the eastern limit of the group to which the term Rætian Alps most properly applies. On the west limit, as we have already seen, is marked by the valley of the Rhine, and the line of depression over which the Splügen road is carried to the head of the lake of Como. In the space between these boundaries the chief mountains of the Rætian Alps appear as islands of crystalline rock, divided by intervening masses of palæozoic and older secondary strata; but on the south side lies a district which differs considerably in geological structure, and is cut off by a distinct orographic boundary. A straight line drawn from the head of the lake of Como to Cles in Tyrol, will throughout lie close to a trench formed by the valley of the Adda, the low pass of Aprica, the head of Val Camonica, the Tonale Pass, and the Tyrolean Val di Sole. On the south side of this trench, and parallel to it, extend in succession a broad band of palæozoic rock and a still broader zone of trias, bordered on the southern slope by a narrow girdle of jurassic rocks which decline towards the plain of Lombardy. Towards the east these are interrupted by a great mass of very peculiar granite, the most considerable tract of true granite to be found in the Alps. Beyond this the ridges and valleys no longer preserve the direction from east to west, but become parallel to the lake of Garda and the valley of the Adige. The district thus limited is enumerated hereafter as a distinct division under the designation *Lombard Alps*, the boundary between this and the Rætian division being the trench above described, which is prolonged from near Cles over the low Gampen Pass to the neighbourhood of Meran. On the northern side the Rætian Alps are divided from the Vindelician by a well-marked trench closely corresponding with the

northern limit of the crystalline rocks of the Silvretta group, formed by the valley of the Ill, the Vorarlberg Pass, and the course of the Rosanna. Within the limits here assigned the Rætian Alps occupy an area measuring about 80 miles by 60. The entire mass is divided into two nearly equal portions by the upper valley of the Inn, known in Switzerland as the Engadine.

10. *Lombard Alps.*—The limits of the Lombard Alps have been already pointed out. They are enclosed on the east and west sides by the Adige and the lake of Como, extending through about 90 miles from near Meran to Lecco. Their northern boundary is the great orographic trough that stretches from the head of the lake of Como along the valley of the Adda to Tresenda, thence by the low Aprica Pass to the upper Val Camonica, and over the Tonale Pass to the Val di Sole. Where that valley bends abruptly to SSE., the trough still keeps its original direction across the Gampen Pass to the right bank of the Adige below Meran. In spite of the zeal with which

travellers have of late years explored the unfrequented parts of the Alps, this group continues to be very imperfectly known, although it offers abundant attractions to the naturalist and the lover of picturesque and grand scenery.

11. *Vindelician Alps.*—Reference has already been made to the contrast offered by the orderly arrangement of the Eastern Alps, as compared with the far more complicated and irregular disposition of the masses that make up the Western and Central Alps. In the former we have a broad zone of crystalline or metamorphic palæozoic rocks, extending from the upper valley of the Adige to the frontier of Hungary, flanked on either side by a parallel zone of secondary rocks, which rise into peaks that do not much exceed the limit of perpetual snow. The northern zone extends for a distance of fully 260 miles from the lake of Constance to the neighbourhood of Vienna, with an average width varying from 30 to 40 miles. For the greater part of that distance this is separated from the central range by broad and deep valleys, through which the Inn, Salza, and Enns flow from west to east, till each of them, turning abruptly northward, runs through an opening that cuts across the general strike of the stratification to reach the plain of South Germany. In geological structure and general aspect the mountains of this tract show many common characteristics, and convenience supplies the only good reason for dividing it into two main groups, separated by the valley of the Inn, the greatest of the tributaries which the Alps send to the Danube. Of the western portion of this region the larger part belongs to Bavaria, but a considerable share lies in the Austrian provinces of Tyrol and Vorarlberg; and on this account the designations *Bavarian Alps* and *North Tyrol Alps* are open to objection, and have the further disadvantage of excluding the Alpine districts of Bavaria and North Tyrol lying east of the Inn. The name *Suabian Alps* is liable to the serious objection that none but a very small part of this district was ever included in the circle of Suabia. On the whole, it seems that the region lying north of the Vorarlberg road and the valley of the Inn, between the lake of Constance and the latter river, may best be termed the *Vindelician Alps*. The whole was included within the territory of the *Vindelici* before that powerful tribe was conquered by the Romans, and their territory joined to that of the Rhatians to form a single Roman province. In height the mountains of this division fall considerably short of those hitherto enumerated, not more than four or five exceeding 9000 feet. It is impossible to consider a map of this region without being struck by the

fact, that although the general slope inclines northward towards the plain of Bavaria, or southward towards the Ill and the Inn, nearly all the ridges and minor valleys lie east and west parallel to the course of those rivers and to the outcrop of the sedimentary strata, which is equally the direction of the line of depression followed by the Vorarlberg road forming the southern boundary of this group.

12. *Northern Noric Alps.*—We have already spoken of the broad mountain zone extending from the Inn to the neighbourhood of Vienna, and bearing a general resemblance in orographic and geological character to the group last described. For reasons given hereafter, it seems impossible to preserve the ancient designation *Noric Alps* for any portion of the central chain of the Eastern Alps, but the name *Northern Noric Alps* seems the most suitable for a region which was altogether included in the Roman province of *Noricum*, and which closely coincides with the northern half of the Alpine district known to them as *Alpes Noricæ*. The boundaries of this division are easily determined. To the north and east the mountains subside towards the valley of the Danube. To the west it is bounded by the Inn, which bends first to north-east, then to north, to enter the plain of Bavaria. On the south side the boundary runs from the Inn through a part of the Zillerthal, over the low Gerlos Pass, and along the valleys of the Salza and the Enns, evidently forming a single line of depression; but where the Enns enters the defile of Gesäuse, a broad and low valley, through which runs the road from Rottenmann to Leoben, seems to form the most natural division between this and the central chain. The line of separation is completed by the valley of the Mur and the depression of the Semmering Pass, over which the railroad is carried to Vienna. The highest peaks of the Dachstein group form the most considerable prominence in the entire range of the Northern Alps; but the average height of the mountains of this division does not exceed that of the Vindelician Alps.

13. *Central Tyrol Alps.*—To the eye of the geologist, taking a cursory view of the Eastern Alps, it may appear that the great central zone, extending from the upper valley of the Adige eastward to the neighbourhood of Gratz, forms but a single district of tolerably uniform structure. He will, however, remark that about the centre of the range the prevailing crystalline rocks—gneiss and mica-schist—give place to metamorphic schists, probably of palæozoic age, that rise into several of the highest peaks of the entire mass. Those who are disposed to regard the above-named crystalline rocks as merely extreme forms of metamorphic sedimentary strata, may not attach much importance to this circumstance; but it is a still more significant fact that at a short distance east of the same extension of the metamorphic rocks we have proof of the former existence of a depression which seems to have cut completely through the central range. On the north side triassic rocks extend from the Enns to the upper valley of the Mur, and the presence of miocene deposits at several points in the latter valley, the Lieserthal and the Malta-thal, seems to show that at a much later period this portion of the chain underwent great relative depression as compared with those on either side. Another and more obvious character that distinguishes the western from the eastern portion of the central zone, is the fact that in the latter the great range that extends like a vertebral column from the Weisskugel to the Hochalpenspitz forks into two branches of inferior height, that enclose between them the upper valley of the Mur. Ancient geographers divided the main mass of the Alps between the Bernardine Pass and the frontier of Hungary into two vast divisions, respectively called the Rætian and Noric Alps, placing the boundary between these at or about the Dreiherrnspitz, at the head of the Ahrental, and their example has been followed by some modern geographers. Nothing in the form or structure of the chain justifies the adoption of that arbitrary boundary between two main divisions of the Alps. We have already assigned reasons for fixing the western boundary of the Rætian Alps at the upper valley of the Adige, and we propose to retain the designation Central Tyrol Alps for the portion of the main chain extending thence to the head of the Malta Thal in Carinthia, nearly the whole of which lies within the limits of Tyrol. The exact boundaries of this division are, on the north, the course of the Inn from Landeck to the opening of the Zillertal, the track thence over the Gerlos Pass to the head of the Pinzgau, and the valley of the Salza to the opening of the Gross Arl Thal; to the east, the way through the latter valley, over the Arlscharte, through the Malta Thal to Gmünd, and the road thence to Villach; on the south, the continuous trough extending from near the latter town to Mühlwald, on the Reinz, through the Gail Thal, the Lessach Thal, the head of the Drauthal and the

upper valley of the Rienz. From Mühlwald the tortuous course of the Eisack forms the boundary as far as Botzen, whence the high road running N.W. along the Adige and though the Finstermünz completes the western boundary. Although the region thus limited does not present many prominent peaks, it is remarkable for the great average height of the main chain which forms the watershed between the affluents of the Danube on one side, and those of the Adige and the Drave on the other. In a distance of 120 miles—which would be much increased if measured along the sinuosities of the main chain—there is but a single low pass, that of the Brenner, none other being below 8000 feet in height, or suited for the construction of a carriage road. The Brenner is the lowest pass in the entire range of the Alps, and has from a remote period afforded the easiest access from middle Europe to the plains of northern Italy, but is properly described as a pass rather than as a breach in the continuity of the chain.

14. *Styrian Alps*.—The boundary between the central range of lofty peaks that extends through Tyrol and the adjacent province of Salzburg, and the much lower masses that spread eastward through Styria to the frontier of Hungary, has been already fixed at the Arlscharte. On the east side of that pass the mass whose conspicuous summits are the Markkahrspitz and the Hafnereck is divided into two parallel branches that enclose between them the upper valley of the Mur. The northernmost of these ranges is cut through by the broad and deep valley, traversed by the road that leads from Liesing on the Enns to Leoben, which we have regarded as the limit between the Northern Noric Alps and the central mass. The eastern boundary of this division, which we at the same time regard as the proper limit of the Alps, is marked by the river Mur, which, after flowing eastward for about 100 miles to Bruck-an-der-Mur, turns southward, and finally joins the Drave in Hungary. The eastern limit of the Alps is completed by the depression between Spielfeld and Marburg, over which is carried the railway from Vienna to Trieste. The southern boundary of the central range is unmistakably marked by the great valley of the Drave. The whole of this region was, along with large portions of the adjoining divisions, included under the term *Noric Alps* by ancient geographers; but as the retention of that designation can only lead to confusion, we readily adopt the name *Styrian Alps*, proposed by Karl v. Sonklar, whose writings have done so much to increase our knowledge of the Eastern Alps. It must, however, be remarked that the region above defined also includes a considerable district of Carinthia, along with a small part of the province of Salzburg, which extends to the head of the valley of the Mur. Excepting the comparatively high mass in which that river takes its source, the summits of this region do not attain nearly so great a height as those of the other main divisions of the Alps, and only two or three reach the limit of perpetual snow.

15. *South Tyrol and Venetian Alps*.—It has been seen that the mountain zone on the northern side of the main range of Tyrol extends from the lake of Constance to near Vienna, with a remarkable uniformity both of general aspect and of geological structure, so that no reason much more valid than convenience could be assigned for forming it into two separate divisions. The same remark does

not hold good on the southern side of the main range. There is, indeed, a general similarity between the northern and southern zones, especially in their geological structure, so far as regards the sedimentary rocks; but in the western portion of the latter—in the region lying between the Adige and the sources of the Piave—the intrusion of igneous rocks on a large scale, and the accumulation of deposits formed from ejected volcanic matter, have profoundly modified the structure and outward aspect of the country. Nowhere else in the Alps do the peaks rise so abruptly and with so little apparent connection, and nowhere are the contrasts depending on differences of geological structure so marked as those which strike the mere passing traveller, when, beside rounded masses of red and black porphyry, he sees white and pink crystalline dolomite limestone rising in towers and pinnacles of extraordinary height and steepness. Dolomite limestone is found in many other parts of the Alps, but nowhere else is it developed on so grand a scale, and the exquisite beauty of this region has of late years led an increasing number of travellers to spots that before were scarcely known even to the inhabitants of adjoining valleys. Though there are abundant grounds for regarding the district here spoken of as a separate division of the Alps, it is very difficult to assign to it a satisfactory designation. The larger portion of the region has long been politically connected with Tyrol, and is partly inhabited by a German-speaking population, while the remainder has been politically connected with Venice, and the inhabitants are thoroughly Italian in language and manners. Were it not for a reluctance to introduce new and unfamiliar terms, the present division might be denominated *Cimbria Alps*, as, according to ancient tradition, the Cimbrici, after their final defeat by Marius, sought and found a refuge in this part of the Alps; but for the present it seems best to designate as *South Tyrol and Venetian Alps* the region lying between the valley of the Adige and the sources of the Drave and the Piave, and south of the great valley traversed by the Eisack and the Rienz between Botzen and Innichen. The eastern limit may best be fixed by the track leading through the Sextenthal from Innichen to San Stefano in the head valley of the Piave, and by the road from that place to Conegliano.

16. *South-Eastern Alps*.—Ancient geographers, and those who have followed their example, use the terms *Carnic Alps* and *Julian Alps* to designate two of the main divisions of the Alps; but the letter of these at least has

been applied in a vague and inconsistent way. In point of fact, the south-eastern portion of the Alps, which includes both the groups above specified, presents three principal groups which are very closely connected together. The first of these—the Carnic Alps, properly so called—have been defined as including the region between the upper valley of the Drave and the plain of Friuli. But to the orographer the true head of the Drave valley is the Gailthal, which extends in an almost straight and broad trench from near Innichen to Villach, while the main stream flows through a sinuous and contracted valley. For this reason we have taken the Gailthal as the boundary between the Central Tyrol and the Carnic Alps. Almost continuous with the Carnic Alps is a range, very similar in geological structure, which divides the Drave from the northern branch of the Save, and includes the mountains locally known as the Karawankas and the Sulzbacher Alps. Throughout these, which may be called the main range of the South-Eastern Alps, palaeozoic rocks, probably of carboniferous age, extend in a narrow band for a distance of fully 100 miles, giving place at the eastern extremity to the small granitic mass that forms the hills of the Bacher Gebirge near Marburg. On the south side of the main range of the Carnic Alps two mountain masses, mainly formed of triassic rocks and Dachstein limestone, attain a considerable height in the Monte Cavallo on the west, and the Monte Canin on the east side of Friuli. In a similar position as regards the Karawankas is a still loftier mass which is crowned by the Terglou—the highest peak of the South-Eastern Alps. This group is referred by geographers to the Julian Alps, which are said to divide the Save and its tributaries from the Adriatic. As has been already said, there is no range to which the term Alps can properly be applied forming such a boundary. The plateau of the Karst, though rising here and there into hills of moderate height, has an average elevation of about 2000 feet above the sea, and cannot correctly be spoken of as a mountain chain. The orographer, if seeking an eastern prolongation to the Terglou group, would prefer the hilly region between the Save and the southern Gurk; but the low country through which the railway is carried from Marburg to Laybach, and the road thence to Gorizia, may for all practical purposes be taken as the south-eastern limit of the Alps and of the division here described.

It is well known that as we rise from the sea-level into the upper regions of the atmosphere the temperature decreases. The effect of mountain chains on prevailing

winds is to carry warm air belonging to the lower region into an upper zone, where it expands in volume at the cost of a proportionate loss of heat, often accompanied by the precipitation of moisture in the form of snow or rain. The position of the Alps about the centre of the European continent has profoundly modified the climate of all the surrounding regions. The accumulation of vast masses of snow, which have gradually been converted into permanent glaciers, maintains a gradation of very different climates within the narrow space that intervenes between the foot of the mountains and their upper ridges; it cools the breezes that are wafted to the plains on either side, but its most important function is to regulate the water supply of that large region which is traversed by the streams of the Alps. Nearly all the moisture that is precipitated during six or seven months is stored up in the form of snow, and gradually diffused in the course of the succeeding summer; and even in the hottest and driest seasons the reserves accumulated during a long preceding period of years in the form of glaciers are available to maintain the regular flow of the greater streams. Nor is this all; the lakes that fill several of the main valleys on the southern side of the Alps are somewhat above the level of the plains of Lombardy and Venetia, and afford an inexhaustible supply, which, from a remote period, has been used for that system of irrigation to which they owe their proverbial fertility. Six regions or zones, which are best distinguished by their characteristic vegetation, are found in the Alps. It has been a common error to suppose that these are indicated by absolute height above the sea-level. Local conditions of exposure to the sun, protection from cold winds, or the reverse, are of primary importance in determining the climate and the corresponding vegetation.

1. *Olive Region.*—The great plain of Upper Italy has a winter climate colder than that of the British Islands. The olive and the characteristic shrubs of the northern coasts of the Mediterranean do not thrive in the open air, but the former valuable tree ripens its fruit in sheltered places at the foot of the mountains, and penetrates along the deeper valleys and the shores of the Italian lakes. The evergreen oak is wild on the rocks about the lake of Garda; and lemons are cultivated on a large scale, with partial protection in winter. The olive has been known to survive severe cold when of short duration, but it cannot be cultivated with success where frosts are prolonged, or where the mean winter temperature falls below 42° Fahr.; and to produce fruit it requires a heat of at least 75° Fahr. during the day, continued through four or five months of the summer and autumn.

2. *Vine Region.*—The vine is far more tolerant of cold than the olive, but to produce tolerable wine it demands, at the season of ripening, a degree of heat not much less than that needed by the more delicate tree. These conditions are satisfied in the deeper valleys of the Alps, even in the interior of the chain, and up to a considerable height on slopes exposed to the sun. The protection afforded by winter snow enables the plant to resist severe and prolonged frosts, such as would be fatal in more exposed situations. Along with the vine, many wild plants characteristic of the warmer parts of middle Europe are seen to flourish. A mean summer temperature of at least 68° Fahr. is considered necessary to produce tolerable wine, but in ordinary seasons this is much exceeded in many of the great valleys of the Alps.

3. *Mountain Region, or Region of Deciduous Trees.*—Many writers take the growth of corn as the characteristic of this region; but so many varieties of all the common species are in cultivation, and these have such different climatal requirements, that they do not afford a satisfactory criterion. A more natural limit is afforded by the presence

imate of  
e Alps.

of the chief deciduous trees—oak, beech, ash, and sycamore. These do not reach exactly to the same elevation, nor are they often found growing together; but their upper limit corresponds accurately enough to the change from a temperate to a colder climate that is further proved by a change in the wild herbaceous vegetation. This limit usually lies about 4000 feet above the sea on the north side of the Alps, but on the southern slopes it often rises to 5000 feet, sometimes even to 5500 feet. It must not be supposed that this region is always marked by the presence of the characteristic trees. The interference of man has in many districts almost extirpated them, and, excepting the beech forests of the Austrian Alps, a considerable wood of deciduous trees is scarcely anywhere to be found. In many districts where such woods once existed, their place has been occupied by the pine and Scotch fir, which suffer less from the ravages of goats, the worst enemies of tree vegetation. The mean annual temperature of this region differs little from that of the British islands; but the climatal conditions are widely different. Here snow usually lies for several months, till it gives place to a spring and summer considerably warmer than the average of our seasons.

4. *Subalpine Region, or Region of Coniferous Trees.*—This is the region which mainly determines the manner of life of the population of the Alps. On a rough estimate, we may reckon that, of the space lying between the summits of the Alps and the low country on either side, one quarter is available for cultivation, of which about one-half may be vineyards and corn-fields, and the remainder produces forage and grass. About another quarter is utterly barren, consisting of snow-fields, glaciers, bare rock, lakes, and the beds of streams; and there remains about one-half, which is divided between forest and pasture, and it is the produce of this which mainly supports the relatively large population. For nearly half the year the flocks and herds are fed on the upper pastures; but the true limit of the wealth of a district is the number of animals that can be supported during the long winter, and while one part of the population is engaged in tending the beasts and in making cheese and butter, the remainder is busy cutting hay and storing up winter food. The larger villages are mostly in the mountain region, but in many parts of the Alps the villages stand in the subalpine region at heights varying from 4000 to 5500 feet above the sea, more rarely extending to about 6000 feet. The most characteristic feature of this region is the prevalence of coniferous trees, which, where they have not been artificially reduced, form vast forests that cover a large part of the surface. These play a most important part in the natural economy of the country. They protect the valleys from destructive avalanches, and, retaining the superficial soil by their roots, they mitigate the destructive effects of heavy rains. In valleys where they have been rashly cut away, and the waters pour down the slopes unchecked, every tiny rivulet becomes a raging torrent, that cuts away and carries off the grassy slopes and devastates the floor of the valley, covering the soil with gravel and debris. In the pine forests of the Alps the prevailing species are the common spruce and the silver fir; on siliceous soil the larch flourishes, and surpasses every other European species in height. The Scotch fir is chiefly found at a lower level, and rarely forms forests. The Siberian fir is found scattered at intervals throughout the Alps, but is not common. The mughus, creeping pine, or *Krummholz* of the Germans, is common in the Eastern Alps, and sometimes forms on the higher mountains a distinct zone above the level of its congeners. In the Northern Alps the pine forests rarely surpass the limit of 6000 feet above the sea, but on the south side they commonly attain to 7000 feet; and the

larch, Siberian fir, and mughus often extend above that elevation.

5. *Alpine Region.*—Throughout the German Alps the word *alp* is used specifically for the upper pastures, where cattle are fed in summer, but this region is held to include the whole space between the uppermost limit of trees and the first appearance of permanent masses of snow. It is here that the characteristic vegetation of the Alps is developed in its full beauty and variety. Shrubs are not wanting. Three species of rhododendron vie with each other in the brilliancy of their masses of red or pink flowers; the common juniper rises higher still, along with three species of bilberry; and several dwarf willows attain nearly to the utmost limit of vegetation. The upper limit of this region coincides with the so-called limit of perpetual snow, which demands further explanation.

6. *Glacial Region.*—On the higher parts of lofty mountains more snow falls in each year than is melted on the spot. A portion of this is carried away by the wind before it is consolidated; a larger portion accumulates in hollows and depressions of the surface, and is gradually converted into glacier-ice, which descends by a slow secular motion into the deeper valleys, where it goes to swell perennial streams. As on a mountain the snow does not lie in beds of uniform thickness, and some parts are more exposed to the sun and warm winds than others, we commonly find beds of snow alternating with exposed slopes covered with brilliant vegetation; and to the observer near at hand there is no appearance in the least corresponding to the term *limit of perpetual snow*. But the case is otherwise when a high mountain chain is viewed from a distance. Similar conditions are repeated at many different points, so that the level at which large snow-beds show themselves along its flanks is approximately horizontal. But this holds good only so far as the conditions are similar. On the opposite sides of the same chain the exposure to the sun or to warm winds may cause a wide difference in the level of permanent snow; but in some cases the increased fall of snow on the side exposed to moist winds may more than compensate the increased influence of the sun's rays. Still, even with these reservations, the so-called line of perpetual snow is not fixed. The occurrence of favourable meteorological conditions during several successive seasons may and does increase the extent of the snow-fields, and lower the limit of seemingly permanent snow; while an opposite state of things may cause the limit to rise higher on the flanks of the mountains. From these remarks it may be inferred that all attempts to fix accurately the level of perpetual snow in the Alps are fallacious, and can at the best approach only to local accuracy for a particular district. In some parts of the Alps the limit may be set at about 8000 feet above the sea, while in others it cannot be placed much below 9500 feet. As very little snow can rest on rocks that lie at an angle exceeding 60°, and this is soon removed by the wind, some steep masses of rock remain bare even near the summits of the highest peaks, but as almost every spot offering the least hold for vegetation is covered with snow, few flowering plants are seen above 10,000 feet. There is reason to think, however, that it is the want of soil rather than climatal conditions that checks the upward extension of the Alpine flora. Increased direct effect of solar radiation compensates for the cold of the nights, and in the few spots where plants have been found in flower up to a height of 12,000 feet, nothing has indicated that the processes of vegetation were arrested by the severe cold which they must sometimes endure. The climate of the glacial region has often been compared to that of the polar regions, but they are widely different. Here, intense solar radiation by day, which raises the surface when dry, to a temperature approaching 80° Fahr.,

alternates with severe frost by night. There, a sun which never sets sends feeble rays that maintain a low equable temperature, rarely rising more than a few degrees above the freezing-point. Hence the upper region of the Alps sustains a far more varied and brilliant vegetation.

At the earliest period of which records are preserved the Alps appear to have been mainly inhabited by Celtic tribes, some of which, before they were subjugated by the Romans, had made considerable progress in the knowledge of the useful arts. The Rhetians and Vindelicians especially, in whom a primitive Turanian stock seems to have been amalgamated with a dominant Celtic race, readily assimilated the civilisation of Rome; and the language of the conqueror, modified by peculiarities of pronunciation and the retention of some native terms, still survives in Eastern Switzerland, and in a few isolated valleys of Tyrol. Throughout by far the larger part of the Alps, however, the flood of Teutonic invasion either exterminated or drove into exile the previous population. The Alemanni and other kindred tribes settled in the main valleys of the Eastern Alps, and finally became masters of the greater part of Switzerland, leaving to the original Celtic population the Western Alps and both slopes of the great Pennine chain. At a later period the invasion of Slavonic hordes threatened to substitute a new nationality throughout the same region, but after prolonged contests these tribes were restricted to its south-eastern portion, being nearly confined to the upper valleys of the Drave and the Save, with their tributaries. The Italian valleys of the Alps, from the Val d'Ossola to the Tagliamento, inhabited by people of mixed race, have, with a few exceptions, preserved the language of Italy, much varied in the local dialects; while the western districts, in which the Celtic element remained predominant, have for the most part clung to the French tongue. The estimates formed of the present population of the Alps are uncertain, because they usually include towns and populous districts lying without the mountain region. It is usually reckoned that there are about 1,500,000 of Celto-Gallic stock in the French and Savoy Alps, western Switzerland, and some valleys of Piedmont; about 4,000,000 of Teutonic origin in the Swiss and German Alps; about 1,000,000 of Slavonic stock, chiefly Slovenes; and about 1,000,000 of Italians in the valleys of Northern Italy, the Swiss cantons of Tessin and Grisons, and in the Italian Tyrol, making an aggregate of 7,500,000. To these should be added about 70,000 people speaking some dialect of the Ræto-Roman or Romansch. All these numbers excepting the last are excessive, if we would restrict the estimate within the proper limits of the Alps.

Although no conspicuous species of quadruped or bird is known to be exclusively confined to the Alps, they have afforded an asylum to many animals that have become rare or extinct elsewhere. The great urus, the elk, and the wild swine have disappeared since the Roman period, and the beaver in more recent times; but the brown bear, the lynx, the wild cat, and the wolf still survive. Among Ruminants, the red deer, fallow deer, and roebuck, chiefly found in the lower forest region, are common to other mountain districts. More characteristic of the Alps is the chamois, which is found elsewhere only in the Carpathians, Pyrenees, and the mountains of European Turkey, and is the sole representative of the antelopes in this part of the world. Much rarer is the ibex or bouquetin, which still lives in the higher Alpine region of the Graian Alps, and possibly also in some recesses of the Pennine chain. Unlike the chamois, which descends at night to find sustenance as low as the verge of the pine forests, this fine animal remains, at least in the summer, in the upper region, on the verge of the snow-fields, or on the rocks that

rise amidst the glaciers. The massive horns of the male are often a yard or more in length. Closely allied species are found in the Pyrenees and other mountain ranges of the Iberian peninsula, and in the Caucasus, but the true ibex seems to be now confined to this small corner of the Alps. The few endemic species of Mammalia found in the Alps are chiefly small Rodentia and Insectivora, which alone can multiply rapidly in the midst of a large and increasing human population. The marmot, which is the most characteristic of the Rodentia, maintains its ground in the stony recesses of the Alpine region, and does not diminish in numbers as most other wild animals have done. The most singular of this group is the snow-vole (*Arvicola nivalis*), whose nearest ally is a native of East Siberia. Several forms (varieties or sub-species) are found in various parts of the Alps. They ascend through the Alpine region to the rocks of the glacial zone, at least as far as 12,000 feet above the sea; and, unlike other animals framed to endure severe cold, they continue in activity throughout the long winter. There is at least one species of shrew (*Sorex alpinus*) peculiar to the Alps. The Cheiroptera are represented by numerous forms, which, with one exception (*Vesperugo maurus*), are not confined to this region; but the Alps form a limit to the distribution of many of this order: some species of middle Europe do not cross the main range, while several species of the Mediterranean region find their northern limit in the valleys on the southern side.

The Birds of the Alps are proportionately very numerous. Many southern species find a home in the warmer Italian valleys, and there meet northern forms that descend during the winter and spring, but return to the upper zone in the warm season. Of the more conspicuous species of the high Alps, the lammergeyer (*Gypætos barbatus*)—once common, but now become very rare—is pre-eminent. It is also found in Algeria, in Syria, and in Northern Asia, but is one of those animals that is threatened with extinction by the progress of civilisation. The rock chough (*Pyrrhocorax alpinus*), distinguished by golden-yellow bill and feet, builds on rocks in the glacial region as high as 10,000 feet above the sea. Several song birds, such as the snow lark and snow finch, ascend to the limits of vegetation. The Gallinæ are well represented. The cock of the woods (*Tetrao urogallus*), the grouse, ptarmigan, blackcock, gelinotte, and rock partridge (*Caccabis saxatilis*), are the most remarkable. The first, which is somewhat rare and extremely shy, surpasses the dimensions of an ordinary well-grown fowl.

Several Reptiles are found even in the upper region of the Alps, though none are very common. Of three venomous species of viper, *Vipera berus* ascends to about 8000 feet; and the black viper (*V. prester*) also reaches the Alpine region. *V. Redii* is confined to the warmer Italian valleys. The snakes and lizards frequent the lower zones, excepting *Lacerta pyrrhogastra*, which is sometimes seen in the upper region.

Batrachians are more common than true reptiles. An Alpine frog attains the extreme limit of vegetation, and a toad ascends nearly as far. These have been considered by some as distinct species, by others as varieties of the common animals. At least one triton (*T. Wurfbeini*) is peculiar to the Alps. The spotted salamander is common in the sub-Alpine region, but in the Eastern Alps it is replaced by *S. atra*, which is entirely black. This is sometimes found far above the limit of the pine forests.

The great lakes of the Alps are very rich in Fish, not only as regards the number of individuals, but in species also. Thus in the Chiemsee, at the northern foot of the Bavarian Alps, thirty-three species have been found, in the lake of Constance twenty-six species, and twenty-four

in the lake of Lucerne. The most esteemed are those of the trout and salmon tribe, whose specific differences have not yet been fully investigated by ichthyologists. First in rank is the saibling (*Salmo salvelinus*), which flourishes in lakes between 2000 and 4000 feet above the sea, and occasionally extends to those of the Alpine region between 6000 and 7000 feet. The fish of the northern side of the Alps are fully described in Siebold's *Süsswasser-Fische Mitteleuropas*. Those of the waters running to the Mediterranean have not been so fully investigated. Two or three peculiar species have been found in the lake of Geneva. In some of the Lombard lakes, the *agone*, a small fish of the herring tribe (*Clupea finta*), is a much esteemed article of diet.

In the classes hitherto noticed the number of species peculiar to the Alps is very small. This rule is reversed among the Invertebrata, especially as regards the Articulata and Mollusca. The number of insects is very great, and a considerable proportion extend to the limit of perpetual snow. Oswald Heer has pointed out several peculiarities in the insect fauna of the higher Alps. In ascending from the mountain region the proportion of the carnivorous tribes rapidly increases, and the families that feed on living vegetable matter either disappear or are much reduced in numbers. Beetles and other insects either lose their wings in the upper region, or are represented by allied wingless species. Along with the tendency to lose the power of flight, a diminution of brilliancy of colour appears, the prevailing hues being black or dingy grey. These peculiarities are to be explained by the fact that in the upper Alpine zone most insects live under stones, and the power of flight generally proves injurious to animals liable to be carried by the wind and upward air-currents over the snow-fields, whence they are unable to return. This is often seen to occur to butterflies and a few moths, which ascend as far as the highest flowering plants. The snow-fields and glaciers are not devoid of insect life. Several species of snow-flea have been detected; and further observation will probably bring to light other minute animals living in the pools that form on the surface of glaciers, or on the snow-beds, although their activity is often interrupted by the freezing of the surface.

The Arachnida are eminently characteristic of the fauna of the high Alps, where they abound both in species and individuals. Spiders ascend to the utmost limit of vegetation, and are even to be found on the bare rocks that rise out of the snow up to a height of 11,000 feet.

Although most of the orders of Articulata are represented in the Alps by numerous forms, these are far outnumbered by the total number of European species of that class; but among land and fresh-water Mollusca the proportion is reversed, and as many as seven-eighths of all the species known in middle Europe, and a large proportion of those of the Mediterranean region, have been found in the Alps. Still more remarkable is the large proportion of endemic species. In the important group of the Helicæ fully one hundred species, or four-tenths of the whole number, are peculiar to the Alps. Between thirty and forty species only have been found in the Alpine zone, and of these but five—*Vitrina diaphana*, *V. glacialis*, *Helix glacialis*, *H. jetens*, and *Vertigo Charpentieri*—attain the upper limit of vegetation.

The Annulosa and Radiata of the Alps, so far as they are known, do not offer any points of special interest; and the study of the minute organisms, which have been proved to exist as high as 12,000 feet above the sea, is still in its infancy.

In describing the several regions which are found in ascending from the low country to the snow-clad summits of the Alps, and whose existence is due to climatal differ-

ences, it was necessary to refer to the characteristic vegetation of each zone, inasmuch as this affords the chief apparent distinction which climatal conditions impress on the earth's surface. The most cursory observation suffices to show that within each of the zones thus broadly sketched out there exist marked differences in the vegetable population, so that a comparison of the local floras in two spots possessing a similar climate as regards temperature may exhibit but few points of agreement along with many marked contrasts. This partly depends on external conditions, of which the most important are differences in the amount and distribution of moisture in the air and the soil, and differences in the composition and state of aggregation of the soil itself. But a more important element in determining the flora of any particular district depends upon the causes which have operated throughout the whole period since it has become dry land to facilitate migration for certain species, and to impede it for others. The subject of the distribution of Alpine plants, so far as regards the eastern half of the chain, has been very well discussed in an essay by Dr A. Kerner in the 1st vol. of the 2d edit. of Schaubach's *Deutsche Alpen*, although some of the conclusions of the writer may not bear careful criticism. He divides the natural floras of the Alps into four—named respectively *Arctic*, *Baltic*, *Pontic*, and *Mediterranean*, the term *Baltic* referring to the region that includes Germany, Southern Scandinavia, and North-Western Russia; while *Pontic* comprehends the region north and west of the Euxine—the northern provinces of Turkey and the whole space between the Carpathians and the Crimea. It does not appear that the writer holds that the plants existing in the Alps have actually migrated to their present homes from the geographical regions corresponding to the above denominations, but merely that they belong to the types of vegetation characteristic of each of them. It must be borne in mind that the Alps, and especially the mountain and sub-Alpine regions, produce a large number of peculiar forms, many of which have no near allies in the other mountain regions of Europe, while at the same time the differences are seldom so wide as to place these in distinct generic groups; and it seems quite inadmissible to suppose that the flora has been altogether formed by colonisation from surrounding districts. No space can be here found for details, but it may broadly be said that while the highest zone of all, lying close to the limit of permanent snow, exhibits throughout the whole chain an approach to uniformity, several of the most conspicuous species being common to this and to Arctic flora, the zone immediately below this, as well as those lower down, shows a large admixture of quite distinct elements. This is especially true of the southern slopes. In truth, but a very few of the well-marked endemic species of the Alps are confined to the north side of the main chain. A considerable number are common to both slopes, and a still larger proportion are restricted exclusively to the southern side. Of the larger groups which are represented in the Alps by numerous well-marked endemic species, the genera *Alsine*, *Androsace*, *Arabis*, *Campanula*, *Crepis*, *Gentiana*, *Pedicularis*, *Primula*, and *Saxifraga* may be especially noted. Without attempting to enter into details, it may be said that, along with a general Alpine flora, which extends throughout the entire chain, there are three large districts where, along with species common to all, we find a considerable number of others either absolutely local and endemic, or else representative in the Alps of the floras of other distant mountain groups. Only a few of the more remarkable species characteristic of each can be cited. The *West Alpine Flora* is found in Dauphiné, South Savoy, and Western Piedmont, as far north as the group of the Graian Alps. In the following list of the more remark-

able species those which are either identical with or nearly allied to Pyrenean forms have an asterisk prefixed:—

*Arabis pedemontana*, *Huguenina taraxetifolia*, \**Dianthus neglectus*, *Silene cordifolia*, \**Saponaria lutea*, \**Hypericum nummulariifolium*, *Astragalus alopecuroides*, *Saxifraga florulenta*, *S. diapensioides*, \**S. pedemontana*, \**Asperula hexaphylla*, *Cephalaria alpina*, *Achillea Herbarola*, *Berardia subcaulis*, *Campanula Allionii*, *C. latines*, *Primula marginata*, *P. Allionii*, \**Erinus alpinus*, *Veronica Allionii*, *Thymus piperella*, and *Alopecurus Gerardii*.

The Lombard Flora is marked by a considerable number of very distinct species that are limited to the southern declivity of the Alps, between the Lago Maggiore and the lake of Garda. Most of these are absolutely confined within these boundaries, but a few extend some distance east of the lake of Garda. The following deserve to be specified:—

*Viola Comollia*, *V. heterophylla*, *Silene Elizabethæ*, *Arenaria grincensis*, *Cytisus glabrescens*, *Sanguisorba dodecandra*, *Saxifraga Vandellii*, *S. arachnoidea*, *Laserpitium nitidum*, *Telckia speciosissima*, *Leontodon tenuiflorus*, *Hieracium porrifolium*, *Campanula Trimeri*, *C. elatinoidea*, *Daphne rupestris*, *Euphorbia variabilis*, and *Carex baldensis*.

The East Alpine Flora, extending through the region east of the valley of the Adige, is characterised by a large number of peculiar species, and by a perhaps equal number of plants not seen elsewhere in the Alps, but also natives of the Carpathians, or of the region lying between Servia and the Adriatic. In the following list those included in the latter category are marked with an asterisk:—

*Arabis rochianensis*, \**A. Scopoliiana*, \**Cardamine trifolia*, *Braya alpina*, *Cochlearia brevicaulis*, *Silene pumilio*, *S. alpestris*, *Dianthus alpinus*, \**Genista sericea*, *Medicago Pironæ*, \**Potentilla Clusiana*, *Saxifraga Burseriana*, *S. tenella*, \**S. petraea*, \**S. hieracifolia*, \**Hieracium Epipactis*, *Astrantia carniolica*, *Hladnikia golaensis*, *Anthemis alpina*, *Achillea Clusiana*, \**Senecio abrotanifolius*, *Centaurea alpina*, *C. rupestris*, \**Saussurea pygmaea*, *Phyteuma comosum*, *Campanula pulla*, \**C. alpina*, *C. morettiana*, *C. Zoysii*, *Rhododendron chamaecistus*, *Geranium imbricatum*, \**G. frigida*, *G. Fröhlichii*, \**Primula minima*, *P. glutinosa*, *Androsace Hausmannii*, *Pedicularis Bonarota*, *P. Ageria*, *Wulfenia carinthiaca*, *Sesleria sphaerocephala*, and *S. microcephala*.

It is worthy of remark that the central and highest part of the Alpine chain, including the Pennine and Bernese groups, the Lepontine Alps, and those of North Switzerland, produce scarcely a well-marked species—with the doubtful exceptions of *Rumex nivalis* and of *Potentilla grammopetala*, which is confined to a small district south east of Monte Rosa—that does not spread throughout the rest of the chain.

The phenomena of glaciers have been chiefly studied in the Alps, but they are not especially characteristic of the mountains of central Europe. The investigation of their origin and structure, and the laws of their motion, fall within the province of the physical philosopher, and are discussed elsewhere. See GLACIERS.

The geological structure of the Alps is a subject that has occupied the labours of many eminent men of science, especially during the last thirty years, yet it may be safely asserted that it will continue to offer new problems to the researches of at least another generation. There is scarcely a single difficult question regarding the nature and mode of deposition of the strata that make up the earth's crust, the mode of elevation of mountain chains, the causes of the formation of valleys and lake basins, the action of meteoric forces, of rivers and ice-streams, that must not be decided before we can give a rational account of the structure of the Alps. Along with these, and scarcely less important, is the study of the various agencies involved in the phenomena of metamorphism, and that of the part played by volcanic action in some parts of the chain. The study of the organic remains embedded in the rocks is not so constantly the duty of the geologist in the Alps as it is

in most other mountain districts; but of late years this has been actively pursued, and has tended to clear up many difficulties, while much room is left for further investigation. The reader is referred to the article GEOLOGY, and, with reference to detailed information as to the structure of the Alps, to the list of works on alpine geology given below.

The number of publications relating to the Alps has been so largely increased during the last quarter of a century that a bare catalogue would fill a considerable space. The majority of these are of a narrative and descriptive character, and do not add much to our knowledge of the Alps, either topographically or scientifically. It will suffice to give here a brief list of the chief works that may fairly be considered to have achieved that object. Works of exclusively scientific character, especially those relating to Alpine geology, are separately enumerated.

Scheuchzer (J. J.), *Itinera Alpina*, Leyden, 1723. Gruner, *Die Eisgebirge des Schweizerlandes*, Bern, 1760. Saussure (H. B. de), *Voyages dans les Alpes*, Neuchâtel, 1803-6. Hugi (J. J.), *Naturhistorische Alpenreise*, Solothurn, 1830. Agassiz (L.), *Etudes sur les Glaciers*, Neuchâtel, 1840; *Système Glaciaire, ou Nouvelles Etudes*, &c., Paris, 1847. Forbes (J. D.), *Travels through the Alps of Savoy*, &c., Edinburgh, 1843. Desor (E.), *Excursions et Séjours dans les Glaciers et les Hautes Régions des Alpes*; 2 series, Neuchâtel, 1844-5. Saluzzo (A. di), *Le Alpi che cingono l'Italia*, 1<sup>ma</sup> Parte, Torino, 1845. Schlagintweit (H. und A.), *Untersuchungen über die Physicalische Geographie die Alpen*; 2 series, Leipzig, 1850-4. Tyndall (J.), *The Glaciers of the Alps*, London, 1860. Berlepsch (H. A.), *Die Alpen in Natur- und Lebensbildern dargestellt*, Leipzig, 1861. Browne (Rev. G. F.), *Ice-caves of France and Switzerland*, London, 1865. Morell, *Scientific Guide to Switzerland*, London, 1866. Sonklar (Karl von), *Die Oetzthaler Gebirgsgruppe*, &c., Gotha, 1860; *Die Gebirgsgruppe der Hohen Tauern*, &c., Wien, 1866. Schaubach *Die Deutsche Alpen*; 2d edition, Jena, 1865-71. Bonney (Rev. T. G.), *The Alpine Regions of Switzerland and the neighbouring countries*, Cambridge and London, 1868. Ball (J.), *The Alpine Guide*; new edition, in ten parts, London, 1873. Considerable additions to our knowledge of the Alps are also to be found in the periodical publications of the English, Swiss, Austrian, Italian, and German Alpine Clubs; and also in papers that have appeared in *Petermann's Geographische Mittheilungen*.

No general zoological works of a purely scientific character relating exclusively to the fauna of the Alps can be quoted; but much valuable information, conveyed in a popular form, will be found in Tschudi's *Thierleben der Alpenwelt*, of which translations have appeared in English and French. The want of a compact work containing descriptions of all the plants of the Alps has been much felt by botanists. Those of Switzerland and the Eastern Alps are included in Koch's *Synopsis Floræ Germanicæ et Helveticæ*, a work of high authority, written in Latin; but it does not comprehend the species peculiar to Piedmont and the Western Alps. An illustrated work, by J. C. Weber, *Die Alpenpflanzen Deutschlands und der Schweiz*, may also be recommended. Of numerous books and memoirs connected with the geology of the Alps, the following deserve special mention:—L. von Buch, *Geologische Beobachtungen auf Reisen*, 1802. Sir R. I. Murchison, *On the Geological Structure of the Alps, the Apennines, and the Carpathians*, *Quart. Journal Geol. Soc. of London*, vol. v.; a translation of this important memoir into Italian, with an appendix, by P. Savi and G. Meneghini, Florence, 1851. Sedgwick and Murchison, *On the Geology of the Eastern Alps*, *Trans. Geol. Soc. Lond.* 1832. J. de Charpentier, *Essai sur les Glaciers et sur le Terrain Erratique du Bassin du Rhone*, 1841. B. Studer, *Geologie der Schweiz*, 1853; *Id. Index der Petrographie und Stratigraphie der Schweiz*, &c., Bern, 1872. A. Stoppani, *Studi Geologici e Paleontologici sulla Lombardia*, 1857. C. Lory, *Description Géologique du Dauphiné*, 1860. Gümbel, *Geologie des Königreichs Bayern*, 1861. O. Heer, *Die Urwelt der Schweiz*, Zürich, 1865. E. Desor, *Der Gebirgsbau der Alpen*, &c., Wiesbaden, 1865. A. Favre, *Recherches Géologiques dans les Parties de la Savoie*, &c.; *Voisines du Mont Blanc*, Genève, 1867. L. Rüttimeyer, *Ueber Thal- und Seebildung*, Basel, 1869. A copious collection of facts and observations bearing on the physics and recent geology of the Alps will be found in a work by M. Dollfus-Ausset, *Matériaux pour l'Etude des Glaciers*, of which nine volumes have appeared. Many important contributions to Alpine geology are scattered through the Proceedings of scientific societies. The *Bulletin* of the French Geological Society contains valuable papers by Collegno, Dausse, Gras, Huber, Mortillet, Omboni, Rozet, and others. The geology of the Austrian Alps is illustrated by numerous papers in the *Jahrbuch der k. k. Reichsanstalt*. The memoirs of A. Sismonda and B. Gastaldi, in the *Memorie della R. Accademia di Torino*, must be consulted by those who would study the geology of Piedmont. The phenomena of the motion and structure of glaciers have been discussed in numerous

papers that have appeared in the *London and Edinburgh Philosophical Magazine* during the last thirty years. The important memoirs of Professor Tyndall were published in the *Philosophical Transactions* for 1857, 1858, and 1859; and those of the late Mr Hopkins in the *Transactions of the Cambridge Philosophical Society*, vol. viii. Various contributions to illustrate and enforce the views first set forth by the late Principal Forbes in his *Travels through the Alps* were published in a collected form by Messrs Black, Edinburgh, in 1859.

With the exception of special maps of small districts, the only maps of the Alps founded on actual survey are those which have been published under the authority of the governments whose territory is concerned. Among these the first place is due to the federal map of Switzerland, executed under the direction of General Dufour, on the scale  $\frac{1}{100,000}$ , in 25 sheets. Considering the difficulty of the task, this is unsurpassed both for accuracy and skill in execution. The Austrian War Office has brought out, during the last sixty years, a series of maps, executed on a large scale, of the several states of the empire. These are of very unequal merit. That of the kingdom of Venetian Lombardy, in 42 sheets, on the scale of  $\frac{1}{80,000}$ , has considerable merit, but falls short of the standard of the Swiss map. A new map of Tyrol is in preparation, and will doubtless sustain the reputation of Austrian cartographers. The general map of Piedmont, in 91 sheets, on the scale  $\frac{1}{80,000}$ , is sufficiently correct as regards the inhabited districts, but quite unsatisfactory as regards the higher region. Until lately there

existed no tolerable map of the Alpine provinces of France. The general map of France, on the scale  $\frac{1}{80,000}$ , has of late years been extended to the greater part of Dauphiné, and will before long include the newly-acquired departments of Savoy and Nice. The portion already published is quite on a level with modern requirements, and reflects credit on the French war department. The only tolerable map that includes the entire chain of the Alps is that compiled by J. G. Mayr. It is on a small scale ( $\frac{1}{400,000}$ ), and is not free from serious errors. A map published by Wörl, in 48 sheets, on a scale  $\frac{1}{200,000}$ , entitled "Atlas von Südwest Deutschland und dem Alpenlande," is very unsatisfactory. Scheda's general map of the Austrian Empire and adjoining territories, in 20 sheets, is an excellent compilation. It includes the Alps as far west as Monte Rosa and the lake of Thun, but the scale ( $\frac{1}{570,000}$ ) is inconveniently small.

Of geological maps including any considerable portion of the Alps the following deserve to be specified:—

Favre (A.), Carte Géologique des Parties de la Savoie, &c., Voisines du Mont Blanc. Gumbel, Geognostische Karte des Königreichs Bayern. Haner (F. von), Geologische Uebersichtskarte der Oesterreichischen Monarchie; sheets 5 and 6 include the Austrian Alps. Lory (C.), Carte Géologique du Dauphiné. Morlot, Uebersichtskarte der Nordöstlichen Alpen. Sismonda (A.), Carta Geologica di Savoia, Piemonte, e Liguria. Société Géologique de France, Carte Géologique de la Savoie. Studer (B.) u. Escher v. d. Linth, Carte Géologique de la Suisse. (J. B.)

ALPUJARRAS, or ALPUXARAS, a mountainous district in the south of Spain, in the province of Andalusia, lying between the Sierra Nevada and the Sierras Lugar and Contraviesa, and consisting principally of valleys, which descend at right angles from the crest of the Sierra Nevada. These valleys are among the most beautiful and fertile in Spain. They contain a rich abundance of fruit trees, especially vines, oranges, lemons, and figs, and in some parts present scenes of almost Alpine grandeur. The inhabitants are the descendants of the Moors, who vainly sought to preserve the last relics of their independence in their mountain fastnesses, and many of the names of places in the district are of Moorish origin. The principal villages are Lanjaron, Orgiba, Trevelez, and Ugijar, all situated at a considerable elevation—the highest, Trevelez, being 5333 feet above the sea—and containing from 1500 to 4000 inhabitants.

ALREDUS, ALURED, or ALUREDUS, of Beverley, one of the earliest English historians, was born at Beverley, in Yorkshire. He wrote in the reign of Henry I., but little is known with certainty of his life. It is generally believed that he was educated at Cambridge, and afterwards became one of the canons and treasurer of the church of St John's at Beverley. We learn from a note in Bishop Tanner's *Bibliotheca Brit.-Hib.* that, for the sake of improvement, he travelled through France and Italy, and at Rome became domestic chaplain to Cardinal Othoboni. He died in the year 1128 or 1129. His chief work, entitled *Annales sive Historia de gestis Regum Britannicæ*, was edited by Thomas Hearne from a manuscript belonging to Thomas Rawlinson, and was published at Oxford in 1716. It contains an outline of the history of England from Brutus to Henry I., written in elegant Latin, and with remarkable accuracy as to facts and dates, though, of course, much of the earlier portion is fabulous. A manuscript entitled *Libertates Ecclesiæ S. Johannis de Beverlæ*, in the Cottonian library, is also ascribed to him, but on doubtful authority. It is a collection of records relative to the church of Beverley, translated from the Saxon.

ALRESFORD (NEW), a market town in Hampshire, so named from a ford on the river Arle, a tributary of the Itchin, on which it is situated. It is 58 miles distant from London and 7 from Winchester. It suffered severely from a series of conflagrations, and partly on this account and from the decline of a small manufacture of linseys, it is now a place of little importance. Alresford House, the seat of

the Rodney family, is in the neighbourhood, and the naval hero of that name was interred in New Alresford church in 1792. Miss Mitford was a native of Alresford. Alresford is a station on the L. and S.-W. Railway. Population of the parish of New Alresford (1871), 1623.

ALSACE (Germ. *Elsass*), a former province of France, divided after the Revolution into the departments of Haut Rhin and Bas Rhin, and incorporated since the war of 1870 with the German empire. It is bounded on the north by the Rhine palatinate, on the east by the Rhine, on the south by Switzerland, and on the west by the Vosges Mountains; and it comprises an area of 3344 English square miles. The district possesses many natural attractions, and is one of the most fertile in central Europe. There are several ranges of hills, but no point within the province attains a great elevation. The only river of importance is the Ill, which falls into the Rhine after a course of more than 100 miles, and is navigable below Colmar. The hills are generally richly wooded, chiefly with fir, beech, and oak. The agricultural products are corn, flax, tobacco, grapes, and various other fruits. The country has a great wealth of minerals, silver having been found, and copper, lead, iron, coal, and rock-salt being wrought with profit. There are considerable manufactures, chiefly of cotton and linen. The chief towns are Mühlhausen and Colmar in the upper district, and Strasburg in the lower. The province is traversed from east to west by the railway from Strasburg to Nancy, and the main line north and south runs between Basle and Strasburg.

From a very early period and for many ages Alsace has been a disputed territory, and has suffered in the contentions of rival races. It formed part of ancient Gaul, and was therefore included in the Roman empire. The Romans held it nearly five hundred years, and on the dissolution of their power it passed under the sway of the Franks and of the early French monarchs, by whom it was governed until the time of Otho I., Emperor of Germany, who reigned about the middle of the 10th century. It was at that period that Alsace became German: its original population of Celtic tribes, which had been first Romanised and then further qualified by a Frankish element, was now to a great extent supplanted by a purely Teutonic stock. By Otho II. the province was erected into a landgraviate, and it subsequently came into the possession of the House of Austria, which succeeded in 1273 to the imperial dignity of Germany. This state of things continued until 1648, when a large part of Alsace was ceded to France by the treaty of Münster. In the war which preceded this peace (generally known as the Thirty Years' War) Alsace had been so terribly devastated by the French that the German emperor found himself unable to hold it. The population was greatly reduced in numbers, and much of the

and was left uncultivated. In the subsequent war between France and the empire of Germany, arising out of the attempt of Louis XIV. to seize Holland, that part of Alsace which remained to Germany was again overrun by the French. Although this war was terminated in 1678 by the treaty of Nimeguen, the French monarch was desirous of incorporating a still larger amount of Rhine territory; and accordingly, in 1680 he laid claim to a number of territories, belonging to princes of the empire, which he alleged had been dismembered from Alsace. It was ordered that these territories should be at once restored to that province under the crown of France, and several independent sovereigns were cited to appear before two chambers of inquiry which Louis had established at Brisack and Metz. The princes appealed to the German emperor and to the Diet; but the previous wars had so exhausted the power of the former that nothing could be done to resist the aggression. In 1681 the French troops under Louvois seized Strasburg, aided by the treachery of the bishop and other great men of the city. A further war broke out, but by the treaty of Ratisbon in 1684, Strasburg was secured to France. Again the war was renewed in 1688, and continued for nine years, when, at the peace of Ryswick, in 1697, another considerable portion of Alsace was ceded to France. Some remaining territories of small extent were acquired by the French after the revolution of 1789.

It will be seen from the foregoing sketch that Alsace was originally French, that it then became German, and then French again. From the middle of the tenth century, however, the population has in the main been Teutonic; and the French conquests of the seventeenth century, while modifying this element, still left it predominant. The people continued to use German as their native tongue, though the educated classes also spoke French. Protestantism was professed by a large number of the inhabitants; and in many respects their characteristics identified them rather with the race to the east than that to the west of the Rhine. In process of time, however, they considered themselves French, and lost all desire for re-annexation to any of the German States.

Alsace suffered a good deal in the war of 1870-71. The earlier battles of the campaign were fought there; Strasburg and other of its fortified towns were besieged and taken; and its people were compelled to submit to very severe exactions. The civil and military government of the province, as well as that of Lorraine, was assumed by the Germans as soon as they obtained possession of those parts of France, which was very shortly after the commencement of the war. The Alsatian railways were reorganised and provided with a staff of German officials. German stamps were introduced from Berlin; the occupied towns were garrisoned by the Landwehr; and requisitions on a large scale were demanded, and paid for in cheques which, at the close of the war, were to be honoured by whichever side should stand in the unpleasant position of the conquered. The people, notwithstanding their German origin, showed a very strong feeling against the invaders, and in no part of France was the enemy resisted with greater stubbornness. It was evident from an early period of the war, however, that Prussia was resolved to reannex Alsace to German territory. When the preliminaries of peace came to be discussed at Versailles in February 1871, the cession of Alsace, together with what is called German Lorraine, was one of the earliest conditions laid down by Count Bismarck and accepted by M. Thiers. This sacrifice of territory was afterwards ratified by the National Assembly at Bordeaux, though not without a protest from the representatives of the departments about to be given up; and thus Alsace once more became German. By the bill for the incorporation of Alsace and German Lorraine, introduced into the German Parliament in May 1871, it was provided that the sole and supreme control of the two provinces should be vested in the Emperor of Germany and the Federal Council until January 1st, 1873, when the constitution of the German empire was to be established. Bismarck admitted the aversion of the populace to Prussian rule, but said that everything would be done to conciliate the people. This policy appears really to have been carried out, and it was not long in bearing fruit. Many of the inhabitants of the conquered districts, however, still clung to the old connection, and on the 30th

of September 1872—the day by which the people were required to determine whether they would consider themselves German subjects and remain, or French subjects and transfer their domicile to France—45,000 elected to be still French, and sorrowfully took their departure. The German system of compulsory education of every child above the age of six was introduced directly after the annexation. The population in 1871 amounted to upwards of 1,060,000.

ALSEN, an island in the Baltic, situated off the coast of Schleswig, in the Little Belt. It formerly belonged to Denmark, but, as a result of the Danish war of 1864, was incorporated with Germany. Its area is 105 square miles; the length nearly 20, and the breadth from 3 to 12 miles. The island is fertile, richly wooded, and yields grain and fruit. Sonderburg, the capital, a town of 5475 inhabitants, with a good harbour and a considerable trade, is situated on the narrow channel that separates Alsen from the mainland. Population, 22,500.

ALSOP, VINCENT, a celebrated Nonconformist divine, was educated in St John's College, Cambridge. He received deacon's orders from a bishop, whereupon he settled as assistant-master in the free school of Oakham, Rutland. He was recovered from indifferent associates here by a very worthy minister, the Rev. Benjamin King. Subsequently he married Mr King's daughter, and "becoming a convert to his principles, received ordination in the Presbyterian way, not being satisfied with that which he had from the bishop." He was presented to the living of Wilby in Northamptonshire; but was thence ejected by the Act of Uniformity in 1662. After his ejection he preached privately at Oakham and Wellingborough, sharing the common pains and penalties of Nonconformists—e.g., he was imprisoned six months for praying with a sick person. A book against Sherlock, called *Antisozzo* (after Socinus), written in the vein of Andrew Marvell's *Rehearsal Transposed*, procured him much celebrity as a wit. Dr Robert South, who cannot be supposed to have been favourably disposed towards the Nonconformists, publicly pronounced that Alsop had the advantage of Sherlock in every way. Besides fame, *Antisozzo* procured for its author an invitation to succeed the venerable Mr Cawton in Westminster. He accepted the call, and drew great multitudes to his chapel. The other books he published showed a fecundity of wit, a playful strength of reasoning, and a provoking indomitableness of raillery. Even with Dr Goodman and Dr Stillingfleet for antagonists, he more than held his own. His *Mischief of Impositions* in answer to the latter's *Mischief of Separation*, and *Melius Inquirendum* in answer to the former's *Compassionate Inquiry*, remain historical landmarks in the history of Nonconformity. Later on, from the entanglements of a son in alleged treasonable practices, he had to sue for and obtained pardon from King James II. This seems to have given a somewhat diplomatic character to his closing years, inasmuch as, while remaining a Nonconformist, he had a good deal to do with proposed political-ecclesiastical compromises. He died May 8, 1703.

(A. B. G.)

ALSTED, JOHANN HEINRICH, a German Protestant divine, and one of the most voluminous writers of the 17th century, was born in 1588. He was some time professor of philosophy and divinity at Herborn, in the county of Nassau, and afterwards at Weissenburg in Transylvania, where he continued till his death in 1638. His *Encyclopadia*, the most considerable of the earlier works of that class, was long held in very high estimation. It was published in 1630, in two large folio volumes, the whole having been composed by himself. His *Thesaurus Chronologicæ* has gone through several editions. He published in 1627 a treatise, *De Mille Annis*, in which he asserted

that the reign of the saints on earth was to begin in 1694.

ALSTON, CHARLES, M.D., a botanical and medical writer, was born in the west of Scotland in the year 1683. He began his studies at the university of Glasgow; and on the death of his father, prosecuted them under the patronage of the Duchess of Hamilton. After studying at Leyden under Boerhaave, along with Alexander Monro (1716-19), he returned to Edinburgh, and shared with Monro, Rutherford, Sinclair, and Plummer, the honour of laying the foundation of the renowned school of medicine there. He lectured on botany and materia medica with increasing reputation till his death in November 1760. He was a man of great ability, and an assiduous student of science. His most valuable work is his *Lectures on Materia Medica*, 2 vols., 1770.

ALSTROEMER, JONAS, a Swedish industrial reformer, was born at Alingsaas, in West Gothland, on the 7th Jan. 1685. He left his native village at an early age, and in 1707 became clerk to Alberg, a merchant of Stockholm, whom he accompanied to London. After carrying on business for three years, Alberg failed, and Alström (as the clerk then called himself) engaged in the business of shipbroker on his own account, which eventually proved very successful. After travelling for several years on the Continent, he was seized with the patriotic desire to transplant to his native country some of the industries he had seen flourishing in Britain. He accordingly returned to Alingsaas, and in 1724 established a woollen factory in the village, which after preliminary difficulties was completely successful. He next established a sugar refinery at Gothenburg; introduced improvements in the cultivation of potatoes and of plants suitable for dyeing; and directed attention to improved methods in shipbuilding, tanning, and the manufacture of cutlery. But his most successful undertaking was the importation of sheep from England, Spain, and Angora. In return for his services he received many marks of distinction. He was created (1748) knight of the order of the North Star; and a few years later received letters of nobility, with permission to change his name to Alströmer. He died June 2, 1761, leaving several works on practical industrial subjects. A statue was erected to his honour in the exchange at Stockholm. One of his sons, Clas (*i.e.*, Claude), was a naturalist of considerable eminence.

ALT, or ALUTA, a tributary of the Danube, which, rising in the eastern Carpathian mountains, flows through Transylvania and Wallachia, entering the latter by the pass of Rothenthurm, and joins the Danube opposite Nicopoli, after a course of more than 300 miles.

ALTAI MOUNTAINS, a group of mountains in central Asia, separating the table-lands of Mongolia from Siberia. The irregular chains of which the group consists extend from 85° to 103° E. long., and from 48° to 34° N. lat. The great Siberian rivers, the Obi, Irtish, and Yenesei, take their rise in these mountains, which are said to abound in scenes of picturesque beauty. The highest summits exceed 12,000 feet. The range is rich in mineral productions, particularly silver, copper, and iron. See ASIA, and GEOGRAPHY, PHYSICAL.

ALTAMURA, a cathedral town in the south of Italy, province of Terra di Bari, 28 miles S.W. of Bari. It is situated in a fertile country, which produces wine and oil, and is said to occupy the site of the ancient *Lupatia*. Population, 17,365.

ALTAR, in *Classical Antiquity*, was a solid base or pedestal on which supplication was made and sacrifice offered to the gods and deified heroes. According to this difference in the service for which they were employed, altars fell into two classes, of which the one, smaller and

lower so that the suppliant could kneel upon it, stood inside temples, in front of the sacred image; while the other, destined for burnt sacrifice, was placed in the open air, and, if connected with a temple, in front of the entrance. Possibly altars of the former class were substitutes for, and rendered the same service in historical times as, in an early age, the base of the sacred image within a temple. In this case the altar of Apollo at Delphi, on which Neoptolemus is frequently represented on the Greek vases as taking refuge from Orestes, might be regarded as the pedestal of an invisible image of the god, and as fulfilling the same function as did the base of the actual image of Minerva in Troy, towards which Cassandra fled from Ajax. The other class of altars, called *βωμοί* by the Greeks and *altaria* by the Romans, appear to have originated in such temporary constructions as heaps of earth, turf, or stone, made as occasion offered for kindling a fire for sacrifice. The next step was

FIG. 1.—Greek altar: usual form.

to allow the bones and ashes of the victims sacrificed to accumulate, and upon this to kindle new fires. Altars so raised were viewed with particular sanctity, the most remarkable recorded instances of them being the altars of Juno at Samus and at Olympia (Pausanias, v. 14, 5; v. 15, 6), of Apollo at Thebes (Pausanias, ix. 11, 5), and of Jupiter at Olympia. The last-mentioned stood on a platform (*πρόθυσος*) measuring 125 feet in circumference, and led up to by steps, the altar itself being 22 feet high. Women were excluded from the platform. Where hecatombs were sacrificed, the *πρόθυσος* necessarily assumed colossal proportions, as in the case of the altar at Parion, where it measured on each side 600 feet. The altar of Apollo at Delos (*ὁ κεράτινος βωμός*) was made of the horns of deer believed to have been slain by Diana; while at Miletus was an altar composed of the blood of victims sacrificed. The altar used at the festival in honour of Dædalus on Mount Cithæron was of wood, and was consumed along with the sacrifice (Pausanias, ix. 3, 2). Others, of bronze, are mentioned; but while these were exceptional, the usual material of an altar was marble, and its form, both among the Greeks and Romans, either square or round; polygonal altars, of which examples still exist, being exceptions. When sculptured decorations were added they frequently took the form of imitations of the actual festoons with which it was usual to ornament altars, or of symbols, such as crania and horns of oxen, referring to the victims sacrificed. As a rule, the altars which existed apart from temples bore the name of the person by whom they were dedicated, and the names of the deities in whose service they were; or, if not the name, some obvious representation of the deity. Such is the purpose of the figures of the Muses on an altar to them in the British Museum. An altar was retained for the service of one particular god, except where, through local tradition, two or more deities had become intimately associated, as in the case of the altar at Olympia to Diana and Alpheus jointly, or that of Neptune and Erechtheus in the Erechtheum at Athens, and others. Such deities were styled

FIG. 2.—Polygonal Greek Altar

Greek and Roman Altars.

*τύμβωμοι*, each having a separate part of the altar, if we may judge from that at the Amphiareum at Oropos (Pausanias, i. 34, 2). Deities of an inferior order, who were conceived as working together—*e.g.*, the wind gods—had an altar in common. In the same way, the “unknown gods” were regarded as a unit, and had in Athens and at Olympia one altar for all (Pausanias, i. 1, 4; v. 14, 5; Acts of Apostles, xvii. 18). An altar to all the gods is mentioned by Æschylus (Suppl. v. 225). Among the exceptional classes of altars are also to be mentioned those on which fire could not be kindled (*βωμοὶ ἄπυροὶ*), and those which were kept free from blood (*βωμοὶ ἀναίμακτοι*), of which in both respects the altar of Zeus Hypatos at Athens was an example. The *ἐστία* was a round altar; the *ἔρχαρα*, one employed apparently for sacrifice to inferior deities or heroes, or on comparatively unimportant occasions, as was also the *ara* among the Romans; though *ara* is sometimes used with the same signification as *altare*, and etymologically would have the same meaning if it is correctly derived from *ἀέρω*, not from *ardere*; while *altare* is connected with *altus*, “high.”

Egyptian altars were monoliths, in the form of a truncated cone about four feet in height. Some are extant, made of granite, others of green basalt; in almost every case they bear hieroglyphical inscriptions. In the temple of Jupiter at Babylon there was an altar of massive gold. Assyrian, Egyptian, and Persian altars were either square or oblong.

The most ancient altars of which any record has been preserved are those mentioned in the Bible. As sacrifice implies an altar, there must have been altars for those of Cain and Abel; but the first which is mentioned is that which Noah after the flood “built unto Jehovah” (Gen. viii. 20). The three patriarchs, Abraham, Isaac, and Jacob, are repeatedly said to have built an altar in the different parts of the land of Canaan in which they sojourned; and though it is not stated expressly, yet it may be inferred from there having evidently been a place where Abraham was accustomed to “stand before Jehovah” (*ibid.* xix. 27), that, once built, it remained during the whole period of the encampment at the particular place, and was frequently used for the purpose of sacrificing.

But the most remarkable altar mentioned in the book of Genesis is that which Abraham built for the sacrifice of his son Isaac, from which we glean several particulars relative to the patriarchal worship. The altar was evidently something distinct from the wood by whose fire the sacrifice was to be burnt, for Abraham “built an altar and laid the wood in order,” which he had brought with him from Beersheba, as if he could not count upon finding it at the place. The victim also was bound, laid upon the wood, and there slain. This was contrary to the practice under the Levitical dispensation, when the fire on the top of the altar was kept continually burning, and the animal was killed before being carried up to it; but it is probably alluded to in a verse of the Psalms, which has given much trouble to commentators who have tried to reconcile it with the precepts of the Mosaic law—“Bind the sacrifice with cords unto the horns of the altar” (Ps. cxviii. 27). To this simple patriarchal ritual belong also the rules about the construction of altars given to the Israelites shortly after they left Egypt (Exod. xx. 24–26). While sojourning in that country they do not seem to have offered any sacrifice to Jehovah, till, just as they were leaving it, they were commanded to sacrifice the passover. It is not unlikely that they might have despised the simple altars of their forefathers, and tried to imitate those which they had seen in Egypt, as they so soon copied their late oppressors in a still graver matter, the making a supposed likeness of the Deity. They were therefore ordered to make their altars of earth. Stones might also be used,

but they were not to be hewn, nor were the altars to be so high as to require the offerer to go up by steps to arrange the sacrifices upon them.

The first altar that is mentioned as having been built after these directions were given, was the one for the solemn covenanting sacrifice between God and the Israelites (Ex. xxiv. 4–8). There it is mentioned that Moses “built an altar under the hill, and twelve pillars, according to the twelve tribes of Israel.” Its being *under* the hill may have been a significant protest against the prevalent heathen error of localising the Deity in the sky, and the twelve pillars or rough blocks of stone appear to have been a principal part of the materials used in constructing it. They may be compared with the “twelve stones, according to the number of the tribes of the sons of Jacob,” with which Elijah built his altar on Carmel (1 Kings xviii. 31). We seem to learn from these examples that when an altar was to be constructed for a special occasion, it was fitting that it should bear a symbolism of all in whose name the sacrifice was offered. It is to be observed that this precept about making altars of earth or of unhewn stones was anterior to the Levitical ceremonial, and was superseded by it. After the sin of making the golden calf, the whole ceremonial of the worship of the Israelites was altered. According to the new ritual, two different altars were required, and they were permanent, being carried about in the people’s wanderings, and replaced by others, similar, but larger and more costly, when the ark was placed in the temple on Mount Moriah.

The first of these altars was that for *burnt offerings*. For the tabernacle this was hollow, made of boards of shittim-wood, covered with brass. It was three cubits or about five feet high, and five cubits or eight feet square. It had a horn at each corner, and was carried about by means of staves. The corresponding altar in the temple was of greatly larger dimensions, ten cubits or about 18 feet high, and in the first temple 20 cubits square, and in the second 24 cubits. The tradition of the Jews is, that it was 32 cubits (about 50 feet) square at the base, contracting to 24 at the top, by several ledges round it at different heights. It must therefore have been an immense structure, and though called “an altar of brass,” was probably built of stones, and merely covered with plates of that metal. From the account of the building of the altar in the second temple given in 1 Macc. iv. 45–47, it is probable that it consisted merely of a mass of masonry of the proper form. Ezekiel, in his vision of the temple, gives a description of the altar of burnt-offerings, from which we learn that it was surrounded by several ledges or steps, each a cubit broad. The uppermost of these was two cubits (about 3 feet) below the top of the altar, so that, standing upon it, the priest was able to arrange the sacrifice upon the fire, which was kept always burning, to supply it with fuel, and to remove the ashes. The lower ledges were to enable him to sprinkle the blood on the sides of the altar, which (according to the Levitical ritual) was sometimes to be done on the upper part of the altar, and sometimes on the lower part. The lowest step is said to have had a raised ledge on the outside, by which the blood poured upon it was confined till it ran through a hole into a subterranean pipe.

One of the most difficult questions about the Levitical altars is their having horns; for these do not seem to have been used in that ritual, yet they are specially ordered to be made, not only in the altar of burnt-offerings, but also in that of incense; and on certain solemn occasions they were sprinkled with blood, as if they were not mere appendages or ornaments of the altar, but had a special significance of their own. From the way they are spoken of in the book of Exodus, we see that they must then have been

well known, and it might almost be thought that they were retained from the older ritual, according to which they were used to bind the victim that was slain upon the altar.

The second temple having suffered greatly in the wars between the kings of Syria and Egypt, and been plundered by the Romans, was almost rebuilt by Herod, the restoration occupying forty-six years. The altar of burnt-offering erected then is thus described by Josephus (*De Bell. Jud.* v. 5, 6):—"Before this temple stood the altar, 15 cubits high, and equal both in length and breadth, each of which dimensions was 50 cubits. The figure it was built in was a square: it had corners like horns, and the passage up to it was by an insensible acclivity from the south. It was formed without any iron tool, nor did any iron tool so much as touch it at any time." A pipe was connected with the south-west horn, through which the blood of the victims was discharged by a subterraneous passage into the brook Kedron. Under the altar was a cavity to receive the drink-offerings. This was covered with a marble slab, and cleansed from time to time. On the north side of the altar several iron rings were fixed to fasten the victims. Lastly, a red line was drawn round the middle of the altar to distinguish between the blood that was to be sprinkled above and below it.

The second altar belonging to the Jewish worship was the altar of incense, the golden altar (Ex. xxx. 1). It was placed in the holy place, between the table of shew-bread and the golden candlestick. This altar, in the tabernacle, was made of shittim-wood overlaid with gold plates, 1 cubit in length and breadth, and 2 cubits in height. It had horns of the same materials; and round the flat surface was a border of wrought gold, underneath which were the rings to receive "the staves, made of shittim-wood overlaid with gold, to bear it withal;" (Exod. xxx. 1-5; Joseph. *Antiq.* iii. 6, 8). The altar in Solomon's temple was similar in form, but made of cedar overlaid with gold (1 Kings vi. 20). It is a question whether it was hollow or filled up with stones, the construction of the Hebrew being doubtful, but the former supposition appears the more probable. The altar in the second temple was taken away by Antiochus Epiphanes (1 Macc. i. 21), and restored by Judas Maccabæus (1 Macc. iv. 49). The archangel Gabriel stood at the right side of this altar when he announced the birth of John the Baptist to Zacharias, who was burning incense upon it (Luke i. 11); and it is alluded to in the vision shown to St John (Rev. viii. 3), where it is immediately "before the throne," the veil, which under the Mosaic dispensation had separated it from the holy of holies, having been rent asunder at the crucifixion.

On this altar incense was offered twice every day, and this was the only use of incense under the Levitical ritual; for though the word "censer" is repeatedly used in our common translation of the Old Testament, neither in the Hebrew nor the Greek has the word any connection with incense, but denotes the fire-pan in which the burning charcoal was carried from the brazen altar to be emptied out upon that of incense. The true equivalent for censer is only used of sinful or heathen worship (2 Chron. xxvi. 14; Ezek. viii. 11, and perhaps 2 Chron. xxx. 14). The fire-pans used as censers in the story of Korah, and of the atonement subsequently made by Aaron burning incense among the people, do not belong to the Levitical ritual, but were to prove whether it was to be observed or not.

The single exception to the exclusive use of the golden altar for incense was on the great day of atonement, when the high priest went into the holy of holies, carrying a fire-pan containing lighted charcoal from the great altar, and having set it down, threw incense upon it, and left it for some time before the ark while he went and came

back once and again to sprinkle it with the blood of the sacrifices. This fire-pan is accordingly called a golden censer by the author of the Epistle to the Hebrews (ix. 4); but even this is no precedent for the swinging censers which have been used for so many centuries in the Latin churches. Incense, indeed, was put on the loaves of shew-bread; but it does not appear that it was burned upon that table, which is nowhere called an altar. More probably, when the loaves were taken away, the incense was burnt on the proper altar. But the shew-bread was so completely special an appointment of the Mosaic ritual that it is impossible to class it among sacrifices.

Among the early Christians, alike in the East and West, that on which the bread and wine were put in the celebration of the Eucharist appears to have been regarded as an altar, and accordingly sacrificial words were used in connection with it, such as "offering," "unbloody sacrifice." It should be observed, however, that the Greek fathers scarcely ever apply the word *βωμός* to Christian altars, confining themselves to *θυσιαστήριον*; while in the West there seems to have been a preference for *altare* rather than *ara*, though the latter term is often found. As the Christians generally shrunk from disclosing to the heathen the details of their worship, their enemies used to taunt them with having neither temples nor altars, and some of the apologists admit this; but all they meant by this was that they had no such altars as the heathen had, altars for slain beasts and for the burning of their bodies.

From the privacy with which the early believers had to meet, their altars at first would naturally be simple and unobtrusive. We have seen that the Levitical altars were four-square, but Christian altars seem to have been always longer than they were broad, and to have been placed "athwart" the length of the basilica or church, so as to present one of the broad sides and both the sacred vessels to the eyes of the great body of the worshippers.

There does not seem to have been any rule as to the material of which altars might be made. At first they appear to have been mostly of wood, as being easily procured and fashioned. But when the persecutions ceased, and the Christians began to erect churches for worship, there seems to have sprung up some diversity of usage, each province following its own traditional custom, which perhaps was affected in some degree by the nature of the building-stone found there, and the use commonly made of it. It seems that in Egypt and the region afterwards called Barbary the altars were of wood; and there is a tradition that this was also the case originally at Rome. On the other hand, in the latter half of the 4th century, they were made of stone in Asia Minor. Early in the 6th century a council, held at Epaone in Burgundy, ordered that only altars made of stone should be consecrated with the chrism, which shows that wooden altars also were still made in that province. In England the change from wood to stone seems to have taken place about the time of the Norman Conquest, Wulfstan, bishop of Worcester, being mentioned as having introduced it in his diocese. No doctrinal significance can be ascribed to the change, which was simply in keeping with the greater costliness of the whole structure, when the cessation of the invasions of the Scandinavian sea-kings allowed the nations of Western Europe to accumulate wealth, of which a portion was dedicated to religion. A few exceptional instances are mentioned of altars of silver, and they were sometimes even covered in part with plates of gold; but the current set in steadily in favour of stone as the most suitable material, and by degrees the legislation of the Latin church on this point grew more definite. The altar could only be of stone; not that it was necessary that the whole structure should be so, for it was enough if there was a slab of

stone on the top large enough for the sacred vessels to stand upon; the upper face of the altar must have five crosses incised in the stone; before being used, it must have been consecrated by the bishop with the chrism, according to the ritual prescribed in the pontificals, which by degrees grew more elaborate; and at first a plain cross, and afterwards a crucifix, was placed erect upon it.

At the Reformation the altars in churches were looked upon as symbols of the old Catholic doctrine, in those countries where the struggle lay between the Catholics and the "Reformed" or Calvinists, who on this point went much further than the Lutherans. In England the name "altar" was retained in the Communion Office in English, printed in 1548, and in the complete English Prayer-book of the following year, known to students as the First Book of Edward. But orders were given soon after that the altars should be destroyed, and replaced by movable wooden tables; while from the revised Prayer-book of 1552 the word "altar" was carefully expunged. The short reign of Mary reversed all this, but the work was resumed on the accession of Elizabeth, and has been carried out so thoroughly that the industry of recent antiquaries has only been able to find about thirty cases in all England where the old stone altar-slabs still exist, and of these that at Arundel is almost the only one which is still used.

The name "altar" has been all along retained in the Coronation Office of the kings of England, where it occurs frequently. It was also recognised in the canons of 1640, and an important change was then made in the position of the communion tables, which has become universal throughout the Church of England. In primitive times the position of the Christian altar seems to have been such that, like the Jewish and patriarchal altars, they could be surrounded on all sides by the worshippers. The chair of the bishop or celebrant was on their west side, and the assistant clergy were ranged on each side of him. But in the Middle Ages the altars were placed against the east wall of the churches, or else a screen, called a *reredos* (generally much decorated with carving), was erected close to the east of the altar, so as to cut off any one on that side from joining in the worship, and the celebrant was brought round to the west side, to stand between the people and the altar; while there were often curtains on the north and south sides. When tables were substituted for altars in the English churches, these were not merely movable, but at the administration of the Lord's Supper were actually moved into the body of the church, and placed table-wise as it was called—that is, with the long sides turned to the north and south, and the narrow ends to the east and west—the officiating clergyman standing at the north side. In the time of Archbishop Laud, however, the present practice of the Church of England was introduced. The communion table, though still of wood and movable, is, as a matter of fact, never moved; it is placed altar-wise—that is, with its longer axis running north and south, and close against the east wall, with for the most part a *reredos* behind it; it is also fenced in by rails, within which the laity do not enter.

When, under the superintendence and partly at the charge of the Camden Society, the church of Saint Sepulchre at Cambridge, founded 1101, was restored, a stone altar, consisting of a flat slab resting upon three other upright slabs, was presented to the parish, and set up in the church at the east wall of the chancel. This circumstance was brought before the Court of Arches in 1845, and Sir H. Jenner Fust (*Faulkner v. Lichfield and Stearn*) ordered it to be removed, on the ground that a stone structure so weighty that it could not be moved, and seeming to be a mass of solid masonry, was not a communion-table within the meaning of the Church of England. No attempt

has been made to obtain a reversal of this judgment; but from other decisions some infer that only such altars as cannot also be considered as tables are forbidden.

Few particulars have come down to us regarding the construction of the wooden altars used by the Christian Church in early times, except that several circumstances indicate that they were hollow. Gregory of Tours applies the word "arca" or "chest" to them; and in other cases they must have been simply like ordinary tables supported by legs, since we read of persons taking refuge beneath them. There is nothing, therefore, either in the matter or the form of the ordinary English communion-tables, to prevent them serving as altars. The stone altars at first were probably only one or more blocks of rough hewn stone; but by degrees they were ornamented, and this produced two different types. Either the altar remained a solid mass of masonry, but had its front richly panelled (in later times it had figures in bas-relief), or the upper slab was supported by from one to five columns, often of highly-polished stone. It was in the 16th century that a new fashion was introduced in France, according to which the altar was regarded as being itself a tomb or sarcophagus, and to which are due the unsightly altars which now disfigure the wonderfully beautiful mediæval churches of that country. So complete was the change, that now, perhaps, there are not more ancient altars in France than there are in England.

In early times, before the altars were placed close to the east wall or to a large *reredos*, they were often surmounted by a canopy or baldacchino, supported by four pillars rising from the ground just beyond the corners of the altar.

At first there was but one altar in a church; but for many centuries this rule has been disregarded in the Latin churches, and almost every large church contains several altars dedicated in honour of different saints, and sometimes appropriated to the use of particular guilds, or endowed for a series of masses for the repose of the founder. These, however, must not be confounded with the principal altar, called the high altar or *maître autel*, situated towards the east end of the choir or chancel. A few cases occur where there are two high altars, the second being placed near the west end of the church.

Altars are "vested" during service; that is, covered with cloths of various kinds. There is often a frontal, richly embroidered, whose colour depends upon the ecclesiastical season or the particular festival; but in all cases the uppermost cloth on the top is of linen, to represent that in which the body of the Lord was wrapped in the sepulchre.

Since the age of Bede, portable altars have been used in the Latin Church; but the East has never adopted them, and they quite put out of sight the symbolism of the form of an altar. They consist simply of a small slab of stone, large enough to support the chalice and paten. This must bear the incised crosses and must have been consecrated by the bishop. They may be carried about on a journey by a bishop or priest in a heathen or heretical country, as now it is not allowed to say mass except on a duly consecrated altar, and they are also used in oratories attached to private houses.

Those who wish to investigate the matter further may be referred to the standard works on church ritual and ecclesiastical architecture. For the altars of the Israelites, much information will be found in Lightfoot's two treatises on the Temple Service, and in Carpzov's notes to his translation of Godwin's *Moses and Aaron*. Christian altars are described by Bona, Martene, and Bingham; but the standard work on the subject is probably that by the Lutheran Voigt, published after his death by J. A. Fabricius. Nearly twenty years ago an Essay on Christian Altars, by Laib

and Schwartz, appeared at Rottenburg; while for France, the Abbé Thiers' Dissertation on the subject is full of curious information, like all his works. Drawings of mediæval altars which have been preserved will be found in many works on architecture. Parker's *Glossary* gives the most noticeable preserved in England; but the *Dictionnaire de l'Architecture* of Viollet le Duc is much superior, and, with its beautiful illustrations and careful descriptions, has nearly exhausted the subject so far as regards French examples, to which it is almost exclusively confined.

(G. H. F.)

ALTDORF, or ALTORF, a town in Switzerland, capital of the canton of Uri, situated at the northern end of the pass of St Gotthard, near the lake of Lucerne. It contains the oldest Capuchin monastery in Switzerland, but is otherwise of little interest, except as the place pointed out by tradition where William Tell shot the apple from his son's head. The lime tree, under which it is alleged the boy stood, has disappeared, but a fountain still marks the spot. There is also an old tower, with rude frescoes commemorating the feat. Bürglen, a village in the neighbourhood, is Tell's reputed birthplace. Population, 2724.

ALTDORFER, ALBRECHT, a painter and engraver of the early German school, was born at Regensburg, not later than 1480, and died in 1538. His paintings are remarkable for minute and careful finish, and for close study of nature. The most important of them are to be found in the Pinakothek at Munich. A representation of the battle of Arbela, included in that collection, is usually considered his chief work. His engravings on wood and copper are very numerous, and rank next to those of Albert Dürer.

ALTENBURG, a town in Germany, capital of the duchy of Saxe-Altenburg, situated near the river Pleisse, about 24 miles south of Leipsic. The town, from its hilly position, is irregularly built; but many of its streets are wide, and contain a number of large and beautiful buildings. Its ancient castle is picturesquely situated on a lofty rock, and is memorable as the place from which, in 1455, Kunz von Kaufungen carried off the young princes Albert and Ernest, the founders of the present royal and ducal families of Saxony. Altenburg is the seat of the higher courts of the duchy, and possesses a cathedral and several churches, a gymnasium, a library, a gallery of pictures and a school of art, several elementary schools, an infirmary, and various learned societies. There is considerable traffic in grain and cattle brought from the surrounding district; twice a year there are large horse fairs; and the book trade is extensive. Cigars, woollen goods, gloves, hats, and porcelain are among the chief manufactures. Population (1871), 19,966.

ALTEN OETTING, or ALTOETTING, a small market town in Upper Bavaria, situated on the Mörn, not far from its junction with the Inn. It has long been famous as a place of pilgrimage to which Roman Catholics resort in very large numbers, especially from Austria, Bavaria, and Swabia, on account of a celebrated image of the Virgin Mary in one of the churches. Another church contains the tomb of Tilly. Population, 1500.

ALTENSTEIN, a castle upon a rocky mountain in Saxe-Meiningen, on the south-western slope of the Thüringer Wald, not far from Eisenach. It is the summer residence of the dukes of Meiningen, and is surrounded by a noble park, which contains, among other objects of interest, a remarkable underground cavern, 500 feet long, through which flows a large and rapid stream. Boniface, the apostle of the Germans, lived and preached at Altenstein in 724; and near the castle is the place from which, in 1521, Luther was seized, to be carried off to the Wartburg. There used to be an old beech called "Luther's

tree," which association connected with the Reformer, but it was blown down in 1841, and a small monument now stands in its place.

ALTIN, a lake of Siberia, which gives rise to the Bija, one of the head streams of the Obi, is situated among the Altai mountains, 320 miles south of the city of Tomsk. It is about 80 miles long, and its greatest breadth is about 50 miles; but the large quantities of melted snow which flow down from the surrounding mountains make it larger in summer than in winter. It is remarkable that in winter the northern part is frozen so hard as to be passable on sledges, while the southern is never covered with ice.

ALTING, HEINRICH, a German divine, was born at Embden in 1583. His father, Menso Alting, was minister of Embden, and early destined his son to the same profession. He studied with great assiduity and success at the universities of Herborn and Gröningen. In 1608 he was appointed tutor of Frederick, afterwards elector-palatine, at Heidelberg, and in 1612 accompanied him to England. Returning in 1613 to Heidelberg after the marriage of the elector with the Princess Elizabeth of England, he was appointed professor of theology, and in 1616, director of the *Collegium Sapientie*. In 1618, along with Scultetus, he represented the university in the synod of Dort. When Count Tilly took the city of Heidelberg, and handed it over to plunder, Alting found great difficulty in escaping the fury of the soldiers. He first retired to Schorndorf; but in 1623 he removed with his family to Embden, and afterwards followed to the Hague his late pupil, the Elector Frederick, who had been compelled to flee from his new kingdom of Bohemia. Such was the regard this prince had for Alting that he made him preceptor to his eldest son, and prevented him from accepting the charge of the church at Embden, and likewise a professorship in the university of Franeker. In 1627, Alting, with some difficulty, obtained leave from his patron to remove to Gröningen, where he was appointed to the chair of divinity; and there he continued to lecture, with increasing reputation, until his death, which took place in 1644. Alting was a man of great ability and extensive learning. Among the productions of his pen are:—*Note in Decadem Problematum Jacobi Behm*, Heidelberg, 1618; *Scripta Theologica Heidelbergensia*, Amst. 1662; *Exegesis Augustanæ Confessionis*, Amst. 1647.

ALTING, JACOB, son of the preceding, was born at Heidelberg in 1618. He studied theology and the Oriental languages at Gröningen, and in 1638 he put himself under the tuition of a Jewish rabbi at Embden. In 1640 he went to England, and was admitted to clerical orders by Dr Prideaux, bishop of Worcester; but an offer of the Hebrew professorship in the university of Gröningen induced him to return to Holland in 1643. In 1667 he was appointed professor of theology in the university. In this office he gave great offence to his colleague, Samuel Desmarets, by his disuse of the scholastic method of teaching. Desmarets preferred a charge of heresy against him; but the divines at Leyden pronounced that Alting was not guilty of anything more serious than imprudent fondness for innovation. Alting died of a fever in 1679. The fondness which he showed for rabbinical learning gave birth to the general report that he was inclined to become a Jew. His opinions, which seem to have excited more general attention than they deserve, may be seen in his writings, which were collected a few years after his death, and published in five volumes folio, by his pupil, the well-known Balthasar Bekker.

ALTON, a town of Hampshire, on the Wey, 17 miles E. of Winchester, and 47 S.W. of London by road; by the London and South-Western Railway it is 60 miles from London. Large markets and fairs are held for corn, hops,

cattle, and sheep; and the town contains some highly reputed ale breweries, besides paper manufactories and an iron foundry. The church, a fine old building, was the scene of a fierce conflict between the royalist and parliamentary troops in 1643. Population in 1871, 4092.

ALTON, a town in Madison county, Illinois, United States, stands on a high bluff on the left bank of the Mississippi, 21 miles above St Louis, and 3 above the mouth of the Missouri. It is a place of considerable importance, and carries on a thriving export trade in the produce of the surrounding country—grain, hay, fruit, coal, and lime. It has an excellent wharf, and good means of communication by railway, the two great lines from Chicago and Indianapolis having their junction at Alton. The town contains a Roman Catholic cathedral, about ten other churches belonging to various sects, and several schools. It has also a printing trade, with daily and weekly newspapers. Population in 1870, 8665.

ALTONA, the richest and most populous city of the Prussian province of Schleswig-Holstein, is situated on the north bank of the Elbe, so close to Hamburg that the two cities are virtually one. The rise of Altona to its present position has been rapid, at least for a continental city, and is mainly due to the fostering care of the Danish government, who established it as a rival to Hamburg. In 1640, when it became the property of Denmark, it was a small fishing village; in 1871 it contained 74,131 inhabitants. After the war of 1864 it ceased to belong to Denmark, and eventually became part of Prussia, although, with Hamburg, it is not included in the Zollverein. It carries on a large trade with Britain, France, the West Indies, and other countries; but it has by no means succeeded in depriving Hamburg of its commercial pre-eminence—great part of the business of Altona being, indeed, transacted on the Hamburg exchange. Tobacco is probably the chief manufacture, but there are also breweries, tanneries, oil-works, soap-works, and linen factories. Altona is a well-built modern town, really dating from 1713 (when the Swedes burnt it to the ground), with a higher situation than that of Hamburg, and consequently a purer and healthier atmosphere. It contains an observatory of some celebrity, several churches, two synagogues, a gymnasium, and an infirmary. It is the terminus of the Altona-Kiel Railway, which places it in connection with the principal towns of Schleswig-Holstein.

ALTOONA, a town of the United States, in Blair county, Pennsylvania, on the Central Railway, 244 miles west of Philadelphia, situated near the eastern base of the Alleghany Mountain, where the railroad begins to ascend it. It contains extensive locomotive and railway carriage manufactories belonging to the Pennsylvania Central Railway Company. Near Altoona is the famous "Horse Shoe Bend," where trains of but ordinary length are seen to be moving in opposite directions at the same time. The line of railway, in its ascent between Altoona and Cresson, winds round the side of the mountain, affording some of the finest mountain scenery on the continent. Population in 1870, 10,610.

ALTO-RILIEVO (*high relief*) is the term applied to sculpture that projects from the plane to which it is attached to the extent of more than one-half the outline of the principal figures. It is thus distinguished from *basso-rilievo*, in which there is a greater or less approximation to the pictorial method, the figures being made to appear as projecting more than half their outline without actually doing so. See RELIEF and SCULPTURE.

ALTRINGHAM, or ALTRINCHAM, a market town in the north of Cheshire, 8 miles south of Manchester, with which it is connected by railway. It is a neat, clean place, surrounded by villas of Manchester manufacturers, who

are attracted by its healthy climate and pleasant situation. It has no parish church, but there is a chapel of ease belonging to the parish of Bowdon, in which it is situated, and also a Roman Catholic and several dissenting places of worship. Yarn, worsted, and cotton are the chief manufactures; and large quantities of fruit and vegetables are sent to the Manchester market. Population in 1871, 8478.

ALUM, a compound salt employed in dyeing and various other industrial processes. It is soluble in water, has an astringent, acid, and sweetish taste; reddens vegetable blues, and crystallises in regular octahedrons. When heated, it liquefies; and if the heat be continued, the water of crystallisation is driven off, the salt frothes and swells, and at last a white matter remains, known by the name of *burnt alum*.

Its constituents are sulphuric acid, alumina, an alkali, and water. The alkali may be either *potash*, *soda*, or *ammonia*. Hence there are three distinct species of alum, depending upon the nature of the alkali which each contains. *Potash alum* (in which the alkali is potash) is the common alum of this country, although both soda alum and ammoniacal alum are manufactured. The term alum is now used in chemistry as a generic one, and is applied to the class of double salts formed by the union of the sulphates of alumina, chromium, or iron with the sulphates of the alkalis. The composition of the ordinary potash alum is represented by the formula  $\text{AlK}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ .

The progress made by chemists in the discovery of the constitution of alum was very slow. The species first investigated was potash alum. That it contained sulphuric acid as a constituent was known even to the alchemists. Pott and Marggraff demonstrated that alumina was another constituent. Pott, in his *Lithogognosia*, showed that the earth of alum, or the precipitate obtained when an alkali is poured into a solution of alum, is quite different from lime and chalk, with which it had been confounded by Stahl. Marggraff went much farther. He not only showed that alumina is one of the constituents of alum, but that this earth possesses peculiar properties, is different from every other substance, and is one of the ingredients in common clay ("Expériences faites sur la Terre d'Alun," Marggraff's *Opusc.* ii. 111). Marggraff showed likewise, by many experiments, that crystals of alum cannot be obtained by dissolving alumina in sulphuric acid, and evaporating the solutions. The crystals formed are always soft, and quite different in their appearance from alum crystals. But when a solution of potash or ammonia is dropt into this liquid, it immediately deposits perfect crystals of alum ("Sur la Régénération de l'Alun," Marggraff's *Opusc.* ii. 86). He mentions likewise that manufacturers of alum in general were unable to procure the salt without a similar addition, that at first it had been customary to add a quantity of putrid urine, and that afterwards a solution of carbonate of potash was substituted in its place. But subsequent chemists do not seem to have paid much attention to these important observations of Marggraff: they still continued, without any rigid examination, to consider alum as a sulphate of alumina.

Bergmann indeed had observed that the addition of potash or ammonia made the alum crystallise, but that the same effect was not produced by the addition of soda or of lime ("De Confectione Aluminis," Bergmann's *Opusc.* i. 225). He had observed likewise that sulphate of potash is frequently found in alum. He decomposed the solution of alum by means of ammonia, evaporated the filtered liquid to dryness, and exposed the residue to a red heat. A quantity of sulphate of potash often remained behind in the crucible (*ibid.*, p. 326). From these facts he drew

the conclusion that sulphate of potash readily combines with sulphate of alumina.

After Klaproth had discovered the existence of potash as an ingredient in *leucite* and *lepidolite*, it occurred to Vauquelin that it was probably an ingredient likewise in many other minerals. He recollected that alum crystals often make their appearance during the analysis of stony bodies; and, considering that alum cannot be obtained in crystals without the addition of potash, he began to suspect that this alkali constituted an essential ingredient in the salt. A set of experiments, undertaken on purpose to elucidate this important point, soon satisfied him that his conjecture was well-founded. Accordingly, in the year 1797 he published a dissertation demonstrating that alum is a double salt, composed of sulphuric acid, alumina, and potash (*Annales de Chimie*, xxii. 258). Soon after, Chaptal published the analysis of four different kinds of alum, namely, Roman alum, Levant alum, British alum, and alum manufactured by himself. This analysis led to the same result as that of Vauquelin (*Ann. de Chim.* xxii. 280).

Since that time alum has been admitted by chemists to be a triple salt, and various analyses of it have been made to determine its constituents. Vauquelin (*Ann. de Chim.* l. 167), Thenard and Roard (*ibid.*, tom. lix. 72), Curaudau (*Journal de Physique*, lxxvii. 1), and Berzelius (*Ann. de Chim.* lxxxii. 258), successively published the results of their experiments. These analyses gradually led to an accurate knowledge of the composition of this salt.

One of the most remarkable differences between the three species of alum is the solubility of each in water. At the temperature of 60°, 100 parts of water dissolve—

9·37 parts of ammoniacal alum,
14·79 parts of potash alum,
327·6 parts of soda alum.

This great solubility of soda alum renders the manufacture of it very difficult. It does not easily crystallise; indeed, when the weather is hot, crystals of it can hardly be obtained. Its great solubility would render it more convenient and more economical for dyers and calico-printers, provided it could be furnished at the same rate with common alum. But the greater difficulty attending the making of it would probably prevent it from being saleable at a price sufficiently low to make it available as a mordant.

Soda alum was first mentioned by Mr Winter in 1810, in his account of the Whitby alum processes (Nicholson's *Jour.* xxv. pp. 254, 255); but before that time it had been made by Mr Charles Macintosh of Crossbasket. Mr William Wilson, at Hurler, near Glasgow, afterwards made it in considerable quantities. Specimens of it have been sent by Dr Gillies from the neighbourhood of Mendoza, in South America, where it occurs native in considerable quantity.

These three different species of alum differ also somewhat from each other in their specific gravities, which are as follows:—

Ammoniacal alum.....	1·56
Potash alum.....	1·75
Soda alum.....	1·83 <sup>1</sup>

The word *alumen*, which we translate *alum*, occurs in Pliny's *Natural History*. In the 15th chapter of his 35th book he gives us a detailed description of it. By comparing this with the account of *στυπτηρία* given by Dioscorides in the 123d chapter of his 5th book, it is obvious that the two are identical. Pliny informs us that alumen

was found naturally in the earth. He calls it *salsugoterra*. Different substances, he informs us, were distinguished by the name of alumen; but they were all characterised by a certain degree of astringency, and were all employed in dyeing and medicine. The light-coloured alumen was useful in brilliant dyes, the dark-coloured only in dyeing black or very dark colours. One species was a liquid, which was apt to be adulterated; but when pure it had the property of striking a black with the juice of the pomegranate. This property seems to characterise a solution of sulphate of iron in water. It is quite obvious that a solution of our alum would possess no such property. Pliny says that there is another kind of alum which the Greeks call *schistos*. It forms in white threads upon the surface of certain stones. From the name *schistos*, and the mode of formation, there can be little doubt that this species was the salt which forms spontaneously on certain slaty minerals, as alum slate and bituminous shale, and which consists chiefly of sulphate of iron and sulphate of alumina. Possibly in certain places the sulphate of iron may have been nearly wanting, and then the salt would be white, and would answer, as Pliny says it did, for dyeing bright colours. Several other species of alumen are described by Pliny, but we are unable to make out to what minerals he alludes.

The alumen of the ancients, then, was not the same with the alum of the moderns. It was most commonly a sulphate of iron, sometimes probably a sulphate of alumina, and usually a mixture of the two. But the ancients were unacquainted with our alum. They were acquainted with sulphate of iron in a crystallised state, and distinguished it by the names of *misy*, *sory*, *chalcantum* (Pliny, xxxiv. 12). As alum and green vitriol were applied to a variety of purposes in common, and as both are distinguished by a sweetish and astringent taste, writers, even after the discovery of alum, do not seem to have discriminated the two salts accurately from each other. In the writings of the alchemists we find the words *misy*, *sory*, *chalcantum*, applied to alum as well as to sulphate of iron; and the name *atramentum sutorium*, which ought to belong, one would suppose, exclusively to green vitriol, applied indifferently to both.

When our alum was discovered is entirely unknown. Beckmann devoted a good deal of attention to the history of this salt, and published a curious dissertation on the subject; but his attempts to trace its origin were unsuccessful. The manufacture of it was discovered in the East, but at what time or place is totally unknown. It would appear that, about four or five hundred years ago, there was a manufactory of it at Edessa in Syria, at that time called *Rocca*,—hence, it is supposed, the origin of the term *rock alum*, commonly employed in Europe; though others allege that the term originated at Civita Vecchia, where alum is made from a yellow mineral which occurs in the state of a hard rock.

Different alum works existed in the neighbourhood of Constantinople. About the time of the fall of the Grecian empire the art of making alum was transported into Italy, at that period the richest and most manufacturing country in Europe. Bartholomew Pernix, a Genoese merchant, discovered alum ore in the island of Ischia, about the year 1459. Nearly at the same time John di Castro, who was well acquainted with the alum works in the neighbourhood of Constantinople, suspected that a mineral fit for yielding alum existed at Tolfa, because it was covered with the same trees that grew on the alum mineral near Constantinople. His conjecture was verified by trials, and the celebrated manufactory at Tolfa established. Another was begun in the neighbourhood of Genoa; and the manufacture flourished in different parts of Italy. To

<sup>1</sup> The soda alum whose specific gravity is here given was the native, from the province of St Juan, on the north of Mendoza. It contains less water, and therefore is probably heavier than common soda alum.

this country it was confined for the greater part of a century. Various manufactories of it were established in Germany by the year 1544.

England possessed no alum works till the reign of Charles I. Thomas Chaloner, son of Dr Chaloner, who had been tutor to Charles, while hunting on a common in Yorkshire took notice of the soil and herbage, and tasted the water. He found them similar to what he had seen in Germany where alum works were established. In consequence of this he got a patent from Charles for an alum work. Since that time various alum works have been established in different parts of Great Britain,—the most important now in operation being the Whitby works, originally established by Mr Chaloner; and the works at Pendleton, near Manchester, and Goole, Yorkshire, and at Hurler and Campsie, both in the neighbourhood of Glasgow.

Several alum works exist in Sweden, particularly in West Gothland. There is one, for example, at Hænsæter, near the borders of the Wener Lake. But for a description of the Swedish works we refer to Bergmann's *Opuscula*, i. 284, or English translation, i. 342.

Various minerals are employed in the manufacture of alum, but by far the most important of them are the following three: *alum-stone*, *alum-slate*, *bituminous shale*.

Alum-stone or Alunite was first observed at Tolfa, near Rome, in the 15th century, and afterwards in Hungary and several other places, chiefly in trachyte or other volcanic rocks. It appears to be produced by the action of sulphureous vapours on the felspars they contain, and generally occurs in compact, granular, or earthy masses, mixed with quartz or felspar. Small crystals are found in cavities, and are either rhombohedrons with angles of  $89^{\circ} 10'$ , and thus nearly cubes, or these with the polar angles replaced by the basal plane. The specific gravity ranges from 2.58 to 2.752, the compact varieties being the lighter. Its hardness is 3.5 to 4, or rather softer than fluor spar. It has a distinct cleavage perpendicular to the axis of the rhombohedron, and conchoidal fracture in other directions. The pure varieties are white and colourless, but it is often coloured greyish, yellowish, or reddish. The crystals decrepitate before the blowpipe, but are infusible, as well as the compact alunite. The alum is extracted from this mineral by repeated roasting and treating with water. The absence of iron accounts for the superior purity for which the Roman alum was long celebrated.

Alum-slate is a far more abundant substance, occurring in beds in different formations. Thus it is common in the older Palæozoic or Silurian strata of Scandinavia and Scotland. Generally it is distinctly slaty, but sometimes forms rounded balls or concretions. It contains much carbonaceous matter, and hence its colour is greyish or bluish-black. It has a dull lustre, is soft and sectile. It contains much disseminated iron pyrites, and on decomposition in the air yields sulphate of iron, and alum as an efflorescence on the surface.

Many of the shales or slate clays in the coal formation also contain much iron pyrites, and thus also produce alum when acted on by the atmosphere. Such are those used for manufacturing alum at Campsie and other places near Glasgow. Where they contain much bituminous matter they show a shining resinous streak and greyish-black colour, and are named bituminous shales. These burn when heated, with a pale flame and sulphureous odour.

The alum slates at Whitby in Yorkshire belong to the Lias, and are used in the alum works in that neighbourhood. In other places, as in many parts of Germany, similar beds are found in Tertiary formations, particularly in connection with the brown coal deposits. When fresh

dug they often show no trace of alum, which only appears after exposure to the air, or when the decomposition of the iron pyrites is assisted by the action of heat.

Several native varieties of sulphate of alumina and soda alum occur in South America, some of the most remarkable of which it may be proper to specify.

1. Sulphate of alumina, or Alunogene, was first found at Rio Saldanha, but is now obtained from several places in Europe and America. The colour is white, here and there tinged yellow, obviously from external impurities. It occurs in fine crystalline needles; lustre silky; taste that of alum, but stronger; specific gravity, 1.6 to 1.7; soft; before the blowpipe behaves like alum.

2. Soda-alum. It occurs native in the province of St Juan, situated to the north of Mendoza, on the east side of the Chilian Andes, at about  $30^{\circ}$  S. lat. The alum is white, and composed of fibres adhering longitudinally, and having a certain breadth, but very thin. It bears some resemblance to fibrous gypsum, but it is harder, not being scratched by the nail, though the knife scratches it with great ease. It is sectile. The outer fibres are white and only slightly translucent, as if they had lost a portion of their water; but the internal fibres are transparent, and have a silky aspect. It tastes precisely like alum, and is very soluble, water at the temperature of  $62^{\circ}$  dissolving 3.773 parts of it, and boiling water dissolving any quantity whatever. When exposed to heat, it behaves very nearly as common alum.

3. There is a mineral called *aluminite*, which was observed in the environs of Halle many years ago, and which was afterwards detected by Mr Webster in clay resting on chalk at Newhaven in Sussex. This, if it were sufficiently abundant, would constitute an excellent material for the manufacture of alum. Its colour is snow-white. It occurs in reniform pieces of greater or smaller size; fracture fine earthy; dull; streak glistening; opaque; adheres feebly to the tongue; soils very slightly; very soft; feels fine, but meagre; specific gravity, 1.7054. It consists of alumina, sulphuric acid, and water.

Four different processes are employed in the manufacture of alum, according to the nature of the mineral from which the alum is to be extracted.

The process employed at Tolfa is the simplest of all. If the Tolfa stone be kept constantly moistened with water for about two months, it falls to powder of itself, and yields alum by lixiviation. But this is not the process employed by the manufacturers. The alum-stone is broken into small pieces, and piled on the top of a perforated dome, in which a wood fire is kindled. The smoke and flame of the wood penetrate through the pieces of alum-stone, and a sulphureous odour is disengaged, owing to the decomposition of a portion of the sulphuric acid in the stone. This roasting is twice performed; the pieces of ore which the first time were at the edge of the dome, being the second time put in the middle. The process of roasting this stone requires considerable attention. If the heat be too great, the quality of yielding alum is destroyed: if the heat be too small, the stone does not readily fall to powder. There can be little doubt that the unroasted stone would yield more alum than the roasted; but probably the additional labour requisite in the latter case would more than swallow up the increase of product.

The roasted stone, which has now acquired a reddish colour, is placed in rows between trenches filled with water. This liquid is so frequently sprinkled on it that the stone is always moist. In two or three days it falls to powder, like slacked quicklime; but the daily watering is continued for a month. The success of this part of the operation is said to depend very much on the weather. When the weather is rainy, the alum is all washed

out, and little or nothing left for the manufacturer to extract.

When the stone has by this process been reduced to a sufficiently fine powder, it is thrown into a leaden boiler filled two-thirds with water. During the boiling the powder is frequently stirred up, and the water that evaporates is replaced. When the boiling has been continued for a sufficient time, the fire is withdrawn, and time allowed for the earthy matter to subside to the bottom. A cock is then opened, which allows the clear liquor to flow out into deep wooden square vessels, so made that they can be easily taken to pieces. Here the alum gradually crystallises, and attaches itself to the sides and bottom of the vessel. The mother liquor is then drawn off into shallower wooden troughs, where more alum crystals are deposited. The liquid has now a red colour, and is muddy; and the last alum crystals are mixed with this red matter. They are washed clean in the mother liquor, which is finally pumped into a trough, and used in subsequent processes.

The alum obtained at Tolfa is known by the name of *Roman alum*, and is in very high estimation. It is always mixed with a little reddish powdery matter, which is easily separated from it.

Alum-slate, being very different in its composition, requires a different treatment to fit it for yielding alum. If the alum-slate contain a notable quantity of lime or magnesia, it does not answer the purposes of the manufacturer so well. The essential ingredients in alum-slate, for the alum-makers, are alumina and iron pyrites.

The first process is to roast the ore. In Sweden, where the fuel is wood, and consequently expensive, it is customary to use the alum-slate itself as fuel for roasting the ore. For this purpose a small layer of brushwood is covered with pieces of alum-slate, and set on fire; and, as the combustion proceeds, new layers of alum-slate are added. It is usual to place alternate layers of roasted and unroasted alum-slate. The combustion continues for a month or six weeks. At Whitby, coal is employed for roasting the alum-slate. Indeed the alum-slate of Whitby is lighter coloured than that of Sweden, and probably would not burn of itself. So great is the quantity of combustible matter in the Swedish alum-slate that it is employed as fuel for burning limestone. Great quantities of limestone are burnt in this manner at Hunneberg, near the south side of the lake Wener. The roasted ore has usually a brown colour. When it is red the quantity of alum which it yields is considerably diminished.

By this roasting the pyrites is oxidised into sulphate of iron and sulphuric acid, thus:—

The sulphuric acid as it is produced is, however, at once neutralised by the large excess of alumina producing sulphate, so that the result of the action is to produce a mixture of the sulphates of iron and alumina.

The roasted ore has an astringent taste, owing to the sulphate of iron and sulphate of alumina which it contains. The next process is to lixiviate it with water, in order to dissolve these salts. For this purpose it is put into reservoirs made of wood or masonry, with a stop-cock at the bottom to draw off the water. The usual method is to keep the water for twelve hours in contact with ore that has been twice lixiviated; then to draw it off, and allow it to remain for an equal period on ore that has been once lixiviated. Lastly, it is run upon fresh ore, and allowed to remain on it for twelve hours longer. If the specific gravity of the liquid thus treated be 1.25 at the temperature of 55°, it may be considered as saturated with sulphate of alumina and sulphate of iron; but probably this specific gravity is not often obtained.

The liquid, thus impregnated with salt, is now boiled down in leaden vessels to the proper consistency for crystallisation. In Sweden the fuel employed for this purpose is alum-slate. By this means a double effect is produced—the liquid is evaporated, and the alum-slate is roasted. During the boiling abundance of oxide of iron falls, mixed with selenite, if lime be one of the constituents of the alum-slate. When the liquid is sufficiently concentrated it is let into a square reservoir, in order to crystallise. Great quantities of sulphate of iron crystals are usually deposited in this vessel. These are collected by drawing the liquid off into another reservoir. When all the sulphate of iron that can be obtained has been separated, a quantity of sulphate of potash or ammonia, muriate of potash, or putrid urine, is mixed with the liquid. The sulphate of potash is procured from the sulphuric acid makers, and the muriate of potash from the soap-makers. By this addition alum is formed in the liquid, and it gradually deposits itself in crystals on the sides of the vessel. These crystals are collected, and dissolved in the smallest quantity of boiling water that will take them up. This solution is poured into large wooden casks. In a fortnight or three weeks the alum crystallises, and covers the sides and bottom of the cask. The hoops are now taken off, and the staves of the cask removed. A mass of alum crystals, having the shape of the cask, remains. This mass is pierced, the mother liquor allowed to run out, and preserved for a subsequent process. The alum, being now broken in pieces, is fit for sale.

The manufacture of alum from bituminous shale and slate-clay bears a considerable resemblance to the manufacture from alum-slate, but differs in several particulars. We shall give a sketch of the processes followed in two works of this kind that are in operation in the neighbourhood of Glasgow. The bituminous shale and slate-clay employed are obtained from old coal-pits, which are very extensive near Glasgow. The air in these coal-pits is moist, and its average temperature about 62°. The shale having been exposed for many years, has gradually opened in the direction of its slaty fracture, so as to resemble in some respects a half-shut fan; and all the chinks in it are filled with a saline efflorescence in threads. This salt is white, with a shade of green, has a sweetish astringent taste, and consists of a mixture of sulphate of iron and sulphate of alumina. In order to obtain these salts in a state of solution, nothing more is requisite than to lixiviate this shale with water. The lixiviated ore being left exposed to the weather, forms more salt, which is gradually washed out of it by the rain-water, and this water is collected and preserved for use.

The next step in the process is to boil down the liquid to a sufficient state of concentration. At Campsie all the boilers are composed of stone, and the heat is applied to the surface. This is a great saving, as leaden vessels are not only much more expensive, but require more frequent renewal. When the liquid is raised to a sufficiently high temperature in the stone reservoir, pounded sulphate of potash, or muriate of potash, as they can be procured, is mixed with it; and there is an agitator in the vessel, by which it is continually stirred about. This addition converts the sulphate of alumina into alum. The liquid is now let into another trough, and allowed to remain till it crystallises. In this liquid there are two salts contained in solution—viz., sulphate of iron and alum; and it is an object of great consequence to separate them completely from each other. The principal secret consists in drawing off the mother liquor at the proper time; for the alum is much less soluble in water than the sulphate of iron, and therefore crystallises first. The first crystals of alum formed are very impure. They have a yellow colour, and

seem to be partly impregnated with sulphate of iron. They are dissolved in hot water, and the solution poured into troughs, and allowed to crystallise a second time. These second crystals, though much purer, are not quite free from sulphate of iron; but the separation is accomplished by washing them repeatedly with cold water; for sulphate of iron is much more soluble in that liquid than alum. These second crystals are now dissolved in as small a quantity of hot water as possible, and the concentrated liquid poured while hot into large casks, the surface of which is covered with two cross beams. As the liquor cools, a vast number of alum crystals form on the sides and surface. The casks are allowed to remain till the liquid within is supposed to be nearly of the temperature of the atmosphere. This, in winter, requires eleven days; in summer, fourteen or more. The liquid, after standing eleven days in summer, has been observed to be still above blood heat. The hoops are then removed, precisely as in the manufacture of alum from alum-slate.

There always remains in the boilers a yellowish substance, consisting chiefly of peroxide of iron. This is exposed to a strong heat in a reverberatory furnace, and it becomes red. In this state it is washed, and yields more alum. The red residue is ground to a fine powder, and dried. It then answers all the purposes of Venetian red as a pigment. By altering the temperature to which this matter is exposed, a yellow ochre is obtained instead of a red.

In France, where alum ores are by no means abundant, alum is manufactured from clay. This method of making the salt was first put in practice by Chaptal when professor of chemistry at Montpellier. His methods have been since gradually improved, and brought to a state of considerable perfection. The first process tried was this: The clay was reduced to a fine powder in a mill, and then mixed with sulphuric acid. After remaining some days, it was exposed for twenty-four hours to a temperature of about 130°. It was then lixiviated, and the liquid mixed with urine or potash. This method being found inconvenient, was abandoned for the following:—The clay being well ground, was mixed with half its weight of the saline residue from a mixture of sulphur and nitre. This residue is little else than sulphate of potash. The mixture was formed into balls about 5 inches in diameter, which were calcined in a potter's furnace. They were then placed on the floor of a chamber in which sulphuric acid was made. The acid vapour caused them to swell, and to open on all sides. In about a month they were sufficiently penetrated with the acid. They were then exposed to the air, under shades, that the saturation might become more complete. Finally, they were lixiviated, and the liquid being evaporated, yielded pure alum.

This process was considerably improved by Berard, of the Montpellier alum work. Instead of exposing the calcined balls to the fumes of sulphuric acid, he sprinkled them with a quantity of sulphuric acid of the specific gravity 1.367, equal to the weight of the clay employed; but it is obvious that the proportion must vary with the nature of the clay. The solution takes place with the greatest facility, and crystals of alum are obtained by evaporating the liquid.

Another process was put in practice by Chaptal, in the neighbourhood of Paris. A mixture is made of 100 parts of clay, 50 parts of nitre, and 50 parts of sulphuric acid of the specific gravity 1.367; and this mixture is put into a retort and distilled. Aquafortis comes over, and the residue in the retort being lixiviated with water, yields abundance of excellent alum.

For chemical constitution and relations of the alums, see CHEMISTRY.

ALUMBAGH, the name of a large park or walled enclosure, containing a palace, a mosque, and other buildings, as well as a beautiful garden, situated about 4 miles from Lucknow, near the Cawnpore road. It was converted into a fort by the mutineers in 1857; and after its capture by the British was of importance in connection with the military operations around Lucknow. See LUCKNOW.

ALUMINIUM, a metallic substance, first separated from the chloride by Wöhler in 1828. It remained a laboratory product until Deville, about 1858, succeeded in improving the mode of production, so as to render the operations capable of management on the manufacturing scale. The process consists in heating to a red heat a mixture of the double chloride of aluminium and sodium, or the double fluoride of aluminium and sodium (cryolite), with the metal sodium. A vigorous action takes place, chloride of sodium being formed and the metal aluminium separated. On the large scale the reduction is effected by throwing a mixture of 10 parts of the double chloride, 5 parts of cryolite, and 2 parts of sodium on the hearth of a reverberatory furnace. Immediately after the action, the fused metal and slag, consisting of common salt and fluoride of aluminium, are run out, and a new quantity of the previous mixture introduced. The various patents that have been secured with reference to this manufacture have all regard to the saving of the metal sodium. The metal aluminium may be separated from the double chloride by electrolysis. For this purpose the fused salt has the electric current from ten cells of a battery passed through it, carbon poles being used. The metal appears at the negative pole in large globules, which may be collected and melted together under a layer of fused salt.

Aluminium is a white metal resembling silver in appearance. It is very malleable and ductile, and may be beaten and rolled into thin sheets, or drawn into fine wire. By hammering in the cold it becomes as hard as soft iron, but may be softened again by fusion. Being highly sonorous, it has been used for making bells. It is very light, being only 2½ times heavier than water, and is thus four times lighter than silver. After fusion it has a specific gravity of 2.56; by hammering this may be increased to 2.67. It melts at a red heat, and is non-volatile at very high temperatures. The metal conducts heat and electricity as well as silver. Aluminium does not oxidise in air, even at a red heat, has no action on water at ordinary temperatures, and is not acted upon by sulphuretted hydrogen or sulphide of ammonium, and thus preserves its lustre where silver would be tarnished and blackened. It is not attacked by nitric acid, even when concentrated, and is not soluble in dilute sulphuric acid, but is readily soluble in dilute or concentrated hydrochloric acid with evolution of hydrogen. Solutions of caustic potash or soda dissolve the metal with great ease, forming aluminate of potash or soda, and giving off hydrogen. Aluminium forms alloys with most metals. The copper alloy called aluminium-bronze is the most important because of its colour, hardness, and malleability, and is largely used for articles of jewellery, for mounting sextants and other astronomical instruments, and for making balance beams.

ALUTA, an affluent of the Danube. See ALT.

ALVA, a village in Stirlingshire, Scotland, situated at the foot of Craigeith, one of the Ochil range, 7 miles N.E. of Stirling, with which it is connected by railway. Besides the parish church, there are places of worship belonging to the Free and United Presbyterian churches. Yarn spinning and the manufacture of shawls and tweeds are carried on to a considerable extent. Population in 1871, 4096.

ALVA, or ALBA, FERNANDO ALVAREZ DE TOLEDO, Duke of, born in 1508, was descended from one of the most illustrious families in Spain. His grandfather, Ferdinand

of Toledo, educated him in military science and politics ; and he was engaged with distinction at the battle of Pavia while still a youth. Selected for a military command by Charles V., he took part in the siege of Tunis (1535), and successfully defended Perpignan against the Dauphin of France. He was present at the battle of Mühlberg (1547), and the victory gained there over John of Saxony was due mainly to his exertions. He took part in the subsequent siege of Wittenberg, and presided at the court-martial which tried the Elector and condemned him to death. In 1552 Alva was intrusted with the command of the army intended to invade France, and was engaged for several months in an unsuccessful siege of Metz. In consequence of the success of the French arms in Piedmont, he was made commander-in-chief of all the emperor's forces in Italy, and at the same time invested with unlimited power. Success did not, however, attend his first attempts, and after several unfortunate attacks he was obliged to retire into winter quarters. After the abdication of Charles he was continued in the command by Philip II., who, however, restrained him from extreme measures. Alva had subdued the whole Campagna, and was at the gates of Rome, when he was compelled by Philip's orders to negotiate a peace. One of its terms was, that the Duke of Alva should in person ask forgiveness of the haughty pontiff whom he had conquered. Proud as the duke was by nature, and accustomed to treat with persons of the highest dignity, yet such was the superstitious veneration then entertained for the papal character that he confessed his voice failed him at the interview, and his presence of mind forsook him. Not long after this (1559) he was sent at the head of a splendid embassy to Paris, to espouse, in the name of his master, Elizabeth, daughter of Henry, king of France. In 1567, Philip, who was a bigoted Catholic, sent Alva into the Netherlands at the head of an army of 10,000 men, with unlimited powers for the extirpation of heretics. When he arrived he soon showed how much he merited the confidence which his master reposed in him, and instantly erected a tribunal which soon became known to its victims as the "Court of Blood," to try all persons who had been engaged in the late commotions which the civil and religious tyranny of Philip had excited. He imprisoned the counts D'Egmont and Horn, the two popular leaders of the Protestants, brought them to an unjust trial, and condemned them to death. In a short time he totally annihilated every privilege of the people, and, with unrelenting cruelty, put multitudes of them to death. The executioner was employed in removing all those friends of freedom whom the sword had spared. In most of the considerable towns Alva built citadels. In the city of Antwerp he erected a statue of himself, which was a monument no less of his vanity than of his tyranny: he was figured trampling on the necks of two smaller statues, representing the two estates of the Low Countries. By his unusual and arbitrary demand of new supplies from the states he greatly aggravated this insult. The exiles from the Low Countries, roused to action by his oppression, fitted out a fleet of privateers, and after strengthening themselves by successful depredations, ventured upon the bold exploit of seizing the town of Breil. Thus Alva, by his cruelty, became the unwitting instrument of the future independence of the seven Dutch provinces. The fleet of the exiles having met the Spanish fleet, totally defeated it, and reduced North Holland and Mons. Many cities hastened to throw off the yoke; while the States-General, assembling at Dordrecht, openly declared against Alva's government, and marshalled under the banners of the Prince of Orange. Alva's preparations to oppose the gathering storm were made with his usual vigour, and he succeeded in recovering Mons, Mechlin, and Zutphen,

under the conduct of his son Frederick. With the exception of Zealand and Holland, he regained all the provinces; and at last his son stormed Waerdan, and massacring its inhabitants, proceeded to invest the city of Haarlem, which, after standing an obstinate siege, was taken and pillaged. Their next attack was upon Alkmaar; but the spirit of desperate resistance was raised to such a height in the breasts of the Hollanders that the Spanish veterans were repulsed with great loss, and Frederick constrained reluctantly to retire. Alva's feeble state of health and continued disasters induced him to solicit his recall from the government of the Low Countries; a measure which, in all probability, was not displeasing to Philip, who was now resolved to make trial of a milder administration. In December 1573 the much oppressed country was relieved from the presence of the Duke of Alva, who, returning home accompanied by his son, made the infamous boast that during the course of six years, besides the multitudes destroyed in battle and massacred after victory, he had consigned 18,000 persons to the executioner. (For further details of his administration in the Netherlands, see HOLLAND.)

On his return he was treated for some time with great distinction by Philip. A tardy and imperfect justice, however, overtook him, when he was banished from court and confined in the castle of Uzeda for complicity in certain disgraceful conduct of his son. Here he had remained two years, when the success of Don Antonio in assuming the crown of Portugal determined Philip to turn his eyes towards Alva as the person in whose fidelity and abilities he could most confide. A secretary was instantly despatched to Alva to ascertain whether his health was sufficiently vigorous to enable him to undertake the command of an army. The aged chief returned an answer full of loyal zeal, and was immediately appointed to the supreme command in Portugal. It is a striking fact, however, that the liberation and elevation of Alva were not followed by forgiveness. In 1581 Alva entered Portugal, defeated Antonio, drove him from the kingdom, and soon reduced the whole under the subjection of Philip. Entering Lisbon, he seized an immense treasure, and suffered his soldiers, with their accustomed violence and rapacity, to sack the suburbs and vicinity. It is reported that Alva, being requested to give an account of the money expended on that occasion, sternly replied, "If the king asks me for an account, I will make him a statement of kingdoms preserved or conquered, of signal victories, of successful sieges, and of sixty years' service." Philip deemed it proper to make no further inquiries. Alva, however, did not enjoy the honours and rewards of his last expedition, for he died in January 1583, at the age of 74.

ALVARADO, PEDRO DE, one of the Spanish leaders in the discovery and conquest of America, was born at Badajoz about 1495. He held a command in the expedition sent from Cuba against Yucatan in the spring of 1518, and returned in a few months, bearing reports of the wealth and splendour of Montezuma's empire. In February 1519 he accompanied Hernando Cortez in the expedition for the conquest of Mexico, being appointed to the command of one of the eleven vessels of the fleet. (For the details of this expedition and of Hernando's share in it, see CORTEZ and MEXICO.) He was engaged (1523-4) in the conquest of Guatemala, of which he was subsequently appointed governor by Charles V. In 1534 he attempted to bring the province of Quito under his power, but had to content himself with the exaction of a pecuniary indemnity for the expenses of the expedition. During a visit to Spain, three years later, he had the governorship of Honduras conferred upon him in addition to that of Guatemala. He died in Guatemala in 1541.

ALVAREZ, FRANCISCO, born at Coimbra after 1460, a

priest and almoner to Dom Manuel, king of Portugal, was sent in 1515 as secretary to Duarte Galvão, on an embassy to David, king of Abyssinia. The expedition having been delayed by the way, it was not until 1520 that he reached Abyssinia, where he remained six years, returning to Lisbon in 1527. In 1533 he was sent to Rome on an embassy to Pope Clement VII. The precise date of his death, like that of his birth, is unknown; but it must have been later than 1540, in which year he published at Lisbon, under the king's patronage, an account of his travels, in one volume folio, entitled *Verdadeira Informação do Preste Joas das Índias*. This curious work was translated in Latin, under the title of *De Fide, Regione, et Moribus Æthiopum*, by Damien Goetz, a Portuguese gentleman; and has often been reprinted and translated into other languages. The information it contains must, however, be received with caution, as the author is prone to exaggerate, and does not confine himself to what came within his own observation.

ALVAREZ, DON JOSÉ, the foremost Spanish sculptor of modern times, was born at Priego, in the province of Cordova, in 1768, and died at Madrid in 1827. Bred to his father's trade of a stone-mason, he devoted all his spare time to drawing and modelling. In his twentieth year he became a pupil of the Academy of Granada. A work he executed soon afterwards for a fountain in his native town attracted the notice of the Bishop of Cordova, who took the young artist into his house and maintained him for several years. In 1799 he obtained from Charles IV. a pension of 12,000 reals, to enable him to visit Paris and Rome. In the former city he executed, in 1804, a statue of Ganymede, which placed him at once in the front rank of sculptors. Shortly afterwards his pension was more than doubled, and he left Paris for Rome, where he remained till within a year of his death. The most important of his numerous works, executed during this period, was a group representing Antilochus and Memnon, which was commissioned in marble (1818) by Ferdinand VII., and secured for the artist the appointment of court sculptor. It is now in the Museum of Madrid. Alvarez modelled a few portrait busts (Ferdinand VII., Rossini, the Duchess of Alba), which are remarkable for their vigour and fidelity.

ALVAREZ, DON MANUEL, a Spanish sculptor, was born at Salamanca in 1727, and died in 1797. He followed classical models so closely that he was styled by his countrymen *El Griego*, "The Greek." His works, which are very numerous, are chiefly to be found at Madrid.

ALWAR, a semi-independent state of Rájputáná, and under the control of the Governor-General's agent for Rájputáná, lies between 28° 13' 25" and 27° 14' 34" N. lat., and between 77° 15' 35" and 76° 14' 10" E. long. It is bounded on the E. by the state of Bhartpur and the British district of Gurgáon, on the N. by Gurgáon district and the states of Patiálá and Nábhá, on the W. by the states of Nábhá and Jaipur, and on the S. by the states of Jaipur and Bhartpur. Its configuration is irregular, the greatest length from north to south being about 80 miles, and breadth from east to west about 60 miles, with a total area of about 3000 square miles. The total population of the state, as ascertained by a census taken in 1872, was 778,596, consisting of 598,333 Hindus, 180,225 Mahometans, and 38 Christians. The number of males was returned at 418,723, and females at 359,873, the proportion of males to the total population being 53.76 per cent. The eastern portion of the state is open and highly cultivated; the western is diversified by hills and peaks, which form a continuation of the Aravallí range, from 12 to 20 miles in breadth. These hills run in rocky and precipitous parallel ridges, in some places upwards of 2200 feet in height. The Sabhí river flows through the

north-western part of the state, the only other stream of importance being the Ruparel, which rises in the Alwar hills, and flows through the state into the Bhartpur territory.

The one attempt at road-making in the state is a line which connects the chief town, Alwar, with Rájghar on the one side and with Tijará on the other. The greater portion of this road was metalled during the minority of the present rájá, but it has been neglected since he took the management of the state into his own hands, and is now said to be almost impassable, and worse than the ordinary cart tracks. The earthwork for a road from Alwar to the Bhartpur border was thrown up, but it has never been metalled, and the line is not used for traffic. The Alwar hills are rich in minerals. Iron ore is found in large quantities close to the surface. Thirty smelting furnaces are kept at work, and are capable of turning out 390 tons a-year. They give employment to a large number of people. Two copper mines have been in operation for a number of years, but with doubtful advantage to the state. Silver, lead, and sulphur are also found in small quantities, and attempts have been made to work them, but without success. The principal agricultural products are wheat and barley during the cold weather, with grain to a less extent. Joár, bajrá, and Indian corn are raised during the rains. Cotton is extensively cultivated, and exported on a considerable scale. A ten years' land settlement, which was formed by a late political resident, is now expiring, and a fresh settlement for a longer term is being made. The revenue of the state has for some time been in an unsatisfactory state. When the rájá attained his majority, and was invested with the full administration of his territory in 1863, the treasury contained a surplus of £205,000. Within seven years this surplus had dwindled away, and debts to the extent of £160,000 accumulated. Under these circumstances, the government found it necessary to place the administration of the state in the hands of the political resident, assisted by a council of management consisting of five of the principal chiefs and native gentlemen of the state. In 1870-71, the first year under the new management, the revenue of the state amounted to £213,085, and the expenditure to £135,201, leaving a surplus of £77,884, part of which was devoted to the liquidation of the state debt, the remainder being kept as a working balance. An allowance of £18,000 a-year is made for the household expenses of the rájá, besides an establishment of horses, carriages, and elephants maintained for his use. The educational institutions consist of a high school, attended in 1871-72 by 382 students; a Thákur school, for the education of the sons of chiefs and native gentlemen, and attended by 51 pupils; and sixty other schools, containing a total of 2785 pupils. Seven towns in the state are returned as containing a population of upwards of 5000 souls—namely, Alwar, 52,357; Rájghar, 12,070; Tijará, 7382; Govindgarh, 5720; Rámgarh, 5581; Rampur, 5381; and Bahrór, 5213. The only municipality is the town of Alwar. It derives its municipal revenue from a tax of 1 per cent. on the supposed income of the owners of houses. This tax yields about £800 per annum, out of which, with some assistance from the state, the city police, conservancy establishment, &c., are paid.

ALYPIUS, one of the seven Greek writers on music whose works are collected and published, with a commentary and explanatory notes, by Meibomius (*Antiquæ Musicæ Auctores Septem*, Amstel., 1652). The time in which he flourished cannot be precisely ascertained. He is said to have written before Euclid and Ptolemy; and Cassiodorus arranges his work, entitled *Introduction to Music*, between those of Nicomachus and Gaudentius. The work consists solely of a list of symbols of the various scales and modes, and is therefore probably only a fragment.

ALYPIUS OF ANTIOCH, a geographer of the 4th century, who was sent by the Emperor Julian into Britain as prefect, and was afterwards commissioned to rebuild the temple of Jerusalem. Among the letters of Julian are two (29 and 30) addressed to Alypius; one inviting him to Rome, the other thanking him for a geographical treatise, which no longer exists.

ALYTH, a town on the eastern borders of Perthshire, in a parish of the same name, situated in the valley of Strathmore, 13 miles west of Forfar. It is tolerably well built, and contains a handsome parish church, and also Free, United Presbyterian, and Scottish Episcopal churches. The chief industrial employments are linen manufacturing and wool spinning, and there is a fair nearly every month. Alyth was created a burgh of barony by James III. Population in 1871, 2134.

AMADEUS V., surnamed the *Great*, Count of Savoy, was born at Bourget in 1249, and succeeded his uncle Philip in 1285. The cautious prudence of Amadeus enabled him greatly to increase his territory by means of marriage, purchase, and donations. He gradually rose to such eminence among the European powers, that he was constituted their umpire to settle their differences—an office which he performed with much reputation to himself and advantage to them. In 1310 he was created a prince of the empire by Henry VII. When the Turks attempted to retake Rhodes from the knights of St John of Jerusalem, he acquired great renown by the valour with which he led an expedition to the relief of the island. A Maltese cross with the letters F.E.R.T. (*Fortitudo ejus Rhodum tenuit*), it is said, became the arms of Amadeus and his successors, in memory of this victory. Amadeus undertook a journey to Avignon to persuade Pope John XXII. to preach a crusade in favour of Andronicus. He died there in the year 1323.

AMADEUS VIII., Count and first Duke of Savoy, and latterly pope or anti-pope, under the name of Felix V., was born at Chambery in 1383, and succeeded his father, Amadeus VII., in 1391. Having, by purchase or otherwise, added large territories to his patrimonial possessions, he became so powerful that the Emperor Sigismund erected Savoy into a duchy in 1416; and after his elevation Amadeus added Piedmont and other provinces to his dominions. After this increase of rank and of territory he suddenly, in 1434, retired to a monastery at Ripaille. He does not appear, however, to have resigned his duchy, but continued to administer it through his son Louis. It is said, too, although some historians have cast doubts upon the story, that, instead of leading a life of asceticism, he spent much of the ducal revenues in furthering his own luxury and enjoyment. In 1439, when the pope, Eugenius IV., was deposed by the council at Basle, Amadeus, although not in orders, was elected, through bribery some say, his successor; and after resigning his duchy, was crowned in the following year as Felix V. In the stormy conflict that followed, the Emperor Frederick sided with Eugenius, and the nations of Europe, except Germany, which remained neutral, declared for the one pope or the other. In 1449 Amadeus thought it prudent to renounce his claim to the pontificate in favour of Nicholas V., who had been elected on the death of Eugenius. He, however, induced Nicholas to annul all the acts of Eugenius; to confirm the determination of the council of Basle to appoint him perpetual apostolical legate in Savoy, Piedmont, and the other places of his own dominions; and even to confer on him the bishoprics of Basle, Lausanne, Strasburg, and Constance. It was also conceded to Amadeus that he should continue to wear the pontifical dress, except in a very few particulars; that he should not be obliged to go to Rome to attend any general council; and that he, instead of kissing the pope's toe, should be permitted to kiss his cheek. Amadeus died at Geneva in 1451.

AMADIS OF GAUL. The best edition for English readers of this famous work is to be found in the abridged translation of Southey, and the best account of it is to be found in his preface, which, however, is not void of error. Here, for example, is its final sentence:—" *Amadis of Gaul* is among prose what *Orlando Furioso* is among metrical romances—not the oldest of its kind, but the best." We, of course, in England would place the *Morte d'Arthur* above all romances of the kind; and the praise that we allow to *Amadis of Gaul* is precisely that which Cervantes bestows upon it—of being the earliest and best of the Spanish romances. When the licentiate and the barber burnt the library of Don Quixote, they spared from the flames only three romances—*Amadis of Gaul*, *Palmerin of England*, and *Tirante the White*. "I have heard," said

the licentiate, "that *Amadis of Gaul* was the first book of chivalry printed in Spain, and that all the rest sprung from it; I think, therefore, as head of so pernicious a sect, we ought to condemn him to the fire without mercy." "Not so, sir," said the barber, "for I have heard also that it is the best of all the books of this kind; and therefore—as being unequalled in its way—it ought to be spared." "You are right," said the priest, "and for that reason its life is granted." Although Cervantes speaks of the romance as a Spanish one, and although Southey translated it from the oldest extant edition, which is also Spanish, it is currently supposed to have been originally written in Portuguese by Vasco Lobeira, himself a good knight, who received his spurs on the field of battle from King Joam, and who died in 1403. The work, however, has been claimed as of French origin by the Comte de Tressan. Southey ridicules this theory, and insists upon the claims of the Portuguese author. It is quite certain that the Comte de Tressan attempted to prove too much; but, on the other hand, Southey has not allowed weight enough to the fact that the *Amadis of Gaul* is but the first work of romance which appeared in the Portuguese and Castilian languages; that it was preceded for more than a century by other romances of Anglo-Norman origin; and that, if not in its names and personages, yet in its idea—in the character of its incidents and in much of its geography—it belongs to the world of Anglo-Norman romance. What though we cannot lay our hands on the French original from which Lobeira translated, any more than we can lay our hands on Lobeira's own work from which the Castilian version has been made, we still know that all the ideas and materials, all the design, all the machinery of *Amadis of Gaul*, belong to the Anglo-Norman cycle of romance which was in vogue before Lobeira was born. And in this creed we cheat him of nothing when we say that we know not to what extent he is entitled to the praise of originality. Knowing what we do of these romances, it is not enough to say, for the establishment of Lobeira's claims, that we cannot trace the *Amadis of Gaul* to any one before him. Expressions of his own throughout his work show that if he was not a literal translator, he was at least a borrower. Thus, towards the end of his third chapter he writes—"The author ceaseth to speak of this, and returneth to the child whom Gandales brought up." The Spanish translator, Montaluz, confesses to have taken liberties with the Portuguese version from which he worked, altering, adding, and abridging. The Comte de Tressan maintains that the original French work must have ended with the third book and the rescue of Oriana; and that from this point we can distinctly trace the work of Spanish hands. Southey, again, thinks that the work, as it left the hands of Lobeira, ended in the fourth book with the marriage of Amadis and Oriana, and that all which follows is due to the tasteless accretions of Montaluz. Although this is mere conjecture, still it is natural that we should attach no little force to the correct feeling of Southey. For the story itself, it is impossible to give a summary of it—the plot being too disconnected; but he who has read one such tale, or even a few chapters of one, may have a general impression of all—hacking and hewing in every page, knights always at war and seeking adventures, giants in the path, lions in the forest, damsels in durance, castles to be attacked, wizards and witches with hate in their hearts, kings everywhere plentiful as blackberries, and lovely ladies abounding in tenderness. The sentiment of the work is very noble, and some of the descriptions are full of fire; but the reader owes more than he is aware to the curtailments of Southey.

AMADOU (*Polyporus fomentarius*), a fungus that grows upon old trees, especially the oak, ash, fir, and cherry. When beaten soft it is used as a styptic for slight hæmorrhage,

and as material for surgical pads. After being boiled in a solution of nitre it is employed as tinder.

AMAGER, or AMAK, a small island belonging to Denmark, lying in the Sound, close to the east coast of Seeland. The channel which separates its northern extremity from Seeland forms the harbour of Copenhagen; and nearly the third part of that city, the suburb of Christianshafen, is situated in Amager. The island is about 9 miles long and 4 broad, with a fertile soil, which produces large quantities of vegetables for the Copenhagen market. It is peopled chiefly by the descendants of a Dutch colony which Christian II. brought there in 1516, who still retain many of the old peculiarities of dress, language, and manners. Population about 9000, exclusive of the inhabitants of Christianshafen. The other towns are Dragoë and Castrup.

AMALASONTHA, or AMALASUENTHA, daughter of Theodoric, king of the Ostrogoths, was born about 498 A.D. In 515 she married Eutharic, the last representative of the Amali family, who died (524-5), leaving an only son, Athalaric. The latter was designated by his grandfather Theodoric as the heir to the throne, and Amalasontha was appointed his guardian. On the death of Theodoric in 526, Amalasontha became regent, and endeavoured by a wise and vigorous administration to carry on the work of civilisation and enlightenment which her father had commenced. She devoted herself with special solicitude to the education of Athalaric, but her efforts were frustrated by the opposition of the Gothic nobles. Encouraged by them, the young heir to the throne threw off the restraints imposed by his mother, plunged into debauchery, and died at the age of sixteen (534). In the same year Amalasontha married her cousin Theodahadus, and made him co-regent with herself. A few months later (April 535) she was assassinated by order of her husband in an island on Lake Bolsena.

AMALEKITES, an ancient people, widely spread throughout the country lying on the south and east of Palestine, often mentioned in the Jewish Scriptures, and celebrated also in Arabian tradition. In Scripture they occur first in Gen. xiv. 7, occupying the territory around Kadesh, and suffering from the invasion of Chedorlaomer and his confederates. They appear next assaulting the Israelites, shortly after the exodus from Egypt, at Rephidim, in the neighbourhood of Mount Sinai (Ex. xvii. 8; cf. Deut. xxv. 17). They again occur falling upon a party of the Israelites on the southern verge of the promised land (Num. xiv. 45; cf. xiii. 29). In the time of the judges they are found associated with the Moabites, the Ammonites, the Midianites, and "the children of the east," in repeated attacks upon the Israelites, invading their territory from the eastern side of Jordan (Judges iii. 13; vi. 3). Saul, by divine command, led an expedition into the country of Amalek, waging against them an exterminating war, "smiting them from Havilah until thou comest to Shur, that is over against Egypt" (1 Sam. xv. 1). David also "invaded the Geshurites, and the Gezrites, and the Amalekites; for these nations were of old the inhabitants of the land as thou goest to Shur, even unto the land of Egypt" (1 Sam. xxvii. 8). The last notice occurs in 1 Chron. iv. 43, from which we learn that in the days of Hezekiah a body of Simeonites "went to mount Seir" and "smote the rest of the Amalekites that were escaped;" a notice showing the accomplishment of the doom of extermination which had been denounced against them (Ex. xvii. 14-16; Num. xxv. 20), and finding an echo in the words of an Arabian poet, "The race of Amlak has disappeared, and there is left of it neither mean man nor mighty" (Maçoudi, *Les Prairies d'Or*, par Meynard et Courteille, vol. iii. 104). We twice

hear of Agag as the name of the king of the nation (Num. xxiv. 7; 1 Sam. xv. 8); and it is reasonably supposed that this, like Pharaoh in Egypt, was a name common to all their kings. It has been generally supposed that the Haman of the book of Esther, called "the Agagite," belonged to the royal line of the Amalekites; but it is now found, from Assyrian records, that Agagi was the name of a country east of Assyria, from which it may be assumed that the title was derived. See Lenormant, *Lettres Ass.* i. 45.

Josephus agrees with Scripture in assigning to the Amalekites the territory immediately to the south of Palestine. Thus he speaks of them as inhabiting "Gobolitis and Petra" (Gobolitis = Gebal, in Ps. lxxxiii. 7; cf. Reland, *Palestina*, p. 71); and as reaching "from Pelusium to the Red Sea" (*Ant. Jud.* iii. 2, 1; vi. 7, 3; cf. ii. 1, 2). The country which they are thus represented as occupying is suited only to a nomadic population; and accordingly the indications of the Scripture narrative point to this as the general character of the Amalekite people. They appear as the Bedouins of ancient times, rapid and devastating in their movements (1 Sam. xxx. 1); and in their expeditions "coming up with their cattle and their tents" (*Jud.* vi. 5). At the same time, in the more fertile portions of their territory they doubtless had settled abodes. We read in 1 Sam. xv. 5 of "a city of Amalek;" and Josephus speaks, apparently in an exaggerated way, of their cities being captured by means of elaborate siege operations (*Ant. Jud.* vi. 7, 2).

The ethnical character and relation of this people, and their complete national history, it is impossible satisfactorily to make out from the fragmentary materials in our hands. They are not mentioned in the table of nations in Gen. x., while in Gen. xxxvi. 12, 16, their ancestry seems to be referred to Esau. At the same time, the existence of the nation is noticed in Gen. xiv., long before Esau; and it seems unnatural to understand this, with Hengstenberg and others, in a proleptic sense, especially as there are other independent grounds for referring the beginning of their history to an earlier date. It is certain that the genealogical tables of Scripture, like those of Arabia, include cases of adoption or affiliation as well as of direct descent, and probably it is in this sense that the notice referring Amalek to Esau should be understood. In Balaam's prophecy Amalek is called "the first of nations" (אֲמֵלֵק הָאֵוֹלָם, *præstantissima gentium*, Gesenius), Num. xxiv. 20, an expression scarcely reconcilable in the circumstances with descent from Jacob's brother. Again, though found in Jewish scripture located in the immediate south and east of the Israelitish territory, yet there are indications in Scripture itself that at one time they had had a wider extension. "The mount of the Amalekites" is mentioned as situated in "the land of Ephraim" (*Jud.* xii. 15), apparently warranting the inference that they once held possessions on the west of the Jordan (see Stanley, *Sin. and Pal.*, p. 237, n.) "Amalek" also is found in some copies of the LXX., as the translation of Maacah, in 2 Sam. x. 6, 8, giving some ground for the belief that a section of the same race had once been settled on the north-east of Palestine (see Ewald, *Gesch. Israel's*, Bd. I. 335). There is little in the Bible to illustrate their linguistic affinity; but so far as appears their language was Shemitic, identical with or very closely allied to the Hebrew. Samuel and the captive Agag (1 Sam. xv. 32), and David and the Amalekite youth (2 Sam. i. 13) converse together; and it has been attempted also to explain the names Amalek and Agag by Shemitic analogies (Meier, *Zeitschrift d. morg. Ges.*, Bd. xvii. p. 577). By Philo (*Vita Moses*, § 39) the Amalekites of the Sinaitic peninsula are called Phœnicians.

The traditions of the Arabians regarding this race are confused and conflicting, yet certainly are not to be summarily rejected as destitute of any claim to historic credibility; and with all their entanglement they speak strongly for the ancient and far-extended power of the people in question, and also more doubtfully for their Shemitic affinities. In these traditions, Amlak or Amlik, the father of the Amalekites, is represented sometimes as the son of Laud (*i. e.*, Lud), the son of Shem; sometimes as the son of Aram, the son of Laud; while sometimes also he is spoken of as a son of Ham. They belong, with the Adites, Thamudites, and others, to the primitive races of Arabia. They are said to have been expelled from Babylonia by the Assyrian conquerors, and driven westward into Arabia and Syria, to have built and reigned in Aleppo, to have conquered and for some centuries retained possession of Egypt, and to be the ancestors of the Berbers in North Africa (see Abulfeda, *Hist. Antc-Isrl.*, pp. 16, 178; Maçoudi, *op. cit.*, vol. iii., p. 106; C. de

Perceval, *Hist. des Arabes*, vol. i., p. 18); Knobel, *Volkertafel*, p. 198; Movers, *Phönizier*, 2ter Th., Bd. ii., p. 422). With these Arabian accounts it is natural to bring into connection the facts narrated by Manetho, and now in substance ascertained from old Egyptian records, regarding the conquest of the Nile valley by an Arabian race, called Hysesos by the former, and *Menti*, or shepherds, in the latter (see Bunsen, *Egypt's Place*, vol. iii., p. 266; Brugsch, *Hist. d'Egypte*, vol. i., p. 75; Chabas, *Les Pasteurs en Egypte*, p. 9). Now, from the time of the eighteenth dynasty, northern Arabia is found in Egyptian monuments to be in possession of a people called Shasu, a name which Egyptologists generally compare with the second syllable of Hysesos, and which also, perhaps, corresponds with Zuzim of Gen. xiv. 5. These Shasu may with confidence be identified with the Amalekites of Scripture; their *locale* and their habits are the same; and of them we learn that "they were spread over a vast territory, quite like the wandering Arabs of our day. They are found near Djor, on the north-east frontier of Egypt, as well as in the defiles of Lebanon, where their depredations made themselves felt fourteen centuries before our era" (Chabas, *Etudes sur l'Antiquité Historique*, p. 114; cf. his *Voyage d'un Egyptien*, p. 111). "They wear short tunics, a turban-like head-dress, and are armed with spears and axes. A characteristic feature is the long beard, as among the Canaanitish nations" (Brugsch, *Geog. Inschriften*, Bd. ii. 53).

The notices occurring in Arabian writers, which speak of Amalekites as spread over various more southern portions of Arabia, may probably be referred to the period subsequent to their expulsion from their northern seats by the Israelites and other enemies. The Benu-Kerker, who dwell around Mecca, are by some referred to this stock; the same is true of the Benu-Amila, who, before migrating northwards into Syria, dwelt in Yemen. We hear of Amalekites also in "Cheibar, Jatrib, and other parts of Hedjaz" (Abulfeda, *op. cit.*, p. 179); in regard to which notice a certain degree of confirmation is afforded by the mention by Pliny of an Arabian town, the name of which reads Marippa Palmalacum, but which probably should be read Jatrippa Alamalacum, that is, Jatrib the Amalekite (see Pliny, *Hist. Nat.* vi. 32; Blau, *Zeitschrift d. m. Ges.*, Bd. xxii. 668; cf. Noldeke, *Über d. Amalekiter*, 37). According to some (Tuch, Blau, and others), the famous Sinaitic inscriptions, ascertained to be written in a Semitic dialect, are to be ascribed to the Amalekite race. Doubtless their authors dwelt in the country once inhabited by this people, but that they belonged to them, and not to some succeeding race, has not yet been demonstrated.

From the cuneiform records we have gained as yet no illustration of this subject, unless the people Malikhu, or Malaku, mentioned in the inscriptions of Sennacherib among certain Aramean tribes inhabiting the valley of the Euphrates, may be identified with Amalek (see *Records of the Past*, vol. i., pp. 26, 57).

AMALFI, a town of Italy, in the Principato Citeriore, situated at the entrance of a deep ravine on the north side of the Gulf of Salerno. It was founded, according to the common account, under Constantine the Great, and was one of the first cities to recover from the irruption of the barbarians into Italy. During the 10th and 11th centuries it was an independent republic of great commercial importance, with a trade which extended to Egypt and the east, and a population of 50,000. Its code of maritime laws (*Tabula Amalfitana*) is said to have regulated commerce at one time throughout the whole of Italy, but the truth of this statement appears to be extremely questionable. In 1135 Amalfi was plundered by the Pisans, who are said to have then discovered and carried off the far-famed manuscript of the Pandects of Justinian, which is now in the Laurentian library at Florence. Soon after this the town passed under the dominion of Naples, and from that time rapidly declined. In 1343 a terrible storm buried a large part of the town under the sea, and at the present day it is a mere wreck of its former greatness. It has only about 6500 inhabitants, whose chief employments are fishing and the manufacture of macaroni, silk, and paper. It is still the seat of an archbishop, and contains an ancient cathedral dedicated to St Andrew. Flavio Gioja, to whom the invention of the mariner's compass has been ascribed, and Masaniello were born at Amalfi.

AMALGAM, the name given to an alloy of mercury and another metal. The amalgams are a very numerous class of compounds, and many of them are used largely in the arts. Many amalgams are produced by direct contact of the metals, with evolution of heat. Others are obtained

by the action of mercury on a salt of the metal, or the action of the metal on a salt of mercury, assisted by the passage of a weak electric current in some cases. Some amalgams are solid, others liquid. They are, generally speaking, weak compounds, many of them being decomposed by pressure, and all are decomposed at a white heat. Tin amalgam is used for "silvering" mirrors, gold and silver amalgam in gilding and silvering, cadmium and copper amalgam in dentistry, and an amalgam of zinc and tin for the rubbers of electrical machines. See MERCURY and CHEMISTRY.

AMALIA, ANNA, Duchess of Saxe-Weimar, was born at Wolfenbüttel on the 24th October 1739, and married Duke Ernest of Saxe-Weimar in 1756. Her husband died in 1758, leaving her regent for their infant son, Karl August. During the protracted minority she administered the affairs of the duchy with the greatest prudence, strengthening its resources and improving its position in spite of the troubles of the Seven Years' War. She was a warm patroness of art and literature, and attracted to Weimar many of the most eminent men in Germany. Wieland was appointed tutor to her son; and the names of Herder, Goethe, Knebel, Böttiger, Musæus, and Schiller shed an undying lustre on her court. In 1775 she retired into private life, her son having attained his majority. In 1788 she set out on a lengthened tour through Italy, being accompanied by Goethe. She died on the 10th April 1807. A memorial of the duchess is included in Goethe's works under the title *Zum Andenken der Fürstin Anna-Amalia*.

AMALRIC or AMAURI OF BENA, so called from his birthplace, a small village in the diocese of Chartres, was the founder of a school of pantheists known by his name. He lectured at Paris about the year 1200, and attracted a large circle of hearers. In 1204 his doctrines were condemned by the university; and on a personal appeal to Pope Innocent III. the sentence was ratified, Amalric being ordered to return to Paris and recant his errors. This he did in 1207. His death, two years later, was caused, it is said, by grief at the humiliation to which he had been subjected. In the same year (1209) ten of his followers were burnt before the gates of Paris, and Amalric's own body was exhumed and burnt, and the ashes given to the winds. The doctrines of the Amalricians were formally condemned by the fourth Lateran Council in 1215.

AMALTEO, the name of a family belonging to Oderzo, Treviso, several members of which were distinguished in literature. The best known are three brothers, Geronimo (1507-74), Giambattista (1525-73), and Cornelio (1530-1603), whose Latin poems were published in one collection under the title *Trium Fratrum Amaltheorum Carmina* (Venice, 1627; Amst. 1689). The eldest brother, Geronimo, was a celebrated physician; the second, Giambattista, accompanied a Venetian embassy to England in 1554, and was secretary to Pius IV. at the Council of Trent; the third, Cornelio, was a physician and secretary to the republic of Ragusa.

AMALTEO, POMPONIO, a painter of the Venetian school, was born at San Vito in Friuli in 1505, and died in 1584. He was a pupil of Pordenone, whose style he closely imitated. His works consist chiefly of frescoes and altar-pieces, and many of them have suffered greatly from the ravages of time.

AMARA SINHA, a Sanscrit grammarian and poet, of whose personal history hardly anything is known. He is said to have been "one of the nine gems that adorned the throne of Vikramaditya," and accordingly to have flourished about 56 B.C. This seems on the whole the most probable date, though the fifth century of the Christian era,

and even the eleventh, have also been assigned, on the supposition that the Vikramaditya spoken of was not the first but a later monarch of the name. Amara seems to have been a Buddhist; and an early tradition asserts that his works, with one exception, were destroyed during the persecution carried on by the orthodox Brahmins in the fifth century. The exception is the celebrated *Amara-Kosha* (Treasury of Amara), a vocabulary of Sanscrit roots, in three books, and hence sometimes called *Trikanda*, or the "Tripartite." It contains 10,000 words, and is arranged, like other works of its class, in metre, to aid the memory. The first chapter of the *Kosha* was printed at Rome in Tamil character, in 1798. An edition of the entire work, with English notes and an index by Colebrooke, appeared at Serampore in 1808. The Sanscrit text was printed at Calcutta in 1831. A French translation by Loiseleur-Deslongchamps was published at Paris in 1839.

AMARANTH, or AMARANT (from the Greek *ἀμάραντος*, unwithering), a name chiefly used in poetry, and applied to certain plants which, from not soon fading, typified immortality. Thus Milton (*Paradise Lost*, iii. 353):—

"Immortal amarant, a flower which once  
In paradise, fast by the tree of life,  
Began to bloom; but soon for man's offence  
To heaven removed, where first it grew, there grows,  
And flowers aloft, shading the fount of life,  
And where the river of bliss through midst of heaven  
Rolls o'er elysian flowers her amber stream:  
With these that never fade the spirits elect  
Bind their resplendent locks."

The famous flowers, however, still live upon earth, and are known in our gardens as love-lies-bleeding, prince's feather, cockscorn, and the globe amarant. As we wreath our churches in winter with holly and ivy, the churches in Portugal and other southern countries are adorned with the purple tints of the globe amarant, which is said to retain its colour for years. It should be noted that the proper spelling of the word is amarant; the more common spelling seems to have come from a hazy notion that the final syllable is the Greek word for *flower*, which enters into a vast number of botanical names.

AMARAPURA, literally "the City of the Gods," a town of independent Burmah, situated on the east bank of the Irawadi river, in 21° 57' N. lat., and 73° 4' E. long. The town was founded in 1783, and made the capital of the Burmese kingdom. It increased rapidly in size and population, and in 1810 was estimated to contain 170,000 inhabitants; but in that year the town was destroyed by fire, and this disaster, together with the removal of the native court in 1819, caused a decline in the prosperity of the place. In 1827 its population was estimated at only 30,000. Since then it has suffered another severe calamity from an earthquake, which in 1839 destroyed the greater part of the city. It is regularly laid out, but, with the exception of some temples, is built only of bamboos, although several of the buildings, being richly gilt, have a showy appearance. The most remarkable edifice is a celebrated temple, adorned with 250 lofty pillars of gilt wood, and containing a colossal bronze statue of Buddha. The remains of the ancient palace of the Burmese monarchs still survive in the centre of the town. During the time of its prosperity Amarapura was defended by a rampart and a large square citadel, with a broad moat, the walls being 7000 feet long and 20 feet high, with a bastion at each corner.

AMASIA, or AMASIAYAH, a town in Anatolia, Turkey, situated on both sides of the Yeshil-Irmak, or Iris, in a narrow gorge about 80 miles from the mouth of the river. The houses being ill-built and the streets narrow, the town would have a mean appearance but for its situation and the splendid remains of antiquity in its neighbourhood.

The most remarkable of these are the Acropolis, which is built on a lofty rock overhanging the town; the tombs of the kings of Pontus, described by Strabo the geographer, a native of Amasia; and a handsome mosque, erected in 1490 by the Sultan Bajazet II. The chief productions of Amasia and the surrounding districts are silk, salt, wheat, wine, and cotton. Population of the town, 25,000.

AMASIS, King of Egypt, ascended the throne 569 B.C. From the rank of a common soldier he gradually rose to be one of the principal officers in the court of Apries, the last king of the line of Psammetichus. Being commissioned by Apries to quell an insurrection, he went over to the rebels, who proclaimed him king. Apries, whose tyranny had caused nearly all his subjects to desert him, took the field with an army of mercenaries, and meeting Amasis near Memphis, was defeated and taken prisoner. The usurper treated the captive prince with great lenity; but so violent was the popular hatred, that he was compelled to deliver him into the hands of his enraged countrymen, who instantly put him to death by strangling. Under the prudent administration of Amasis, Egypt enjoyed the greatest prosperity. He adorned it with numerous and splendid buildings, among which were a portico to the temple of Minerva at Sais, and the great temple of Isis at Memphis. He also erected a colossus before the temple of Vulcan, 75 feet in length, resting on its back; and on the basis stood two statues, each 20 feet high, cut out of the same stone. To gain the alliance of the Greeks, he allotted settlements for them on the sea-coast, permitting them to build temples, and to observe all the rites of their religion unmolested; and when the temple of the Delphians was burnt he presented them with 1000 talents to assist them in rebuilding it. He also married a Grecian lady, named Ladice, the daughter of Battus of Cyrene, and had a bodyguard of Greeks in his pay. Solon, the celebrated lawgiver, is reported to have visited Amasis. The close of his reign was disturbed by the threatened invasion of Cambyses, king of Persia, and by the rupture of the alliance between Amasis and Ptolemy of Samos. (See POLYCRATES.) Amasis, however, did not live to see the conquest of Egypt, for he died in 525, before the Persians had entered the country.

AMAT, FELIX, a Spanish ecclesiastical historian, was born at Sabadell, in the diocese of Barcelona, 10th August 1750. He entered the church in 1767, and after taking his doctor's degree at Grenada in 1770, was made professor of philosophy and librarian in the episcopal seminary at Barcelona. In these offices, and in that of director of the seminary, which he subsequently held, his talents and energy did much to advance the efficiency of the institution. In 1803 he was made archbishop of Palmyra by the pope, and in the same year the king, Charles IV., created him abbot of St Ildefonso. When the war with France broke out in 1794, Amat was at first looked upon as an undoubted patriot, but latterly he was suspected, and with some reason, of favouring the French cause. He was compelled to leave Madrid on the entry of the British in 1812; and was subsequently, in 1814, banished to Catalonia. He died in a Franciscan convent near Salent on 28th September 1824. Amat's chief work is his *Ecclesiastical History*, from the birth of Christ to the end of the 18th century, originally published in twelve volumes (1793-1803). It was condemned by the Inquisition, but rather on political than on religious grounds. His other works are numerous, the most important being his *Observations on Ecclesiastical Power* and his *Six Letters to Irenicus*, in which he attacked the theory that consent of the subjects is the necessary foundation of sovereignty. Amat was a man of gigantic stature, being, it is said, at the age of seventeen, 7 feet 2 inches in height.

AMATI, the name of a family of violin-makers who flourished at Cremona from about 1550 to 1692. According to Fétis, Andrea and Nicolo Amati, two brothers, were the first Italians who made violins. They were succeeded by Antonio and Geronimo, sons of Nicolo. Another Nicolo, son of Geronimo, was alive in 1692. The violins made by this family are distinguished by their small size, exquisite finish, and the mathematical proportion of the parts. Their tone is soft and sweet, but deficient in intensity, owing to the flatness of their model. Stradivari was a pupil of the Amatis.

AMATITLAN, the name of a lake and town in Guatemala, Central America. The lake is 18 miles from the city of Guatemala, and is about 9 miles long and 3 broad. The town, which is sometimes called St Juan d'Amatitlan, is situated on the shores of the lake. The houses are all of one storey, and are mostly built of mud. The Jesuits formerly had extensive sugar plantations at Amatitlan, but the chief industry now is the raising of the cochineal. The wells of the town are strongly impregnated with salt and alum, and in the vicinity there are several hot springs. Population about 10,000, chiefly mulattoes and samboes.

AMAUROSIS (*ἀμαύρωσις*), a deprivation of sight. The term is now limited chiefly to those forms of defect or loss of vision which are caused by diseases not directly involving the eye, although sooner or later the optic nerve undergoes changes recognisable by the ophthalmoscope. Sometimes the amaurosis is temporary, disappearing with the removal of the disease with which it is associated; but in many cases, more especially where the brain and spinal cord are affected, the amaurosis remains permanent.

AMAXICHI, a seaport town on the N. of the Ionian island of Santa Maura. It is the capital of the island, and the residence of a Greek archbishop. The frequent occurrence of earthquakes compels the inhabitants to construct their houses of wood; hence the town is of mean appearance. Its harbour admits small craft only. Population, 7000.

AMAZON, MARAÑON, ORELLANA, or SOLIMOENS, a river of South America, the largest in the world. Its head stream is either the Ucayale or Apurimac, which rises in Peru about 16° S. lat., and 72° W. long.; or the more northerly Marañon, also called Tunguragua, which flows from Lake Lauricocha, 10° 30' S. lat., and 76° 10' W. long. The former is the longer river, but the latter has perhaps the weight of authority in its favour. The Marañon flows in a north-westerly direction, parallel to the Ucayale, as far as 6° S. lat., when it bends to the north-east, and, on reaching the frontiers of Equador, turns almost due east. It thence forms the boundary between Equador and Peru, with an easterly direction, until it joins the Ucayale. The united river continues to separate Equador and Peru as long as these countries are conterminous, and thereafter strikes through Brazil, the general direction being north-north-east. It finally discharges itself into the Atlantic under the equator. From the source of the Apurimac to the ocean this mighty river has a length, including windings, of nearly 4000 miles. It receives enormous tributaries—from the north, the Napo and the Putumayo, each about 700 miles long; the Yapura, 1000 miles; the Negro, 1400; as well as others of less importance: from the south, besides the Yavari, the Yutai, the Yurua, Tefe, the Puruo, and others, there are the Madeira, of nearly 2000 miles; the Topayos, of 1200; the Xingu, of 1300; and the Tocantins, of 1200. In addition to these, the Huallaga, of 500 miles, joins the Marañon, from the south, above its union with the Ucayale. The area drained by the Amazon and its tributaries is probably not less than 2,500,000 square miles, or more than a third part of South America. The breadth of the river,

of course, varies at different points. At some distance below Jaen, on the Marañon, it was found to be 860 feet wide; at a pass called the Pongo de Manseriche its bed is suddenly contracted from 250 to 25 fathoms, being enclosed on either side by rocks, which rise like perpendicular walls to a great height; at the junction with the Napo its breadth has increased to 900 fathoms. Between the Negro and the Madeira it has the breadth of a league, which extends to two leagues at those parts where islands abound; but during the annual rise of the water it covers a great part of the adjacent country, and has then no determinate limits. The main mouth is about 50 miles wide above the island of Caviana, but the whole delta, including the Para mouth and the island of Joannes, is nearly 200 miles from shore to shore. The depth of the Amazon in some parts exceeds 50 fathoms, and the river is navigable for vessels of the largest size up to the confluence of the Marañon and the Ucayale. Beyond this point vessels of a smaller size can proceed as far as San Borja, on the Marañon, and a considerable distance up the Ucayale and the Huallaga. The velocity of the water above San Borja so greatly exceeds the average (which is about 2½ miles an hour), that navigation becomes difficult, and among the rapids is impossible, even to canoes. Nearly all the branches of the Amazon are navigable to a great distance from their junction with the main stream; and collectively the whole presents an extent of water communication unparalleled in any other part of the globe. It may be mentioned, too, that as the wind and current are usually, at least from July to December, opposed to each other, a vessel can make her way either up or down with great facility by availing herself of her sails in the one case, and committing herself to the force of the current in the other. Since the introduction of steamers, however, this circumstance is of less importance. The influence of the tides is felt 400 miles above the mouth of the Amazon, while on the other hand the river current is distinctly perceptible in the ocean for more than 200 miles from the shore. The curious tidal phenomenon called the *bore*, or *proroca*, is thus described by La Condamine:—

“During three days before the new and full moons, the period of the highest tides, the sea, instead of occupying six hours to reach its flood, swells to its highest limit in one or two minutes. The noise of this terrible flood is heard five or six miles off, and increases as it approaches. Presently you see a liquid promontory 12 or 15 feet high, followed by another, and another, and sometimes by a fourth. These watery mountains spread across the whole channel, and advance with a prodigious rapidity, rending and crushing everything in their way. Immense trees are sometimes uprooted by it, and sometimes whole tracts of land are swept away.”

The Amazon traverses a region thickly covered with lofty forests, which are the haunts of the jaguar, bear, panther, and other wild animals, and are inhabited by numerous small tribes of savages, among whom the Spaniards and Portuguese have established missionaries. The river abounds with fish, many of which are delicious eating; and turtles of an excellent quality are numerous. Large alligators may be frequently seen stretched motionless in the mud like trunks of trees. The name Amazon (which is also written *Amassona* and *Amazonas*) is derived from the Indian word *Amassona*, or “boat-destroyer,” the reference being to the destructive *proroca*. According to native usage, the name Amazon ought to be restricted to the lower part of the river, below the mouth of the Rio Negro, the portion above that point, as far at least as the junction of the Marañon and the Ucayale, being termed by the natives Solimoens. The other two designations by which the river is sometimes known owe their origin respectively to Francis Orellana, who in 1540 sailed from the mouth of the Rio Napo to the ocean, and Marañon,

who visited the upper waters in 1513. Yañez Pinzon, however, visited the river before either, having discovered the mouth in 1500. (See the works of Bates, Wallace, and W. H. Edwards, and the article BRAZIL.)

AMAZONS (*Ἀμαζόνες*), a race of women represented in Greek legend as having lived in the north-east of Asia Minor, near the shore of the Black Sea, and as having there formed an independent state, with a queen at its head, and with the mythical town of Themiscyra, on the river Thermodon, as its capital. From this centre they made warlike excursions, sometimes northward, but chiefly against the people on the coast of Asia Minor. From the traditions that to repel and conquer them was assigned as a task to Bellerophon by the King of Lycia, and again to Hercules by Eurystheus, it may be inferred that they were regarded by the Greeks at least as a permanent source of danger. But equally, if the task of conquering them is to be strictly compared with the other tasks in which these heroes were generally opposed to monsters and beings impossible in themselves, but possible as illustrations of permanent danger and damage, it would follow that the Amazons were mythical illustrations of the dangers which beset the Greeks on the coast of Asia Minor. Their impossibility as actual beings is further recognised in works of art, in which combats between them and Greeks are placed on the same level as, and often associated with, combats of Greeks and centaurs. The belief in the existence of the Amazons, however, having been once accepted and introduced into the national poetry and art, it became necessary to surround them as far as possible with the appearance of not unnatural beings. Their occupation was hunting and war; their arms the bow, spear, axe, a half shield, nearly in the shape of a crescent, called *pelta*, and in early art a helmet, the model before the Greek mind having apparently been the goddess Athene (Minerva). In later art they approach the model of Artemis (Diana), wearing a thin dress, girt high for speed; while on the later painted vases their dress is often peculiarly Persian—that is, close-fitting trousers, and a high cap called the *kidaris*. They fought partly on foot, partly on horseback, and always without quarter; so that the epithet of *ἀνδροκτόνοι*, or *oiropata*, which is the Seythian equivalent (Herod. iv. 110), was applied to them. To maintain their stock, annual visits were paid to the neighbouring peoples; and when, in consequence of this, children were born, the males were either sent over the borders or retained and brought up crippled, and in the condition of slaves, while the female children were assiduously trained to hunting and war. So as to have freedom in the use of the bow, the right breast was either removed by burning and other processes, or was checked in its growth; hence the ancient derivation of the name Amazon from *ἄ-μάζος*, “breastless.” But instead of there being any indication of this in works of art, it is noticeable that in the case of wounded Amazons the wound is in the breast, as if the artist conceived them as truly womanly in that region. The other derivations are—(1) from *ἄ-μάζος*, in the sense of “strong-breasted,” so as to compare with their deity Artemis *Polymazos*; (2) from *ἄ-μάσσω*, “not touching (men);” (3) from the Seythian *am azzen*, a “virago.” The deities of the Amazons were Ares (Mars) and Artemis, the former being consistently assigned to them as a god of war, and as a god of Thracian and generally northern origin. In the case of Artemis, it was not here the usual Greek goddess of that name, but an Asiatic deity in some respects her equivalent, but different, among other points, in this, that troops of women (*hierodulae*) were associated with her worship, especially as it existed at Ephesus in historical times. That it may have been so also in the early myth-making age, and that

accordingly the idea of the Amazons as a race may have originated in the ecstatic lawless life of these women, has been conjectured. With regard to Ephesus, it was said that a body of Amazons, under a princess named Lampedo, had founded that town, and established the worship of Artemis; though in another account they appear as enemies of this religion, and as having burnt the temple of Artemis at Ephesus. Several other towns of Asia Minor claimed to have been founded by Amazons; but according to Diodorus (ii. 52, 55), the Amazons in this case were a race of women who inhabited the west of Libya, and who once, led by their queen Myrina, advanced through Asia Minor and on to Thrace, where they were defeated by Mopsus, and compelled to return. Other memorials of the expeditions and battle-fields of the Amazons were recognised in the tumuli in the Troad and elsewhere in Asia Minor. These ancient local traditions derived a strong colour of reality afterwards, when inroads of barbarians, under a female leader, occurred, as in the time of Cyrus, or when Thalestris appeared before Alexander the Great, announcing herself as the queen of the Amazons; but chiefly when it was observed that certain characteristics of the Amazons actually existed among the women of Sarmatia. The effect of this mixture of fact and legend may be seen in the account given by Herodotus (iv. 110) of the collapse of the Amazonian state, or in the origin of it as related by Justin (ii. 4). On the other hand, the Persian war seems to have freshened, as if to supply a mythical prototype, the national legends of combats between Greeks and Amazons. These legends recounted the defeat of the Amazons, first by Bellerophon, and secondly by Hercules, who had been ordered by Eurystheus to bring him the girdle of their queen Hippolyte, or, in other words, since the girdle of their queen would in Greek eyes be the most sacred object, to conquer the whole race of Amazons. It is supposed that he was accompanied by his friend Theseus, and that this was the occasion on which the latter became possessed of the Amazon princess Antiope. From his possession of her originated a third legend, which described an invasion of Attica by a body of Amazons, with the view of carrying off Antiope. Their utter defeat by Theseus must have seemed, in the light of Marathon and Salamis, as a forecast of the glory then won by Athens. The fourth legend, which deals with the appearance of an army of Amazons, led by their queen Penthesilea on the side of the Trojans in the Trojan war, was developed by Arctinus of Miletus in his poem the *Æthiopis*. Achilles and the queen meet in battle, and she falls by his hand; but the hero is smitten with grief, and lifts her gently before she dies. It is this feeling of regret on the part of a hero who is compelled to kill a woman in his own defence, that gives the principal tone to the existing works of Greek art, in which combats with Amazons are represented, and especially to works of sculpture. Of this class there exist (besides a number of reliefs, among which those from the temple of Apollo at Phigalia, now in the British Museum, are conspicuous for many touching motives of this kind), several statues of wounded Amazons, the sad expression of which, combined with the nobility of form and power of limb, shows what was the highest conception of them in the best days of Greek art.

(A. S. M.)

AMBÁLÁ, a division, district, and city of British India, under the jurisdiction of the Lieutenant-Governor of the Panjáb. The Ambálá DIVISION comprises the districts of Ambálá and Ludhiáná in the plains, and the district of Simlá in the Hinnálayas. The last-named district consists of a few detached patches of territory, scattered among the territories of the petty chieftains by whom the neighbouring hills are held. Simlá district is, however, the

seat of the supreme government of India during the hot weather, and its chief town, of the same name, is the largest hill station in India. The other two districts of the division lie upon the plains at the foot of the Himálayas. They are bounded on the N.E. by those mountains, on the N.W. by the river Satlej, on the S.W. by the district of Firozpur, the independent native state of Patiálá, and the district of Karnál, and on the S.E. by the river Jamná.

AMBÁLÁ DISTRICT stretches N.W. and S.E. along the lower face of the Himálayas, and lies between 29° 55' and 31° 14' N. lat., and between 76° 37' and 77° 38' E. long. It is bounded on the N.E. by the Himálayas, on the N.W. by the river Satlej, on the S.E. by the river Jamná, and on the S.W. by the district of Ludhiáná, the state of Patiálá, and the district of Karnál. The total area of the district is 2628 square miles, or 1,681,930 acres, of which 945,526 acres are cultivated, 283,989 acres are cultivable, but not actually under tillage, and 452,415 acres are uncultivable and waste. The total population of the district, according to the census of 1868, amounts to 1,035,488 souls, divided into the following classes:—Hindus, 689,333; Mahometans, 286,874; Sikhs, 56,440; others, 2841. The males numbered 567,930, and the females 467,558; the proportion of males to the total population being 54·84 per cent. The principal tribes and castes in point of numbers are—(1.) Játs, viz., Hindus and Sikhs, 161,967; Mahometans, 13,368; total, 175,335. (2.) Chámárs (Hindus), 125,638. (3.) Rájputs—viz., Hindus and Sikhs, 20,121; Mahometans, 62,866; total, 82,987. (4.) Bráhmans, 63,744. (5.) Gujjars—viz., Hindus and Sikhs, 24,500; Mahometans, 24,195; total, 48,695. (6.) Baniás (Hindus), 39,093. The total agricultural population was 501,056. Taking the population as compared with the area, the result gives 1·62 acres per head of the population, or 3·35 acres per head of the agricultural population. Putting aside the uncultivable and waste land, there are 1·18 acres of cultivated or cultivable land per head of the population, or 2·45 acres per head of the agricultural population. Taking only the area under actual cultivation, there are ·91 acres per head of population, or 1·88 acres per head of the agricultural population. With one small exception, the whole district consists of a level alluvial plain, sloping away gradually from the foot of the Himálayas, and lying between the rivers Jamná and Satlej. These rivers do not materially affect the district, which has a drainage system of its own, consisting of the numerous torrents and water-courses which pour down upon it from the hills. In the southern portion of the district these torrents run in broad sandy beds scarcely below the surface of the country, and vary from 200 yards to a mile in width, until, at a distance of 20 or 30 miles from the hills, they assume the form of comparatively docile streams, with well-defined clay banks. Towards the northern portion of the district the torrents run in deep beds from the point where they debouch from the hills; they also differ from the streams of the southern tract in being free from sand. The principal of these northern streams is the Ghaggar, into which all the other minor streams sooner or later empty themselves, some within and some beyond the limits of the district. Whatever surplus water of this river is not swallowed up by irrigation passes on through Patiálá state and Sirsá, and is finally lost in the sands of Rájputáná. The Ghaggar is the only perennial stream within the district, and even it dwindles down to a tiny rivulet in the dry weather, and disappears altogether beyond the border of the district.

The Sind, Panjáb, and Dehli railway passes through the centre of the district from south-east to north-west. The other principal land routes are two main lines of road, one passing through the district parallel to the line of railway, and the other coming from Dehli and

Karnál, entering it on the south, and running northward till the two roads meet at Ambálá city. A less important road runs northward from this town to the foot of the Himálayas, and forms the route to the hill station of Simla. The principal agricultural products of Ambálá district are wheat, grain, and barley for the spring harvest, and rice, joár (spiked millet), and Indian corn in the autumn. The total area under cultivation in 1871-72 was, for the spring harvest 437,377 acres, and for the autumn crop 496,542 acres. The land settlement of the southern portion of the district was completed in 1855, and that of the northern part in 1855. Both will expire in 1880. The following eight towns are returned as containing a population of upwards of 5000 souls, the first-named seven being also municipalities: Ambálá, population, 50,662 souls; Sháhábád, 11,678; Jagádhri, 11,678; Sadhaurá, 11,198; Rupar, 8700; Búná, 8351; Tháneswar, 7929; Mani Majrá, 5989. A municipal income is also raised from the following seven towns:—Kharar, Sísván, Morindah, Pihewah, Rádaur, Ladwah, and Khizirábád. All the municipalities derive their revenue from a system of octroi duties. The total revenue of Ambálá district for 1871 was £101,362, of which 74 per cent., or £74,446, was derived from the land. The other principal items of revenue were as follows:—Distilleries, £3594, 14s.; drugs and opium, £3151, 4s.; income-tax, £2709, 14s.; stamps, £2308, 14s.; local rates levied under Act xx. of 1871, £7653, 18s. Ambálá is one of the territories previously held by a Sikh Sardár which lapsed to the East India Company in default of rightful heirs. The district was seized by Ranjít Singh during one of his marauding expeditions. This aggression caused the movement of British troops in 1809 which resulted in the treaty with Ranjít Singh by which he was required to withdraw his army from the left bank of the Satlej, and to relinquish his recent conquests in Sirhind.

AMBÁLÁ CITY, the capital of the district of the same name, is situated in 30° 24' N. lat., and 76° 40' E. long. It forms a large and important station on the Sind, Panjáb, and Dehli railway. The military station and cantonments lie a few miles south-east of the town. Ambálá is a large walled town, situated in a level and highly-cultivated country, well supplied with water, and capable of furnishing abundant supplies. The houses are built of burnt brick, and the streets are very narrow. The town population is returned at 50,662 souls, but this probably includes the English station. The population within municipal limits numbers 24,040, divided as follows:—Agriculturists, 3226; non-agriculturists, 20,814. The town has been constituted a second-class municipality, the affairs of which are conducted by a committee consisting of six official and five non-official members. The municipal income is derived from an octroi duty, and the revenue has increased from £836, 16s. in 1867-68, to £1520 in 1871-72. The average incidence of municipal taxation in the latter year was 1s. 3½d. per head of the population within municipal limits.

AMBARVALIA, or AMBARVALE SACRUM (*ambis* and *arvum*, to go round the field), an annual festival celebrated in ancient Rome on three days during the month of May. The private *ambarvalia* is to be distinguished from the *sacrificium deæ diæ* celebrated by the twelve *fratres arvales*, though the two festivals were coincident in point of time and had a common object, namely, to obtain from the gods a favourable harvest. The *sacrificium* was offered up on behalf of the entire state; the *ambarvalia* was celebrated by each proprietor for himself. The victims were a sow, a sheep, and a bull, and were called by the combined name *suovetaurilia*. Previous to the sacrifice these were led round the fields, while the peasants sang hymns to Ceres. The form of prayer used (*carmen ambarvale*) is preserved in an inscription of the date of the Emperor Elagabalus (218 A.D.), which was discovered in 1777. The same inscription gives an interesting account of the entire ceremony. (See Marini's *Gli Atti e Monumenti de Fratelli Arvali*, Rome, 1792.) The Christian festival that seems to have taken the place of the *ambarvalia* is the Rogation or *Gang Week* of the Roman Catholic Church, for which the perambulation of the parish boundaries was substituted at the Reformation.

AMBASSADOR, a word introduced into the English language from the Fr. *ambassadeur*, the Ital. *ambasciatore*, or the Span. *embaxador*, which Wicquefort derives, perhaps without sufficient authority, from the Span. *embar*, to send. The word denotes a public minister of the highest rank, accredited and sent by the head of a sovereign state to a foreign court or country, with power to represent the person of the sovereign by whom he is sent, to negotiate with a foreign government, and to watch over the interests of his own nation abroad. The power thus conferred is contained in the credentials or letters of credence of which the ambassador is the bearer, and in the instructions under the sign-manual delivered to himself. The credentials consist in a sealed letter addressed by the sovereign in person whose representative he is, to the sovereign to whom he is sent, and they contain a general assurance that the sovereign by whom he is despatched will approve and confirm whatever is done by the ambassador in his name. In England these letters of credence are under the sign-manual of the Queen, and are not countersigned by the Secretary of State. On special occasions, as for the negotiation of treaties, additional express powers are given to an ambassador under the great seal, and sometimes (but very rarely) full general powers to treat on all subjects. Lord Clarendon held such powers at the congress of Paris in 1856

Diplomatic envoys are of three ranks, as was finally determined by a common agreement of all the powers which was annexed to the final act of the treaty of Vienna in 1815:—1. Ambassadors; the ambassador of the pope being called a nuncio, and the ambassador of the Emperor of Austria to the Sublime Porte being called his inter-nuncio. These only have representative rank. 2. Envoys extraordinary or ministers plenipotentiary, accredited to sovereigns (*auprès des souverains*). 3. Chargés d'affaires, who are only entitled to transact business with the Minister of Foreign Affairs. We shall confine ourselves in this article to the diplomatic officers of the first rank. The relative number of ambassadors, as distinguished from ministers, has of late years been considerably increased. The Emperor Nicholas refused for many years to send an ambassador to the court of France, and he therefore suppressed the grade for a time altogether. His example was imitated by other powers. But the old practice has now been reverted to. The Queen of England has embassies at Paris, Constantinople, Vienna, St Petersburg, and Berlin. The number of British ministers plenipotentiary is twenty-three, and three chargés d'affaires; but these numbers vary.

From the 15th century, when the practice of sending resident embassies may be said to have commenced in Europe, down to the close of the 18th century, these missions were surrounded with a prodigious amount of splendour, ceremonial, and contentious dignity. British ambassadors were commonly sent out till within the last thirty years in ships of war. The ambassador represented a monarch, and was to play the part of one. The memoirs of those ages are full of the magnificence and profuse display which marked their progress—lacqueys, liveries, state coaches, led horses, and all the pageantry of state. Fierce disputes frequently arose between rival ambassadors for precedence; sometimes these disputes even extended to the courts and ministers to whom these envoys were despatched as messengers of peace, and a vast deal of time was lost (especially at the Congress of Münster) in adjusting them. On the part of the sovereign to whom they were to present their credentials the same display was made. The new ambassador was fetched by the master of the ceremonies in the king's coaches and feasted at the king's expense. The solemn entry and the public audience, as they were termed, were an essential part of the mission.

The ambassador had the right to stand covered in the presence of royalty. At Venice the doge placed Sir Harry Vane, covered and seated, on his right hand in the Council of Ten. A speech was then delivered, in which the ambassador declared the friendly sentiments of his own sovereign, and his own humble desire to give effect to them. Modern simplicity and the facility of intercourse has swept away many of these formalities. Traces of them survive at the courts of Berlin and Vienna, but elsewhere an ambassador is presented with little more than the customary ceremony of a court. It has long been held that every state is at liberty to receive ambassadors with or without ceremony, just as it pleases, provided they are all treated alike. Formalities of this kind are, however, still of moment in dealing with Oriental states, where ceremony is the language of power. Perhaps it is nowhere carried to higher perfection than at the court of Japan. The knotty question of precedence was also settled at the Congress of Vienna by an agreement that precedence should be regulated by seniority, dating from the notification of the arrival of the envoy. In foreign countries the senior ambassador is known as the dean or doyen of the diplomatic body; but in England the diplomatic body has no general mouthpiece or representative.

Every state or sovereign has the right, if it thinks fit, to refuse to receive a particular person as an ambassador, or even to receive any ambassador at all. It is therefore customary to ascertain beforehand whether the person designated for an embassy is favourably regarded, and will be well received. There have been instances, not very remote, of unfavourable answers or refusals to receive given individuals.

The rank of an ambassador, as regards the society of the nation to which he is accredited, places him immediately after the princes of the blood royal, because he represents a sovereign power, and this rank is universally conceded to him. The rank of a minister plenipotentiary is rather more dubious, but by a rule laid down by Her Majesty for the court of St James they follow dukes and precede marquises. An ambassador or minister not actually accredited to this court has of course no official rank at all, and must take his personal rank. No distinction is made between the ambassadors of monarchies and of republics. The Venetian ambassadors held in their time a very prominent rank in Europe; so in our day do the ministers of the United States; but the United States have never sent any ambassador to Europe—their representatives therefore rank in the second class of public ministers.

We shall now proceed briefly to enumerate that which constitutes the essential dignity and utility of an ambassador—on the one hand his rights and privileges, on the other his duties.

A. The first right of an ambassador is that of personal audience of the sovereign. His credentials must invariably be presented to the sovereign in person, and he may ask for an audience on any fitting occasion. In England, however, the sovereign does not officially receive an ambassador except in the presence of one or more of the ministers of the crown. Mr Canning complained bitterly of the influence of Prince Lieven and Prince Esterhazy over George IV., who lived on intimate terms with these ambassadors, and used to say "his father would never have done so." In England the right of audience is now generally limited to the presentation of some congratulatory letter; but at Continental courts it is not without considerable utility and importance, as was shown by the memorable conversation of Sir Hamilton Seymour with the Emperor Nicholas, and the personal interviews of Lord Cowley and Lord Clarendon with the Emperor Napoleon III.

In all ages the perfect personal security of persons invested with high diplomatic functions, as the representa-

tives of a foreign power, has been an essential and fundamental principle of the law of nations. Indeed it was the law of nations when there was no other. Alexander the Great destroyed Tyre for an insult offered to his ambassador; and it stands recorded in the Roman law, "Si quis legatum hostium pulsasset, contra jus gentium id commissum esse existimatur, quia sancti habentur legati" (*Dig. L. Tit. vii. § 17*). In moments of excessive excitement or revolutionary frenzy even this principle has been violated, as in the murder of Dr Dorislaus at the Hague (1649), and of the French envoys at Rastadt (1799); but such acts leave an indelible disgrace on those who have committed them. For it is the interest of all mankind that ambassadors and envoys should have absolute security to perform their missions with freedom of speech and the liberty "eundi et redeundi" undisturbed, insomuch that to intercept or refuse passage to an ambassador, even through the territory of a third party, is justly regarded as a base action, though probably the leave of the third party to grant the passage ought to be asked. It was the barbarous custom of Turkey to send an ambassador to the Seven Towers on a declaration of war, and detain him there as long as the war lasted; but the Porte formally relinquished and abandoned this practice on the breaking out of war with Russia in 1827. To secure this immunity from all interference, an accredited ambassador or envoy is wholly free from the jurisdiction of the courts of law, or of any other authority in the country in which he is sent to reside. This constitutes the doctrine of *extraterritoriality*. His house is as sacred as his person. It is supposed, like a ship at sea, to form part of the territory represented by the flag which he may hoist over it. All the members of the embassy, and even the servants of the ambassador, share the same inviolability. They cannot even be arrested and prosecuted for offences without his consent. Hence, as the courts of justice have no jurisdiction over them, and indeed would have no means of enforcing an adverse decision either by distress or imprisonment, these diplomatic agents cannot be impeached or sued. The only means of obtaining redress for an injury or breach of contract is an appeal to the head of the mission, or a further appeal to the government which he represents, which, it must be presumed, will not allow a wrong to be committed with impunity under the shelter of privilege. In England, by the statute 7 Anne, c. 12, it is expressly enacted that any process against foreign ambassadors or ministers, or their goods and chattels, shall be altogether void. This Act was passed in consequence of an attempt, made in 1708, to arrest an ambassador of Peter the Great in London for a debt of £50, and it is still law; but in fact it is only declaratory, and in confirmation of the common law and the law of nations.

An ambassador or envoy pays no taxes or contributions to the public revenue of the country in which he resides, and on this principle he is entitled to receive commodities from abroad free of customs duties. But he is not exempted from the payment of local rates,—though, indeed, if he were to decline to pay them, no process could issue against him for the purpose of levying them. He also pays the ordinary rates of postage, but he has the privilege of sending his own couriers carrying sealed despatches, which exempts him from the monopoly of the post office. These couriers, and their despatches or mails, are also regarded by common consent as inviolable messengers, unless they chance in time of war to fall into the hands of a hostile belligerent. In some countries ambassadors and their couriers have been allowed to have a prior claim for post horses over private travellers.

Another of the important privileges of an ambassador or envoy is the free exercise of the religion or form of worship

to which he adheres; but it is laid down by the best writers on the subject that a foreign minister has not the right of maintaining a chapel or chaplain within his hotel, under the law of nations; hence the liberty of religious worship for the ambassador and his suite was made a matter of treaty engagement between Catholics and Protestants, and between Christians and Mussulmans. By courtesy, though not of strict right, the usage of ambassadors' chapels has, however, become general; and it had a real importance in countries where the free exercise of different forms of belief was not tolerated by law. Thus, at the time when the rites of the Church of Rome were forbidden in England, the Spanish and Bavarian chapels in London were free; and they have remained in existence till our own days, although the enlarged tolerance of the present age has removed in every civilised country those barriers. In China and Japan the free exercise of the Christian religion by the Christian embassies is formally secured by treaty.

*B.* We now pass to the duties of an ambassador, and we place at the head of them that of keeping his own sovereign well informed of all that may concern his interests in foreign countries. He is the eye of the government he serves, specially directed to a particular spot, and he ought to be thoroughly acquainted with the course of policy, the movements of parties, the character and disposition of individual statesmen, and the material and commercial resources of the country in which he resides. His public despatches, and his private correspondence with the Minister of Foreign Affairs under whom he serves, ought to be a record of all that can interest or concern the state which he represents. In this sense the diplomatic reports of the ambassadors of former times are invaluable materials for history. His next duty is to protect and defend, if necessary, the persons and interests of his fellow-countrymen abroad; and this is of especial moment in the case of a British ambassador, whose countrymen are to be met with as travellers, navigators, or merchants in all parts of the globe. To them the presence and influence of the diplomatic representatives of their country is of incalculable value, and nothing can be more ill-judged than the proposals that have been made to cut down and contract our foreign embassies and missions. A third, but not less important, duty of an ambassador is to maintain the most amicable relations with the sovereign to whom he is accredited, and with his ministers, and to observe towards them the strictest respect, veracity, and good-will. It has been said in joke that the first duty of an ambassador is to keep a good cook; but if this implies that he is to exercise a liberal hospitality and to make his house agreeable, those no doubt are means which may powerfully assist him in the objects of his mission. In former times it was considered to be essential to good diplomacy to act as a spy upon the motives and conduct of foreign statesmen, to cheat without being cheated, to use clandestine means to obtain information, to endeavour to form a party in foreign states favourable to the ambassador's own national interests, to observe and resist with the utmost jealousy the demeanour of other foreign envoys, and to carry on a species of warfare under the mask of courtesy and good-breeding. These practices have given diplomacy and the functions of ambassadors a bad name, but it must be said that they are repudiated by the principles and practice of the present time, and more especially by the foreign policy of this country. Down to a recent period, these struggles for ascendancy in foreign countries were carried on with great eagerness, and they led to unfortunate results. In Spain, for example, the untoward marriage of Queen Isabella was notoriously brought about by the violent and arbitrary interference of the French ambassador; and in 1848, when Lord Palmerston instructed

Sir Henry Bulwer to represent to the Spanish minister that they would do well to adopt a more liberal and constitutional system of government, General Narvaez immediately sent the British envoy out of the country. This was the exercise of an extreme right, for which the British government could claim no redress. So, again, when in the course of the Russian war (1855) it appeared to the American government that the British envoy in Washington had infringed the neutrality laws of the United States by endeavouring to enlist recruits for the service of Her Majesty, he was compelled to leave the country, and Great Britain had no just cause of complaint. These modern cases are important, because they prove that no state which respects itself will tolerate, on the part of a foreign envoy, a direct interference in the internal affairs of government or an infraction of its own laws. Hence arises the great principle on which our modern practice is founded, namely, that it is the duty of an ambassador to observe a strict neutrality between contending parties in the state to which he is accredited; to accept the government *de facto* with which he communicates as the government and sovereign of the nation; to pay implicit obedience to the laws of that state, whatever they be; and to abstain as much as possible from all intervention in its internal affairs. These doctrines are comparatively new, but they are sound, and they may be said to have received the assent and the approval of the most enlightened governments of Europe. Great changes have occurred within the last few years in France, Germany, Austria, Italy, and Spain; but they have all the distinguishing mark that they are wholly independent of foreign diplomatic influence. The first, perhaps we ought to say the sole duty, of an ambassador is to protect his own national interests and to promote the most friendly relations with the sovereign to whom he is accredited; and experience has proved that these objects are best secured by confining himself to the principal objects of his mission, and by relying on no arts but those of sincerity, forbearance, and truth. (H. R.)

AMBATO, or ASIENTO D'AMBATO, a town of Ecuador, on the northern slope of Chimborazo, about 65 miles south of Quinto, 8859 feet above the sea. It was destroyed by an eruption of Cotopaxi in 1698, but was soon rebuilt, and now carries on a flourishing trade in grain, sugar, and cochineal. Population, 12,000.

AMBER (Gr. ἤλεκτρον; Lat. *Succinum*, *Electrum*; Fr. *Succin*, *Ambre*; Ger. *Bernstein*) is a hard, brittle substance with a resinous lustre, sometimes found perfectly transparent, but more usually of varying degrees of translucency, and possessing a prevailing yellow colour, passing from a pale straw tint to a deep orange. It occurs in irregular masses, and has neither taste nor, at ordinary temperatures, odour. It develops electrical phenomena by friction, a property which doubtless early drew attention to amber, and invested it with the romantic interest which attached to it in ancient times. The popular regard for the substance among the nations of antiquity was further maintained by the fabulous tales of the manner in which amber was formed and the mystery connected with its occurrence.

The earliest notice of amber we find occurs in the *Odyssey* of Homer, where in the list of jewels offered by Phœnician traders to the Queen of Syra occurs "the gold necklace hung with bits of amber" (*Od.* xv. 460). Thales of Miletus, 600 B.C., noticed that amber when rubbed attracted light bodies, and that remote and simple observation is the foundation of the modern science of *electricity*, so named from the Greek ἤλεκτρον. Among the Greek fables purporting to account for the origin of amber, it is narrated that the Heliadae, on seeing their brother Phæthon hurled by the lightning of Jove into the Eridanus, were

by the pitying gods transformed into poplar trees, and the tears they shed were dropped as amber on the shores of the river. Hence arose the Greek term for amber, ἤλεκτρον being one of the names of the sun god. A less poetical theory of its origin states that it was formed from the condensed urine of the lynx inhabiting northern Italy, the pale varieties being produced by the females, while the deeper tints were attributed to males. In such repute was amber in Rome in the time of Pliny that he sarcastically remarks, "the price of a small figure in it, however diminutive, exceeds that of a living healthy slave." Besides its application to jewellery and carved ornaments, and its use, partly decorative and partly prophylactic, as necklaces, peculiar virtues were attributed to it. Pliny observes—"True it is that a collar of amber beads worn about the necks of young infants is a singular preservative to them against secret poison, and a counter-charm for witchcraft and sorceries." As an article of personal ornamentation, the same authority states that amber was used to produce imitations of precious stones by artificial staining, a use to which it was peculiarly adapted owing to its brilliant lustre combined with the ease with which it could be worked and polished.

The great source of supply of amber in all ages appears to have been the Baltic coasts, from which the supplies of commerce still continue to be drawn. During the reign of Nero an expedition was sent from Rome to explore the amber-producing country, and so successful was the party that a present of 13,000 lb of amber was brought back to the emperor, including a piece weighing 13 lb. It occurs in regular veins along the Baltic coast, but in greatest abundance between Pillau and Grosz Hubenicken, on the Prussian coast. Professor Phillips thus describes the mines:—

"Near the sea-coast in Prussia there are regular mines for the working of amber: under a stratum of sand and clay, about 20 feet thick, a stratum of bituminous wood occurs, from 40 to 50 feet thick, of a blackish brown colour, and impregnated with pyrites. Parts of these trees are impregnated with amber, which sometimes is found in stalactites depending from them. Under the stratum of trees were found pyrites, sulphate of iron, and coarse sand, in which were rounded masses of amber. The mine is worked to the depth of 100 feet; and from the circumstances under which the amber is found it seems plain that it originates from vegetable juices."

After heavy storms large quantities are usually found thrown up on the coast at the localities where it is regularly excavated, and the assumption is, that amberiferous deposits crop up in the shallow waters near the shores, from which pieces become detached during the violent commotion of the water. It is further sparingly cast on the Swedish and Danish coasts, and occasionally pieces are picked up along the shores of Norfolk, Essex, and Sussex in England. It occurs at numerous localities inland throughout Europe, among which may be noted the neighbourhood of Basle in Switzerland, the departments of Aisne, Loire, Gard, and Bas Rhin in France, and in the Paris clay it is associated with bituminous deposits. In England it has been found in the sandy deposits of the London clay at Kensington. The coasts of Sicily and the Adriatic likewise afford amber. The most beautiful specimens are perhaps those which are found at Catania. They often possess a beautiful play of colour, approaching to purple, not to be observed in the product of other places. Professor Dana gives the following note on its occurrence in America:—

"It has been found in various parts of the greensand formation of the United States, either loosely embedded in the soil or engaged in marl or lignite, as at Gay Head or Mather's Vineyard, near Trenton, and also at Camden, in New Jersey, and at Cape Sable, near Magothy river, in Maryland."

It is said to be taken in large quantities from the north of Burmah to the markets of China, where it is highly prized.

The appearance of enclosed foreign bodies, such as insects, leaves, twigs, &c., which amber very often presents, and the markings on its surface, very early led to correct inferences as to its origin. Pliny states that "amber is an exudation from trees of the pine family, like gum from the cherry and resin from the ordinary pine; and in accordance with this opinion is its Latin name *succinum*, the gum-stone. The opinion expressed by Pliny is that which at the present day may be fairly held as established; but of course amber differs from other resins owing to changes induced by its fossilised condition. Sir David Brewster has pointed out that in optical properties it agrees with other resinous exudations. The insects found enclosed in amber are for the most part of extinct species, and so also are the remains of plants. A species of conifer has been established provisionally as the amber-yielding tree, *Pinites succinifer*, but Göppert has shown that many trees may have yielded the exudation, and these not all necessarily belonging to the pine order.

The close relation of amber to ordinary resins is further brought out by its chemical properties and composition. According to Berzelius, it consists mainly of a resin, succinite, insoluble in alcohol, in combination with small proportions of two others, isomeric with the first, but soluble in alcohol and ether. By dry distillation it gives off at a low temperature water, succinic acid, and oil of amber, which last substance was formerly used in medicine in combination with alcohol and ammonia under the name of *cau de luce*; but now amber and all its products have disappeared from the standard pharmacopœias. Its composition is, according to Schrötter—

Carbon .....	78.94
Hydrogen .....	10.53
Oxygen .....	10.53

and mineralogically it belongs to Dana's class of oxygenated hydrocarbons. It burns with a pale yellow flame, with a good deal of black smoke, evolving an agreeable odour, and leaving a shining black carbonaceous residue.

It is said that by exposing amber covered with sand in an iron pot to the influence of heat for forty hours, or boiling it for twenty hours in rape oil, it will become transparent, and pieces will cement and mould together. The great size of vessels of amber which have come down from ancient times suggests the probability of some such art being practised in remote periods. It is now applied to few useful purposes among western nations beyond forming the mouthpieces for tobacco-pipes and cigar-holders. Fine pieces are in some demand for public collections and for the purposes of the carver. In the East, besides its being highly prized for ornamental purposes, a feeling of veneration for its mystic properties still enhances its value. The Turks esteem it highly as a mouth-piece for tobacco pipes, and believe that it resists the transmission of infection. The principal demand for the amber of commerce is among the Armenians, through whom it is conveyed to Egypt, Persia, China, and Japan; and a great quantity is purchased to be consumed at the shrine of Mahomet by the pilgrims bound to Mecca. The value of amber depends upon its colour, its lustre, and its size. In 1576 a mass weighing 11 lb was found in Prussia, and deemed worthy of being presented to the emperor; later, a mass of 13 lb was found, for which it is said 5000 dollars were refused. In the royal cabinet at Berlin a piece is shown weighing 18 lb; but such masses are of very great rarity.

AMBERG, a walled town of Bavaria, formerly the capital of the Upper Palatinate, and at present the seat of the appeal court for the district, is situated on both sides

of the Vils, 35 miles east of Nuremberg. It is a well-built town, and has a library, a gymnasium, a lyceum, elementary schools, an arsenal, and several churches, the finest of which is St Martin's, with many fine paintings, and a tower 300 feet high. The principal manufactures are fire-arms, ironmongery, earthenware, woollen cloth, beer, and salt; in the neighbourhood are iron and coal mines. The French under Jourdan were defeated by the Austrians near Amberg in 1796. Population in 1871, 11,688.

AMBERGRIS (*Ambra grisea*, *Ambre gris*, or Grey Amber) is a solid, fatty, inflammable substance of a dull grey or blackish colour, the shades being variegated like marble, possessing a peculiar sweet earthy odour. It is now known to be a morbid secretion formed in the intestines of the spermaceti whale (*Physeter macrocephalus*), and is found floating upon the sea, on the sea-coast, or in the sand near the sea-coast. It is met with in the Atlantic Ocean, on the coasts of Brazil and Madagascar; also on the coast of Africa, of the East Indies, China, Japan, and the Molucca Islands; but most of the ambergris which is brought to England comes from the Bahama Islands, Providence, &c. It is also sometimes found in the abdomen of whales, always in lumps in various shapes and sizes, weighing from  $\frac{1}{2}$  oz. to 100 or more lb. A piece which the Dutch East India Company bought from the King of Tydore weighed 182 lb. An American fisherman from Antigua found, inside a whale, about 52 leagues south-east from the Windward Islands, a piece of ambergris which weighed about 130 lb, and sold for £500 sterling. Like many other substances regarding the origin of which there existed some obscurity or mystery, ambergris in former times possessed a value, and had properties attributed to it, more on account of the source from which it was drawn than from its inherent qualities. Many ridiculous hypotheses were started to account for its origin, and among others it was conjectured to be the solidified foam of the sea, a fungoid growth in the ocean similar to the fungi which form on trees, the excreta of sea-birds, &c. The true source and character of ambergris was first satisfactorily established by Dr Swediaur in a communication to the Royal Society (*Philosophical Transactions*, vol. lxxiii.) It was found by Dr Swediaur that ambergris very frequently contained the horny mandibles or beaks of the squid (*Sepia moschata*), on which sperm whales are known to feed. That observation, in connection with the fact of ambergris being frequently taken from the intestines of the sperm whale, sufficiently proved that it was formed within that creature, and not an extraneous substance swallowed by the whale. It was further observed that the whales in which ambergris was found were either dead or much wasted and evidently in a sickly condition. From this it was inferred that ambergris was in some way connected with a morbid condition of the sperm whale. Ambergris, when taken from the intestinal canal of the sperm whale, is of a deep grey colour, soft consistence, and a disagreeable smell. On exposure to the air it gradually hardens, becomes pale, and develops its peculiar sweet earthy odour. In that condition its specific gravity ranges from 0.780 to 0.926. It melts at a temperature of about 145° Fahr. into a fatty yellow resinous-like liquid; and at 212° it is volatilised into a white vapour. It is soluble in ether, volatile and fixed oils, but only feebly acted on by acids. By digesting in hot alcohol, a peculiar substance termed ambrein is obtained, which deposits in brilliant white crystals as the solution cools. In chemical constitution ambrein very closely resembles cholesterin, a principle found abundantly in biliary calculi. It is therefore more than probable that ambergris, from the position in which it is found and its chemical constitution, is a biliary concretion analogous to what is formed in other mammals. The

use of ambergris in Europe is now entirely confined to perfumery, though it formerly occupied no inconsiderable place in medicine. As a material of perfumery its price varies from 15s. to 25s. per ounce; and in minute quantities its alcoholic solution is much used for giving a "floral" fragrance to bouquets, washes, and other preparations of the perfumer. It occupies a very important place in the perfumery of the East, and there it is also used in pharmacy, and as a flavouring material in cookery. The high price it commands makes it peculiarly liable to adulteration, but its genuineness is easily tested by its solubility in hot alcohol, its fragrant odour, and its uniform fatty consistence on being penetrated by a hot wire.

AMBERT, chief town of an arrondissement of the same name in the department of Puy de Dôme, France, situated on the Dore, 35 miles from Clermont. Its chief manufactures are paper, linen, lace, ribands, and pins; it has also an extensive trade in cheese of a very fine quality. Population in 1872, 7625.

AMBLESIDE, a small market town in Westmoreland, situated about a mile from the head of Lake Windermere, and 14 miles from Kendal. During the summer it is much frequented by tourists on account of its beautiful situation. In its vicinity is Rydal Mount, for many years the residence of the poet Wordsworth. Some indistinct remains of Roman fortifications, in which coins, urns, and other relics have been frequently discovered, exist in the neighbourhood. Coarse woollen cloths are manufactured at Ambleside. Population in 1871, 1988.

AMBLETEUSE, a seaport town of France, in the department of the Pas de Calais, on the English Channel, 6 miles north of Boulogne. From the accumulation of sand in its harbour it has lost its importance as a seaport, and the town is now almost deserted. It possesses an historical interest as the landing-place of James II. after his abdication in 1688; and Napoleon I. in 1804 attempted to improve the harbour for the flat-bottomed boats by means of which he was to invade England. Near Ambleteuse is the column which he erected to the grand army in 1805. Population, about 700.

AMBO, or AMBON (Gr. ἄμβων, from ἀναβαίνω), a reading-desk or pulpit in early Christian churches which was placed in the middle of the nave. It was ascended by a flight of steps on both the east and west sides, and was in some cases so large as to accommodate fifty persons. From it the lessons were read, and hence it was sometimes called *suggestus lectorum* and βήμα τῶν ἀναγνοστῶν. It was also occasionally used by the preacher. Two movable ambos may be seen in the church of St John Lateran at Rome. The purposes of the ambo were served in mediæval churches by the rood-loft, a gallery across the chancel-arch, and in modern churches it has given place to the lectern and the pulpit.

AMBOISE, a town situated in a rich wine-producing district in the department of Indre-et-Loire, France, on the left bank of the Loire, 14 miles east of Tours. Its chief manufactures are cloth and files. At Amboise the French Protestants were first called Huguenots, and 1200 of them were massacred there in 1560 on the discovery of their conspiracy against the Guises. The ancient castle, which is situated on a height above the town, was a seat of the French kings, and it was set apart as a residence for the Arab chief Abd-el-Kader during his captivity in France. Population, 4570.

AMBOYNA, one of the Moluccas or Spice Islands, belonging to the Dutch, lying south-west of Ceram, in 3° 41' S. lat. and 128° 10' E. long. It is 32 miles in length, with an area of about 280 square miles, and is of very irregular figure, being almost divided into two. The south-eastern and smaller portion (called Leitimor) is united to

the northern (known as Hitoe) by a neck of land about a mile broad. The island is mountainous, but is for the most part fertile and well-watered. Large tracts are covered with rich tropical forests, which embrace a great variety of trees, although ordinary building timber is scarce. The climate is comparatively pleasant and healthy; the average temperature is 80° Fahr., rarely sinking below 72°. The rainfall, however, after the eastern monsoons, is very heavy, and the island is liable to violent hurricanes and earthquakes. Amboyna produces most of the common tropical fruits and vegetables, including the sago-palm, bread-fruit, cocoa-nut, sugar-cane, maize, coffee, pepper, and cotton. Cloves, however, form its chief product, and the only one that is of any real commercial importance. The Dutch have done much to foster the cultivation of this article in the island, and at one time prohibited the rearing of the clove-tree in all the other islands subject to their rule, in order to secure the monopoly to Amboyna. Each tree yields annually from 2 to 5 lb of cloves, and sometimes even more; while the total annual quantity produced probably averages about 500,000 lb. The animal kingdom is poorly represented. Indigenous mammals are feeble in species as well as few in number; birds are more abundant, but of no greater variety. The entomology of the island is, however, very rich, particularly among the *Lepidoptera*. The aborigines of Amboyna are a race called Horaforas, but Malays constitute the main body of the population; there are also Chinese, Dutch, and a few Portuguese. The Malays in most points resemble those of Java. They are naturally lazy and effeminate, but when properly trained make good soldiers. The inhabitants are mostly Christians or Mahometans. Amboyna is the chief island of the Dutch residence of the Moluccas, which comprises, in addition, the islands of Boeroe, Amblauw, Ceram, Manipa, Kilang, Bonoe, Harockoe, Honimoa or Saparoa, Noesa-laut, and Hila. The Portuguese were the first European nation to visit Amboyna (1512). They established a factory there in 1521, but did not obtain peaceable possession of it till 1580, and were dispossessed by the Dutch in 1605. About the year 1615 the British formed a settlement in the island, at Cambello, which they retained until 1623, when it was destroyed by the Dutch, and frightful tortures inflicted on the unfortunate persons connected with it. In 1654, after many fruitless negotiations, Cromwell compelled the United Provinces to give the sum of £300,000, together with a small island, as compensation to the descendants of those who suffered in the "Amboyna massacre." In 1796 the British, under Admiral Rainier, captured Amboyna, but restored it to the Dutch at the peace of Amiens in 1802. It was recaptured by the British in 1810, but once more restored to the Dutch in 1814. Population, about 50,000. See MOLUCCAS.

AMBOYNA, the chief town of the above island, and also of the Dutch Moluccas, is situated towards the north-west of the peninsula of Leitimor. The streets are broad and unpaved, running at right angles to one another, and intersected by numerous rivulets. The houses are of wood, roofed with palm leaves, and mostly of one storey, on account of the frequent earthquakes. An esplanade of 250 yards reaches from Fort Victoria to the town, and is terminated by a handsome range of houses. The town-house is a neat structure of two storeys; and among the other buildings are two Protestant churches and a hospital. The government offices are in Fort Victoria. The roadstead of Amboyna is safe and commodious. Population, about 13,000.

AMBRACIA, or AMPRACTIA, an important city of ancient Epirus, situated on the eastern bank of the river Arachthus, about seven miles from the Ambracian Gulf.

According to tradition, it was originally a Thesprotian town, founded by Ambrax, son of Thesprotus, or by Ambracia, daughter of Augeas. About 635 B.C. it was colonised by Corinthians, and so became a Greek city. Its power increased rapidly until the time of the Peloponnesian war, when it commanded the whole of Amphilochia, including the town of Argos, from which the original inhabitants were expelled. In 432 B.C. the expelled citizens, with the assistance of the Athenians under Phormion, retook Argos. In 430 the Ambracians made an unsuccessful attempt to recover the town, and a second attack in 426 resulted in a still more disastrous failure. The power of Ambracia now declined as rapidly as it had grown. In 338-7 it was compelled to submit to Philip of Macedonia, and it remained subject to that kingdom until it was ceded by Alexander V. to Pyrrhus of Epirus about 295. The latter made it his capital, and enriched it with numerous works of art. It subsequently came under the power of the Ætolian League (239), and sustained a memorable siege in the war between the latter and Rome (189). In the end the city opened its gates to the enemy, who removed many of its most valuable works of art to Rome. In 31 B.C. the inhabitants of Ambracia were removed by Augustus to Nicopolis, the town he had founded in commemoration of the victory of Actium. The site of Ambracia is occupied by the modern Arta, near which remains of the ancient fortifications may be seen.

AMBROSE OF ALEXANDRIA lived in the beginning of the third century. Jerome and Eusebius differ in the account they give of him, the one calling him a Marcionite, the other a Valentinian; but they agree in alleging that he was converted to the orthodox faith by the preaching of Origen. Origen dedicated many of his works, among others his book *On Martyrdom*, to Ambrose, at whose desire and expense they were published, and the two lived on terms of the most intimate friendship. According to some, Ambrose died a martyr in the persecution under Maximin, about the year 236; but the dedication of Origen's *Eight Books against Celsus* proves that he lived to the year 250, or near that period. Origen speaks of him as a man of sincere piety, and much devoted to the study of the Scriptures.

AMBROSE, SAINT, Bishop of Milan, was one of the most eminent fathers of the church in the fourth century. He was a citizen of Rome, born in Gaul,—according to some historians, in the year 334, but according to others in 340. At the period of his birth his father was prætorian prefect of Gallia Narbonensis; and upon his death the widow repaired to Rome with her family. Ambrose received a religious education, and was reared in habits of virtue by his mother, an accomplished woman, and eminent for her piety. The names of his instructors in the rudiments of Greek and Roman literature have not been transmitted to posterity; but in these branches he made early proficiency, and having directed his attention to the law, he employed his eloquence with such reputation in the prætorian court of Anicius Probus, that he was soon deemed worthy of a place in the council. After he had continued in this station for some time, Probus appointed him consular prefect of Liguria and Æmilia, comprehending the territories of Milan, Liguria, Turin, Genoa, and Bologna. Milan was chosen as the place of his residence; and, by the prudent and gentle use of his power, he conducted the affairs of the province with general approbation and growing popularity.

The death of Auxentius, bishop of Milan, in the year 374, made a sudden change in the fortune and literary pursuits of Ambrose. At that period the tide of religious contention ran high between the orthodox and the Arians, and a violent contest arose concerning the choice of a successor

to Auxentius. When the people were assembled in the church to elect the new bishop, Ambrose, in the character of governor of the place, presented himself to the assembly, and in a grave, eloquent, and pathetic address, admonished the multitude to lay aside their contentions, and proceed to the election in the spirit of religious meekness. It is reported that when Ambrose had finished his address, a child cried out, "Ambrose is bishop," and that the agitated multitude, regarding this as a miraculous intimation, unanimously elected Ambrose bishop of Milan. Some suppose that this was entirely a device of Ambrose or his friends; others ascribe it to mere accident. Ambrose professed strong reluctance, and even fled, or pretended to fly, from the city in order to avoid the intended honour. The place of his concealment, however, was soon discovered; the emperor's confirmation of his election was made known to him; and after being baptized, he was ordained bishop of Milan, about the end of the year 374. Whatever we may think of the singular conduct of Ambrose in accepting an office for which he was certainly unqualified in respect of previous studies, habits, and employments, it must be admitted that he immediately betook himself to the necessary studies, and acquitted himself in his new elevation with ability, boldness, and integrity. Having apportioned his money among the poor, and settled his lands upon the church, with the exception of making his sister tenant during life, and having committed the care of his family to his brother, he entered upon a regular course of theological study, under the care of Simplician, a presbyter of Rome, and devoted himself to the labours of the church.

The irruption of the Goths and the northern barbarians, who rushed down upon the Roman empire at this time, spreading terror and desolation all around, compelled Ambrose, along with several others, to retire to Illyricum, but his exile was of short duration, for the northern invaders were quickly defeated by the forces of the emperor, and driven back with considerable loss into their own territories.

The eloquence of Ambrose soon found ample scope in the dispute between the Arians and the orthodox. About this era the doctrine of Arius concerning the person of Christ had been extensively received, and had many powerful defenders both among the clergy and the common people. Ambrose espoused the cause of the Catholics. Gratian, the son of the elder Valentinian, took the same side; but the younger Valentinian, who had now become his colleague in the empire, adopted the opinions of the Arians; and all the arguments and eloquence of Ambrose were insufficient to reclaim the young prince to the orthodox faith. Theodosius, the emperor of the East, also professed the orthodox belief; but there were many adherents of Arius scattered throughout his dominions. In this distracted state of religious opinion, two leaders of the Arians, Palladius and Secundianus, confident of numbers, prevailed upon Gratian to call a general council from all parts of that empire. This request appeared so equitable that he complied without hesitation; but Ambrose, foreseeing the consequence, prevailed upon the emperor to have the matter determined by a council of the Western bishops. A synod, composed of thirty-two bishops, was accordingly held at Aquileia in the year 381. Ambrose was elected president; and Palladius being called upon to defend his opinions, declined, insisting that the meeting was a partial one, and that the whole bishops of the empire not being present, the sense of the Christian church concerning the question in dispute could not be obtained. A vote was then taken, when Palladius and his associate Secundianus were deposed from the episcopal office.

Ambrose was equally zealous in combating the heathen

superstitions. Upon the accession of Valentinian II., many of the senators who remained attached to the pagan idolatry made a vigorous effort to restore the worship of the heathen deities. Symmachus, a very opulent man and a great orator, who was at that time prefect of the city, was intrusted with the management of the pagan cause, and drew up a forcible petition, praying for the restoration of the altar of Victory to its ancient station in the hall of the senate, the proper support of seven vestal virgins, and the regular observance of the other pagan ceremonies. In the petition he argued that this form of religion had long been profitable to the Roman state, and reminded the emperor how much Rome had been indebted to Victory, and that it had been the uniform custom of the senators to swear fidelity to the government upon that altar. He likewise adduced many facts to prove the advantages accruing to the state from its ancient religious institutions, and pleaded that, as it was one divinity that all men worshipped under different forms, ancient practice should not be rashly laid aside. He even proceeded so far as to assert the justice of increasing the public revenue by robbing the church, and attributed the late famine which had overtaken the empire to the neglect of the ancient worship. To this petition Ambrose replied in a letter to Valentinian, arguing that the devoted worshippers of idols had often been forsaken by their deities; that the native valour of the Roman soldiers had gained their victories, and not the pretended influence of pagan priests; that these idolatrous worshippers requested for themselves what they refused to Christians; that voluntary was more honourable than constrained virginity; that as the Christian ministers declined to receive temporal emoluments, they should also be denied to pagan priests; that it was absurd to suppose that God would inflict a famine upon the empire for neglecting to support a religious system contrary to His will as revealed in the Scriptures; that the whole process of nature encouraged innovations, and that all nations had permitted them, even in religion; that heathen sacrifices were offensive to Christians; and that it was the duty of a Christian prince to suppress pagan ceremonies. In the epistles of Symmachus and of Ambrose both the petition and the reply are preserved, in which sophistry, superstition, sound sense, and solid argument are strangely blended. It is scarcely necessary to add that the petition was unsuccessful.

The increasing strength of the Arians proved too formidable for Ambrose. In 384 the young emperor and his mother Justina, along with a considerable number of clergy and laity professing the Arian faith, requested from the bishop the use of two churches, one in the city, the other in the suburbs of Milan. The prelate believing the bishops to be the guardians both of the temporal and spiritual interests of the church, and regarding the religious edifices as the unquestionable property of the church, positively refused to deliver up the temples of the Lord into the impious hands of heretics. Filled with indignation, Justina resolved to employ the imperial authority of her son in procuring by force what she could not obtain by persuasion. Ambrose was required to answer for his conduct before the council. He went, attended by a numerous crowd of people, whose impetuous zeal so overawed the ministers of Valentinian that he was permitted to retire without making the surrender of the churches. The day following, when he was performing divine service in the Basilica, the prefect of the city came to persuade him to give up at least the Portian church in the suburbs. As he still continued obstinate, the court proceeded to violent measures: the officers of the household were commanded to prepare the Basilica and the Portian churches to celebrate divine service upon the arrival of the emperor and his mother at the ensuing festival of Easter. Perceiving

the growing strength of the prelate's interest, the court deemed it prudent to restrict its demand to the use of one of the churches. But all entreaties proved in vain, and drew forth the following characteristic declaration from the bishop:—"If you demand my person, I am ready to submit: carry me to prison or to death, I will not resist; but I will never betray the church of Christ. I will not call upon the people to succour me; I will die at the foot of the altar rather than desert it. The tumult of the people I will not encourage; but God alone can appease it."

Many circumstances in the history of Ambrose are strongly characteristic of the general spirit of the times. The chief causes of his victory over his opponents were his great popularity and the superstitious reverence paid to the episcopal character at that period. But it must also be noted that he used several indirect means to obtain and support his authority with the people. He was liberal to the poor; it was his custom to comment severely in his preaching on the public characters of his times; and he introduced popular reforms in the order and manner of public worship. It is alleged, too, that at a time when the influence of Ambrose required vigorous support, he was admonished in a dream to search for, and found under the pavement of the church, the remains of two martyrs, Gervasius and Protasius. The vulgar crowded to behold these venerable relics, and, according to report, a number of sick persons were healed by touching the bones. Ambrose exulted in these miracles, and appealed to them in his eloquent sermons; while the court derided and called in question their existence. It is remarkable that these and many other miracles obtained current credit among the Christian historians of the second, third, and fourth centuries; and Dr Cave, in speaking of them, says—"I make no doubt but God suffered them to be wrought at this time on purpose to confront the Arian impieties."

Although the court was displeased with the religious principles and conduct of Ambrose, it respected his great political talents; and when necessity required, his aid was solicited and generously granted. When Maximus usurped the supreme power in Gaul, and was meditating a descent upon Italy, Valentinian sent Ambrose to dissuade him from the undertaking; and the embassy was successful. On a second attempt of the same kind Ambrose was again employed; and although he was unsuccessful, it cannot be doubted that, if his advice had been followed, the schemes of the usurper would have proved abortive; but the enemy was permitted to enter Italy, and Milan was taken. Justina and her son fled; but Ambrose remained at his post, and did good service to many of the sufferers by causing the plate of the church to be melted for their relief. Theodosius, the emperor of the East, espoused the cause of Justina, and regained the kingdom.

In the year 390 a tumult happened at Thessalonica, in which Botheric, one of the imperial officers, was slain. Theodosius was so enraged at this that he issued a royal mandate for the promiscuous massacre of the inhabitants of the place, and about 7000 persons were butchered without distinction or mercy. The deed called forth a severe rebuke from Ambrose, who charged the emperor not to approach the holy communion with his hands stained with innocent blood. The emperor reminded him that David had been guilty of murder and of adultery. The bishop replied, "You have imitated David in his guilt; go and imitate him in his repentance." The prince obeyed, and after a course of eight months' penance he was absolved, on condition that in future an interval of thirty days should intervene before any sentence of death or confiscation was executed.

The generosity of Ambrose was favourably exhibited in

the year 392, after the assassination of Valentinian and the usurpation of Eugenius. Rather than join the standard of the usurper, he fled from Milan; but when Theodosius was eventually victorious, he supplicated the emperor for the pardon of those who had supported Eugenius. Soon after acquiring the undisputed possession of the Roman empire, Theodosius died at Milan (395). Bishop Ambrose did not long survive him, having died in the year 397.

On many accounts the character of the bishop of Milan stands high among the fathers of the ancient church. With unvarying steadiness he delivered his religious sentiments on all occasions; with unwearied assiduity he discharged the duties of his office; with unabated zeal and boldness he defended the orthodox cause in opposition to the Arians; with a liberal hand he fed the numerous poor who flocked to his dwelling; with uncommon generosity he manifested kindness to his adversaries; and with Christian affection he sought the happiness of all men. His general disposition and habits were amiable and virtuous, and his powers of mind vigorous and persevering. Ambition and bigotry were the chief blemishes in his character.

The writings of Ambrose are voluminous, but many of them are little more than reproductions of the works of Origen and other Greek fathers. The great design of them was to defend and propagate the Catholic faith. His expositions of Scripture contain many extreme examples of allegorical and mystical interpretation. Modern readers will regard much in the writings of Ambrose as trivial, and even as ludicrous; but his style is vigorous, and the sentiment is often weighty. Gibbon's judgment appears to be too severe: "Ambrose could act better than he could write; his compositions are destitute of taste or genius, without the spirit of Tertullian, the copious elegance of Lactantius, the lively wit of Jerome, or the grave energy of Augustin." His exegetical writings include an exposition of the Gospel of St Luke, and commentaries on certain Psalms. His *Hexaëmeron* is a homiletical treatise on the history of the creation. "The Hymns of St Ambrose have exercised a powerful influence on Christendom. They were designed by him to be a preventive against the errors of Arianism, and to confirm the professors of the true faith in the doctrines of the Trinity and the divinity of Christ.

. . . Very many of them have found a place in the liturgies of the western Church. On account of the celebrity of St Ambrose, many hymns have been attributed to him which are not his; and, on the other hand, some critics have gone into the opposite extreme, and have deprived him of his property. In the Benedictine edition of his works only twelve hymns are admitted; and Dom. Biraghi [of the Ambrosian Library, who has endeavoured, in his *Inni Sinceri di Sant' Ambrogio*, to restore the hymns to their primitive form] shows reason for believing that only seven of these are genuine" (*Journal of a Tour in Italy*, by Chr. Wordsworth, D.D., 1863.) The most accurate and complete edition of his works is that published by the Benedictines, printed at Paris in 1686 and 1690, in two volumes folio.

A liturgical form, the Ambrosian Ritual, which is still in use in the arch-diocese of Milan, has been traditionally ascribed to Saint Ambrose. Several attempts were made, in particular by the Emperor Charlemagne and Pope Nicolas II., to secure uniformity by enforcing the adoption of the Roman breviary throughout the Western Church, but the clergy of Milan refused to yield. The ritual of Ambrose is included in the *Liturgia Latinorum* of Pamelius (Cologne, 1571-6). "Full information concerning its history will be found in the *Ceremoniale Ambrosiano*, by Dom. Giovanni Dozio, published at Milan, 1853" (Wordsworth's *Tour*, 1863).

For a description of the famous church of St Ambrose,

founded by him at Milan 387 A.D., see MILAN. For the Ambrosian Library, see LIBRARIES. Notices of his LITURGY and HYMNS will be found under these headings.

AMBROSE, ISAAC, a Puritan divine. Formerly the practical and devotional writings of this eminent Nonconformist rivalled John Bunyan's in popularity, and his *Looking to Jesus* holds its own even now. Prominent name as his was in his generation, very scanty are the personal memorials of him. His own "Media," under the head of "Experiences," yields a few incidents of his life. According to Anthony à Wood, he was a minister's son, descending from those of the name living at Lowick, and they from the Ambroses of Ambrose Hall in Lancashire. It is probable that his father was Richard Ambrose, vicar of Ormskirk, who was succeeded by another son, Henry. It seems improbable that any of his line could descend of the Lowick Ambroses, inasmuch as they were the most "persistent Catholics of Lancashire;" and there is the additional consideration that, while in our worthy's writings there are many references to the Papists, he makes not the slightest allusion to his conversion from Popery, or to any Catholic relatives or associations. He entered Brazenose college, Oxford, in 1621, in the seventeenth year of his age, and must therefore have been born in 1603-4. Having proceeded M.A. and been ordained, he received at the outset a little cure in Derbyshire, which was at that time and onward to Puritanism what Goshen was to Egypt and Israel. By the influence of the Earl of Bedford, he was appointed one of the king's itinerant preachers in Lancashire. Having later served for a time a curacy in Garstang, he was selected by the Lady Margaret Hoghton as vicar of Preston. He was on the celebrated committee for the ejection of "scandalous and ignorant ministers and schoolmasters" during the Commonwealth. So long as Ambrose continued at Preston he was favoured with the warm friendship of the Hoghton family, as was John Howe,—their ancestral woods and the tower near to Blackburn affording him sequestered places for those devout meditations and "experiences" that give such a charm to his diary. The immense auditory of his sermon at the funeral of Lady Hoghton is a living tradition still all over the county. For some reason which is unknown, perhaps failing strength for so onerous a charge, Ambrose left his great church of Preston, and became minister of Garstang, where before he had been curate. He was vicar of Garstang when the Act of Uniformity was passed. He could have conscientiously complied with many of its requirements, for he was willing to use the Prayer-book, and did not stickle at things whereat other tender consciences did; but the enforcement was so absolute, not to say brutal, that he found himself constrained to form one of the Two Thousand. His after years were passed among old friends at Preston. He spent a great part of his time every summer in Widdiere wood, where, seldom seen by any except on the Sabbath, he communed with his own heart and his God. The last time he was seen alive was by some friends from Garstang, of whom he is said to have taken leave with unusual affection and gravity. Immediately after they left him he retired to his wonted place of meditation, where he was found by an attendant *in articulis mortis*. He died in 1664 at the age of sixty-one. Calamy says he was seventy-two, but his college entry shows he was mistaken. As a religious writer, Ambrose has a vividness and freshness of imagination possessed by scarcely any of the Puritan Nonconformists. He is plaintive as Flavel and as intense as Baxter. Many who have no love for Puritan doctrine, nor sympathy with Puritan experience, have appreciated the pathos and beauty of his writings, which have never been out of print from their original issue until now.

(A. B. G.)

AMBROSIUS, AURELIANUS, a leader of the Britons during the 5th century. He is said, on somewhat doubtful authority, to have been a son of Constantine, who was elected emperor by the Roman army in Britain in 407. The usually received account of his life, based chiefly upon the history of Geoffrey of Monmouth, contains much that is evidently fabulous. It seems probable that he was educated at the court of Aldroën, king of Armorica, who sent him over with a strong force to assist his countrymen against the Saxons, whom Vortigern had invited to Britain. There is also little doubt that, having defeated Vortigern, he was chosen to succeed him as king of Britain. Geoffrey also states that he built Stonehenge (see *STONEHENGE*), that he defeated Hengist, and that he compelled the Saxons to surrender at York; but these stories are inherently improbable. The circumstances of his death are involved in equal obscurity. According to Geoffrey's account, he died of poison at Winchester; but others state that he was killed in a battle with Cerdic the Saxon in 508.

AMBULANCE, the French *ambulance*, *hôpital ambulante*, derived from the Latin *ambulare*, to move from place to place.

Ambulances, in military phraseology, are hospital establishments moving with armies in the field, and organised for providing early surgical assistance to the wounded after battles. They are only prepared for affording help of a more or less temporary kind, and they are thus distinguished from the *stationary* or *fixed hospitals*, in which sick and wounded soldiers receive care and treatment of a permanent character. The term is not unfrequently misapplied in common speech in England to the ambulance waggons, or other conveyances by which the wounded are carried from the field to the ambulances and fixed hospitals. Such vehicles form part of the ambulance equipment, and will be noticed presently.

The constitution of an ambulance includes (1) a certain staff of officers and subordinates, and (2) a certain equipment. The equipment naturally divides itself into (a) the medical and surgical equipment, and (b) the equipment forming the means of transport for the wounded. But the constitution would hardly be understood without a general comprehension of the system on which the functions of ambulances are discharged, or, in other words, the plan of administering surgical assistance in the field to the wounded of armies. *Ambulance administration* will therefore be first noticed, keeping in view the circumstances of armies operating in Europe, and the *ambulance staff* and *equipment* subsequently.

AMBULANCE ADMINISTRATION.—The origin of the ambulance system which now prevails in all civilised armies, though variously modified among them in particular details, only dates from the last decade of the last century. Before that time no ambulance establishments had been organised for effecting the removal of the wounded, or for giving the requisite surgical attention to them, while battles were in progress. Soldiers wounded in the ranks were either carried to the rear by comrades, or were left to lie exposed to all risks, and unheeded, until after the fighting had ceased. The means of surgical assistance did not reach the battle-field till the day after the engagement, or often later, and to a large proportion of the wounded it was then of no avail. In 1792 Larrey introduced his system of *ambulances volantes*, or flying field hospitals, establishments capable of moving from place to place with speed, like the flying artillery of the time. They were adapted both for giving the necessary primary surgical help, and also for removing the wounded quickly out of the sphere of fighting. The first Napoleon warmly supported Larrey in his endeavours to introduce and perfect the new system of surgical aid to the wounded

in battle; and, being received with much favour by the troops, the plan obtained a firm footing, and was subsequently brought to a high state of perfection. About the same time another distinguished surgeon of high position in the French army, Baron Percy, introduced and developed a corps of *brancardiers*, or stretcher-bearers. These consisted of soldiers trained and regularly equipped for the duty of collecting the wounded while a battle was in progress, and carrying them on stretchers to places where means of surgical aid were provided.

From the period when these improvements were introduced most civilised armies have had ambulance establishments formed for giving surgical help near to the combatants. It is only, however, during the last twenty years that ambulances have acquired the completeness of organisation which they have now attained in some armies, especially in those of Germany. In the armies of the United States of America, during the late great civil war, the ambulance system attained a very complete organisation, particularly from March 1864, when an Act was passed by Congress, entitled "An Act to establish a uniform system of Ambulances in the United States." This law fixed a definite and single system of ambulance arrangements for all the armies of the United States at that time in the field.

The ambulance arrangements of the British army have never reached the degree of completeness which they have reached in Continental armies. During the Peninsular war the want of a trained ambulance corps, and of properly-constructed sick-transport carriages, formed a theme of constant complaint. For the former, soldiers from the ranks were substituted—a double evil, as they were unsuited for the work, while their employment lessened the fighting strength; for the latter, commissariat waggons, or the agricultural carts of the country in which the troops were operating. It was not from want of attention being called to the subject, as the writings of Sir J. M'Grigor, Hennen, Millingen, and other Peninsular surgeons sufficiently testify. The last-named military surgeon published a very complete scheme of an ambulance establishment shortly after the war was concluded, approaching closely in its principles to those put into practice of late years in the armies of Germany. There is reason for believing that had the operations of the British troops on the Continent not been discontinued, some plan of the kind would have been introduced. As it was, subsequently to 1815, so far as army hospitals were concerned, administrative attention was chiefly given to improving those for the accommodation of the sick in peace time. The wars that British troops were engaged in in India, China, the south of Africa, and elsewhere, did not lead to improvements like those which have been made in Continental armies; for either the habits of the natives of the respective countries, or the nature of the climate, or the state of the country, necessitated special arrangements for the care of the sick and wounded unsuited for meeting the circumstances of European warfare. Thus, when the Crimean war broke out the English army was still without an ambulance corps, or an ambulance establishment of *matériel*. An ambulance corps of military pensioners was hastily raised, but failed from the habits and enfeebled constitutions of the men. They were succeeded by a corps formed of civilians, unused to the discipline and habits of military life, which likewise failed. Several forms of sick-transport vehicles were tried, but only indifferently answered their intended purposes. Fortunately, as the troops were for the most part stationary during the war, the want of thoroughly organised ambulances was not felt to the same extent as it would have been had the operations been extended far into the interior of the country. The experience of the Crimean war led to efforts to repair the

defects which were then made manifest. Since that time a trained army hospital corps has been constituted, and much of the ambulance equipment has been revised.

One serious impediment to perfecting an ambulance system is the costliness of maintaining, in time of peace, establishments which will only be required for use in time of war. All that can be done is to form a nucleus which can be expanded according to need when war breaks out. But even in Continental armies, with frequent wars pressing upon them, the urgency of giving close attention to the subject, and in countries where the existence of conscription furnishes a greater supply of men at less cost than in England, the deficiencies of the ambulance establishments have hitherto been so great in respect to the numbers and necessities of the wounded on occasions of great battles, that an extensive volunteer organisation, with national societies in every country of Europe, has sprung up for giving additional assistance. This is not the place to discuss the advantages of such volunteer aid; but, if accepted, all who have considered the subject well have admitted the necessity for its being placed under military authority, and under distinct regulations, in order to secure maintenance of order and discipline. It is also generally admitted that volunteer aid to wounded soldiers is out of place in the ambulances, and can best be employed in the fixed hospitals, by which means some of the regular military *personnel* may be set free for work in the field.

One important step, taken a few years since, towards the amelioration of the condition of the wounded of armies in the field must be just mentioned. This was the European Convention signed at Geneva in 1864, by the terms of which, subject to certain regulations, not only the wounded themselves, but the official staff of ambulances and their equipment have been rendered neutral; the former, therefore, not being liable to be retained as prisoners of war, nor the latter to be taken as prize of war. This convention has greatly favoured the development of ambulance establishments.

The conditions of modern warfare have led to the need of army ambulances being arranged on principles different from what were applicable only a few years ago. The immensely increased range of rifles and artillery in the present day, the consequent extension of the area over which fire is maintained, the suddenness with which armies can be brought into the field from increased facilities of locomotion, the rapidity of their movements, the shortened duration of campaigns, the large numbers of wounded which have to be dealt with, not merely from the destructive qualities of the fire-arms, but from the vast forces collected on occasions of important battles, the increased proportion of severe wounds,—are all circumstances which have entailed need for revision of ambulances and their administration. The ambulances must be so organised as to be able to keep up with the troops, and so disposed as in no way to interfere with their movements. They must be capable of meeting the wants of a partial or general engagement at any moment, and if the troops advance, must be prepared to accompany them, so as to be ready to meet future wants.

Whatever the details of organisation may be when an important battle is fought, the ambulance system must admit of three help stations at least being established in rear of the combatants. There must be a station of limited character immediately in rear of the troops for attention to such wounds as entail speedy loss of life if no assistance be rendered; a second station, more remote, where temporary assistance of a more general nature can be afforded; a third, where more thorough attention can be given, and where the wounded can receive food and protection until there are means of sending them away. Recently, in some

armies, the ambulance arrangements have been calculated for furnishing aid at four stations; and, indeed, owing to the increased range of fire, and the consequent distance between the help stations when only three are formed, the fatigue thrown on the bearers is so great, and the time the wounded are left without help so long, that the division of the ambulances into four stations has become almost essential. If this arrangement be followed, there will be—1st, the *field station*, for help of prime urgency; 2d, the *transfer station*, where the wounded will be transferred from the hand conveyances to wheeled vehicles; 3d, the *dressing station*, where the provisional dressings will be applied; and 4th, the *field hospital station*, where definitive treatment will be adopted.

The disposition and distances of these four ambulance sections must vary according to the nature of the battle, the configuration of the terrain, and other circumstances, but in a general way will be as follows:—1st, the field station, in the immediate rear of the troops, moving with them, and therefore under fire; 2d, the transfer station, clear of the enemy's rifle fire, but not too far for the bearers, and at a place practicable for waggons, from 800 to 900 yards behind the troops engaged; 3d, the dressing station, beyond range of artillery fire, at a spot easily reached by the ambulance waggons, and on the way to the fourth station, with a running stream or well at hand if possible, from 800 to 1000 yards in rear of No. 2; and 4th, the field hospital station, at a place free from risk of being brought within the sphere of fighting, from 2 to 4 miles in rear of the combatants. This last station may be at a farm or country house, or in a village, but should not be in a place of strategical importance, or in one likely to be blocked by the general transport of the army. When the four stations are in working order, as men fall badly wounded, those within reach will be placed on stretchers by the men told off for duty as bearers, and, after hasty inspection by the field surgeon, and, as far as practicable, receiving such help as is of vital importance, they will be borne to the second or transfer station, and placed in ambulance waggons, or on wheeled stretchers if they are in use. The bearers, then taking vacant stretchers, will return to the field station for more wounded. The wounded who have been transferred to the wheeled conveyances will be driven by the men of the ambulance train to the third or dressing station, and there receive whatever provisional dressing may be necessary before being sent on to the fourth or field hospital station, where definitive treatment will be adopted, and any surgical operations performed that may be required.

It is obvious that such a system of help can only be carried out, with any approach to regularity and requisite speed, with ambulance establishments proportionate to the number of troops in the field, each ambulance being well organised, provided with a sufficient staff and complete equipment, and acting under the general supervision of an experienced director, whose duty it is to watch the varying events of the contest while it is in progress, and to order changes in the ambulance arrangements according as the troops advance, retire, or otherwise change position. Even with these advantages, the difficulties of adequately meeting the wants of the wounded must always be very great, owing to the rapid manœuvres of the troops, the varying features of the ground over which battles are extended, and the rapidity with which the wounded fall; but without a proper organisation arranged beforehand, the difficulties are insuperable, and no help of much value can be afforded until all fighting has ceased.

Ambulance arrangements have to be modified to suit particular military operations, such as when troops disembark on a hostile shore, on occasion of sieges, &c.

**AMBULANCE STAFF.**—The scheme of ambulance administration and action just described involves the necessity of a staff comprising the following *personnel*, viz. :—1. Bearers of wounded; 2. Surgeons and attendants; 3. Ambulance train *personnel*; 4. Ambulance police; 5. Servants to officers.

*Bearers of Wounded.*—These are soldiers specially trained and told off for the duty of picking up and carrying the badly wounded on stretchers. In Continental armies special provision is made to meet this particular want, but under different systems in different armies. In the Prussian army companies of bearers, distinguished by a particular uniform, and denominated “sanitäts-detachements,” have the duty assigned to them of gathering the wounded during battles, and carrying them to the dressing and field hospital stations. Each of these bearer columns consists of a military staff of officers for discipline and direction, non-commissioned officers, buglers, and a large number of bearers; a special medical staff, with assistants and dressers; a transport staff of non-commissioned officers and drivers, with a certain number of stretchers, wheeled stretcher supports, sick transport waggons, and store waggons for the carriage of instruments, dressings, and other necessary materials. Separate establishments exist for the field hospitals. In addition to these sanitary detachments, auxiliary sick-bearers (*Hilfs-krankenträger*) are provided for service on occasions of great battles. To form these auxiliaries, four men in each company of every battalion of the army are practised at regular periods with the sanitary detachments in time of peace in the modes of picking up, temporarily attending to, and carrying wounded. These auxiliary bearers wear the uniform of their regiments, of which they perform the ordinary duties, but have a distinguishing badge on the left arm when serving as bearers. When a battle is imminent, the auxiliary bearers fall out, are provided with stretchers and other needful appliances from the ambulance waggons, and act under the orders of the officers of the divisional sanitary detachments. The system in the Austrian army is very like that in the Prussian. In the British army no corresponding establishment exists. The hospital attendants belonging to the Army Hospital Corps are trained in all that refers to the care of wounded men, but in time of war they will be too urgently needed for their duties in the field and fixed hospitals to be spared for duty as bearers of the wounded from the field to the dressing stations. The regimental bandmen are generally regarded as available for these duties in the British service; but though the army regulations order that bandmen are liable to serve in the ranks on an emergency, they nowhere constitute them bearers of wounded, nor do bandmen receive the necessary training to fit them for the duties. As it is understood that the ambulance arrangements of the British army are at present under consideration, this, with other details, will probably be shortly placed on a settled basis.

*Surgical Staff.*—This section embraces the medical officers (administrative and executive), the dispensers of medicine, and the officers, non-commissioned officers, and men of the Army Hospital Corps. The last-named corps includes the dressers, nurses, cooks, and all the hospital subordinates who are required for the care, dieting, watching, and protection of the patients, for the hospital correspondence, &c. The men act professionally under the directions of the surgeons; in respect of other matters, under their own officers. The constitution and duties of the several divisions and grades of the army medical department are shown in a special code of instructions known as the “Army Medical Regulations.”

*Ambulance Train.*—On the officers and men of the

ambulance train devolve the duties of conducting the wheeled transport, and the mule litters and cacolets when such conveyances are used. In the British service these duties are entrusted to the ordinary transport branch of the Control department. It has been recommended that the officers and men to whom these duties are entrusted should be specially selected and trained, as well as familiarised, to co-operate with the bearers and ambulance corps. They would thus form an ambulance train somewhat like that which exists in the sanitary detachments of the Prussian army.

*Military Servants.*—Orderlies are required as servants to the ambulance surgeons and other officers, in order that they may give their time fully to the concerns of the sick and wounded. When special orderlies are not provided, men of the Army Hospital Corps usually act as servants to officers,—a bad system, for the whole time and services of these trained men should be devoted to their legitimate functions.

*Ambulance Police.*—Many irregularities are liable to occur in the rear of troops engaged in a general action; not so much from acts of the troops themselves as from camp followers, hired drivers, and others. The officers charged with the military discipline of the bearer, train, and hospital corps have other pressing duties to engage them on such occasions. In the British army it devolves on the provost-marshal to arrange for this service.

**AMBULANCE EQUIPMENT.**—As before mentioned, ambulance equipment divides itself into two categories:—1. The medical and surgical equipment; 2. The equipment for the transport of wounded. These divisions will therefore be noticed separately, and the description will be confined to the equipment supplied in the British army for service in Europe. In India and in tropical countries special ambulance equipments are rendered necessary.

*Medical and Surgical Equipment.*—This portion of ambulance equipment consists of the articles necessary for the service of the wounded in the field itself, at the dressing stations, and in the field hospitals. It has to be distributed in forms such that it may be readily conveyed to the places where it is required, and such also as will admit of its being hastily packed up and removed should the circumstances of the field operations require it. At the same time, these forms must be adapted for use at all seasons of the year, for passage over all descriptions of ground that troops can march over, and must be protected against the effects of exposure to all varieties of weather.

It would occupy too much space to name the articles comprising this equipment. The special forms under which it is issued will be mentioned, and a brief explanation of them and the nature of their contents be added.

The equipment is distributed as follows:—Supplies of instruments, dressings, medicines, and restoratives, of first necessity, in small cases named “medical field companions,” and in large cases named “field panniers;” of cooking utensils and other articles for field hospital service in “canteens;” of articles of light nourishment, stimulants, &c., in “medical comfort boxes;” of hospital tents, bedding, and the bulkier articles of surgical equipment, in ambulance equipment carts or store waggons. In addition, every soldier on taking the field is supplied with a “field dressing;” each surgeon carries a pouch-belt, arranged both for distinguishing his functions and at the same time carrying his “pocket case” of instruments; and each Army Hospital Corps man has his “orderly’s dressing-case.” Every wounded man has therefore on his person the means of a first dressing for his wound, every surgeon has at hand instruments for affording surgical aid, and every ambulance and field hospital attendant the

means of assisting the surgeon in his duties. Moreover, wherever the soldier can go, there the first two forms of the surgical equipment—the medical field companion and the field panniers—can also be taken. The articles for use in the field hospitals, being carried in wheeled vehicles, can only move where the other transport of the army can be taken.

*Medical Field Companions.*—These are small cases carried by men of the Army Hospital Corps selected to accompany surgeons. They consist of two pouches and a wallet, worn nearly in the same way as the pouches and belt-bag in which ammunition is carried by combatant troops. The two pouches, carried on the waist-belt, contain small supplies of essential medicines and styptics; the surgical wallet, also carried on the waist-belt, and supported by valise straps, contains materials for surgical dressings and other articles. As these attendants are not armed with rifles, they can carry their valises and the medical field companions at the same time without inconvenience. With each medical field companion is carried, by a shoulder-strap, a water-bottle and a drinking-cup.

*Field Panniers.*—These are tough wicker baskets covered with hide, each being 2 feet 2 inches in length, by 1 foot 2½ inches in breadth, and 1 foot 4½ inches in depth. They are supplied in pairs, and are arranged for being attached to a pack-saddle and carried on a bāt-pony or mule. They are capable of being opened while on the animal in such a way that all the contents can be readily got at. The field panniers contain instruments for important surgical operations, chloroform, surgical materials (such as splints, bandages, plaisters, &c.), a lamp, supplies of wax candles, restoratives, and medical comforts in concentrated forms, and other articles necessary for urgent cases at the dressing stations and field hospitals. Each pannier has a double lid, and the four lids of the two panniers, when they are laid on the ground, can be connected so as to form a substitute for an operating table.

*Field Hospital Canteens.*—These are also supplied in pairs, and are distinguished as A and B canteens. They are wooden boxes nearly similar in size to the field panniers, so that, although usually carried in the equipment vehicles, they can, in case of need, be carried on the backs of bāt-animals. Their contents consist of camp-kettles and other utensils for cooking purposes; tin plates, drinking-cups, and other such requisites; sets of measures and weights; a lantern of coloured glass for indicating the field hospital at night; together with various articles required for the service of patients in a tent or other field hospital.

*Medical Comfort Boxes.*—These also are supplied in pairs, and resemble the canteens in shape and dimensions. The contents of the two are different, and they are therefore marked No. 1 and No. 2 respectively. Each box is partitioned and fitted with cases or bottles with labels indicating their contents. These principally consist of essence of beef, groceries, arrowroot, preserved vegetables, brandy, wine, and sundry accessory articles. The wounded are supplied with the same rations as the healthy troops, and they are turned to the best account available for their nutriment, supplemented by such medical comforts as are named above.

*Ambulance Equipment Waggon.*—In these vehicles are carried the tents for forming the field hospital in case of no building being available, with a supply of blankets, waterproof covers, and other articles of bedding for the patients. The canteens and medical comfort boxes are also carried in these vehicles. Certain implements, as reaping-hooks, spades, pickaxes, saws, which are constantly required when men are thrown so much on their own resources as they must be in campaigning, are also carried in the equipment waggon.

*Ambulance Equipment for the Transport of Wounded Troops.*—The ambulance conveyances authorised for use in the British army are of four kinds. They are the following:—1. Conveyances carried by the hands of bearers, called *stretchers*; 2. Conveyances wheeled by men, *wheeled stretchers*; 3. Conveyances borne by mules, *mule litters* and *mule cacolets*; and 4. Wheeled conveyances drawn by horses, *ambulance waggons*. The forms of all these conveyances have been lately revised by a committee which was appointed in 1868 by Sir J. Pakington, then Secretary of State for War, to inquire into the general question of ambulance and hospital conveyances for the army, and the new pattern vehicles have now been authorised for use.

(T. L.)

AMELOT DE LA HOUSSAYE, ABRAHAM NICOLAS, historian and publicist, was born at Orleans in February 1634, and died at Paris 8th December 1706. Little is known of his personal history beyond the fact that he was secretary to an embassy from the French court to the republic of Venice. At a later period he was imprisoned in the Bastille by order of Louis XIV. In 1676 he published at Amsterdam his *Histoire du Gouvernement de Venise*, in three volumes. Under the assumed name of De la Mothe Josseval, he published in 1683 a translation of Fra Paolo Sarpi's History of the Council of Trent. This work, and especially certain notes added by the translator, gave great offence to the advocates of the unlimited authority of the pope, and three separate memorials were presented to have it repressed. Amelot also published translations of Machiavel's *Prince*, and of the *Annals* of Tacitus, besides several other works.

AMELOTTE, DENIS, a French ecclesiastic and author, was born at Saintes in Saintonge in 1606, and died October 7, 1678. Soon after receiving priest's orders he became a member of the congregation of the oratory of St Philip Neri. In 1643 he published a Life of Charles de Goudren, second superior of the congregation, which by some of its remarks on the famous abbot of St Cyran, gave great offence to the Port Royalists. Another work, containing a vehement attack on the doctrines of the Jansenists, still further embittered the feelings of the party towards him, and elicited from Nicole a severely satirical reply entitled *Idée Générale de l'Esprit et du Livre du P. Amelotte*. Amelotte in revenge availed himself of his influence with the chancellor to prevent the publication of the newly-completed Port Royalist translation of the New Testament, which had therefore to be issued at Mons in Flanders. He thus secured a free field for a translation of his own with annotations, which appeared in 4 vols. octavo in 1666-8. The dedication to the archbishop of Paris contained another abusive denunciation of the Jansenists.

AMENTIFERÆ, or AMENTACEÆ. Under this name are included apetalous unisexual plants bearing their flowers in catkins (*amenta*). This group of plants includes trees and shrubs chiefly of temperate climates. It is divided into the following orders:—*Salicaceæ*, willows and poplars; *Corylaceæ* or *Cupuliferæ*, hazel, oak, beech, chestnut, hornbeam, &c.; *Betulaceæ*, birch, alder; *Casuarinaceæ*, Casuarina (beefwood); *Altingiaceæ* or *Balsamiflucæ*, liquidambar; *Platanaceæ*, the plane; *Juglandaceæ*, walnut; *Garryaceæ* Garrya; *Myricaceæ*, bog myrtle.

*Betula alba* (the common birch), an amentiferous tree, the male flowers, *a*, are produced in scaly catkins, and so are the female flowers, *b*.

# A M E R I C A

OUR object in this article is to take a comprehensive survey of the American continent in its physical, moral, and political relations. In attempting this, we shall dwell at some length upon those great features and peculiarities which belong to it as a whole, or facts which can be most advantageously considered in connection with one another. The new continent may be styled emphatically "a land of promise." The present there derives its greatest importance from the germs it contains of a mighty future. It is this prospective greatness which lends an interest to the Western continent similar to that which the Eastern derives from its historical associations. But the Western continent also has its past, which abounds in points of interest relating to both the historic and prehistoric periods. Facts show that although America may be called the New World in consequence of its having been the last to come under the general knowledge of geographers, it is from most other points of view an old world. It abounds in the oldest known strata; it has yielded some of the oldest known remains of man, indicating that he has long been a denizen there; and it has afforded evidences of a civilised era, which may even have preceded that of Western Europe.

The new continent, when compared with the old, enjoys three important advantages. First, it is free from such vast deserts as cover a large part of the surface of Asia and Africa, and which not only withdraw a great proportion of the soil from the use of man, but are obstacles to communication between the settled districts, and generate that excessive heat which is often injurious to health, and always destructive to industry. Secondly, no part of its soil is so far from the ocean as the central regions of Asia and Africa. Thirdly, the interior of America is penetrated by majestic rivers, the Mississippi, Amazon, and Plata, greatly surpassing those of the old continent in magnitude, and still more in the facilities they present for enabling the remotest inland districts to communicate with the sea.

In the physical formation of North and South America there is a remarkable resemblance. Both are very broad in the north, and gradually contract towards the south till they end, the one in a narrow isthmus, and the other in a narrow promontory. Each has a lofty chain of mountains near its western coast, abounding in volcanoes, with a lower ridge on the opposite side, destitute of any recent trace of internal fire; and each has one great central plain declining to the south and the north, and watered by two gigantic streams, the Mississippi, corresponding to the Plata, and the St Lawrence to the Amazon. In their climate, vegetable productions, and animal tribes, the two regions are very dissimilar.

The extent of the American continent and the islands connected with it is as follows:—

	Square Eng. miles.
North America.....	7,400,000
South America.....	6,500,000
Islands.....	150,000
Greenland, and the islands connected with it lying north of Hudson's Straits, may be estimated at.....	900,000
	14,950,000

The American continent, therefore, with its dependent islands, is four times as large as Europe, and about one-third larger than Africa, but somewhat less than Asia, while it is nearly five times the size of the Australian continent. It constitutes about three-tenths of the dry land on the surface of the globe. It is characterised by having a greater length from N. to S. than any other continent; and by the northern and southern portions being connected by a

comparatively narrow strip of land. South America has a more regular form, and as a mass is situated much farther east than North America. In South America the most central point lies in about 58° W.; but in North America the most central point would be in about 100° W.

Sketch Map of America.

As regards continuity of land, America comprises some islands at the southern end; a main continental portion, including South America, Central America, and North America; some islands off the north shore, and many other islands along the east and west coasts, those on the east being the most important. The most northern point of the mainland is that of Boothia Felix, in Bellot Strait, 71° 55' N., 92° 25' W. The islands to the north extend beyond 82° 16' N., 65° W., which point was reached by the "Polaris" in August 1871. The southernmost point of the mainland is Cape Froward, which lies close to 54° S., 71° W.; while Cape Horn, the most southern point of the islands, is in 56° S., 67° 20' W. The extreme points traced are consequently 138° apart; and the continental part stretches over about 126 degrees of latitude. This corresponds to lengths of 8280 and 7560 geographical miles respectively. The extreme east points of the continent are Cape St Roque, in 5° 28' S., 35° 40' W., in South America, and Cape St Charles, in 52° 17' N., 55° 35' W., in North America. The most western point of South America is Point Parina, in 4° 40' S., 81° 10' W.; and of North America, Prince of Wales Cape, in 65° 30' N., 167° W. The greatest breadth of North America is

between Cape Lisburne and Melville Peninsula; and of South America, between Pernambuco and Point Aguja. The narrowest part is 28 miles, at the isthmus of Panama. The nearest approach to the Old World is at Behring Strait, which is 48 miles across, and shallow. On the east side the nearest point to the Old World is Cape St Roque, which is opposite the projecting part of the African coast at Sierra Leone. Greenland is separated from the archipelago of Arctic America by a deep and for the most part broad sea, and seems naturally to belong to the European rather than the American area.

North America, with the general form of a triangle, naturally divides itself into five physical regions: 1. The table-land of Mexico, with the strip of low country on its eastern and western shores; 2. The plateau lying between the Rocky Mountains and the Pacific Ocean, a country with a mild and humid atmosphere as far north as the 55th parallel, but inhospitable and barren beyond this boundary; 3. The great central valley of the Mississippi, rich and well wooded on the east side; bare but not unfertile in the middle; dry, sandy, and almost a desert on the west; 4. The eastern declivities of the Alleghany Mountains, a region of natural forests, and of mixed but rather poor soil; 5. The great northern plain beyond the 50th parallel, four-fifths of which is a bleak and bare waste, overspread with innumerable lakes, and resembling Siberia both in the physical character of its surface and the rigour of its climate.

South America is a peninsula likewise of triangular form. Its greatest length from north to south is 4550 miles; its greatest breadth 3200; and it covers an area, as already mentioned, of 6,500,000 square English miles, about three-fourths of which lie between the tropics, and the other fourth in the temperate zone. From the configuration of its surface, this peninsula also may be divided into five physical regions—1. The low country skirting the shores of the Pacific Ocean, from 50 to 150 miles in breadth, and 4000 in length. The two extremities of this territory are fertile, the middle a sandy desert. 2. The basin of the Orinoco, a country consisting of extensive plains or *steppes*, called Llanos, either destitute of wood or merely dotted with trees, but covered with a very tall herbage during a part of the year. During the dry season the heat is intense here, and the parched soil opens into long fissures, in which lizards and serpents lie in a state of torpor. 3. The basin of the Amazon, a vast plain, embracing a surface of more than two millions of square miles, possessing a rich soil and a humid climate. It is covered almost everywhere with dense forests, which harbour innumerable tribes of wild animals, and are thinly inhabited by savages, who live by hunting and fishing. 4. The great southern plain, watered by the Plata and the numerous streams descending from the eastern summits of the Cordilleras. Open *steppes*, which are here called Pampas, occupy the greater proportion of this region, which is dry, and in some parts barren, but in general is covered with a strong growth of weeds and tall grass, which feeds prodigious herds of horses and cattle, and affords shelter to a few wild animals. 5. The country of Brazil, eastward of the Parana and Uruguay, presenting alternate ridges and valleys, thickly covered with wood on the side next the Atlantic, and opening into *steppes* or pastures in the interior.

In our more particular description of the physical conformation, the geological structure, the mountains, rivers, and forests, and the climates of America, we shall first deal with the southern peninsula, as having the more strongly marked conditions.

The mountain areas of South America are, as a general rule, those which have received the thickest accumulations of sedimentary matter, and this thickness is nearly proportional to their height. During the periods of the formation of such deposits, these areas were to a great

extent areas of subsidence, and since those beds which once formed the sea bottoms now constitute the highest peaks, these areas must have been subjected to subsequent upheaval. Vertical movements of this kind have occurred again and again, indicating that these areas are specially liable to disturbance, either from comparative weakness or from the greater comparative power of the moving forces. The history of the mountain chains is almost co-extensive with that of the continent itself. In the sea the beds were deposited horizontally, or nearly so; and at certain intervals the deposition was arrested, in consequence of the beds being uplifted above the sea. Each successive submergence and emergence occupied a long period of time, during which the rocks were at one time faulted, folded, and metamorphosed, and at other times denuded both by the sea and by meteoric agents. As a general rule, the strike or line of direction of the strata ran approximately parallel to the trend of the shore line on the large scale, and the dip was at right angles to their direction. During each elevation the land was uplifted in a broad band, the axis of which ran parallel to the shore of the sea in which the beds were formed. The axes of the principal folds and faults usually run parallel to the stratigraphical axis or strike. The principal ridges formed during the same period usually coincide in direction with the stratigraphical strike of the bed forming them. In the mountains of South America, and especially in the Andes, several of these groups of ridges, formed at different periods, combine to make up a single system of mountains. The high range of mountains which extends from the most southern parts of South America, and runs approximately on the same meridian of 72° to the isthmus of Panama, forms the Andes. These consist of a vast rampart, having an average height of some 11,000 or 12,000 feet, and a width varying from 20 to 300 or 400 miles. In most places the chain rises to heights of several thousand feet, and upon this chain rest two or three principal ridges of mountains, enclosing lofty plains or valleys, separated one from another by mountain knots, which mark the spots where ridges belonging to different systems intersect. In one sense, the lofty plains of the Desaguadero, Quito, and others, are valleys, since they are encompassed by mountains; but in a certain sense they are plateaus, since they form the broad summit of the range or platform on which the bounding ridges themselves stand. Further details respecting the Andes are given under ANDES, and in the geological remarks of this article.

Three branches or transverse chains proceed from the Andes, nearly at right angles to the direction of the principal chain, and pass eastward across the continent, about the parallels of 18° of S. and 4° and 9° of N. latitude; thus forming the three natural areas of the Orinoco, Amazon, and La Plata river basins. The most northern of these is "the Cordillera of the coast," which parts from the main trunk near the south extremity of the lake Maracaybo, reaches the sea at Puerto Cabello, and then passes eastward through Caraccas to the Gulf of Paria. Its length is about 700 miles, and its medium height from 4000 to 5000 feet; but the Silla de Caraccas, one of its summits, has an elevation of about 8632 feet; and its western part, which is at some distance from the sea, contains the Sierra de Merida, 15,000 feet in height. The second transverse chain is connected with the Andes at the parallels of 3° and 4° north, and passing eastward, terminates in French Guiana, at no great distance from the mouth of the Amazon. It consists properly of a succession of chains nearly parallel to the coast, and is sometimes called the Cordillera of Parimé, but is named by Humboldt the "Cordillera of the Cataracts of the Orinoco," because this river, which flows amidst its ridges in the

upper parts of its course, forms the cataracts of Maypure at the point where it descends into the plains. Its mean height is estimated at 4000 feet above the level of the sea; but at about 70° and 75° W. longitude, it sinks to less than 1000 feet, and at other points rises to 10,000. This chain divides the waters of the Orinoco and the rivers of Guiana from the basin of the Amazon, and is covered with magnificent forests. Its breadth is supposed to be from 200 to 400 miles, and it encloses amidst its ridges the great lake Parimé, in longitude 60°, and several of smaller size. At the Caratal gold-field, which lies south of Angostura, the range is about 60 miles across, and the watershed about 1100 feet above the sea. On a table-land forming part of it, about the 67th degree of longitude, the Cassiquari forms an intermediate channel which connects the rivers Orinoco and Negro, so that, during the annual floods, a part of the waters of the former flows into the latter. This singular phenomenon was made known long ago by the Spanish missionaries, but was thought to be a fable till the truth was ascertained by Humboldt. The length of this chain is about 1500 miles. The third transverse chain leaves the main trunk near 17° 25' S., and extends almost as far as Santa Cruz, near the river Mamore. Some of the mountains in the western part are of considerable height. South of this range are a number of ridges having an east and west direction, an average height of about 10,000 feet, and terminating in the plains near the Paraguay. This country, which divides the waters of the Amazon from those of the Plata, is a broad plateau of elevated land, rather than a distinct mountainous ridge, and consists of low hills or uneven plains, with very little wood, presenting in some places extensive pastures, and in others tracts of a poor sandy soil. Its average height probably does not exceed 2000 or 3000 feet above the level of the sea.

The mountains of Brazil, which are of moderate height, and occupy a great breadth of country, form an irregular plateau, bristled with sharp ridges running in a direction approximately parallel to the eastern coast, connected by offsets running in a more or less east and west direction. They extend from 5° to 25° of south latitude, and their extreme breadth may be about 1000 miles. Between Victoria on the north and Morro de St Martha on the south, a range with numerous curves lies a little way back from the coast, and is, for the greater part of its length, known as the Sierra do Mar; somewhat farther inland is a higher range, the different parts of which have different names, but it is best known as the Sierra de Mantiqueira. It contains the highest peaks in Brazil, amongst which may be mentioned Mount Itacolumi, famous for the gold and diamond yielding strata in its vicinity; the Pico dos Orgaos, which is 7700 feet high; and Itambe, 8426 feet. Some of the peaks are believed to be even higher. West of this the uplands of Brazil stretch far into the interior, and at length sink into the great central plain through which flows the Paraguay and its tributaries.

Although large areas of South America remain as yet unexplored by geologists, the researches of D'Orbigny, Humboldt, Boussingault, Darwin, Forbes, Agassiz, and many other travellers, suffice to give an approximately correct general view. This is mainly owing to the simplicity of the stratigraphy of the country. The same groups of rocks spread over such extensive areas, that, from what is seen in the areas which have been examined, we can safely infer the general condition of those which have not been explored. The general disposition of the rocks is as follows:—The oldest rocks, which are Pre-Silurian, possibly Laurentian, form the outermost rim of the continent, of which the N.E. and S.E. corners have probably been swept away. These corners now correspond with the mouths

of the Orinoco, the Amazon, and the La Plata rivers. Within this basin, and following close upon these old rocks, are schists and quartzites, which are in all probability of Silurian age. These enter largely into the transverse ranges by which the central hollow is subdivided into three basins. Within this again are sandstones and limestones, usually referred to the Carboniferous period, which also form part of the transverse ridges. A band of rocks of secondary age follow, some of which are believed to be Triassic, while others are identified as Cretaceous. Tertiary beds, some of Miocene date, together with Post-Tertiary beds, cover the largest part of the areas of the great river basins and the hollows in the mountain range, and also occur on the seaward flanks of the principal chains.

By following the development of these beds, we shall be able to give a brief account of the growth of the present continent. In the Argentine Confederation a few bosses of gneiss protrude through the more recent beds constituting the Pampas. Granite, supporting gneiss and quartzite, occurs along the coast of Chili. In Bolivia we find a range of granitic mountains which have a general direction somewhat to the E. of N., and which are flanked on either side by zones of gneiss and quartzite. The gneiss also prevails along the shores of Peru, Ecuador, and New Granada, or, to call it by the name which it received in 1861, Columbia. The gneiss is again seen at the eastern base of the Andes, in the last-mentioned State, associated with quartzites, and both these can be traced along the Venezuelan coast. Gneiss is largely developed near Angostura, and has a strike approaching E. and W. At Limones, which is near the Caratal gold-field, the country consists largely of granite and gneiss, which latter lies here a little to the E. or to the W. of N. In Brazil the gneiss forms a long band from Bahia to the southern portion of the province of Santa Catharina. Near the coast it rests upon and apparently passes into granite; but towards the west, as far as the Mantiqueira chain, it gradually becomes more and more schistoid. Gneiss, again, is met with in the mountains which stretch through the Bolivian provinces of Moxos and Chiquitos. It has not been ascertained if these older rocks appeared above the waters before the deposition of those which follow, and which will next be noticed.

In Chili the succeeding rocks are slaty schists. In Bolivia the mountainous district crossing the country is largely composed of talcose schists, which, where exposed to the weather, have formed by their decomposition a layer of clay; in advancing from the east towards the west the schists become more and more crystalline, and are at last replaced by gneiss. This, as has already been stated, rests against granite, on the west side of which gneiss is again brought in by an anticlinal arrangement of the beds, and dips beneath a thick mass of schists, which constitute the great bulk of the Andes in this district. In this mountain range the lower portion of the formation is mainly siliceous schist, alternating with beds of compact quartz; above this come talc-bearing quartzites, alternating with slaty schists, which latter become more and more prevalent as we ascend in the strata, and at last constitute the predominating rock. They form, indeed, the crest of the range; the thickness of the formation may be roughly estimated at 10,000 feet. These rocks are much disturbed and faulted against other and probably newer rocks, which with them constitute the great bulk of the lofty eminences in the range of which Mount Illimani forms so conspicuous a feature. The lower argillaceous schist, which is associated with gneiss all along the Pacific coast from lower Peru to Panama, possibly belongs to this group of rocks. In the high valleys of Ecuador the oldest rocks visible are granite, gneiss, and schists, which are frequently in a vertical position. The schistose group appears

to be absent on the east side of the Andes in Columbia, as also along the coast of Venezuela. In the mountain range south of the Orinoco, hornblende, talcose, and mica schists again appear on a large scale, more especially in the Caratal district, where auriferous veins occur. In Brazil the micaceous and talcose schists enter into the composition of the Mantiqueira chain and of the uplands to the west; they probably pass beneath the valley of the Panama, since they occur to the west of it, and extend through the provinces of Goyaz and Matto Grosso, so as to approach within a moderate distance of the similar strata in Bolivia. They are associated with talc-bearing quartzites, which are famous for the diamonds and auriferous particles they have yielded in the district around Mount Itacolumi. The soil is usually a clay, such as would result from the decomposition of talcose schist; but we shall have occasion to refer to the soil of South America subsequently. Some of these rocks in various parts of the continent have yielded Silurian fossils. Facts are not sufficient yet to warrant the correlation of these strata with those of other countries, or to settle how far they belong to distinct geological periods. The prevalent strike of the rocks is about east and west, but sometimes the strike approaches to a north and south direction. At any rate, the rocks which overlie them do so unconformably, indicating that, prior to the deposition of these newer rocks, land had appeared at least once on areas now constituting part of South America. At this early date the continent was represented by a few islands only; one corresponded with part of Brazil, another with parts of Venezuela and Columbia; perhaps a third more or less with Peru, Bolivia, Ecuador, and Chili; while a few small islands appeared where now we have the Pampas. These were the nuclei around which the present land has accumulated, and already we see faint indications of the existing outline and broad geographic features of the future continent.

The next group of rocks are always in stratigraphical discordance with those beneath them; and, in consequence of the highly metamorphosed condition of those on the west side of the continent, it is difficult to correlate them with the rocks of Brazil. In the Andes of Chili they are represented by enormous stratified masses of quartzose porphyries, which there is good reason to believe are metamorphosed argillaceous schists and felspathic sandstones, into which rocks they have been seen gradually to pass. These porphyries not only form the great bulk of the principal chain of the Andes, but also the smaller chain on the west, the interval between them being formed by the longitudinal valley of Chili. Further west they rest on syenitic rocks, beyond which come the older rocks already noticed. On passing into Bolivia, we find that to the west of the great fault developed there, the beds consist of micaceous sandstones and dark bituminous schists, which are believed to be the equivalents of the porphyries of Chili. Such formations constitute the west slope of the Andes from Sorata to Illimani, and also form two bands, one stretching from Illimani to Cochabamba, the other between Calamarca and Chayanta. Towards the west they dip beneath black bituminous and siliceous limestones, which are well developed near Tiahuanaco. Carboniferous strata with seams of coal occur near Pisco and Arequipa in Peru. In Brazil the beds which succeed those previously mentioned are quartzites, rich in mica and magnetic oxide of iron; talcose schists; and crystalline limestones, containing a great deal of talc. These rocks form the highest regions and loftiest peaks in Brazil. Unconformably upon these rest micaceous sandstones and argillaceous schists, which occupy the western part of St Paul province between Ytu and the banks of the Parana. In Mount Arasoyaba and some other places, a carboniferous limestone succeeds and

is overlain by a thick white or yellowish sandstone, siliceous limestones, and bituminous schists. The limestones occupy most of the area between the Uruguay and the Parana. In the Diamantina district the carboniferous limestone is overlain by red sandstone, which belongs to the succeeding group of beds. The beds in Brazil appear to be fuller than those on the west side of the continent, and represent probably both the Devonian and Carboniferous periods. Rocks of this age are also exposed in a narrow band round portions of the basin of the river Amazon. The strata next in succession are of secondary age. The lowest formation is a red sandstone, which is spread over a very extensive area. It is remarkably well developed in Chili, where, together with more recent beds, it is a marked feature in the crest of the Andes. In the small chain to the west it is associated with conglomerates. In the small chain of Colorado, near Tiahuanaco, a thick conglomerate rests on the older limestones, and supports red sandstones and conglomerates dipping west beneath marls. The red sandstone extends across the province of Carangas, and uninterruptedly over both slopes of the western Cordillera. In the desert of Atacama the red sandstone, with the overlying marls, forms a number of parallel chains directed north and south. Red sandstones and conglomerates form the base of the Cordilleras of Quito; they stretch north into the basins of the Magdalena and Cauca rivers, and east over the basin of the Orinoco. In the province of Bahia, and far away to the north, there is a great development of red sandstone. The age of these sandstones has been variously stated; their stratigraphical position would indicate a secondary age, and possibly they may be Triassic. After their deposition, and prior to that of the marls, syenitic rocks were introduced amongst the strata in the Andes, causing the red sandstones, as also the older sandstones and schists, to be converted into porphyries. This eruption was also accompanied by, and probably connected with, the formation of auriferous veins, the elevation of the strata, and the faulting of the rocks. The strike of the strata, as also of the faults, was about  $8^{\circ}$  to the E. of N., but subsequent movements have modified the direction in places. The red sandstone has a similar strike from Venezuela in the north to Magalhaens Strait on the south, and this favours the idea that all are of the same age. Several of the ranges in the Andes have a corresponding direction. As the sandstone is believed to underlie the basins of the great rivers, it appears that during its deposition South America was still represented by a few large islands only. Its elevation gave rise to north and south trending mountains, whereby these scattered portions were connected, and the Andes received their first development. The great features of the continent were then first distinctly marked out, and only a few gaps remained to be filled up. The next succeeding period, represented by strata, is characterised by saliferous and gypseous marls, which rest unconformably on the rocks beneath. In Chili they occur in the lower plains, or abut against the western spurs of the Andes; but they have been largely denuded, so that they now occur in isolated plateaux or basins, and there is a patch capping the lofty Aconcagua. It is stated that in Chili the marls, or at least some of them, are Liassic. In Bolivia, also, they form plateaux between San Andres and the mountains of Tarija. Here they consist of alternations of greenish marls and wine-coloured beds supporting limestones, with interstratified beds of gypsum and saliferous clay. There are beds of gypsum and limestone in the Orinoco plains. Marls are associated with marly sandstones in the Gulf of Bahia and in the plains of Reconavo. These beds are arranged along strikes which are approximately east and west, and their elevation is apparently connected with the formation of chains running

in the same direction, as, for instance, most of the lateral spurs from the Andes. Some geologists think it is also connected with the east and west faults, through which, in the Andes, labradorite and hypersthene rocks have been erupted. This eruption, it is said, has caused the metamorphism of the calcareous rocks into crystalline limestones, marls into jaspers, and red sandstones into porphyries; and has also given rise to the copper-bearing veins. Calcareous beds occupy large areas in Venezuela, Columbia, and other parts of the continent. Miocene strata occur in Venezuela, and probably in other districts. Finally, there are deposits of Post-Miocene date, which chiefly belong to the Post-Pliocene and recent periods, and which cover most of the lower lands along the coasts and in the interior of the continent. In Chili they occur in the valleys, and fill up the gulfs in the old granite range near the coast. Here the succession is a calcareous sandstone abounding in marine shells and beds of lignite; above this is a pumiceous conglomerate, which passes in places into a pebbly conglomerate, and then follow the marine sands which stretch from Coquimbo across the desert of Atacama. The most recent formation is drift, which occurs in patches and sheets. In the valley plains of the Desaguadero there are clays and sandy marls overlain by pumiceous conglomerates, which near La Paz are surmounted by drift. Near this place the drift is many hundred feet thick, and formed of large blocks; but, on receding from the mountains, it passes into a sand which encircles the plains of the Desaguadero, which are chiefly formed by limestone deposits, such as concretionary limestone, which abounds in the fossil remains of plants and fresh water shells. The lacustrine beds approximate in age to the marine tertiary beds near the coast. In Peru the pumiceous conglomerate is overlain by drift. Tertiary beds occur at Guayaquil in Ecuador, while in the valley of Quito there are enormous layers of pumice, scoriæ, and drift, which last has yielded the remains of various Post-Pliocene mammals and terrestrial shells. Drift with similar remains occurs in the lower grounds of Columbia. In the Gulf of Bahia there are recent beds; and near St Paul, as also in many other parts of Brazil, there are patches of lacustrine deposits. On the west side of the continent the pumiceous conglomerate is intimately connected with trachytes, and indeed is formed from them. It is intermediate in age between the lacustrine beds, the marine deposits near the shore, and the drift, which is in its turn covered by the more recent lava overflows; and it is in this intermediate age that the upheaval of the principal chain of the Andes occurred. The ranges and faults which are assigned to this period, probably Pliocene or Post-Pliocene, run very nearly north and south. This elevation did not materially alter the extent of land west of the Andes, its general effect being to add a strip about thirty miles in width. On the east the change was great, since the larger proportion of the great central plain then emerged, and thus connected the high lands on the east, west, and north into one great continent. The eruption of the trachytes, which form so marked a feature in the Andes, was accompanied by a metamorphism distinct in character from those of earlier ages. The rocks were then subjected not only to heat and water, but also to acid vapours, which changed the felspar into sulphates of alumina and iron, salt into anhydrous sulphate of soda; and, probably, by freeing the chlorine and iodine, originated the chlorides and iodides which are so abundant in the argentiferous veins. Since the drift there has been a slight elevation along a meridional axis.

Such is a brief account of the growth of South America. We must, however, mention that Professor Agassiz and his coadjutors believe that the red soil and immediately underlying beds, seen near Rio Janeiro and in the valley of

the Amazon, are true glacial formations, and infer that the similar beds which are spread over such an enormous area in South America have been formed under similar conditions. Professor Agassiz has found moraines and ice-transported boulders in various places in the mountains of Brazil, as also indications of valley glaciers. Professor Orton has found marine shells in these beds at Pebas in Ecuador.

The foregoing sketch indicates that there have been several periods of volcanic activity; and that, so far as our present knowledge goes, such activity has only been manifested along the line of the Andes. Volcanic rocks have rarely been observed on the east side of the continent, but some of the Tertiary and Post-Tertiary beds of the plains contain matter which has been showered upon them during eruptions, and which now forms a portion of the Pampean deposits. At one period or other the whole system of the Andes has been subjected to volcanic disturbance, but at the present time the active volcanoes occur in groups more or less widely separated. The most southern active volcano is Corcovado, in 43° 10' S. There are, besides, some twenty or more volcanic cones, of which about a dozen are known to be active. Bolivia has one or two active vents, and Peru several; but it is in Ecuador, with its dozen ignivomous vents, that have occurred the grandest and most frequent displays. Columbia has four or five volcanoes. With the exception of the Moluccas, no country in the world has had so many and so destructive earthquake shocks as South America. But these are concentrated, both as regards frequency and strength, along the Andes, and more particularly their western slope. Comparatively few are felt in the plains to the east of them; but occasionally it happens that shocks are felt at points on the opposite slopes of this great range without being perceived in the intermediate higher regions. Peru seems to be the principal focus of action; and next to it in importance as a seismic area comes Chili; but although some earthquake shocks spread over both these areas, there does not seem to be the community of action which we should expect between the two areas. In Peru the maxima of seismic intensity were in the decades ending 1590, 1610, 1660, 1690, 1710, 1720, 1730, 1750, 1770, 1790, 1840, 1870. In Chili they occurred in the decades ending 1580, 1640, 1650, 1660, 1690, 1730, 1780, 1800, 1820, 1840, 1850. Nearly every other portion of the continent is subject to earthquakes. Bolivia, which lies between Peru and Chili, is comparatively free from them, as also are Brazil, Patagonia, and the Argentine Confederation, but they are more frequent in Ecuador, Columbia, Venezuela, and the three Guianas.

The mountains of North and Central America will not detain us long. The ranges of Central America have no relation to the Andes, differing from them both as regards age and direction, which is generally N. 55° W., and being separated from them by gaps only a few hundred feet above the sea, and upwards of 100 miles wide. During the Tertiary period the mountains of N. and S. America had still less connection than at present, for where the isthmus now forms a bridge of land there was a broad strait, which lasted up to the end of the Pliocene, or beginning of the Post-Pliocene period. Volcanoes are frequent in Central America; and basalt and other volcanic products cover a large portion of the country. The large development of trachytes indicates an earlier period of volcanic activity, during which most of the Tertiary strata were metamorphosed into porphyries. At any rate these rest upon cretaceous limestones. In many places the clays and sandstones of the Cretaceous age have been metamorphosed into granite rocks. From Puebla to Durango the Mexican mountains no longer present the appearance of a chain, but spread out to a table-land or elevated plain, from 5000

to 9000 feet in height, and from 100 to 300 miles in breadth. Across this plain, close to the 19th parallel, six volcanoes are distributed in a line running east and west, as if a vast rent, extending from the Atlantic to the Pacific, had opened a passage for the internal fires of the globe at this spot. Two of those on the east side of the continent, with a group of four or five other cones lying between Jalapa and Cordoba, have an elevation exceeding 17,000 feet, and are the only mountains in New Spain that rise to the region of perpetual snow, which commences here at 15,000 feet above the level of the sea. Jorullo, the lowest of the six volcanoes, rose suddenly in the middle of a plain, in September 1759, after fearful concussions of the ground, which continued for fifty or sixty days. Near the tropic the Mexican Cordillera divides into three parts. One runs parallel to the eastern coast at the distance of thirty or forty leagues, and terminates in New Leon. Another proceeds in a north-western direction, and sinks gradually as it approaches the Californian Gulf in Sonora. The third or central Cordillera traverses Durango and New Mexico, divides the sources of the Rio Gila from the Rio Bravo del Norte, and dies out before reaching the Rocky Mountains.

In a recent scientific survey of the Rocky Mountains, conducted by Professor Hayden of Yale College, a higher peak has been discovered than was formerly known. Holy Cross mountain was computed to reach 17,000 feet above the sea, or 2000 feet higher than Big Horn (15,000), which has hitherto been supposed to be the highest of the chain. The greatest altitudes on the North American continent are now said to be the following—St Elias (17,850) in Alaska, Popocatepetl (17,884) in Mexico, Orizaba (17,337) in Mexico, Holy Cross (17,000), Rocky Mountains, Big Horn (15,000), and Mount Lincoln (14,300), both in the same chain. The Great Salt Lake of Utah is in 41° N. and 112° W., and has intensely salt waters. It is nearly 300 miles in circumference, and its shores, for a breadth of several miles, are covered with an incrustation of very pure salt. It lies in a basin, which measures about 500 miles each way, and contains much fertile soil.

If we run a line westward across the continent of North America at the latitude of Delaware Bay (38°), the geological formations present themselves in the following order:—1. Tertiary and Cretaceous strata on the shores of the Atlantic; 2. Gneiss underlying these strata, and presenting itself on the eastern slope of the Alleghany or Appalachian mountains, but covered in parts by New Red Sandstone; 3. Palæozoic rocks, consisting of Silurian, Devonian, and Carboniferous strata, curiously bent into parallel foldings, with synclinal and anticlinal axes, the crests of the latter forming the ridges of the Alleghany Mountains, which in this region rise to the height of 2500 feet. Upon these Palæozoic rocks rest three great coal-fields—the Appalachian, that of Illinois, and that of Michigan, covering a large portion of the space between the Alleghanies and the Mississippi, and embracing collectively an area equal to the surface of Great Britain. From the Mississippi westward to Utah the Palæozoic rocks occur in great folds, between which are extensive areas of Triassic, Oolitic, Cretaceous, and Tertiary beds. In California the rocks are chiefly metamorphosed secondary strata on which lie patches of Tertiary sediments. In British America there is an enormous development of the Laurentian and Huronian rocks, which are the oldest yet discovered, and occupy most of the country immediately north of the large lakes. Newfoundland and the neighbouring British territories consist of Pre-Silurian, Silurian, Devonian, Carboniferous (which includes coal-fields of considerable extent), and Triassic rocks. The area north of about 40° N. is also covered and strewed with glacial drift and boulders.

The Ozark Mountains resemble the Alleghanies in their

mineral structure, containing the same rocks from the granite to the carboniferous, and probably upwards to the chalk.

In no single circumstance is the superiority of America N. and S. America Rivers. over the old world so conspicuous, as in the number and magnitude of its navigable rivers. The Amazon alone discharges a greater quantity of water than the eight principal rivers of Asia, the Yenesei, Indus, Ganges, Oby, Lena, Amoor, and the Hoang-ho and Yang-tse of China. The Mississippi, with its branches, affords a greater amount of inland navigation than all the streams, great and small, which irrigate Europe; and the Plata, in this respect, may probably claim a superiority over the collective water of Africa. But the American rivers not only surpass those of the Old World in length and volume of water,—they are so placed as to penetrate everywhere to the heart of the continent. By the Amazon, a person living at the eastern foot of the Andes, 2000 miles of direct distance from the Atlantic, may convey himself or his property to the shores of that sea in forty-five days, almost without effort, by confiding his bark to the gliding current. If he wish to return, he has but to spread his sails to the eastern breeze, which blows perennially against the stream. The navigation is not interrupted by a single cataract or rapid, from the Atlantic to Jaen, in west longitude 78° where the surface of the stream is only 1240 feet above the level of its estuary at Para. The part of North America most remote from the sea is the great interior plain extending from the Rocky Mountains to the Alleghanies and the lakes, between the parallels of 40° and 50°; but the Mississippi, Missouri, and St Lawrence, with their branches, are wonderfully ramified over this region, and the Missouri is in some degree navigable to the centre of the continent. It is only necessary to cast the eye over a map of South America, to see that all the most sequestered parts of the interior are visited by branches of the Plata and the Amazon. These streams, having their courses in general remarkably level, and seldom interrupted by cataracts, may be considered without a figure of speech, as a vast system of natural canals, terminating in two main trunks, which communicate with the ocean at the equator and the 35th degree of south latitude. Since the invention of steam navigation, rivers are, in the truest sense of the term, Nature's highways, especially for infant communities, where the people are too poor, and live too widely dispersed, to bear the expense of constructing roads. There is little risk in predicting, that in two or three centuries the Mississippi, the Amazon, and the Plata, will be the scenes of an active inland commerce, far surpassing in magnitude anything at present known on the surface of the globe. The Mississippi is navigable for boats from the sea to the falls of its principal branch the Missouri, 1700 miles from the Mexican Gulf in a direct line, or 3900 by the stream; and the whole amount of boat navigation afforded by the system of rivers, of which the Mississippi is the main trunk, has been estimated as equal to 40,000 miles in length, spread over a surface of 1,350,000 square miles. This, however, is perhaps an exaggeration; a navigable length of 35,000 miles may be nearer the truth.

The Amazon contains many islands, is broad, and in the upper part so deep, that on one occasion Condamine found no bottom with a line 620 feet long. At its mouth, two days before and after the full moon, the phenomenon called a *Bore* occurs in a very formidable shape. It is a high upright wave of water rushing from the sea, which no small vessel can encounter without certain destruction.

The estuaries of all these great American rivers open to the eastward; and thus Providence seems to have plainly

indicated that the most intimate commercial relations of the inhabitants of America should be with the western shores of the Old World. It should at the same time be observed, that this position of the great rivers of America is but one example of a physical arrangement which is common to the whole globe; for it is remarkable that, in the Old World as well as in the New, no river of the first class flows to the westward. Some, as the Nile, the Lena, and the Oby, flow to the north; others, as the Indus and the rivers of Ava, to the south; but the largest, as the Volga, the Ganges, the Yang-tse, the Hoang-ho, the Euphrates, and the Amoor, have their courses to the east or south-east. This arrangement is not accidental, but depends most probably on the inclination of the primary rocks, which, in all cases where their *direction* approaches to the south and north, seem to have their steepest sides to the west and the longest declivities to the east. We have examples in the Scandinavian Alps, the mountains of Britain, the Ghauts of India, the Andes, and the Rocky Mountains.

The following table exhibits the lengths, size of the basins, and probable extent of the navigable waters of the greater rivers of America.

*Table of Principal American Rivers.*

	Length, miles.	Area of basin, sq. miles.	Navigable waters, miles.
Mississippi to source of Missouri .....	4300	1,350,000	35,000
St Lawrence through the lakes .....			
Orinoco .....	2200	600,000	4,000
Amazon, not including Ara- guay .....	1800	400,000	8,000
Plata, including Uruguay...	4000	2,100,000	50,000
	2400	1,200,000	20,000

The latitude and elevation of the land in each country, its position in reference to the sea, and the direction of the prevailing winds, are the chief circumstances which determine the nature of the climate. We have already mentioned that three-fourths of South America lie within the tropics, and the remaining fourth in the temperate zone; but, in both divisions, it might be naturally inferred that a huge wall like the Andes, rising into the atmosphere to the height of two or three miles, and running across the course of the tropical and extra-tropical winds, would exert a powerful influence on the temperature, the humidity, and the distribution of the seasons. This is actually the case; and it is this vast chain of mountains, with its prolongation in North America, which affords a key to the most remarkable peculiarities in the climate of the whole continent. The subject, which has been frequently misunderstood, admits of being explained in a very simple manner.

The trade-winds blowing from the east occupy a zone 60 degrees in breadth, extending from 30° of N. to 30° of S. latitude. Beyond these limits are variable winds; but the prevailing direction in the open sea, where no accidental causes operate, is well known by navigators to be from the west. Now these winds are the agents which transport the equable temperature of the ocean, and the moisture exhaled from its surface, to the interior of the great continents, where it is precipitated in the shape of rain, dew, or snow. Mountains receive the moisture which floats in the atmosphere; they obstruct and lift the aerial currents, and by causing a reduction of temperature, favour precipitation. Rain, accordingly, in all countries falls most abundantly on the elevated land. Let us consider, then, what will be the effect of a mural ridge like the Andes in the situation which it occupies. In the region within the 30th parallel, the moisture swept up by

the trade-wind from the Atlantic will be precipitated in part upon the mountains of Brazil, which are but low, and so distributed as to extend far into the interior. The portion which remains will be borne westward, and, losing a little as it proceeds, will be arrested by the Andes, and fall down in showers on their slopes. The aerial current will now be deprived of all the humidity which it can part with, and arrive in a state of complete exsiccation at Peru, where no rain will consequently fall. That even a much lower ridge than the Andes may intercept the whole moisture of the atmosphere, is proved by a well-known phenomenon in India, where the Ghauts, a chain only 3000 or 4000 feet high, divide summer from winter, as it is called; that is, they have copious rains on their windward side, while on the other the weather remains clear and dry; and the rains regularly change from the west side to the east, and *vice versa*, with the monsoons. In the region beyond the 30th parallel this effect will be reversed. The Andes will in this case serve as a screen to intercept the moisture brought by the prevailing west winds from the Pacific Ocean; rains will be copious on their slopes, and in Chili on their western declivities, but none will fall on the plains to the eastward, except occasionally, when the winds blow from the Atlantic. The phenomena of the weather correspond in a remarkable manner with this hypothesis. On the shore of the Pacific, from Coquimbo, at the 30th parallel, to Amatapu, at the 5th of south latitude, no rain falls; and the whole of this tract is a sandy desert, except the narrow strips of land skirting the streams that descend from the Andes, where the soil is rendered productive by irrigation. From the 30th parallel southward the scene changes. Rains are frequent; vegetation appears on the surface, and grows more vigorous as we advance southward. "At Conception," says Captain Hall, "the eye was delighted with the richest and most luxuriant foliage; at Valparaiso the hills were poorly clad with a stunted brushwood and a poor attempt at grass, the ground looking starved and naked; at Coquimbo the brushwood was gone, with nothing in its place but a vile sort of prickly pear bush, and a thin sprinkling of gray wiry grass; at Huasco (latitude 28½°) there was not a trace of vegetation, and the hills were covered with bare sand."<sup>1</sup> It follows from the principle we have laid down, that in this southern part of the continent the dry tract should be found on the east side of the mountains, and such is the fact. At Mendoza, in latitude 32°, rain scarcely ever falls, and the district along the east foot of the Andes is known to consist chiefly of parched sands, on which a few stunted shrubs grow, and in which many of the streams that descend from the mountains are absorbed before they reach the sea. The whole country, indeed, south of the Plata, suffers from drought; but on the eastern side this is remedied to some extent by winds from the east or south-east, which bring occasional rains to refresh the soil. From Amatapu northward, on the other hand, the west coast is well watered and fruitful; and this is easily accounted for. The line of the coast here changes its direction, and trends to the north-east as far as the isthmus of Panama, where the mountains sink to a few hundred feet in height, and leave a free passage to the trade-wind, which here often assumes a direction from the north-east, or even the north. The exhalations of the Atlantic are thus brought in abundance to the coast of Quito, which is in consequence well watered; while the neighbouring district of Peru suffers from perpetual aridity.

Our principle applies equally to the explanation of some peculiar facts connected with the climate of North America. The western coast of Mexico, as far as St Blas or

<sup>1</sup> Hall's *Extracts from a Journal*, vol ii. p. 12.

Mazatlan, in latitude  $23^{\circ}$  N., is well watered, because, *first*, the continent here is narrow; *secondly*, the table-land of Mexico, which is much lower than the Andes of Chili, is not so effectual a screen to intercept the moisture; and, *thirdly*, there is reason to believe that a branch of the trade-wind, which crosses the low part of the continent at Panama and Nicaragua, sweeps along the west coast during part of the year, and transports humidity with it. But beyond the point we have mentioned drought prevails. Sonora, though visited occasionally by rains, consists of sandy plains without herbage, where the streams lose themselves in the parched soil without reaching the sea; and even Old California, which has the ocean on one side, and a broad gulf on the other, and ought apparently to be excessively humid, is covered with sterile rocks and sandy hills, where the vegetation is scanty, and no timber is seen except brushwood. This dry region extends as far as  $33^{\circ}$  or  $34^{\circ}$  N.; but immediately beyond this we have another change of scene. New California is in all respects a contrast to the Old. It is rich, fertile, and humid, abounding in luxuriant forests and fine pastures; and the other American possessions to the northward preserve the same character. How can we account for this singular diversity of climate, except upon the principle which has been explained, namely, that in all regions where ranges of mountains intersect the course of the constant or predominant winds, the country on the windward side of the mountains will be moist, and that on the leeward dry; and hence parched deserts will generally be found on the west side of countries within the tropics, and on the east side of those beyond them? Our hypothesis applies equally to the country east of the Rocky Mountains. For the space of about 3000 miles along the foot of this chain the surface consists of dry sands or gravel, sometimes covered with saline incrustations, almost destitute of trees and herbage, and watered by streams flowing from the mountains, which are sometimes entirely absorbed by the arid soil. The central and eastern part of the basin of the Mississippi would in all probability have been equally barren had the configuration of the land been a little different in the south. A tract of country extremely low and level extends along both sides of this river; and a portion of the trade-wind blowing from the Mexican Gulf, finding its motion westward obstructed by the high table-land of the Cordillera, is deflected to the right, and ascends the valley of the Mississippi and Ohio. This wind, whose course was first traced by Volney, bears with it the humidity of the torrid zone, and scatters fertility over a wide region that would otherwise be a barren waste.

The views on the subject of climate we have been unfolding will enable us to throw some light on an interesting point—the distribution of forests. We are induced to think, that in all countries having a summer heat exceeding  $70^{\circ}$ , the presence or absence of natural woods, and their greater or less luxuriance, may be taken as a measure of the amount of humidity, and of the fertility of the soil. Short and heavy rains in a warm country will produce grass, which, having its roots near the surface, springs up in a few days, and withers when the moisture is exhausted; but transitory rains, however heavy, will not nourish trees, because after the surface is saturated with water, the rest runs off, and the moisture lodged in the soil neither sinks deep enough, nor is in sufficient quantity to furnish the giants of the forest with the necessary sustenance. It may be assumed that 20 inches of rain falling moderately, or at intervals, will leave a greater permanent supply in the soil than 40 inches falling, as it sometimes does in the torrid zone, in as many hours. It is only necessary to qualify this conclusion by stating, that something depends on the subsoil. If that is gravel, or a rock full of fissures, the

water imbedded will soon drain off; if it is clay or a compact rock, the water will remain in the soil. It must be

remembered, also, that both heat and moisture diminish as we ascend in the atmosphere, while evaporation increases; and hence that trees will not grow on very high ground, though its position in reference to the sea and the prevailing winds should be favourable in other respects. In speaking of the *region of forests*, we neither restrict the term to those districts where the natural woods present an unbroken continuity, nor extend it to every place where a few trees grow in open plains.

It is not easy to give a definition that will be always appropriate; but in using the expression, we wish to be understood as applying it to ground where the natural woods cover more than one-fourth of the surface.

The small map of America prefixed will enable the reader to follow our statements with ease. The long black lines show the positions of the chains of mountains; the shading represents the regions of forests; the dense forests being marked by the double shading, and the thinner ones by the open lines. The white spaces represent the lands on which little or no wood grows. The equator and the parallel of  $30^{\circ}$  on each side are indicated by the horizontal lines marked 0 and 30. The arrows show the direction of the prevailing winds; but it must be remembered that, though the intertropical wind is assumed to have its course right from the east, this is only true at the equator, its direction inclining to north-east as we approach the northern tropic, and to the south-east as we approach the southern. In North America A is the woody region on the west coast, extending from latitude  $35^{\circ}$  to about  $58^{\circ}$ , and of unknown breadth. B, the region on the east side of the Rocky Mountains, partly a bare desert, partly covered with grass and dotted with trees. C, the forests of the Alleghany chain, thick on the east and south, and thin on the west; bounded by a curved line passing from St Luis, in Mexico, through Lake Huron, to the mouth of the St Lawrence, in latitude  $50^{\circ}$  N. The arrow at M points out the direction of the wind, which ascends the valley of the Mississippi, and nourishes the western part of these forests; and the arrow at R that which blows across the isthmus of Panama. D is the table-land of Mexico, graduating on the north-west into the dry plains of Sonora and California, all bare, or nearly bare, of wood. E is the Llanos or bare plains of Caraccas, nearly fenced round with mountains. F G is the long strip of bare dry sands on the west side of the Andes which constitutes Lower Peru and the north part of Chili; and N is Amatapu, its northern boundary. H is the great region of forests which constitutes the basin of the Amazon, and occupies all the rest of Brazil. Near the equator the moisture is so excessive, that after 150 or 200 inches of rain have fallen on the east coast, there is still sufficient humidity in the atmosphere to afford copious showers to all the country up to the Andes. Here, there-

Sketch Map showing the Forest Regions of America.

fore, the woods reach from side to side of the continent. But as we recede from the equator the humidity diminishes rapidly; and though the continent becomes narrower towards the south, the supply of rain falls off in a still greater proportion, and the forests extend over a much smaller space. At the foot of the Andes the forests extend to 16° or 18° of S. latitude; on the east coast to 25° or probably 30°. K L are the *Pampas* or open lands of Buenos Ayres, extending on the east side of the Andes from Cape Horn to the latitudes just mentioned. If we divide this region into three parts, the most easterly, refreshed by occasional rains from the Atlantic, is covered with a strong nutritive herbage; the second, which is drier, displays a thin coarse wiry grass; and the third portion, which extends to the Andes, receiving little or no rain, is nearly a desert: all the three are destitute of timber, but the surface of the third is dotted with dwarfish shrubs. I is the southern part of Chili. Here the prevailing winds, which are from the west, coming loaded with the moisture of the Pacific Ocean, produce copious rains to nourish the herbage and the forests. This applies, however, chiefly to the country south of the 35th parallel. From that to Coquimbo, in latitude 30°, the wood is scanty. Beyond 50° on the east coast of North America, and 55° or 58° on the west, very little wood grows, in consequence of the rigour of the climate.

Great misapprehensions have arisen with regard to the climate of America, from comparisons being drawn between the east side of the new continent and the west side of the old. We have already pointed out the influence of winds blowing from the sea in modifying the state of the atmosphere over the land, both as to heat and humidity. When this circumstance is attended to, and when the east and west sides of the old and the new continents are respectively compared with one another, the difference is found to be small, and easily accounted for. In the torrid zone, and on the sea-shore, the temperature of both continents is found to be the same, viz., 82°; but in the interior the difference is rather in favour of America. There is no counterpart in the New World to the burning heats felt in the plains of Arabia and N. Africa. Even in the western and warmest part of the parched steppes of Caraccas, the hottest known region in America, the temperature of the air during the day is only 98° in the shade, which rises to 112° in the sandy deserts which surround the Red Sea. At Calabozo, farther east in the Llanos, the common temperature of the day is only from 88° to 90°; and at sunrise the thermometer sinks to 80°. The basin of the Amazon is shaded with lofty woods; and a cool breeze from the east, a minor branch of the trade wind, ascends the channel of the stream, following all its windings, almost to the foot of the Andes. Hence this region, though under the equator, and visited with almost constant rains, is neither excessively hot nor unhealthy. Brazil, and the vast country extending westward from it between the Plata and the Amazon, is an uneven table-land, blest with an equable climate. At Rio Janeiro, which stands low, and is exposed to a heat comparatively great, the temperature in summer varies from 68° to 82° Fahr., and the mean is only about 74°. Farther north, and in the interior, the Indians find it necessary to keep fires in their huts; and in the country near the sources of the Paraguay, hoar-frost is seen on the hills during the colder months, and the mean temperature of the year falls below 65° or 67°. On the declivities of the Andes, and on the high plains of Upper Peru, the heats are so moderate that the plants of Italy, France, and Germany come to maturity. Lower Peru, though a sandy desert, enjoys a wonderful degree of coolness, owing to the fogs which intercept the solar rays. At Lima, which is 540 feet above the sea, the temperature varies from 53° to 82°, but the mean for the whole year is

only 72°. In the plains of La Plata the mean temperature of the year is very nearly the same as at the corresponding north latitudes on the east side of the Atlantic. At Buenos Ayres, for instance, the mean annual heat is 19°·7 of the centigrade thermometer (68° Fahr.), while that of places on the same parallel in the Old World is 19°·8. The range of temperature is probably greater in the basin of the Plata; but as we advance southwards, the diminishing breadth of the continent makes the climate approximate to that of an island, and the extremes of course approach each other. In the Strait of Magalhaens the temperature of the warmest month does not exceed 43° or 46°; and snow falls almost daily in the middle of winter, though the latitude corresponds with that of England. But the inference drawn from this, that the climate is unmatched for severity, is by no means just, for the winter at Staten Island is milder than in London. In point of fact, the climate of Patagonia is absolutely colder than that of places in the same latitude in Europe; but the difference lies chiefly in the very low temperature of the summer. This peculiarity no doubt results chiefly from the greater coolness of the sea in the southern hemisphere; for beyond the parallel of 48°, the difference of temperature in the North and South Atlantic amounts, according to Humboldt, to 10° or 12° of Fahrenheit's scale. If we push our researches a step farther, and inquire what is the cause of the great warmth of the Northern Sea, we shall be forced to admit that a very satisfactory answer cannot be given. Something may be due to the influence of the Gulf Stream, a minute branch of which is supposed to carry the waters of the torrid zone to the shores of Shetland and Norway; but such an agent seems too trifling to account for the phenomenon. The sun, then, of the peculiar qualities which distinguish the climate of South America may be briefly stated. Near the equator the new continent is perhaps more humid than the old; and within the tropics generally, owing to its vast forests, the absence of sandy deserts, and the elevation of the soil, it is cooler. Beyond the tropics the heat is nearly the same in the south temperate zone of America and the northern one of the old continent, till we ascend to the latitude of Cape Horn, where we have cold summers and a very limited range of the thermometer.

The mountain ranges of North America form two widely distant highland regions, separated from each other by the vast interior plain, which contains, in its southern slope, the Mississippi with all its tributaries, and the other rivers flowing into the Gulf of Mexico, while its northern part contains the great fresh-water lakes, and many rivers taking a northward course to Hudson's Bay or to the Arctic seas. The watershed of this plain, dividing the streams that run into the Missouri and Mississippi from those communicating with the Saskatchewan, with Lake Winnipeg, and with Lake Superior, is along a line from west to east nearly coinciding with the 48th parallel of latitude, and has a mean elevation of 1500 feet.

Along the whole of the western side, from near the mouth of the Mackenzie in the Arctic Ocean, and from Alaska on the Pacific shore, to the Isthmus of Nicaragua and Panama, that is, across 60° of latitude from north to south, extends with a grand double curve the continuous length of the Rocky Mountains, and others which prolong the line, having a position in North America similar to that of the Andes in South America, and shutting off, in some parts, a comparatively narrow portion of the continent, with the Pacific shore, from the great central plain. But several minor ranges, branching off or confronting the principal mountain-ridge or backbone of North America, enclose large spaces of a table-land, traversed by the Columbia, the Fraser, and the Colorado rivers, with those which join them, and holding the Great Salt Lake of

Highland  
of N.  
America:

Utah in its central basin. The Cascade Mountains of Washington and Oregon, the Sierra Nevada of California, and the Coast Range prolonged through the Californian peninsula, have a general direction from north to south; while the Wahsatch, the Humboldt, the Blue Mountains, the Salmon River, and other ranges, stand rather across the table-land, or obliquely, from west to east. It may be convenient to speak of the former series, regarded altogether, as the general Pacific Coast Range, which we also observe to be continued northward, with some intervals, beyond latitude 60° N. to the peninsula of Alaska, presenting summits of increased height, that of Mount St Elias being above 17,000 feet, and Mount Fairweather nearly 15,000 feet. In the Cascade Range are Mount St Helens, north of the Columbia River, attaining an elevation of 15,750 feet; Mount Hood and Mount Jefferson, about 15,500 feet. The Sierra Nevada, at its northern extremity, where it forms an acute angle with the coast range, displays the lofty terminal peak of Mount Shasta, having an altitude of 14,400 feet. The minor Californian Coast Range nowhere rises to 4000 feet. The main Cordillera or spine of Western North America, which in the British Dominion and in the United States' territory is called the Rocky Mountains, but which takes the name of the Sierra Madre in Mexico, and in the isthmus, farther south, is split into two lower groups of a volcanic character, attains the height of 16,000 feet in Mount Brown, and 15,700 feet in Mount Hooker, both near the 54th degree of latitude, above the source of the Saskatchewan river; but Fremont, in the Wind River group, between Oregon and Nebraska, is 13,560 feet high, and there are peaks of 10,000 feet or 12,000 feet in Utah and New Mexico. The highest mountains, however, in North America, excelling even Mount St Elias, belong to a volcanic series which crosses the table-land of southern Mexico from west to east, and of which the culminating points are Popocatepetl, 17,884 feet, and Orizaba, 17,373 feet; while Agua, in Guatemala, rises to 13,000 feet. Thus we may remark, at each extremity of the Cordillera, at its north end, towards Alaska, and at its south end, in Central America, it is encountered by a cluster of volcanoes, Mount St Elias being one of this description, which exceed the height of the Rocky Mountains. The spaces enclosed between the main trunk and branches of this immense system of mountains are several hundred miles wide, and their surface is elevated 5000 feet or 6000 feet above the sea-level, as in the Utah lake-basin, the Nevada territory, and the plateau of Anahuac, or southern Mexico, which last has an elevation of 6000 feet to 8000 feet, and has therefore a temperate climate within the tropics.

An outline merely has been given of the western highland region of North America. The eastern highlands of this continent are mainly constituted by the Alleghanies or Appalachian system of mountains, with their dependencies, which are of no great height, the Black Mountain, or Mount Guyot, in North Carolina, being the highest, at 6476 feet; but they extend nearly 2000 miles, from the Gulf of St Lawrence to the Gulf of Mexico, having a general direction from north-east to south-west. The strip of land, one or two hundred miles wide, between these mountains and the Atlantic coast, is of the greatest historical interest, as it includes the seats of all the older English settlements on this continent, which seems destined for the grandest dwelling-place of our nation. North of the Gulf of St Lawrence, through the peninsula that terminates with Labrador between the Atlantic and Hudson's Bay, the Appalachian system of mountains is continued, or resumed, in a range called the Watchish, only 1500 feet high, but in the severe climate of that region covered with perpetual snow. The Alleghanies, south of the St Law-

rence, including the Green Mountains of Vermont and the White Mountains of New Hampshire, are not so much a chain of mountains as a long plateau, crested by several different ridges, and intersected by wide valleys of considerable elevation, but altogether on a much smaller scale than the highlands of Western America. East of the river Hudson the mountains are chiefly granitic, with rounded summits, often covered with turf or moss to the top; they assume a more regular formation in Pennsylvania, Virginia, and North Carolina, but again decline and break into detached groups in approaching their southern extremity in Alabama. Next to the summit in North Carolina, which is named above, Mount Washington in New Hampshire stands pre-eminent, with an altitude of 6428 feet. The scenery of these "White Mountains" is very striking, especially where the Saco river cleaves its way through the barrier of granite by a cutting two miles long, in one place only 22 feet wide, between lofty precipitous walls. It is in the "Green Mountains," succeeding these to the west, and giving their name in French to the neighbouring State, that the prevalent form becomes that of round humps on a broad base, with firs or shrubs growing on the slopes, and with scanty grass or lichens on the summits. Both these two contrasted groups of New England mountains enter the State of Massachusetts from the north; the Hoosac and Taconic extensions of the Green Mountains rise on the west side, while the White Mountains are continued by those of which Mount Holyoke and Wachusett are the most conspicuous; and between their parallel ranges is the Connecticut river, with the Housatonic, Mount Tom, and Blue Hills to overlook its lower course. These features of the country, though of far less physical importance than the towering peaks of Colorado and California, will always be associated with the genuine traditions of English rural, domestic, and social life, transplanted to the New World in the 17th century, and defended by a long struggle against stern nature and savage men in the early age of the American colonies. The natural boundary separating New England from the great and more modern State of New York is that noble river the Hudson, rising in the Adirondack Mountains, near Lake Champlain and the waters of the St Lawrence, but pouring its beautiful and useful stream directly south, to the greatest of American commercial ports and cities. This river passes close by the Catskill and Shawangunk Mountains, from which is continued the general distribution of the eastern American highlands along the Atlantic states, but with a more westerly declination from the coast, running through Pennsylvania, West Virginia, the borders of Tennessee, and North Carolina, the upper parts of Georgia and Alabama. It is in Virginia that the Alleghanies have their greatest breadth, which is about 150 miles. They rise highest in North Carolina and Tennessee, and subsequently keep up a distinct line of position, across the cotton-growing States, between those of the Atlantic seaboard and those of the Lower Mississippi. This circumstance, it may be remarked, has had most important effects on the political and military events of late years, in the results of the attempted secession of the slaveholding States from the Union. Another feature of physical geography, which probably conditioned the earlier stages of that momentous civil struggle, in the disputes relating to the Missouri compromise and to the admission of Kansas as a free-soil State, is the existence of the Ozark range of mountains. These stand in the middle of the great Mississippi valley, stretching across from northern Texas to Arkansas and the confluence of the Missouri with the Mississippi. By the elevation they give to the soil, in latitudes between 30° and 40°, as well as by the raised table-land of New Mexico and Arizona farther west, the

area of United States' territory suitable for cotton plantations and for slave labour was so far limited, and confined to the shores of the Gulf of Mexico and the Atlantic seaboard. At the same time, in the latitudes north of these, between 40° and 50°, the whole vast prairie region from the Ohio to the Rocky Mountains was adapted to the growth of corn, while it had such continuity and uniformity of surface, and was so pervaded by the grand river-system of this middle plain of North America, that it could not well undergo political division. The entire West being thus secured to the Union, and the better part of the South being thus rescued from the curse of Negro slavery, by the moulding hand of nature in planning the distribution of mountain ranges and the level ground all over this continent, we may consider that the political and social destinies of the great English Republic, vindicated in the civil war from 1861 to 1865, were predetermined in the formation of the land.

The North American continent affords an interesting study of the geological changes and adjustments, by which the mighty work of preparation for what promises to be a noble development of humanity was slowly effected in the remote epochs of the past. The oldest sedimentary rocks anywhere found on the globe are those which underlie the whole of Canada, New Brunswick, and Newfoundland, the Labrador peninsula, and the country north of Lake Superior, perhaps also the less explored regions of the far north-west towards the Arctic Sea. This series, named the Laurentian, from the St Lawrence river, is perceived to exist in Europe only in a few scattered instances, in the Hebrides, and in Norway or Sweden. In North America it occupies the most extensive areas; the thickness of its beds is estimated by Sir William Logan at 30,000 feet; it rises to hills or mountains 4000 feet high, and in the deep gorge of the Saguenay river, forms perpendicular cliffs of 1500 feet. Only one fossil animal, which has been called the *Eozoon Canadense*, has been discovered to have left its trace in this most ancient bottom of the primeval ocean; it was one of the Foraminifera, which covered its gelatinous body with a thin crust of carbonate of lime, having numerous holes or pores for the emission of its filament-members, with which to feel and to feed outside. Next to the Laurentian, but with a vast unknown interval of time, comes the Huronian or Lower Cambrian series. It is suggested by geologists that, as the vast level bed of the Laurentian sea was cracked by internal changes of the earth's density, these cracks threw up certain ridges along the surface of the present continent, which laid a foundation for the principal mountain ranges we have described. At the borders and extremities of these mountain ranges, it is evident that there were intense volcanic eruptions, producing great quantities of lava and conglomerate, basalt, greenstone, and other formations resulting from igneous action. The northern shores of Lakes Huron and Superior exhibit results of this kind; but it is in the table-lands between the Rocky Mountains and the west coast ranges, as in the singular lava beds near the Klamath, on the frontier of Oregon and North California, that volcanic forces have made their strongest marks on the earth. On the eastern side also of the grand Cordillera, between the sources of the Missouri and of the Yellowstone rivers, is a wonderful region of boiling springs or geysers, of sulphur beds and other natural curiosities, which have recently been described by Dr Hayden, of the United States' Government Survey. To speak more generally of the local arrangement of different geological formations, it may be remarked that crystalline rocks are spread over the western parts of North America, from Alaska to Nicaragua, and over the most northern parts, also including Greenland; but some of

later date are found in the eastern or Appalachian range, consisting of felspathic gneiss and quartz rocks, mingled with talcose and chloritic schists. The Palæozoic formations occupy that middle part of the continent which lies between the Rocky Mountains and the great lakes, as well as the shores of Hudson's Bay, and some portions of the Atlantic coasts. With reference to the Lower Silurian or Siluro-Cambrian period, it is abundantly illustrated by the Trenton and associated limestones, which can be traced over 40° of longitude, their beds consisting entirely of *débris* of coral, shells, and crinoids, from the shallow inland sea, teeming with animal life, that once filled the whole level space between the Alleghanies and the Rocky Mountains, separated by these ridges from the Atlantic and Pacific Oceans, and sheltered from the cold Arctic currents by the northern Laurentian highlands. This space, which is now the central plain of North America, comprising the prairies and the Mississippi valley, was then a coral sea with archipelagos of volcanic isles, resembling that of Australasia in the South Pacific. The next formation succeeding the Silurian presents immense deposits of sandstone and shale from the muddy waters troubled by subterranean motions; this is the Devonian formation, which in America has been called the Erian, on account of the great development of such beds south of Lake Erie. The deposits of this period in the western continent are stated to be 15,000 feet in thickness. They include the cliff limestones, studded with calcareous corals of great size and beauty of shape, noticed by Sir Charles Lyell at the falls of the Ohio, near Louisville; these limestones are estimated to extend, as an ancient coral reef, over 500,000 square miles of the American middle plain. In the State of New York and in Western Canada there is the coriferous limestone, in which the imbedded corals have been replaced, in the cavities they once filled, by flinty hornstones which present the perfect coral forms, as though cast in a mould. In the Carboniferous age the great internal sea of the continent was slowly changed into swampy flats and shallow lakes or creeks, and gradually filled with a rank vegetable growth, afterwards buried under later marine deposits and pressed into the existing coal-beds. Of this period there are very extensive developments throughout the eastern half of the great middle plain to the Alleghanies. This portion of America seems to have been land, covered with the forests of that period, while the western half of the middle plain, a northward extension of the Gulf of Mexico, was still under water. As the eastern half of North America, between the Mississippi and the Atlantic, was thus in the Carboniferous era well raised out of the sea, it exhibits no traces of the succeeding Permian age, such as we find in Europe. The earliest periods also of Mesozoic time have failed to leave any record here, but their formations appear towards the western range of mountains in what was the bed of a Mediterranean Sea. It is, however, the Cretaceous system, with its characteristic greensand, its sands, clays, marls, and soft grey limestones, that occupies most space in Western America, between the meridians of 97° and 112°. These strata, overlaid sometimes by those of the Tertiary periods, extend through the country up the Missouri, the Platte, the Arkansas, and the Red River, to the Rocky Mountains; they also form parts of the plains enclosed by different mountain ranges beyond the Cordillera. Along the eastern side of the Appalachians there is a broad belt of the Cretaceous formation, stretching from the Delaware across the upper parts of Virginia, Carolina, Georgia, and Alabama. Among the fossil animal remains discovered in this formation in North America, which are enumerated in a separate list, one of the most remarkable is that of the *Mosasaurus*, a combination of the serpent with the lizard

form, sometimes 80 feet in length, and of aquatic habits. The Tertiary deposits, including the boulder clay, prevail chiefly along the seaward districts, from Long Island, above New York, to the peninsula of Florida, and around the shores of the Mexican Gulf, and likewise on the Pacific shore from Lower California to Vancouver Island, also in some detached instances, as in Nebraska, in the midst of the interior plain. The newer Pliocene is met with in the southern part of Maine, and on the shores of Lake Champlain. The drift formation lies mostly north of 40° latitude. Alluvial deposits are of great amount from the large rivers and lakes, especially in the delta of the Mississippi, which has an area of 13,600 square miles, and must, by Sir Charles Lyell's reckoning, have taken 67,000 years for its composition, at the rate of the bringing down of solid matter by that mighty river.

The mineral products of North America are of unequalled richness and variety. Gold is abundant, to a proverb, in California, and likewise in Nevada and Montana. It is also found in British Columbia, Mexico, Central America, and Canada, and sparingly in Virginia and South Carolina. Silver is obtained from Mexico in larger quantities than from any other country; it is supplied also by California and by Honduras, and a vein of this metal is worked in Newfoundland. Great masses of almost pure copper are found in the Huronian rock strata, the north and east shores of Lake Superior being the richest of copper-mining regions; while New York State and Indiana possess a share of the same metal, and it is found among the western mountains in different countries from British Columbia to the isthmus. The iron ores of Pennsylvania, and those of Canada, including New Brunswick, are of the greatest importance; the former are rendered more available by their occurring close to the beds of bituminous coal, giving materials for the manufacturing industry of Pittsburg; while anthracite coal is obtained from the eastern districts of Pennsylvania. It is estimated that one-third of the total area of this State is occupied by coal-fields, which can scarcely be exhausted. Lead is found in Wisconsin, Illinois, and Missouri, in New York State, in Canada, in California, and in Central America, as well as quicksilver; white zinc is got from Arkansas and New Jersey; both Canada and Mexico produce tin. Reverting to the subject of coal, as having an intimate economic connection with all metallic wealth, it should be observed that the united area of all the coal-fields in the United States is estimated at 190,000 square miles, exceeding twentyfold those of Europe. The chief of these coal-fields are, first, the Appalachian, extending from the Susquehanna, in Pennsylvania, to the Tuscaloosa, in Alabama, along the west side of the Alleghany Mountains; the area of this coal-field is 70,000 square miles, and its greatest thickness 2500 feet; secondly, the coal-field of Michigan, about the centre of that State; thirdly, the extensive coal-field between the Ohio and the Mississippi, across the States of Indiana and Illinois; lastly, the Iowa and Missouri coal-field, which occupies a large space in the very centre of the continent. Coal is found also in Nova Scotia, in British Columbia, and Vancouver Island, and wherever the Upper Palæozoic strata prevail in the geological structure. But in the vast extent of British American territory north-west of Lake Superior, around Lake Winnipeg and up the Saskatchewan river, even as far as the Peace river, in latitude 56° N., it may be expected that manufacturing as well as agricultural prosperity will result from the use of immense stores of natural wealth existing in the soil of that long-neglected land, which is now proved to have a climate not more severe than the inhabited provinces of Canada. The iron and copper, more especially of the Canadian Dominion, will employ and enrich, in all probability, at some future

period, a nation that may become greater in material resources than the most powerful kingdoms of Europe. In view of these prospects from the working of the useful metals, by the aid of that most useful product of the earth which supplies heat and mechanical force to the service of human industry, we may regard the Californian gold-fields as a matter of secondary importance. They have indeed been surpassed by the productiveness of those in Australia and New Zealand.

Nine-tenths of North America lying under the temperate zone, the climate follows a different law from what is observed in the southern peninsula, and presents more striking contrasts with that of the best known parts of the Old World. The long narrow region now denominated Central America, which connects the two great divisions of the continent, stretching from Panama to Tehuantepec, has in general a very humid atmosphere; but, for a tropical country, it must be only moderately hot, as every part of it is within a small distance of the sea. At Vera Paz the rains fall during nine months of the year. Mexico is hot, moist, and unhealthy on the low coasts; but two-thirds of its area, comprising all the populous districts, consist of table-land, from 5000 to 9000 feet in height. In consequence of this singular configuration of its surface, Mexico, though chiefly within the torrid zone, enjoys a temperate and equable climate. The mean heat at the capital, which is 7400 feet above the sea, is 62½°, and the difference between the warmest and coldest months, which exceeds 30° at London, is here only about 12°; but the atmosphere is deficient in moisture, and the country suffers from drought. Beyond the parallel of 24° N. the western shores are hot and arid.

In the extensive region lying between the parallels of 30° and 50° N., which comprehends three-fourths of the useful soil of North America, we have three well-marked varieties of climate, that of the east coast, the west coast, and the basin of the Mississippi. On the east coast, from Georgia to Lower Canada, the mean temperature of the year is lower than in Europe by 9° at the latitude of 40°, and by 12½° at the latitude of 50°, according to Humboldt's calculation. In the next place, the range of the thermometer is much greater than in Europe, the summer being much hotter and the winter much colder. At Quebec the temperature of the warmest month exceeds that of the coldest by no less than 60½° of Fahr.; while at Paris, which is nearly under the same latitude, the difference is only 31°. In the third place, the climate undergoes a more rapid change in America as we proceed from south to north, a degree of latitude in the middle of the temperate zone producing a decrease of annual temperature of 1°·13 Fahr. in Europe, and of 1°·57 Fahr. in America. The comparison is greatly to the disadvantage of America when made in this form; but when the east coasts of the two continents are compared, the case is altered; the Old World is found to have no superiority over the New, for Peking has still colder winters and warmer summers than Philadelphia, which is under the same latitude. It is the west coast of the new continent which ought to exhibit the climate of Europe; and from the observations made, we have reason to believe that it is quite as mild and equable. At the mouth of Columbia river, in latitude 46½° N., it appears that the mean heat of the warmest month was about 62° Fahr., of the coldest about 36°, and of the whole year 51°. Now the place is under the same latitude with Quebec, where the snow lies five months, and the mean temperature during the three winter months is 18° below the freezing point. This single circumstance marks emphatically the contrast in the climate of the east and west coasts of North America. But the mouth of Columbia river is also under the same parallel with Nantes at the mouth of the Loire; and we have, therefore, good grounds to conclude that the west

Central  
and Nor  
America  
Climate.

erals.

coast of America, in the middle latitudes, has nearly as mild and equable a climate as the west coast of Europe. The climate of the great central valley, or basin of the Mississippi, has a considerable affinity to that of the east coast. It was long a matter of dispute in what the difference between the two consists, but this seems at last to have been clearly settled by the meteorological registers kept at the military posts of the United States. From a comparison of four of these registers, from posts near the centre of this great valley, with others kept on the Atlantic coast in the same latitudes, it appears that the extremes of heat and cold in the basin of the Mississippi are from 5° to 6° higher and lower than on the coasts of New England. The proportion of fair weather to cloudy is as 5 to 1 in favour of the east coast. The climate of the interior, therefore, exhibits in still greater excess those extremes of temperature which distinguish the eastern coast of this continent from the western, and from the shores of Europe. The fourth region of extra-tropical America includes the parts beyond Mount St Elias on the west coast, and, in the interior, the plains extending from the 50th parallel to the Polar Seas. The intensity of the cold in this tract of country is scarcely equalled by anything that is known under the same parallels in Northern Asia. The northernmost spot in America where grain is raised is at Lord Selkirk's colony, on Red River, in latitude 50°. Wheat, and also maize, which requires a high summer heat, are cultivated here. Barley would certainly grow as far north as Fort Chippewyan, in latitude 58 $\frac{3}{4}$ °, where the heat of the four summer months was found by Captain Franklin to be 4° higher than at Edinburgh. There is even reason to believe, that both this species of grain and potatoes might thrive as far north as Slave Lake, since the spruce fir attains the height of 50 feet three degrees farther north, at Fort Franklin, in latitude 65°. These, however, are low and sheltered spots; but in this dreary waste generally, it will not be found practicable, we suspect, to carry the arts of civilised life beyond the 60th parallel; and the desirable country, capable of supporting a large population, and meriting the name of temperate, can scarcely be said to extend beyond the 52d parallel. At 65° the snow covers the ground in winter to the depth of only two feet, but small lakes continue frozen for eight months. The sea is open only for a few weeks, fogs darken the surface, and the thermometer in February descended in one instance to *minus* 58°, or 90° below the freezing point. At Melville Island, under the 75th parallel, such is the frightful rigour of the climate, that the temperature of the year falls 1° or 2° below the zero of Fahrenheit's scale. It is a peculiarity in the climate of America, that beyond the parallel of 50° or 52°, it seems to become suddenly severe at both extremities. At the one, summer disappears from the circle of the seasons; at the other, winter is armed with double terrors.

The zoology of America is especially interesting, on account of the contrast which exists between the faunas of the north and south portions of the continent—a contrast which is especially exhibited in the case of the Mammalia. The zoological province which naturalists mark off as constituted by South America and part of Central America has been termed the neotropical region, and the area which has the nearest relationship to this is the Indian region. As regards South America, the Andes have the highest value as zoological boundaries; next to them in importance are the rivers, and then the confines of the forest region. The *Quadrumanæ* are well represented, and are especially characteristic of the forest region which principally prevails in the western half of the continent. None are known to occur on the west side of the Andes south of Guayaquil. The sub-order *Platyrrhina* is

peculiar to South America, and so far as research has yet extended, it is not known even to have existed on any other area. On the other hand, no catarrhine or lemurine *Quadrumanæ* have yet been found in South America. Some of the lower forms of monkey appear to have some affinity with the *Lemuridæ*, which occur in India, Africa, and Madagascar. There are two families, viz., the *Cebidæ* and *Hapalidæ*, all the members of which are strictly arboreal in habits. Some of these monkeys are the most highly developed tree-climbers known, and in many cases they rarely if ever descend to the ground; and since the monkeys of South America have never been seen to swim, it might be expected that the broad streams of the continent effectually limit the distribution of certain monkeys. The largest species is *Lagothrix Humboldtii*, so that as a whole the American monkeys are smaller than those of Asia and Africa. As they are the most powerful of arboreal Mammalia, they rule the forests, and this may in part account for the scarcity of squirrels in this region. The *Cebidæ* have a wide range, extending from the south of Mexico to the Uruguay. They include the highest forms of American monkey, and its most specialised representatives are those which have the best adaptation for life in trees, as may be exemplified by *Ateles*, with its long limbs and prehensile tail. This latter organ serves all the purposes of a fifth hand; the under surface is bare and provided with tactile papillæ, so that a monkey not only holds by, but also feels with it. It is as mobile and flexible, and in its way as useful to this genus of monkey as is the trunk to the elephant. The genus includes numerous species, the estimate of different naturalists varying from 8 to 40, but about 10 species have been well established. Most of them occur in Brazil and the Guianas; but each species generally has circumscribed limits. Thus *A. paniscus* occurs in the north-east corner of the continent, between the Rio Negro and the Amazon. On the south side of the Amazon its place is taken by another species, *A. marginatus*. *A. Bartlettii* occurs on the Upper Amazon. *Brachyteles* is represented by a single species in South-East Brazil. Several species of *Lagothrix* have been described, although perhaps all are but varieties of but one species. *L. Humboldtii* is confined to the Upper Amazon, west of the Rio Negro, and in some of the contiguous valleys of the Orinoco basin. *Mycetes* has six species, ranging from Guatemala to South Brazil. *M. seniculus* occurs on the north side of the Lower Amazon; *M. caraya* on the Upper Amazon; and *M. belzebuth* is the species which occurs near Para, and south of the Lower Amazon. All the above genera have prehensile tails, with bare under surfaces. *Nyctipithecus*, with three or four species, occurs in the upper portions of the Rio Negro, Amazon, and Orinoco basins. *Callithrix* ranges over the same ground, but also extends into South-East Brazil. *Carysothrix* occurs throughout the northern part of the region. The genus *Pithecia* (including *Brachyurus*) is represented by about 12 species in the Amazon basin. *P. irrorata* is confined to the south bank of the Upper Amazon; another species only occurs on the north side to the west of the Rio Negro. *P. satanas* is the species east of the Rio Negro, and there is a species limited to the south side of the Upper Amazon. The family *Hapalidæ*, or marmosets, has about 30 species, belonging to the genera *Hapale* and *Midas*, which range throughout the forests of South America. One species, *H. œdipus*, occurs in Costa Rica, but this is the northernmost limit of the family. It seems that the distribution of the monkeys is restricted to the areas clad with continuous forests, so that the absence of monkeys in the Pampean, Andisian, and Peruvian sub-regions is mainly due to the absence of continuous forests. It is also noticeable that the sub-orders, families, and genera extend over the greater portion of the Brazilian sub-region; whereas in

many instances this sub-region is parcelled out into districts by the larger streams, which are characterised by distinct species. Hence it is probable that the continuosness of the forest area has lasted throughout the duration of those species, but not so long as the genera have existed; and that those species which occur on both sides of the Amazon, Rio Negro, and other large rivers, originated at an earlier period than those restricted to one side. The want of means of communication with North America would account for the absence of monkeys in that region. Our space will not allow of our dwelling so fully on the other orders, but we may notice that the arboreal habit is strongly marked in many, and that the strictly arboreal groups are frequently represented in river-bounded areas by distinct species. It often happens that genera, both of vertebrates and invertebrates, which are elsewhere terrestrial, are represented in the Amazonian forests by arboreal species.

The Carnivora do not present so marked a feature as regards distribution as the monkeys. The families Felidæ, Canidæ, Mustelidæ, and Ursidæ are represented; but the Hyænidæ and Viverridæ are absent, unless *Bassaris* of Mexico be referred to the latter family. The Felidæ comprise two groups, one formed of species which are uniformly coloured, the other of those which are striped or spotted. *Felis onca*, the jaguar, is the largest feline animal of this region, and ranges from La Plata to Louisiana, and on both sides of the Peruvian Andes. The puma or *F. concolor* is known everywhere from Patagonia to as far as 50° or 60° N., a range from north to south of about 110°, which is probably greater than that of any other mammal. *F. payeros* occurs on all the pampas of the southern portion of South America. *F. mitis* and *F. macrura* belong to South-East Brazil; *F. tigrina* and *celidogaster* to the Amazon basin; while *F. pardalis*, *F. eyra*, and *F. yagouaroundi* range from Brazil to Texas. The Canidæ family is represented by the genera *Icticyon* and *Canis*. The former comprises but one species, which is confined to Brazil, viz., *I. venaticus*, which is an aberrant form between dogs and badgers. The dogs comprise *C. jubatus*, *C. cancrivorus*, *C. vetulus*, *C. fulvicaudus*, *C. azara*, *C. magellanicus*, and one or two other species. The Mustelidæ are not abundant, there being only a few species of each of the sub-families *Mustelinæ*, *Lutrinæ*, and *Melinæ*; and among others *Mustela frenata*; two species of *Galictis*, a genus only found in this region; *Lutra chilensis* and *braziliensis*; and several species of *Mephitis* belonging to the sub-genus *Thiosmus*. Of Ursidæ there occur *Ursus ornatus* in Peru, and perhaps *Ursus frugilegus*; *Procyon cancrivorus*, *Nasua*, and *Cercoleptes*. The last two genera are characteristic of South America. In this order the species, with the exception of a few which range into North America, are restricted to this area; but only four of the eleven genera are peculiar, the others ranging not only into North America, but also into the Old World. The latter genera do not form a prominent feature in the fauna, and the species have probably migrated from North America in comparatively recent times from a geological point of view.

In the order Artiodactyla the sub-order Ruminantia is represented by a few species only of *Cervus*, belonging to the neotropical sub-genera *Furcifer*, *Coassus*, and *Blastocerus*, and even these only occur sparingly in the open tracts. There is nothing to represent the enormous herds of Antelopes and Bovidæ, which are so characteristic of North America and portions of the Old World. *Auchenia*, however, is a characteristic genus frequenting the Andes, and is interesting on account of its being the only genus of Ruminants which is confined to South America. It is isolated and far distant from the other members of the family Camelidæ, which are now special to Asia; but, as we shall presently find, the gap in distribution and structure is supplied by the extinct species of North America. The

characteristic genus *Dicotyles* is the sole representative in South America of the sub-order Omnivora and of the family Suidæ, a family which is restricted (naturally) to the Neotropical, Æthiopian, and Indian regions. Another remarkable genus is *Tapirus*, which represents in this region the elephants and rhinoceroses of the Old World. Until recently, the tapirs of Sumatra and the Malay Archipelago were considered to belong to the same genus, but Dr Gray has proposed that the latter be ranked in a distinct genus, *Rhinoceros*. There are several species of South American tapirs, viz., *T. americanus*, *T. villosus*, *T. Laurillardii*, *T. Roulinii*, and perhaps one or two others not determined. An allied form exists in the isthmus of Panama, namely *Elasmognathus Bairdii*, which is considered as the type of a distinct sub-family. There are no true Proboscideans in this region. The order Sirenia is represented by the genus *Manatus*, of which three or four species occur in the Amazon and other large rivers. This genus is remarkable for its distribution, since species belonging to it frequent the freshwater streams of the opposite coast of Africa. Several species of dolphins and porpoises occur in the larger rivers; some of them range up almost to their sources, and are strictly river species, being unknown in the adjoining seas. The presence of these cetaceans, together with the distance of the shores (several miles) and the high waves, impart to some portions of these rivers a more or less oceanic aspect. The order Bruta is abundantly represented in this region, of the fauna of which it constitutes the most marked peculiarity. Marsupialism is not a prominent feature in this region, but its presence is important, because it now occurs nowhere else out of the Australian region. It should be observed that the connection is stronger with the extinct marsupial fauna of Palæartic regions than with the living one of Australia.

The fossil and living mammalia of this region seem to indicate that at present our knowledge of the extinct faunas is very fragmentary. This is shown in various ways. None of the remains can be definitely assigned to an older period than the Post-Pliocene. The region was essentially the same as at present, zoologically, the same characteristic groups of plathyrhine apes, rodents, cats, dogs, edentates, and opossums being represented; while the catarrhine apes, insectivora, oxen, rhinoceroses, and other groups were excluded, or at any rate are not known to have existed in it, so that its isolation from the other zoological regions must have commenced before the Post-Pliocene period. The extraordinary development of large forms allied to the sloths and ant-eaters; the restriction of the *Toxodontia* amongst the Post-Pliocene mammals, and of the subungulated Rodents among the living mammals to this region,—these and other facts would lead the palæontologist to believe that the area must have been inhabited by mammals during the periods which preceded the Post-Pliocene, as far back, perhaps, as the Miocene or Eocene. The *Toxodontia* include the forms of *Pachyderms* most nearly allied to the Rodents, while the subungulated Rodents are those of the order which approach nearest to the *Pachyderms*. As both these groups occur here, and here only, we may reasonably expect to find genera partaking of the general features of both orders in beds of an earlier geological age in South America. The principal genera and species found fossil in this region are the following. In the Argentine Confederation we have—

<i>Macrauchenia patachonica.</i>	<i>Felis longifrons.</i>
<i>Glyptodon spinicaudus.</i>	<i>Canis protalopex.</i>
<i>clavipes.</i>	<i>avus.</i>
<i>tuberculatus.</i>	<i>Mephitis primæva.</i>
<i>pumilio.</i>	<i>Ursus bonerensis.</i>
<i>clavicaudatus.</i>	<i>Myopotamus bonerensis.</i>
<i>clavatus.</i>	<i>antiquus.</i>
<i>asper.</i>	<i>Ctenomys bonerensis.</i>
<i>clongatus.</i>	<i>Lagostomus augustidens.</i>
<i>Machairodus neogæus.</i>	<i>Cavia breviplicata.</i>

Megatherium americanum.	Megalonyx meridionalis.
Myiodon giganteus.	jeffersoni.
gracilis.	Equus curvidens.
robustus.	devillei.
darwinii.	Toxodon burmeisteri.
Scelidotherium leptocephalum.	owenii.
cuvieri.	Mastodon humboldtii.

Some of these also occur in Brazil, where species have also been found belonging to the genera *Callithrix*, *Cebus*, *Protopithecus*, *Chlamydothorium*, *Cœlogenys*, *Colodon*, *Dasypus*, *Equus neogæus*, *Equus principalis*, *Euryidon*, *Heterodon*, *Hoplophorus*, *Myrmecophaga*, *Nesodon*, *Pachytherium*, and *Xenurus*. Remains of many of these genera have also been found on the banks of the Rio Negro in Uruguay, and those of some, such as *Mastodon*, *Equus*, *Auchenia*, &c., in Ecuador. As space forbids our dwelling upon the points of interest which these fossil forms present, we pass on to the lists of the extinct faunas of North America.

The oldest species yet found in North America belongs to *Dromatherium*, and was found in the Triassic beds of Virginia. Then nothing is known until we come to the Tertiary deposits which were formed in lakes along the base and in the midst of the Rocky Mountains and neighbouring ranges, and in the marine beds which lie nearer the present sea margin. The following lists are given by Dr Leidy,<sup>1</sup> who considers the oldest beds in Nebraska, which rest on the Cretaceous series, as of Miocene age. They contain *Titanotherium prouti*, *Lophiodons*, and several other forms which would induce us to regard them as Eocene. However, we follow his lists. The Miocene species are—

Carnivora.	Artiodactyla.
Canidæ.	Suidæ.
Amphicyon vetus.	Elotherium ingens.
gracilis.	superbum.
Hyænodontidæ.	leidyænum.
Hyænodon horridus.	Perchærus probus.
cruentus.	Leptocheerus spectabilis.
crucians.	Nanohyus percinus.
Felidæ.	Anthracotheridæ.
Drepanodon ( <i>Machairodus</i> )	Hypopotamus americanus.
primævus.	Anoplotheridæ.
( <i>Machairodus</i> )	Titanotherium prouti.
occidentalis.	Perissodactyla.
Diniectis felina.	Rhinocerotidæ.
Ruminantia.	Rhinoceros.
Oreodontidæ.	Hyocodon.
Oreodon culbertsoni.	Tapiridæ.
gracilis.	Lophiodon.
major.	Solidungula.
affinis.	Anchitheriidæ.
hybridus.	Anchitherium.
bullatus.	Anchippus.
Merycocheerus proprius	Hypohippus.
Leptauchenia major.	Parahippus.
decora.	Anchippodus.
nitida.	Rodentia.
Agriochæridæ.	Leporidæ.
Agriochærus antiquus.	Palaolagus haydeni.
major.	Castoridae.
latifrons.	Palaœocastor nebrascensis.
Camelidæ.	Muridæ.
Pœbrotherium wilsoni.	Eumys elegans.
Protomeryx halli.	Insectivora.
Moschidæ.	Erinacidæ.
Leptomeryx evansi.	Leptictis haydeni.
Artiodactyla.	Ictops dakotensis.
Suidæ.	Omomys carteri.
Elotherium mortoni.	

Since this list was published numerous genera and species have been discovered in Wyoming and other districts in the far west from what appear to be the older or Eocene group of beds. Amongst these the most remarkable is the large *Dinoceras mirabilis*, an animal which had three pairs of horns, and which was intermediate in character between the Proboscideans and the Perissodactyles. There are also

several generalised forms in the foregoing lists, which present a fauna with numerous remarkable features, which we can only briefly allude to. It is quite distinct in character from the present South American fauna, and yet, like it, it has a strong Asiatic facies; at the same time it resembles in many points the older Tertiary fauna of Europe. The occurrence of rhinoceroses, camels, and musk-deer, is noticeable; but its great feature is the abundance of oreodonts (which family is not known elsewhere) and of equine forms. The Pliocene fauna consists of the following genera and species:—

Carnivora.	Ruminantia.
Canidæ.	Antilopidæ.
Canis sævus.	Cosoryx furcatus.
temerarius.	Artiodactyla.
vafer.	Suidæ.
haydeni.	Dicotyles.
Felidæ.	Perissodactyla.
Pseudæurus intrepidus.	Rhinocerotidæ.
Ælurodon ferox.	Rhinoceros.
Ursidæ.	Proboscidæ.
Leptarectus primus.	Mastodon.
Ruminantia.	Elephas.
Oreodontidæ.	Solidungula.
Merychyus elegans.	Equidæ.
medius.	Hipparion.
major.	Protohippus.
Camelidæ.	Merychippus.
Procamelus robustus.	Equus.
occidentalis.	Rodentia.
gracilis.	Castoridae.
Homocamelus caninus.	Castor.
Megalomeryx niobrarenensis.	Hystricidæ.
Merycodus necatus.	Hystrix.
Cervidæ.	
Cervus warreni.	

The Post-Pliocene forms are—

Carnivora.	Perissodactyla.
Canidæ.	Proboscidæ.
Canis.	Mastodon.
Felidæ.	Elephas.
Felis.	Solidungula.
Ursidæ.	Equidæ.
Procyon lotor.	Hipparion venustum.
priscus.	Equus major.
Ursus americanus	fraternus.
amplidens.	pacificus.
Arctodon pristinus.	conversidens.
Mustelidæ.	tau.
Galera macrodon.	fossilis.
Ruminantia.	Rodentia.
Camelidæ.	Leporidæ.
Camelops kansanus.	Lepus sylvatica.
Cervidæ.	Sciuridæ.
Cervus virginianus.	Arctomys monax.
canadensis.	Sciurus.
tarandus.	Castoridae.
americanus.	Castor canadensis.
Capridæ.	Castoroides ohioensis.
Ovis mammillaris.	Cavidæ.
Ovibos moschatus.	Hydrochærus æsopi.
bombifrons.	Chinchillidæ.
cavifrons.	Amblyrhiza inundata
Bovidæ.	Muridæ.
Bison americanus.	Neotoma magister.
latifrons.	Marsupialia.
antiquus.	Didelphys virginiana.
priscus.	Edentata.
Artiodactyla.	Megatherium mirabile.
Suidæ.	Megalonyx jeffersoni.
Dicotyles nasutus.	dissimilis.
Platygonus compressus.	validus.
Perissodactyla.	Megalocinus rodens.
Tapiridæ.	Ereptodon priscus.
Tapirus americanus.	Myiodon harlani.
haysii.	

Here it is observable that, while this fauna has a general resemblance to that of the preceding period, most of the genera are distinct. Several existing genera make their appearance, as also a number of forms which appear to have migrated from South America, and after a temporary estab-

<sup>1</sup> *Journ. Acad. Nat. Sci.* Philadelphia, vol. vii. 1869.

ishment to have disappeared. One remarkable feature is the abundance of horses, which is such that North America may be regarded as the land of horses during the Pliocene and Post-Pliocene period.

The existing mammals of North America must now be considered. We can only refer to a few of the more conspicuous species here. South America has numerous families peculiar to itself, but North America has none which are not also represented in South America. There are numerous representatives of the *Canidae* or dog family, such as the prairie, Mexican, and maned wolves, and several foxes, of which the Arctic, common American, cross, and silver foxes are of high commercial value on account of their furs. Amongst the cats are three or four species of lynx, which afford valuable furs. The beaver, though abundant in some places, is, like the bison, fast diminishing before the encroaching steps of the colonists. The grizzly, the black, and the polar bears are common in the more mountainous and colder regions of the continent, and are much hunted by the fur traders. Racoons and Virginian opossums are prevalent in the south portion of the United States. The Rocky Mountain goat reigns supreme amidst the rocks in inaccessible fastnesses of the Rocky Mountain range; while the rein-deer, the elk, and the wapiti give a character to the mammalian fauna of the more level districts. Further details respecting the mammals of North America will be found under the names of the separate countries; and those who wish for still fuller information may consult the works of Lord, Small, Müller, Harlan, and Allen on the mammals of various regions, *The Quadrupeds of North America* by Audubon and Bachman, the articles by Gilpin in the publications of the Institute of Natural Science at Halifax, Adams' *Field and Forest Rambles*, *The North-West Passage* by Viscount Milton and Dr Cheadle, Morgan's work on the Beaver, and the numerous reports issued by exploration expeditions.

The birds of America are very numerous in almost every great family. The researches of Wilson, Charles Lucien Bonaparte, Audubon, Richardson, DeKay, Blakiston, Cassin, Gundlach, Lord Lawrence, Selater, Salvin, and Baird, have beautifully illustrated the ornithology of North America; while those of Azara, Humboldt, Swainson, Waterton, Edmonstone, Darwin, Landbeck, Philippi, Cassin, &c., have thrown great light on that of South America. The North American species of birds already described amount to nearly 700; the species of South America are over 2300; so that we may fairly estimate the ornithology of America to include upwards of 3000 species. The fossil remains deserve particular notice. It is very probable that the footprints on the older secondary rocks of North America are those of birds. A large number of remarkable genera found in the Cretaceous rocks have recently been described by Professor Marsh and others.

The serpents of America are very numerous, and include amongst others, the following genera:—Tortrix, Calamaria, Coronella, Xenodon, Heterodon, Lycopon, Coluber, Herpetodyras, Psammophis, Dendrophis, Dryophis, Dipsas, Tropidonotus, Homalopsis, Boa, Elaps, Trigonocephalus, Crotalus.

Of these the genera Heterodon and Crotalus or rattlesnake are entirely peculiar to America, and the latter are by far the most deadly of serpents. The reptilia of North America have been well described by DeKay and Holbrooke.

The North American saurians belong to the genera Crocodile, Alligator, Anolis, Skink, Agama, Tropidolepis, Ophisaurus, Leptophis. Of the Ranidæ there are Rana, Bufo, and Hyla.

The North American and Asiatic regions form a zoological kingdom, according to Dr Strauch, which is characterised

by the prevalence of Emydes and by the presence of Trionychides. In the North American region there are 44 species distributed over four sub-regions—viz., the north-west part, which lies west of the Rocky Mountains; the north-east part, which lies east of them; the south-east part and the south-west part, which embraces Central America. South America and Australia together form another kingdom, characterised by the prevalence of Chelydes, and the total absence of Trionychides. There are about 35 species in the South American region.

The multitude of fishes in South America is extraordinary, and still more so is the marvellous variety of form which they exhibit. A large number of species have very circumscribed ranges, so that not only does each river basin have a distinct fauna, but a number of distinct faunas occupy different portions of the same river, as is well exemplified in the Amazons, Tocantins, Rio Negro, and other rivers, where most of the fishes at stations a few hundred miles apart are for the most part specifically distinct. Professor Agassiz, in his scientific journey through Brazil, collected about 2000 species from the Amazon basin only. In fishes, as in other classes, there is a remarkable difference between the faunas of North and South America, and in this class also North America has much in common with Europe and North Asia. The sturgeons abound in North America, but are absent in South America, where the corresponding group is the Goniodonts; the Siluroids are abundant in both portions of the continent; the perches are numerous throughout North America, but none occur in South America, where, however, they are represented by the Chromids. The Cyprinoids are abundant in North America, but absent in South America, where we have the allied group of Cyprinodonts. The Characines of South America represent the Salmonidæ of North America, each group being confined to its own portion of the continent. There are several other small families present in South America, such as the Erythrinoids, Gymnotines, and others.

In the meagre outline of American vegetation which it is possible to attempt here, we shall more or less strictly adhere to the principle laid down by Schouw, viz., that in constituting a botanical region, at least one-half of the species and one-fourth of the genera should be peculiar to it. We shall therefore divide the horizontal range of the vast continent into zones, commencing with the Arctic, and proceeding towards the Antarctic Circle.

In the *Arctic Region* or *Region of Saxifragaceæ*, as near to the Pole as man has yet penetrated, is found the red snow plant (*Protococcus nivalis*), penetrating the snow itself, sometimes to the depth of 12 feet, and covering for miles with its crimson tints the cliffs and ice-floes of the Polar Sea. Greenland is botanically distinguishable from Arctic America proper, inasmuch as it produces heath (*Calluna vulgaris*), which, it is somewhat remarkable, is nowhere to be found on the continent.

The most remarkable of the sub-arctic lichens is that known as *Tripe de Roche*, which has often preserved the lives of famished "trappers," who, but for its sustenance, must have perished of hunger. The *Saxifrages* which distinguish this region vary in species, and sometimes in genera, from those of Europe, but, generally speaking, there is a strong resemblance, which amounts almost to identity, as the Arctic shores are approached.

Emerging from the region of *Saxifragaceæ*, we find ourselves in that of the *Asters* and *Solidagos*, extending to the parallel of 36° N. This region not only produces many species of aster and solidago, but also a great variety of oaks and firs, and numerous species of Vaccinium. Among the oaks of Canada and the United States are, the lime oak (*Quercus virens*), the laurel oak (*Quercus laurifolia*), the black oak (*Quercus tinctoria*), the white or iron oak

N. Ame-  
rica :  
Mammalia.

Birds.

Ophidia.

Fishes.

Botany

(*Quercus alba* and *Quercus obtusiloba*), and the scarlet oak (*Quercus coccinea*). None of these, in regard to the quality of their timber, can stand comparison with the British oak, though some of them are very valuable.

The western or Californian and Oregon districts of this region are in many respects distinct in character. *Polemoniaceæ* abound; also *Eschscholtzia californica*, species of *Platystemon*, *Nemophila*, *Gilia*, *Collinsia*, *Clarkia*, *Bartonia*, and *Eutocha*. Coniferæ also exist in abundance, some of them possessing great botanical interest, such as *Abies Douglasii*, *Pattoniana*, *nobilis*, *amabilis*, *grandis*, *lasiocarpa*, *Pinus Lambertiana*, *Sabiniana*, *insignis*, *Jeffreyi*, *ponderosa*, *monticola*, *californica*, *Fremontiana*, *Coulteri*, *flexilis*, *Thuja gigantea*, *Sesquioia gigantea*, *Juniperus dealbata* and *occidentalis*, and *Castanea chrysophylla*. *Pinus ponderosa* predominates in the forests of Upper Oregon, and along with it occur *Abies balsamea*, *canadensis*, *Douglasii*, *nobilis*, and *alba*. Vivid colours mark the basaltic region of Upper Oregon. *Rhododendron macrophyllum* is found in Vancouver Island. Barley, oats, rye, wheat, buckwheat, and maize, along with the common fruit-trees and culinary vegetables of the temperate regions, are cultivated.

The region of *Magnolias* lies between parallels 30° and 36°, embracing the southern portion of North America. Nearly seventy species are known to exist. *Cycadaceæ*, *Anonaceæ*, *Sapindaceæ*, *Zingiberaceæ*, *Melastomaceæ*, *Cactaceæ*, and numerous other tropical forms, show themselves.

The forest trees display either broad shining foliage like the *Liriodendron* and *Æsculus*, or pinnated leaves like the *Acacia* and *Robinia*. They are, moreover, decked with magnificent blossoms. Rice, sugar-cane, and cotton are the special objects of culture in this region.

The region of *Cactuses* and *Peppers* includes Mexico, Guatemala, and South America to the Amazon (to an elevation of 5000 feet above the sea-level), as also Guiana, certain parts of Peru, and New Granada. The leaves of the plants of the isthmus of Panama are covered with hair and tomentum, while greenish and yellow flowers predominate. The included portion of South America produces *Mauritia flexuosa*, the *Murichi* or *Ita Palm*, and *Victoria regia*. The vegetable-ivory palm (*Phytelephas macrocarpa*) is a native of Columbia and Peru. Yams, plantains, chocolate, sugar, coffee, cocoa-nut, &c., are cultivated in this region.

The Mexican highlands, rising over 5500 feet above the sea-level, produce *Pinus religiosa*, *Pinus apulcensis*, *Pinus Hartwegii*, *Pinus Montezumæ*, and *Taxodium distichum*. European grains are cultivated with success.

The region of medicinal bark trees (*Cinchonas*) embraces the Cordilleras between parallels 5° N. and 20° S., where the elevation ranges between 5000 and 9600 feet. In the lower parts of this region coffee, maize, and potato are cultivated.

The region of *Calceolarias* and *Escallonias* is, generally speaking, coextensive with the preceding, but at an elevation greater than 9600.

The West Indian region is marked by the prevalence of ferns and orchids, and has a vegetation intermediate between that of Mexico and the north of South America.

We next come to the region of *Palms* and *Melastomas*, which lies to the east of the Andes, between the Equator and the Tropic of Capricorn. Here the luxuriance of vegetable life is almost startling to European eyes. The forest trees of Brazil tower to an almost incredible height, while the very underwood is composed of *Palms*, *Melastomaceæ*, *Myrtaceæ*, *Crotons*, and *Tree Ferns*. In the treeless belts are found *Heli-onias*, *Dorstenias*, and tall grasses. Immense *Compositæ*, *Vernonias*, arborescent *Solanums*, and species of *Fuchsia*, *Solandra*, *Lasiandra*, *Laurus*, *Ficus*, and *Cassia* abound. The trees are covered, stem and branch,

with *Ferns*, *Araceæ*, *Tillandrias*, *Orchids*, *Cactuses*, *Peperomias*, *Gesneras*, and innumerable other epiphytic plants.

The region of arborescent *Compositæ*, extending from the Tropic of Capricorn to lat. 40° S., embraces Southern Brazil, La Plata, and Chili. The distinctive features of the Upper Cordilleras reappear here; *Calceolarias* and *Escallonias* abound. *Thuja tetragona*, *Podocarpus chiliana*, *Thuja chilensis*, and Chili pine (*Araucaria imbricata*), are native to this region, the last-named being a hardy conifer, extending along the Chilian Andes from 37° to 40° S. In the neighbourhood of Rio Janeiro is found *Araucaria braziliiana*. Wheat, vine, peach, and many European plants are cultivated to great perfection in this region.

The Antarctic region comprehends the Strait of Magalhães, Tierra del Fuego, and the Falkland Islands. Many European, and more especially British, genera appear in this region, and species of *Saxifraga*, *Gentiana*, *Arbutus*, *Primula*, and other Arctic and North Temperate forms are common. In Fuegia the evergreen beech (*Fagus Forsteri*), the deciduous beech (*Fagus antarctica*), and *Drymis Winteri*, correspond to the birch, oak, and mountain ash of Scotland. The *Fuchsia* is a native of Fuegia. Among shrubs may be mentioned *Chiliotricum amelloides*, *Veronica elliptica* and *decussata*, *Empetrum rubrum*, and *Pernettya empetrifolia*; among ferns, *Lomaria alpina* and *Majel-lanica*; and among lichens, *Usnea melazantha*.

Northern America, though its vast forests have now been exposed for centuries to the axe of civilised man, is still one of the best wooded regions of the world. Among the principal forest-trees are the pine, oak, ash, hickory, red-beech, Canadian poplar, chestnut, black walnut, maple, tulip-tree, and white cedar.

Central America produces extensively mahogany, pimento, sarsaparilla, vanilla, Peruvian balsam, and many other valuable woods and drugs.

Nearly two-thirds of the surface of South America are still covered with gigantic forests, which must ultimately disappear, like many of those in the north, before the combined efforts and necessities of commerce and agriculture. The most distinctive and valuable forest-trees of South America are the greenheart and the mora. The cow-tree, which yields a juice very like milk in its properties, is also a remarkable product of this region.

Maize is by far the most important farinaceous product of the New World. It was the only grain which the earliest European settlers found cultivated, to some extent, by the natives. For nutrition it is inferior to wheat, but it is much more prolific, and is suited to a greater variety of soils. Tobacco is also indigenous to America, whence its use has extended over the whole world. Among roots, the potato, which we also owe to America, is without a rival. Millet, tapioca, arrow-root, cocoa, copaiva, cinchona, jalap, sassafras, nux-vomica, the cochineal plant, the agave or American aloe, and the pine-apple are also indigenous to the continent.

It is impossible here to do more than touch on the vast subject of the botany and the indigenous vegetable products of the New World. For fuller information, in addition to that contained in articles in the present work that treat of the geographical distribution of plants, the reader is referred to the numerous valuable American works of such authors as Beck, Bigelow, Breckenridge, Brown, Carson (Medical Botany), Darby, Darlington (Agricultural Botany), Asa Gray, Harvey (Algæ), Ravenel, Sprague, Strong, Torrey, &c. An extended description of the forest trees of North America will be found in the great work of Michaux and Nuttall, *The North American Sylva*.

The origin, history, languages, and condition of the American nations present ample materials for speculation; but before touching on these subjects, the question presents

Ethnolog

itself, What is the total of the indigenous population? Humboldt, in 1823, estimated the number of Indians at 8,610,000. Bollaert estimated the number existing in 1863 as follows :—

Mexico.....	4,000,000
Peru.....	1,600,000
Bolivia.....	1,400,000
Central America.....	1,000,000
Paraguay.....	700,000
Ecuador.....	500,000
United States.....	500,000
Other countries.....	1,814,710
Total.....	11,014,710

It is probable that these numbers have been diminished: the latest official returns for the United States' territories, in 1872, estimate the Indian population at 300,000.

The indigenous population of America presents man under many aspects, and society in various stages, from the regular but limited civilisation of Mexico and Peru, to savage life in its most brutal state of abasement. At one extremity of the country we find the pigmy Esquimaux of four feet and a half in height, and at the other the Patagonian standing above six feet. In complexion the variety is great, and may be said to embrace almost every hue known elsewhere on the face of the earth, except the pitchy black of the Negro. About one-half of all the known languages belong to America; and if we consider every little wandering horde a distinct community, we have a greater number of nations here than in all the rest of the world. Amidst all this diversity philosophers have thought they were able to discover certain general characters, sufficiently marked to distinguish the American nations from those of the old continent. It is foreign to our purpose to inquire whether the varieties of form, stature, and complexion, in the human species, are modifications produced by external causes operating differently on distinct portions of the progeny of one primitive pair, or whether several races were originally created, and have given birth, by their mixture, to the amazing varieties we witness. We assume the former opinion as true, because the probabilities seem to be in its favour; but the phenomena present themselves to us in the same light in whichever way they originated.

Physiologists are not at one in their accounts of the characteristics of the aborigines of the new world, nor are they agreed as to whether they should be considered one race or several. Blumenbach places them all under one class, except the Esquimaux. Bory St Vincent divides them into four races, or five if we include the Esquimaux, under the following designations:—1. The *Colombian*, which comprehends the tribes formerly inhabiting the Alleghany Mountains, Canada, Florida, the eastern coasts of Mexico, and Central America; and the Caribs, who occupied the West India Islands and Guiana. 2. The *American*, embracing the tribes which occupy all the other parts of South America east of the Andes, except Patagonia. 3. The *Patagonian* race, inhabiting the southern extremity of the continent. 4. The *Neptunian*, inhabiting the western coasts of both divisions of the continent, from California to Cape Horn, and which he considers as essentially the same with the race spread over the Malay Peninsula and the Indian Archipelago. With this race are classed the Mexicans and Peruvians. By another writer the species are reduced to two, the *Colombian* and the *American*; the former including all the North American tribes, with the Caribs, the Mexicans, and Peruvians, and other inhabitants of the Cordillera; and the latter the Brazilian Indians and Patagonians. Neither of these systems, when tested by facts, is very satisfactory. Dr Prichard thinks that the mutual resemblance among the American nations has been exaggerated by some writers; yet it is certain

that there is more of a common family character in their organisation than in that of the indigenous population of Asia or Africa. "The Indians of New Spain," says Humboldt, "bear a general resemblance to those who inhabit Canada, Florida, Peru, and Brazil. We have the same swarthy and copper colour, straight and smooth hair, small beard, squat body, long eye, with the corner directed upwards towards the temples, prominent cheek-bones, thick lips, and expression of gentleness in the mouth, strongly contrasted with a gloomy and severe look. Over a million and a half of square leagues, from Cape Horn to the river St Lawrence and Behring's Straits, we are struck at the first glance with the general resemblance in the features of the inhabitants. We think we perceive them all to be descended from the same stock, notwithstanding the prodigious diversity of their languages. In the portrait drawn by Volney of the Canadian Indians, we recognise the tribes scattered over the savannahs of the Apure and the Carony. The same style of features exists in both Americas."

On the authority of Dr Morton, the most natural division of the Americans is into two families, the *Toltecan* and the *American*; the former of which bears evidence of centuries of half-civilisation, while the latter embraces all the barbarous nations of the New World, with the exception of the Polar tribes, which are evidently of Mongolian origin. In each of these, however, there are several subordinate groups, which may be distinguished as the *Appalachian*, the *Brazilian*, the *Patagonian*, and the *Fuegian*. The Appalachian branch includes all the nations of North America, except the Mexicans, together with the tribes of South America north of the river Amazon and east of the Andes. In this race the head is rounded, the nose large, salient, and aquiline; the eyes dark brown, with little or no obliquity of position; the mouth large and straight; the teeth nearly vertical; and the whole face triangular. The neck is long, the chest broad but rarely deep, the body and limbs muscular, and seldom disposed to fatness. In character these nations are warlike, cruel, and unforgiving; they turn with aversion from the restraints of civilised life, and have made but little progress in mental culture or the useful arts. The Brazilian branch is spread over a great part of South America, east of the Andes, including the whole of Brazil and Paraguay, between the River Amazon and 35° S. latitude. Their physical characteristics differ but little from those of the Appalachian branch; they possess, perhaps, a larger and more expanded nose, with larger mouths and lips. The eyes are small, more or less oblique, and far asunder; the neck short and thick; the body and limbs stout and full, even to clumsiness. In character, also, they differ little. None of the Americans are less susceptible of cultivation; and what they are taught by compulsion seldom exceeds the humblest elements of knowledge. The Patagonian branch includes the nations to the south of the Plato, as far as the Strait of Magalhaens, including also the mountain tribes of Chili. They are chiefly distinguished by their tall stature, handsome forms, and indomitable courage. The Fuegians, who call themselves *Yacannacunnee*, rove over the sterile wastes of Tierra del Fuego, which is computed to be half the size of Ireland, and yet their whole number has been computed as not exceeding 2000. The physical aspect of the Fuegians is altogether repulsive. They are of low stature, with large heads, broad faces, and small eyes. Their chests are large, their bodies clumsy, with large knees, and ill-shaped legs. Their hair is lank, black, and coarse, and their complexion a decided brown, like that of the more northern tribes. Their expression of face is vacant, and their mental operations are to the last degree slow and stupid; they are almost destitute of the usual curiosity of savages, caring little for anything that does not minister to their present wants.

The American race is distinguished by the form of the skull, which, except in its greater length, resembles the Mongol type. The cheek-bones are prominent, but not so angular, as in the Mongol head; the occiput is rather flat, the cavity for lodging the cerebellum small, the orbits large and deep. The nose is generally aquiline, but in some tribes flat, and the nasal cavities are large. Compared with the head of the Negro, that of the American is broader, and the teeth are less prominent: when placed by the side of the Caucasian head, it is seen to be smaller in size, less rounded and symmetrical, and less developed in the part before the ear. The skull is generally thin and light. There are, however, many deviations from this typical form. The Carib skull and the Araucanian are large; the Peruvian small, and singularly flattened behind, so as to present a short line from the forehead to the occiput.

The colour of the Americans, though it includes a considerable diversity of shade, is more uniform than that of the inhabitants of Asia or Africa; and, what is more remarkable, its varieties do not bear any visible relation to the temperature of the climate. A brownish yellow, or copper colour, as it has been called, pervades nearly all the numerous tribes from the Arctic Ocean to Cape Horn, but still with many different degrees of intensity. The eastern nations of Chili have but a slight tinge of the brown colour, and the Boroanes are still whiter. On the north-west coast, from latitude 43° to 60°, there are tribes who, though embrowned with soot and mud, were found, when their skins were washed, to have the brilliant white and red which is the characteristic of the Caucasian race. But within the tropics, the Malapoques in Brazil, the Guaranis in Paraguay, the Guaiacas of Guiana, the Scheries of La Plata, have tolerably fair complexions, sometimes united with blue eyes and auburn hair; and, in the hot country watered by the Orinoco, Humboldt found tribes of a dark, and others of a light hue, living almost in juxtaposition. It is remarkable, too, that the nations whose colour approaches nearest to black are found in the temperate zone, namely, the Charruas of the Banda Oriental, in latitude 33° S., and the Cochimies, Pericus, and Guaycurus, spread over the peninsula of California. These people have skins of a very deep hue, but are not absolutely black; and they have neither the woolly hair of the Negroes, nor their social and good-humoured disposition. The Charruas, especially, are distinguished by a high degree of that austerity and stern fortitude which are common to the American nations. The Caribs and some Brazilian tribes have the yellowish hue of the Chinese, and the same cast of features. Among the nations dwelling on the west side of the Alleghanies, and near the northern lakes, there is also a considerable variety of complexion; but the brown or copper shade is found more or less in them all. It may be said, then, of the American nations, that, with the exception of two or three tribes on the north-west coast, who probably arrived from Asia at a later period than the others, the two extremes of complexion, the white of Northern Europe and the black of Ethiopia, are unknown amongst them; and that, when compared with the Moors, Abyssinians, and other swarthy nations of the Old World, their colour inclines less to the yellow, and more to the reddish brown.

Long, black, lank hair is common to all the American tribes, among which no traces of the frizzled locks of the Polynesian, or the woolly texture of the African Negro have ever been observed. The beard is very deficient, and the little that nature gives them they assiduously root out. A copper-coloured skin has been also assumed by most writers as a characteristic distinction of the Americans; but their real colour is in general brown, of the hue most nearly resembling that of cinnamon; and Dr Morton coincides in opinion with Dr McCulloch, that no epithet derivable from the colour

of the skin so correctly designates the Americans as that of the brown race. There are, however, among them occasional and very remarkable deviations, including all the varieties of tint from a decided white to an unequivocally black skin. That climate has a very subordinate influence in producing these different hues must be inferred from the fact that the tribes which wander in the equinoctial regions are not darker than the mountaineers of the temperate zone. The Puelches, and other tribes of the Magellanic regions, beyond 55° S. latitude, are darker than the Abipones, Mocobies, and Tobas, who are many degrees nearer the equator; and the Botocudos are of a clear brown colour, sometimes approaching nearly to white, at no great distance from the tropic; while the Guaiacas under the line are characterised by a fair complexion; the Charruas, who are almost black, live at the 30th degree of S. latitude; and the still blacker Californians are 25° north of the equator. Everywhere, indeed, it is found that the colour of the American depends very little on the local situation which he actually occupies; and never, in the same individual, are those parts of the body which are constantly covered of a fairer colour than those which are exposed to a hot and moist atmosphere. Children are never white when they are born, as is the case among even the darkest of the Caucasian races; and the Indian caciques, who enjoy a considerable degree of luxury, and keep themselves constantly dressed, have all parts of their body, except the palms of the hands and the soles of the feet, of the same brownish-red or copper colour. These differences of complexion are, however, extremely partial, forming mere exceptions to the general tint which characterises all the Americans, from Cape Horn to Canada. The cause of such anomalies is not easily ascertained; that it is not climate is sufficiently obvious; but whether or not it arises from partial immigrations from other countries remains yet to be decided.

The Americans of indigenous races might also be divided into three great classes distinguished by the pursuits on which they depend for subsistence, namely, hunting, fishing, and agriculture. The greater number of them are devoted to hunting; the fishing tribes are not numerous, and are wholly destitute of the spirit of maritime adventure, and even of fondness for the sea. A few tribes were strictly agricultural before the arrival of Europeans, but a much greater number have become so since. Many tribes regularly resort to all these modes of subsistence, according to the seasons; employing the spring in fishing, the summer in agriculture, and the autumn and winter in hunting.

The intellectual faculties of this great family appear to be decidedly inferior, when compared with those of the Caucasian or Mongolian race. The Americans are not only averse to the restraints of education, but are for the most part incapable of a continued process of reasoning on abstract subjects. Their minds seize with avidity on simple truths, but reject whatever requires investigation and analysis. Their proximity for more than two centuries to European institutions has made scarcely any perceptible change in their mode of thinking or their manner of life; and, as to their own social condition, they are probably in most respects exactly as they were at the earliest period of their national existence. They have made few or no improvements in constructing their houses or their boats; their inventive and imitative faculties appear to be of very humble capacity, nor have they the smallest taste for the arts and sciences. One of the most remarkable of their intellectual defects is the great difficulty they find in comprehending the relations of numbers; and Mr Schoolcraft, the United States Indian agent, assured Dr Morton that this deficiency was one cause of most of the misunderstanding in respect to treaties entered into between the United States Government and the

native tribes. The natives sell their land for a sum of money, without having any conception of the amount; and it is only when the proceeds come to be divided that each man becomes acquainted with his own interest in the transaction. Then disappointment and murmurs invariably ensue.

Every unwritten tongue is subject to continual fluctuations, which will be numerous and rapid in proportion as the tribe using it is exposed to frequent vicissitudes of fortune, and the individuals composing it have little intercourse with one another. When the population of one of these societies increases, it splits into several branches; and if these have little intercourse, the original language divides by degrees into as many dialects. These smaller societies subdivide in their turn with the same effects; and, in such continual subdivisions, the dialects of the extreme branches deviate farther and farther from one another, and from the parent tongue, till time, aided by migrations and wars, producing mixtures of different hordes, obliterates all distinct traces of a common origin. The cause of these changes becomes more obvious when we reflect on the principles which give stability to a language. These are—1. The abundant use of writing; 2. The teaching of a language as a branch of education; 3. Frequency of intercourse among all the people speaking it; 4. The existence of an order of men, such as priests or lawyers, who employ it for professional purposes; 5. Stability of condition in the people, or exemption from vicissitudes and revolutions; 6. A large stock of popular poetry, which, if universally diffused, may almost become a substitute for writing. All these conditions were wanting (with some trifling exceptions) in the whole of the wandering tribes of America. The great multiplication of languages, therefore, proves two things—first, that the people are in a low state of savage life; and, secondly, that they have been for many ages in this condition; for time is a necessary element in the process of splitting human speech into so many varieties.

Among the seven or eight millions of American aborigines, it is estimated that there are as many languages spoken as among the seven or eight hundred million inhabitants of the Old World. Just as there is a marked physiological resemblance attaching to all the New World tribes, so judged by the evidence of language, the native American is *sui generis*, having no connection, except the most remote, with the rest of the human family. The few corresponding words in Old and New World languages, which are not of an imitative character, bear the stamp of fortuitous coincidence rather than that of common origin. Vater, in his *Linguarum Totius Orbis Index*, estimated the number of American aboriginal languages at about 500, and Balbi at 423, of which 211 belonged to North, 44 to Central, and 158 to South America. In the absence of certain data, it may be safe to set down the number of native American languages at about 450.

Throughout the whole of these runs a thread of connection. They are all characterised by *polysynthesis*, as Duponceau calls it, or *holophrasm*, to adopt the phraseology of Dr Lieber. Holophrasm is a process more or less common to every language at a particular stage of its development. We have glimpses of it in most of the Turanian group of languages, and it appears, in a faint degree, in the Basque; but it belongs to a very large proportion of the languages of America, so extremely numerous, and many of which have nothing else in common. This diffusion of a peculiar and common character over materials so dissimilar has been plausibly accounted for by the supposition of a community of origin in the tribes, whether few or many, which peopled the continent. As no person has the full command of all the vocables in his native lan-

guage, individual terms must be continually dropping out of dialects preserved by oral communication; and new ones will be introduced as new wants and new objects solicit attention. But during the gradual change which thus takes place, the new words will be combined and modified according to the rules which belong to the genius of the spoken dialect with which they are incorporated; and thus it may happen that the grammatical forms of an ancient language may live, while its materials perish. The changes of structure which present themselves in the history of European languages, it must be remembered, took place in *progressive* communities. Among nations like the American Indians, whose barbarism, we may suppose, remained almost stationary, the forms of speech might be more permanent, though its substance was in a state of slow but constant mutation. But even were this community of origin admitted, it cannot be looked on as entire and absolute among the American nations.

Analysis and generalisation are processes that distinguish the languages of reflective and civilised races. "Nothing," says Schoolcraft, "could apparently be further removed from the analytical class of languages than the various dialects spoken by the Indians of America, who invariably express their ideas of objects and actions *precisely as they are presented to their eyes and ears, i.e.*, in all their compound associations." To "encapsulate" words, as Dr Lieber expresses it, "is the striking feature of all these languages, and hence a word will consist sometimes of seven or eight syllables, each one conveying one individual idea, like a set of boxes each one contained in the other." This common feature of American languages is both psychologically and philologically of the greatest interest. Of all the groups of American languages, the various dialects of the Algonquin stock furnish the most inviting field for the philologist. It is from the Algonquin, therefore, that we draw the following examples of the process of syllabical agglutination:—

Thus, *waub* is the root of the verb *to see*, and of the word *light*. *Waubun* is the *east* or *sunlight*, and inferentially *place of light*. *Aub* is the *eye-ball*; hence, *aiaub* = *to see, to eye*. *Waub* itself appears to be a compound of *aub* and the letter *w*, which is the sign of the third person. *Waubuno* is a *member of a society of men who continue their orgies till daylight*. The simplest concrete forms of the verb *to see* are as follow:—

*Ne waub* = I see.

*Ke waub* = Thou seest.

*O waub* = He or she sees.

But all this is vague to the Indian mind until the verb is made transitive, and the class of objects acted on is thereby shown. The Indian order of thought, moreover, requires that the object should generally precede the verb, *e.g.*—

*Inine ne waru bum au* = man, I see him. *Wah kie-gun ne waub bun dau* = house, I see it.

Such examples show the tendency of these languages to accretion. The verb is made to include within itself, as it were, the noun, pronoun, and adjective. "Declension, cases, articles, are deficient," says Bancroft, "but everything is conjugated. The adjective assumes a verbal termination, and is conjugated as a verb; the idea expressed by a noun is clothed in verbal forms, and at once does the office of a verb. . . . Then, since the Indian verb includes within itself the agent and the object, it may pass through as many transitions as the persons and numbers of the pronouns will admit of different combinations; and each of these combinations may be used positively or negatively, with a reflex or a causative signification. In this manner changes are so multiplied, that the number of possible forms of a Chippewa

verb is said to amount to five or six thousand; in other words, the number of possible variations is indefinite." The formidable array of syllables arises partly from the fact, that there are some sixteen modes of forming the plural of nouns represented in the verb by sixteen corresponding modifications. Nouns are divided, as in the Dravidian languages of South India, into animate and inanimate.

The best account of those peculiarities, as well as the best general distribution of the American languages, are given by Professor Whitney of Yale College, in his work on *Language and the Study of Language*, pp. 346-351:—

"The conditions of the linguistic problem presented by the American languages are exceedingly perplexing, for the same reason as those presented by the Polynesian and African dialects, and in a yet higher degree. The number, variety, and changeableness of the different tongues is wonderful. Dialectic division is carried to its extreme among them; the isolating and diversifying tendencies have had full course, with little counteraction from the conserving and assimilating forces. The continent seems ever to have been peopled by a congeries of petty tribes, incessantly at warfare, or standing off from one another in jealous and suspicious seclusion. Certain striking exceptions, it is true, are present to the mind of every one. Mexico, Central America, and Peru, at the time of the Spanish discovery and conquest, were the seat of empires possessing an organised system of government, with national creeds and institutions, with modes of writing and styles of architecture, and other appliances of a considerably developed culture, of indigenous origin. Such relics, too, as the great mounds which are scattered so widely through our western country, and the ancient workings upon the veins and ledges of native copper along the southern shore of Lake Superior, show that other large portions of the northern continent had not always been in the same savage condition as that in which our ancestors found them. Yet these were exceptions only, not changing the general rule; and there is reason to believe that, as the civilisation of the Mississippi valley had been extinguished by the incursion and conquest of more barbarous tribes, so a similar fate was threatening that of the southern peoples: that, in fact, American culture was on its way to destruction even without European interference, as European culture for a time had seemed to be during the Dark Ages which attended the downfall of the Roman empire. If the differentiation of American language had been thus unchecked by the influence of culture, it has been also favoured by the influence of the variety of climate and mode of life. While the other great families occupy, for the most part, one region or one zone, the American tribes have been exposed to all the difference of circumstances which can find place between the Arctic and the Antarctic oceans, amid ice-fields, mountains, valleys, on dry tablelands, and in reeking river-basins, along shores of every clime. Moreover, these languages have shown themselves to possess a peculiar mobility and changeableness of material. There are groups of kindred tribes whose separation is known to be of not very long standing, but in whose speech the correspondences are almost overwhelmed and hidden from sight by the discordances which have sprung up. In more than one tongue it has been remarked that books of instruction prepared by missionaries have become antiquated and almost unintelligible in three or four generations. Add to all this, that our knowledge of the family begins in the most recent period, less than four hundred years ago; that, though it has been since penetrated and pressed on every side by cultivated nations, the efforts made to collect and preserve information respecting it have been only spasmodic and fragmentary; that it is almost wholly destitute of literature, and even of traditions of any authority and value; and that great numbers of its constituent members have perished, in the wasting away of the tribes by mutual warfare, by pestilence and famine, and by the encroachments of more powerful races—and it will be clearly seen that the comprehensive comparative study of American languages is beset with very great difficulties.

"Yet it is the confident opinion of linguistic scholars that a fundamental unity lies at the base of all these infinitely varying forms of speech; that they may be, and probably are, all descended from a single parent language. For, whatever their differences of material, there is a single type or plan upon which their forms are developed and their constructions made, from the Arctic Ocean to Cape Horn, and one sufficiently peculiar and distinctive to constitute a genuine indication of relationship. This type is called the incorporative or polysynthetic. It tends to the excessive and abnormal agglomeration of distinct significant elements in its words; whereby, on the one hand, cumbersome compounds are formed as the names of objects, and a character of tedious and time-wasting polysyllabism is given to the language—see, for example, the three to ten-syllabled numeral and pronominal words of our western Indian

tongues; or the Mexican name for 'goat,' *kwa-kwauh tentson*, literally 'head-tree (horn) - lip - hair (beard),' or 'the horned and bearded one'—and, on the other hand, and what is of yet more importance, an unwieldy aggregation, verbal or quasi-verbal, is substituted for the phrase or sentence, with its distinct and balanced members. Thus, the Mexican says, 'I-flesh-eat,' as a single word, compounded of three elements; or if, for emphasis, the object is left to stand separate, it is at least first represented by a pronoun in the verbal compound; as, 'I-it-eat, the flesh;' or, 'I-it-him-gives the bread, my son,' for 'I give my son the bread.'

"The incorporative type is not wholly peculiar to the languages of our continent. A trace of it (in the insertion, among the verbal forms, of an objective as well as a subjective pronominal ending) is found even in one of the Ugrian dialects of the Scythian family, the Hungarian; and the Basque, of which we shall presently speak more particularly, exhibits it in a very notable measure. It is found, too, in considerably varying degree and style of development in the different branches of the American family. But its general effect is still such that the linguist is able to claim that the languages to which it belongs are, in virtue of their structure, akin with one another, and distinguished from all other known tongues.

"Not only do the subjective and objective pronouns thus enter into the substance of the verb, but also a great variety of modifiers of the verbal action, adverbs, in the form of particles and fragments of words; thus, almost everything which helps to make expression forms a part of verbal conjugation, and the verbal paradigm becomes well-nigh interminable. An extreme instance of excessive synthesis is afforded in the Cherokee word-phrase *wi-ni-law-ti-ge-ga-na-ti-skaw-lung-ta-naw-ne-li-ti-sc-sti*, which they will by that time have nearly finished granting [favours] from a distance to thee and me.'

"Other common traits, which help to strengthen our conclusion that these languages are ultimately related, are not wanting. Such are, for example, the habit of combining words by fragments, by one or two representative syllables; the direct conversion of nouns, substantive and adjective, into verbs, and their conjugation as such; peculiarities of generic distinction—many languages dividing animate from inanimate beings (somewhat as we do by the use of *who* and *what*), with arbitrary and fanciful details of classification, like those exhibited by the Indo-European languages in their separation of masculine and feminine; the possession of a very peculiar scheme for denoting the degrees of family relationship; and so on.

"As regards their material constitution, their assignment of certain sounds to represent certain ideas, our Indian dialects show, as already remarked, a very great discordance. It has been claimed that there are not less than a hundred languages or groups upon the continent, between whose words are discoverable no correspondences which might not be sufficiently explained as the result of accident. Doubtless a more thorough and sharp-sighted investigation, a more penetrating linguistic analysis and comparison—though, under existing circumstances, any even distant approximation to the actual beginning may be hopeless—would considerably reduce this number; yet there might still remain as many unconnected groups as are to be found in all Europe and Asia. It is needless to undertake here an enumeration of the divisions of Indian speech: we will but notice a few of the most important groups occupying our own portion of the continent.

"In the extreme north, along the whole shore of the Arctic Ocean, are the Eskimo dialects, with which is nearly allied the Greenlandish. Below them is spread out, on the west, the great Athapaskan group. On the east, and as far south as the line of Tennessee and North Carolina, stretches the immense region occupied by the numerous dialects of the Algonquin or Delaware stock; within it, however, is enclosed the distinct branch of Iroquois languages. Our south-eastern states were in possession of the Florida group, comprising the Creek, Choctaw, and Cherokee. The great nation of the Sioux or Dakotas gives its name to the branch which occupied the Missouri valley and parts of the lower Mississippi. Another widespread sub-family, including the Shoshonee and Comanche, ranged from the shores of Texas north-westward to the borders of California and the territory of the Athapaskas; and the Pacific coast was occupied by a medley of tribes. Mexico and Central America, finally, were the home of a great variety of tongues, that of the cultivated Aztecs, with its kindred, having the widest range."

For further information regarding the aboriginal languages of America, the reader is referred to the researches of Balbi, Gallatin, Vater, and Schoolcraft; to Lewis H. Morgan's Tables, with accompanying text and forms, vol. xvii. of the *Smithsonian Contributions to Knowledge* (1871), entitled "Systems of Consanguinity and Affinity of the Human Family," and to an invaluable work, *The Literature of American Aboriginal Languages*, by Dr Ludewig, edited by Nicolas Trübner, 1858.

Though any attempt to reduce the American population under a few general classes, either on physical or

ethnographical grounds, would be idle, we may notice one or two of the most remarkable nations or families.

All the northern coast of the continent is tenanted by the Esquimaux, a dwarfish race, rarely exceeding five feet in height. Their territories commence near Mackenzie's River, in 68° N. lat., and extend to the Arctic Ocean. They occupy all the northern Archipelago, the shores of Hudson's and Baffin's Bays, of Labrador, and of Russian America round by Behring's Straits, to the peninsula of Alaska. They live entirely by fishing, the whale and the seal being their most common food; they inhabit skin tents during their short summer, and in winter caves or houses built with snow in the shape of domes, within which a single rude lamp is kept perpetually burning. They are crafty and dirty, but appeared to Captain Franklin more intelligent and provident than the northern Indians. There is a wide diversity in their dialects, which still display decided marks of identity in their roots.

The north-west coast of Alaska, from Cook's Inlet to the 48th parallel, is inhabited by four tribes, of whom the Kaluschi are the most remarkable. These people are distinguished from all the native races of America by having as fair a complexion when their skins are washed as the inhabitants of Europe; and this distinction, accompanied sometimes with auburn hair, has been considered as indicating an origin different from that of the copper-coloured tribes who people all the rest of the continent.

The Indians of the east coast belong almost entirely to three stems; and, before the arrival of the English colonists, occupied both sides of the Alleghany Mountains, from the Gulf of Mexico to Canada and New Brunswick. 1. The Delaware or Algonquin Indians, comprehending the Ottogamies, Shawnees, Narragansets, Chippeways, Knisteneaux, Delawares, and other nations, to the number of thirty or forty, were spread over the space between the Mississippi and the Atlantic, as far north as Hudson's Bay, and all spoke dialects of one language. 2. The Iroquois, often called the "Five Nations," and the "Six Nations," but comprehending 15 tribes or more, among whom were the Mohawks, Oneidas, Hurons, and Senecas, all spoke dialects of one language. They lived on the south side of the great lakes, and finally obtained a complete ascendancy over the Algonquin race. 3. The Florida Indians, including the Creeks, Seminoles, Choctaws, Chickasaws, Natches, and Mobiles. Tribes belonging to these three families (with the Wocons and Catawbias) occupied nearly all the region east of the Mississippi, from the Gulf of Mexico to Hudson's Bay, comprising more than a million of square miles. The Catawbias alone, however, are said to have included 20 tribes, and nearly as many dialects. The Powhattans were a confederacy of 33 tribes, comprehending 10,000 persons. It is probable that when the English settlers landed in the country, the region mentioned was inhabited by a quarter of a million of Indians, divided into many tribes, and speaking dialects belonging to half a dozen radically distinct languages.

These nations have the virtues of savage life—a high sense of honour, according to their perceptions of duty, mutual fidelity among individuals, a fortitude that mocks at the most cruel torments, and a devotion to their tribe which makes self-inmolation in its defence easy. On the other hand, they treat their wives cruelly, and their children with indifference. The apathy under the good and ill of life which the Stoic affected, is the grand element of the Indian's character. Gloomy, stern, and severe, he is a stranger to mirth and laughter. All outward expression of pleasure or pain he regards as a weakness; and the only feeling to which he ever yields is the boisterous joy which he manifests in the moment of victory, or under the excitement of intoxication. He is capable of great

exertions in war or the chase, but has an unconquerable aversion to regular labour. He is extremely improvident; eats enormously while he has abundance of food, without thinking of the famine which may follow; and, when liquors are supplied to him, will continue drunk for days.

Most of the Indians of North America believe in the existence of a supreme being, whom they call the Great Spirit; and of a subordinate one, whose nature is evil and hostile to man. To the latter their worship is principally addressed; the Good Spirit, in their opinion, needing no prayers to induce him to aid and protect his creatures. They generally believe in a future state, in which the souls of brave warriors and chaste wives enjoy a tranquil and happy existence with their ancestors and friends, spending their time in those exercises in which they delighted when on the earth. The Dakotas believe that the road to these "villages of the dead" leads over a rock with an edge as sharp as a knife, on which only the good are able to keep their footing. The wicked fall off, and descend to the region of the Evil Spirit, where they are hard worked, and often flogged by their relentless master.

Polygamy is allowed; and a number of wives is considered as adding to a man's consequence. Marriage customs differ in different tribes, but in every case the presenting of gifts to the father of the intended wife is an essential feature of the transaction, and shows that the wife is considered as procured by purchase. Deformed children, and lame or decrepit old persons, are destroyed sometimes; but the practice is uncommon. Incest and unnatural vices are practised in some tribes, but they are always viewed as matters of reproach. The Indian funerals are conducted with much decorum. The deceased is dressed in his best clothes, and laid in a grave, in a vertical, horizontal, or inclined position, according to his own previous directions, with his moccasins, knife, money, and silver ornaments beside him, and a small quantity of food near his head. It is usual to mark the graves with a post, on which figures are carved expressive of the nature of the pursuits and achievements of the deceased.

Some nations of Indians wear little or no clothing; but the general dress of the men in the temperate and cold parts of the country, previous to the arrival of the Europeans, consisted of three articles: a cloak of buffalo-skin hanging from the shoulders, a piece of skin used as an apron, and a pair of moccasins or loose boots, made of undressed skin also. The women wore a long robe of the same material, which was fastened round the waist; but among the tribes living near the whites, coarse woollens are now frequently substituted for the hides of wild animals, except for the moccasins. The habitations of the Indians are huts or cabins, generally of a circular form and small size, but sometimes of 30 or 40 feet in diameter, formed by stakes fixed in the ground, and covered with the bark of trees. Sometimes the spaces between the stakes are filled up with twigs, grass, and mud, and the roof is covered nearly in the same way. A hole in the top serves for the escape of the smoke, and the skins of wild beasts form the beds and seats. When they go to a distance to hunt, they erect for temporary use large tents, which are covered with skins. On the west side of the Mississippi, where the ground is open, many of the tribes make use of horses, which are seldom employed amidst the woods covering the territories east of that river. The custom of painting their bodies is nearly universal. They introduce the colours by making punctures on their skin; and the extent of surface which this ornament covers is proportioned to the exploits they have performed. Some paint only their arms, others both their arms and legs, others again their thighs; while those who have attained the summit of warlike

renown have their bodies painted from the waist upwards. This is the heraldry of the Indians, the devices of which are probably more exactly adjusted to the merits of the persons who bear them than those of more civilised countries. Besides these ornaments, the warriors also carry plumes of feathers on their heads, their arms, or ancles. Their arms were the tomahawk, the war-club, knife, the bow and arrow, but now they have muskets.

Each tribe is governed by a chief and council, who are elective; but in matters of importance the whole warriors are consulted; and Mr Keating informs us that questions are not decided by the votes of a majority, but the resolution adopted must have the consent of every individual warrior. Their assemblies are conducted with much formality and decorum. The eldest chief commences the debate, which is often carried on by set speeches, abounding in bold figures and metaphors, and bursts of a rude but impassioned eloquence. The young are permitted to be present and to express their approbation by cries, but not to speak. In their wars the object commonly is, to secure the right of hunting within particular limits, to maintain the liberty of passing through their accustomed tracts, and to guard from infringement those lands which they consider as their own tenure. War is declared by sending a slave with a hatchet, the handle of which is painted red, to the nation they intend to break with. They generally take the field in small numbers. Each warrior, besides his weapons, carries a mat, and supports himself till he is near the enemy by killing game. From the time they enter the enemy's country, no game is killed, no fires lighted, or shouting heard, and their vigilance and caution are extreme. They are not even permitted to speak, but must communicate by signs and motions. Having discovered the objects of their hostility, they first reconnoitre them, then hold a council; and they generally make their attack just before daybreak, that they may surprise their enemies while asleep. They will lie the whole night flat on their faces without stirring, and, at the fit moment for action, will creep on their hands and feet till they have got within a bow-shot of those they have doomed to destruction. On a signal given by the chief warrior, which is answered by the yells of the whole party, they start up, and, after discharging their arrows, they rush upon their adversaries, without giving them time to recover from their confusion, with their war-clubs and tomahawks. If they succeed, the scene of horror which follows baffles description. The savage fury of the conquerors, the desperation of the conquered, the horrid yells of both, and their grim figures besmeared with paint and blood, form an assemblage of objects worthy of pandemonium. When the victory is secured, they select a certain number of their prisoners to carry home: they kill the rest in cold blood, take their scalps, and then march off with the spoil. The prisoners destined to death are soon led to the place of execution, where they are stripped, have their bodies blackened, and are bound to a stake. In this situation, while the burning faggots embrace his limbs, and the knives of his revengeful enemies are inflicting a thousand tortures, it is common for the warrior to recount his exploits, boast of the cruelties he has committed upon his enemies, and to irritate and insult his tormenters in every way. Sometimes it happens that this has the effect of provoking one of the spectators to dispatch him with a club or tomahawk. Sometimes the male adult prisoners are given as slaves to women who have lost their husbands in the war, and by whom they are often married. The women taken are distributed among the warriors; the boys and girls are considered as slaves.

Nearly all the Indian tribes raise maize, beans, and

pumpkins, by the labour of their women, but only to a small extent, and as a resource against famine, their chief reliance being upon the chase. The buffaloes which wander over the prairies of the west, in herds of tens of thousands, are their great support; but deer, bears, and in time of need otters, beavers, foxes, squirrels, and even reptiles, are devoured.

The Toltecan family embraced the civilised nations of Mexico, Peru, and Bogota, extending from the Rio Gila in 33° N. latitude along the western shore of the continent to the frontiers of Chili; and on the eastern coast, along the Gulf of Mexico, in North America. In South America, on the contrary, this family chiefly occupied a narrow strip of land between the Andes and the Pacific Ocean, bounded on the south by the great desert of Atacama. Farther north, however, in New Granada, were the Bogotese, a people whose civilisation, like their geographical position, was intermediate between that of the Peruvians and the Mexicans. But, even before the Spanish conquest, the Toltecan family were not the exclusive possessors of the regions which we have assigned to them; they were only the dominant race or caste, while other tribes of the American race always constituted a large mass of the population. The arrival of the Spaniards reduced both classes alike to vassalage; and three centuries of slavery and oppression have left few traces of Mexican and Peruvian civilisation, except what may be gleaned from their history and antiquities. These nations can no longer be identified in existing communities; and the mixed and motley races which now respectively bear the name, are as unlike their predecessors in moral and intellectual character, as the degraded Copts are unlike the ancient Egyptians. It is in the intellectual faculties that the great difference between the Toltecan and the American families consists. In the arts and sciences of the former we see the evidences of an advanced civilisation; their architectural remains everywhere surprise the traveller and confound the antiquary. Among these are pyramids, temples, grottoes, bas-reliefs, and arabesques; while their roads, aqueducts, and fortifications, and the traces of their mining operations, sufficiently attest their attainments in the practical arts of life.

The origin of the populations of America is a problem which has yet to be solved. It is known that in Europe man was in existence at a very remote period; and there are facts which lend some support to the view that man has also been a denizen of America for ages. Thus there have been found portions of the human skeleton and fragments of human handiwork, associated with the bones of mammals which now have no existence, under circumstances which imply great antiquity. In most instances, however, it is not certain that such relics are of the age of the deposit in which they have been found. Human skeletons and bones in a fossilised state, or associated with bones of extinct mammals, have been found at Guadaloupe, in Missouri, near Natchez, at New Orleans, in the coral reef of Florida, near Charleston, in California, in Orchilla, at Petit Anse, and in Kansas. Some of these are referred to a very distant period. Thus the conglomerate in which the remains occur in the Florida reef is estimated by Agassiz to be 10,000 years old; but, what is still more amazing, the skeleton found by Dr Dowler beneath four buried forests in the delta near New Orleans, is said to be 50,000 years old, and the remains from California were found in a deposit beneath Table Mountain, which deposit was formed in an old river of the Post-Pliocene, or Pliocene period. At any rate, when this deposit was formed there was a river valley here, down which an overflow of volcanic matter was poured. Since that time denudation has been so great, and the volcanic matter so hard, that the sides of the valley have been swept away, leaving the valley bottom with its pro-

Toltecan  
races—

Peru.

Origin of  
America  
populations.

Antiquity  
of man in  
America.

tecting cover standing up far above the level of the neighbouring country. Articles made by man also occur under conditions indicating great antiquity. Thus along the coast of Ecuador there are volcanic deposits which belong to the period of volcanic activity preceding the present, which may probably be referred to the Post-Pliocene period. This matter is arranged in terraces, and in one of these terraces, now 24 miles from the coast and 150 feet above the sea, Mr Wilson has found beneath the vegetable mould, beds of clay with sand and gravel which contain fragments of pottery. These beds, it is believed, were deposited beneath the sea, implying an elevation of 150 feet since their formation. On the coast there is a pottery-containing stratum, which has been followed for 80 miles, and patches of a similar bed occur over a further distance of 200 miles. These facts, taken in conjunction with what we learn from the traditions and histories of numerous nations, as also the characters of the present natives, render it highly probable that man existed in America long before the origin or arrival of the civilised communities to which allusion will be presently made. The histories of these communities generally agree that civilisation was introduced by persons who first appeared as strangers amidst the people already in possession of the country. Hence the question has a twofold aspect, viz., the origin of the earliest uncivilised as well as that of the earliest civilised tribes. It is possible, as the traditions suggest, that people have arrived from various quarters and at various times. As yet we have little positive evidence to rely upon, and caution is required in drawing conclusions from resemblances in customs or religion. For instance, to take one remarkable case. Amongst tribes living high up the Amazon basin there are customs which correspond with those in Borneo. In both areas we find blow-pipes for discharging arrows; large houses inhabited by several families and similarly constructed; baskets and bamboo boxes of almost identical form and construction; and the smoke-dried heads of enemies hung up in the houses. In one tribe on the Amazon the throwing-stick is used, and not the blow-pipe, which is employed by all the surrounding tribes; the throwing-stick is also used by the Esquimaux, the Andaman Islanders, and the Australians. On the Amazon an arrow or spear is used for catching turtle, which has the barb loosely attached to the shaft, so that when the turtle disappears the shaft floats on the surface and indicates its movements and position. The Australians catch turtle in precisely the same way. Again, many other customs are common to the Americans and tribes living in areas far remote from them, with which they have no apparent direct relationship. If these analogies were always proofs of affinities, then we might infer, as has been done, that America was first peopled by emigrants from the opposite shores of Africa, W. Europe, E. Asia, and Polynesia.

In the great valley of the Mississippi and its mighty tributaries, the Ohio and Missouri, are the remains of the works of an extinct race of men, who seem to have made advances in civilisation far beyond the races of *red men* discovered there by the first European adventurers. These remains consist chiefly of tumuli and ramparts of earth, enclosing areas of great extent and much regularity of form. Some of them recall the barrows of Europe and of Asia, or the huge mounds and ramparts of Mesopotamia, as displayed at Babylon and Nineveh; while others remind us of the ruined hippodromes and amphitheatres of the Greeks and Romans. In that part of North America the barrows are usually truncated cones; but in advancing farther south, they often assume the figure of four-sided pyramids in successive stages, with flattened tops, like the *Teocallis*, or temples of Mexico and Yucatan. They have been accurately described, and many of them delineated in the *Smithsonian*

*Contributions to Knowledge*, from the researches of Messrs Squier and Davis.

The barrows and ramparts are constructed of mingled earth and stones; and from their solidity and extent, must have required the labour of a numerous population, with leisure and skill sufficient to undertake combined and vast operations. The barrows often contain human bones, and the smaller tumuli appear to have been tombs; but the larger, especially the quadrangular mounds, would seem to have served as temples to the early inhabitants. These barrows vary in size, from a few feet in circumference and elevation, to structures with a basal circumference of 1000 or 2000 feet, and an altitude of from 60 to 90 feet, resembling, in dimensions, the vast tumulus of Alyattes near Sardis. One in Mississippi is said to cover a base of six acres. The ramparts also vary in thickness, and in height from 6 to 30 feet, and usually enclose areas varying from 100 to 200 acres. Some contain 400; and one on the Missouri has an area of 600 acres. The enclosures generally are very exact circles or squares, sometimes a union of both; occasionally they form parallelograms, or follow the sinuities of a hill; and in one district, that of Wisconsin, they assume the fanciful shape of men, quadrupeds, birds, or serpents, delineated with some ingenuity, on the surface of undulating plains or wide savannahs.

These ramparts are usually placed on elevations or hills, or on the banks of streams, so as to show that they were erected for defensive purposes, and their sites are judiciously chosen for this end. The area enclosed, therefore, bears no proportion to the relative labour bestowed on such ramparts: thus, in Ohio, an area of not more than 40 acres is enclosed by mounds of a mile and a half in circumference; and on the Little Miami, in the same state, is found an enclosure fully four miles round, that contains an area of about 100 acres. These remains are not solitary and few, for in the state of Ohio they amount to at least 10,000.

The enclosures in the form of animals are more rare than those now noticed, and seem nearly confined to Wisconsin. One of these represents a gigantic man with two heads, the size of which may be estimated, by the body being 50 feet long, and 25 feet across the breast. Another on a slope near Bush Creek, represents a tolerably designed snake, with an oval ball in its mouth; the undulating folds of its body and spiral of its tail extending to a length of 700 feet. The forms of quadrupeds and birds are also characteristically represented in these works. Those that have been explored contain human bones; but, though the Indians deposit their dead within them occasionally, they have no tradition of their having belonged to their ancestors. The most probable supposition respecting them is that of Mr R. C. Taylor, that each was the sepulchral monument of a different tribe, who have all disappeared from America.

The question immediately suggests itself, to what people must we ascribe those vast works? They can scarcely be the works of the ancestors of the red men discovered by Europeans in North America. Neither can we ascribe them to the early Greenland and Iceland colonists, who seem never to have passed westward of the Alleghanies. We can scarcely attribute them to the somewhat apocryphal advent of the Welsh Madoc. Can their authors be the people obscurely mentioned in the Icelandic *sagas*, as the inhabitants of *New Iceland*?

A curious tradition of the present Iroquois records, that when the *Lenni Lenapi*, the common ancestors of the Iroquois and other tribes, whose language is still widely spread among the Indians, advanced from the north-west to the Mississippi, they found on its eastern side a great nation more civilised than themselves, who lived in fortified towns and cultivated the ground. This people at first granted the Lenni Lenapi leave to pass through their territories to seek

an eastward settlement, but treacherously attacked them while crossing the river. This conduct gave rise to inveterate hostilities, that terminated in the extermination or subjugation of their opponents, and the establishment of the red men in those regions. This not improbable, though imperfect, account of such rude communities, where neither letters nor hieroglyphics existed, is probably all that we shall ever learn of the people who executed those works that now excite our surprise.

As we advance southward we find proofs of still greater refinement on the table-land of Anahuac or Mexico; and on descending into the humid valleys of Central America, the peninsula of Yucatan, and the shores of Honduras, we find striking remains of the semi-civilisation of the races that inhabited those countries before the Spanish invasion. The barbarous policy of Cortez and other invaders was to eradicate every trace of the former grandeur of the native races, and thereby to inure them to a degrading servitude. The systematic destruction of the native works of art and gorgeous buildings in Mexico was relentlessly carried on for ages, to the infinite regret of the modern ethnographical inquirer. Little positive information on these subjects can be gleaned from the early Spanish historians of the conquest; and it was not until the publication of Humboldt's *Researches* that Europe knew anything of the state of the Great Mexican pyramid, or of the wonderful remains of Palenque and Papanla.

In the middle of the last century, however, some Spanish adventurers penetrated with difficulty the dense forests of the Mexican province of Chiapas, in which they discovered the remains of an ancient city, of which all memory had been lost, and to which they gave the name of PALENQUE, from a poor adjacent village. Stimulated by their report, the Spanish Government some years afterwards despatched two intelligent travellers to explore those wilds; but the report of Del Rio and Du Paix, from the commotions that agitated Europe and convulsed Spain, remained unpublished until a few years ago. It has since appeared, with very interesting designs of the ruins they explored. Our knowledge of such remains, however, has been greatly enlarged by the labours of an enterprising North American traveller, Mr Stephens, given to the world in four volumes, entitled *Incidents of Travel in Central America, Chiapas, and Yucatan*, 1838, and *Incidents of Travel in Yucatan*, 1842. This gentleman discovered, in the almost impenetrable forests of those regions, the remains of no less than 44 towns, some of them with extensive and highly decorated structures. These exhibit walls of hewn stone, admirably put together with mortar, often enriched by sculptures in bold relief, and hieroglyphical inscriptions, exactly resembling the Aztec MSS. in the museums of Europe, and in the publications of Humboldt; well executed vaulted roofs, and obelisks covered with mythic figures and pictorial or hieroglyphical inscriptions. These curious remains have been concealed for ages by a luxuriant tropical vegetation, so dense that they seem to have been unknown to people living within half a mile of their site.

The most conspicuous ruins are those of temples and palaces, which almost invariably have a pyramidal form, in several stages, with wide intervening terraces, the ascent to which is by grand flights of steps. The chambers in those buildings have generally a length disproportioned to their width, they have no windows, but receive their light from the doors, just as the rooms do at this day in Barbary and some other eastern countries. The apartments are in two parallel rows, a narrow corridor or series of chambers runs along the front, and the apartments behind this receive their light only from the front rooms into which they open. Yet these interior apartments are often richly decorated with

sculptures, ornamented with stuccos, and gaily painted red, yellow, white, and black.

The ruins of Palenque, as may be seen in the researches of Humboldt, have the characters just mentioned. They are covered with hieroglyphics, and sculptures in relief, with ornamental cornices. The largest building stands on a terrace, faced with stone, measuring 310 by 260 feet; the building itself is 200 by 180 feet; its walls are 25 feet high. The stone has been originally covered with painted stucco; fronts the east, and contains 14 doors, separated by piers ornamented with stucco figures. In this building some of the figures are erect, while others sit cross-legged, in what we term the oriental fashion; one statue, 10½ feet high, was found at Palenque; and two fragments of two torsos and a head were also discovered that exhibited a severe but fair style of sculpture, that recalls something of the early style of Greek art.

The ruins at Copan, in Honduras, are of vast extent. Here a pyramidal structure remains, with an elevation of 150 feet measured along its slope, and this appears to be a principal temple, included with several smaller structures within a *sacred enclosure*, in the manner of the temples of ancient Egypt. On its walls are many skulls of a quadrumanous animal, well executed in high relief; a large figure of a baboon was discovered among the ruins, bearing no inconsiderable resemblance to the cynocephalus of the Egyptians. Here also several sculptured obelisks occur, from 11 to 13 feet in height, and from 3 to 4 feet wide, which, as well as the walls of the temple, were highly ornamented with sculptures in bold relief.

The similarity between the ruins at Copan and Palenque, and the identity of the hieroglyphic tablets in both, show that the former inhabitants of Chiapas and Honduras had the same *written* language, though the present Indians of those provinces do not understand each other.

At several places, but more especially at Uxmal, in Yucatan, are very magnificent ruins of the same kind. Here are found sculptured obelisks, bearing on their principal face the figure, probably, of some deity, with a benignant countenance represented in full, and the hands applied to the breast. The other sides of the obelisks are covered with hieroglyphical tablets, proving that the same race once inhabited the plains of Honduras and the table-land of Anahuac. The principal building at Uxmal seems to have been a very magnificent pyramid in three stages or terraces, faced with hewn stone, and neatly rounded at the angles. The first terrace is 575 feet long, 15 feet broad, and 3 feet high, serving as a sort of plinth to the whole; the second terrace is 545 feet long, 250 feet wide, and 20 feet high; the third terrace is 360 feet long, by 30 feet wide, and 19 feet in height. From the centre of the second terrace, the upper part is gained by a vast flight of well-constructed steps 130 feet wide. This leads to the temple, the facade of which is no less than 322 feet long, but has not had a greater elevation than 25 feet; yet its grandeur is enhanced by the rich sculpture that covers the upper part above a fillet, or cornice, that surrounds the whole building at about half its elevation. The interior consists of two parallel ranges of chambers, 11 in each row. The front apartments are entered by 11 doorways, enriched with sculpture, which gives sufficient light to those rooms; but the posterior row receives no light except what enters by their doors from the exterior rooms. The roofs here, unlike those of Palenque and Copan, are not stone arches, but are supported on bearers of a very hard wood, that must have been brought from a distance of some hundred miles, and these beams too are covered with hieroglyphics. The flat roof of this building has been externally covered with a hard cement. In a building placed on a lower level is a rectangular court, which has been once wholly paved with well-

carved figures of tortoises in demi-relief. These are arranged in groups of four, with their heads placed together; and from the dimensions of the court, this *sala de las Tortugas* must have required 43,660 of such carved stones for its pavement.

The ruins of Chichen, also in Yucatan, extend over an area of two miles in circumference. One of the best preserved buildings with an ambit of 638 feet, is constructed in three terraces, which gave it an apparent altitude of 65 feet. The buildings here, on the second terrace, have the façades highly sculptured, both above and below the horizontal fillet; and the doorways are enriched with mouldings, and *truss*-like ornaments supporting a drip-stone. The staircase here is 56 feet wide. The front apartments are 47 feet long and only 9 wide. There are three doors in the front, and in the central apartment are nine niches. The roofs are stone arches; and all has been once painted of various colours. A curious adjoining structure consists of two parallel stone walls, 274 feet long, and 30 feet apart. The walls are 30 feet thick. It has been conjectured to have been connected with the celebration of some public games, like the *palaestrae* of the Greeks.

In several of the ruins now noticed are found buildings to which there is no access. They have doorways, but these seem to have been walled up when the buildings were erected. Their use is unknown; they are named *casas cerradas*, or "shut up houses." Their interior does not differ from the other apartments above described.

It is worthy of notice, that the builders of those cities took great pains to supply them with one of the prime essentials of human comfort—abundance of good water, by means of wells and cisterns of excellent construction.

The remains in all the 44 ancient towns visited by Stephens have a similar character; so that we can have no hesitation to ascribe them to the same nation, or to kindred races of men, who had certainly attained no inconsiderable civilisation, although unacquainted with the use of iron, or even of bronze. Many of these towns are repeatedly referred to in the native histories, and it is almost certain that a large proportion of them were founded and inhabited by the Tutul-Xius, Nahoas, and other tribes speaking the Nahuatl tongue. In not a few instances the dates and the names of the founders have been preserved.

It has been generally admitted by physiologists, that the temperate regions of the globe are best fitted to develop all the powers of our nature; and it is a fact in accordance with this opinion, that among the aborigines of America, civilisation followed very closely the chain of the Andes, and was found either upon their sides or the table-land of their summits, where the elevation of the ground moderates the heat of the tropical sun, and produces a climate analogous to that of Central and Southern Europe. This civilisation did not exist merely at the two distant and isolated points of Mexico and Peru, but presented itself at intermediate places, and may be said to have formed a continuous line from lat. 35° N. to lat. 35° S, with few interruptions, except at those parts where the mountainous chain disappears, or sinks down to a trifling elevation. Some large buildings near the Rio Gila, in lat. 33° N., with fragments of porcelain, indicate the existence of a people there who had some knowledge of the arts. These were most probably a branch of the Aztecs or Toltecs, who afterwards occupied Mexico, as the annals of that country tell. Though some pursued their march southward, it may be reasonably supposed that a part remained in the district; and the Indians living here, who cultivate corn, weave cloth, and live in villages consisting of houses built of solid materials, sometimes two stories in height, may either be their descendants, or have borrowed from them the improvements they possess. Next

in order as we proceed southward, are the various nations of Mexico, of whose condition we shall speak by and by. In Chiapa were the Zapotecs, in Yucatan the Mayas, in Guatemala the Quiches and Kachiquels, all nearly as much advanced in civilisation as the Mexicans, and probably of the same primitive stock. From this point, where the Andes lose their elevation, or break into isolated cones, no distinct traces of civilisation appear till we enter the southern continent. Here were found the Muyscas or Moscas, on the table-land of Bogota, a nation consisting of several tribes, who worshipped the sun and practised some of the useful arts. To these succeeded the nations of Peru, living under the Incas, whose dominion extended from the equator to the 35th degree of S. latitude. Beyond this boundary were the Chilian tribes, who, though inferior to the Peruvians, had made some advances beyond the rudeness of the savage state. It is proper to mention that some of the nations named were extinct before the arrival of the Spaniards; but the degree of civilisation they had attained is attested by the monuments they have left behind them. There were no other tribes in the new continent which had made any progress in social improvement. We would not except the Guaranis of Brazil, and a few others, who derived their subsistence chiefly from agriculture, but were in other respects savages. We place among the exceptions, however, the extinct race of the Allegewis, or whatever was the name of the people, who erected the military works existing between the Ohio and the northern lakes; but they also, it must be remembered, inhabited a temperate climate, though not a mountainous country. It may be affirmed, then, as a general proposition, that from 35° of N. to 35° of S. latitude, the sides and summits of the Andes were the exclusive seats of American civilisation. We admit that some of the tribes in Chiapa, Oaxaca, and Yucatan, inhabited low districts; but they were still near the Cordillera, and may be fairly considered as offsets from the nations dwelling upon it. The fact is important, as marking the effect of climate on the active energies of our species. There is no doubt that, with the improved arts of modern times, civilisation can subsist under the burning sky of the torrid zone, but not in such vigour as in countries which enjoy a more moderate temperature. Perhaps it will be found that the moral and physical powers of man attain their highest perfection in those regions where he is accompanied by *wheat* and the *vine*. The zone occupied by the former extends from the 30th to the 57th or 58th parallel; and within the tropics the corresponding climate is found on the flanks or summits of mountains, from 4500 to 10,000 feet above the level of the sea.

It is remarkable that the Mexican annals reach to a very remote date, although they were preserved merely by picture-writing. We do not pretend to enter into the question as to the authenticity of the records themselves, and their correctness. It is enough that they have received credit from Humboldt, Vater, and other men of learning and judgment. From the annals thus preserved, of which further details will be subsequently given, we learn that at the earliest dawn of history the Quinames were in possession of the country, that civilisation was introduced by strangers coming from the east, and that several nations belonging to one race migrated in succession from the north-west, and settled in *Anahuac* or Mexico. The Toltecs, it is stated, left their original seat, far to the west, in 544 of our era, and after a long journey invaded Mexico, then occupied by wandering hordes, in 648. This people, who penetrated to Nicaragua, if not to South America, were nearly destroyed after the lapse of some centuries; but were followed by the Chichimecs, a half savage tribe, about 1120, and these a few years afterwards by the Anahuatlles,

or seven tribes, including the Acolhuans, the Tlascaltecs, and the Aztecs or proper Mexicans. All these people spoke dialects of one language, and had similar arts, customs, and institutions. The town of Mexico or Tenochtitlan was founded in 1325, and the series of Mexican kings which commenced in 1352 was continued through eight monarchs to Montezuma. The monarchy was small at first, and passed through many vicissitudes; but it was gradually enlarged, especially by the policy and enterprise of the later princes of the line. When Cortes arrived, it embraced what are now the provinces of Vera Cruz, Oaxaca, Puebla, Mexico, and part of Valladolid, a surface of 130,000 square miles; but within this were comprehended three small independent states, Tlascala, Cholullan, and Zapeaca. The pastoral state, which forms the intermediate stage between savage and civilised life, had never existed in Mexico; for the native wild ox had not been tamed, and the use of milk as food was unknown. The Mexican nations derived their subsistence from agriculture, which, however, was conducted in the rudest manner, with very imperfect instruments. They cultivated maize, potatoes, plantains, and various other esculent vegetables. They raised cotton, and understood the art of spinning and weaving it into cloth, of a texture which excited the admiration of the Spaniards. They had no iron, but showed considerable skill in fashioning the gold, silver, and copper, found in a native state, into domestic utensils and ornamental articles. In some of their buildings the stones were hewn into regular forms, and accurately joined; and from the ruins of the palace of Mitla, in Oaxaca, still existing, it appears that they had the art of designing ornaments like arabesques, in paste, with great neatness, and attaching them to the walls; but solid structures of masonry evincing any considerable skill are extremely rare in the country. Their carvings in wood were tolerably well executed, but the figures were disproportioned and uncouth. The same remark applies to their hieroglyphical drawings, which were far inferior in taste and design to those of the Hindoos, Japanese, and Thibetians. For paper they employed sometimes the large leaves of the aloe, sometimes cotton cloth, or the skins of deer dressed. Their books consisted of strips or webs of such materials, composed of pieces neatly joined, one or two feet broad and twenty or thirty long, which were divided into pages by folding them in a zig-zag manner; and two pieces of thin deal attached to the outermost folds served as boards, and gave these manuscripts, when closed, an appearance very much like our old folios in wooden binding. The written language of Mexico contained a few real hieroglyphics or symbols, purely conventional, to designate such objects as water, earth, air, day, night, speech, and also for numbers; but it was essentially a system of *picture-writing* in which objects were represented by coloured figures having a resemblance more or less exact to themselves. With all its necessary imperfections, this instrument was familiarly employed to a prodigious extent in deeds and instruments for effecting the transmission and sale of property. The government kept couriers for conveying intelligence from all parts of the empire; and the capital was watched and cleaned by a sort of police establishment. This is the bright side of Mexican civilisation. On the other hand, it must be kept in view, that the Mexicans had no tame animals, no made roads, no money to serve as a universal medium of exchange in commercial transactions. The government was originally a perfect feudal monarchy, in which all power was monopolised by a numerous nobility and the priesthood. The great mass of the people were serfs, attached to the soil, and transferred with it from owner to owner by descent or purchase. The peasants or slaves of a nobleman were allowed a certain portion of land, which they cultivated in common

for their subsistence: the rest of their labour belonged to their lord. The country swarmed with beggars, and thousands were swept off every few years by famine. As among the ancient Egyptians and the Chinese, immutable custom, regulating every act of civil and common life, chained up the course of improvement, and spread a languid monotony over society. The crown was elective, and the powers of the monarch small, till the privileges of the nobles were destroyed by the policy and ambition of Montezuma. The religion of the Mexicans breathed a savage spirit, which degraded them, in a moral point of view, far below the hordes of wandering Indians. Their deities, represented by mis-shapen images of serpents and other hideous animals, were the creation of the darkest passions of the human breast, of terror, hatred, cruelty, and revenge. They delighted in blood, and thousands of human sacrifices were annually offered at their shrines. The places of worship, called Teocallis, were pyramids composed of terraces placed one above another, like the temple of Belus at Babylon. These were built of clay, or of alternate layers of clay and unburnt bricks, but in some cases faced with slabs of polished stone, on which figures of animals are sculptured in relief.<sup>1</sup> One or two small chapels stood upon the summit, enclosing images of the deity. The largest known, which is composed of four stories or terraces, has a breadth of 480 yards at the base, and a height of 55. These structures served as temples, tombs, and observatories; and it is remarkable that their sides are always placed exactly in the direction of the meridian. This leads us to the most interesting fact connected with Mexican civilisation, we mean the perfection of their calendar. The civil year was composed of 365 days, divided into 18 months of 20 days, and 5 supplementary days. The Mexicans had besides a ritual or religious year for the regulation of their festivals; and, by means of a cycle of 52 years, and a very complicated method of computation, the religious and civil periods were connected with one another, and the civil year was made to correspond with the natural by the intercalation of 13 days at the end of the cycle. The month was divided into four weeks of five days, but each day of the month had a distinct name; and Humboldt has given strong reasons for believing that these names were borrowed from an ancient zodiac formed of 27 or 28 lunar houses, which was made use of from the remotest antiquity in Tartary, Thibet, and India. The calendar of the Mexicans bespeaks a degree of scientific skill, and an accuracy of observation, which are not easily reconciled with their semi-barbarous habits, their general ignorance in other things, and the recent date of their civilisation according to their own account. It is here, indeed, and not in their language, that we find distinct traces of their connection with Asiatic nations. The character of the Mexicans is probably the same at this day as before the conquest, which, we are disposed to think, made less change in the situation of the people than is often supposed, though it annihilated the rank and privileges of the nobles. The Mexican Indian is grave, suspicious, and taciturn; quiet and placid in his external deportment, but rancorous in his spirit; submissive to his superiors, harsh and cruel to those beneath him. His intellect is limited, and chiefly develops itself in imitative labours and mechanical arts. Slow, cautious, and persevering, he loves, both in his acts and thoughts, to travel in a beaten track. The people, though speaking many different languages, have nearly the same physical character. The Mexicans have olive complexions, narrow foreheads, black

<sup>1</sup> Robertson was mistaken in believing that the Teocallis were in all cases mere masses of earth, without masonry. See Humboldt's *Researches*, vol. i. p. 111, English translation.

eyes, coarse glossy black hair, and thin beards. They are of the middle size, and well-proportioned in their limbs. A person with any defect or deformity is rarely seen amongst them. They are healthy, and live to an advanced age, when life is not shortened by drunkenness. The Toltec and Aztec races, when they established themselves in the country, diffused their own language partially from the Lake of Nicaragua to the 37th parallel. They reclaimed, by degrees, many of the neighbouring savage tribes to a settled mode of life, and spread a feeble degree of civilisation over a mixed mass of nations, speaking, according to Clavigero, 35 languages, of which Humboldt tells us that 20 still exist. The Aztec language is one of the most copious and polished of the American tongues, and abounds in words of the immoderate length of 12 or 15 syllables. It is uncertain what was the number of subjects over whom Montezuma ruled. The ruins in the valley of Tenochtitlan, on which the capital stands, show that it must have been more populous before the conquest than now; but the population at present is diffused over an incomparably wider space; and, upon the whole, there are no good grounds for believing that the number of civilised Indians was much greater when Cortes landed, than in 1803, when it amounted to 2,000,000.

The civilisation of Mexico, as well as of Peru, owed its existence to a single cause,—the patient, submissive, and superstitious character of the people, which fitted them to be beasts of burden, under an aristocracy of priests and nobles, who were led, perhaps, partly by influences from abroad, partly by the instinct of self-interest, to devise means for holding the mass of the community in subjection. Many of the nations which continued savage, such as the Algonquins and Iroquois, were probably equal to the Mexicans in intellect; but their propensity to superstition was less, and their energy of character was too great to permit of their being enslaved by their chiefs. It is chiefly in the variety of their primitive character that we must seek for the cause of the diversity of manners and institutions we find among the American nations.

The ancient empire of Peru, more extensive than that of Mexico, embraced the whole sea-coast from Pastos to the river Maule, a line of 2500 miles in length. Its breadth is uncertain; but as it included both declivities of the Andes, it must have extended in some cases to 500 miles, and the entire surface of the empire probably exceeded 500,000 square miles. It is plain, however, from the imperfect history of the Incas which has been preserved, that within this space there were many districts where their authority was feeble, and others inhabited by tribes which were entirely independent. One part of the country, besides, consisted of a sandy desert, while the most elevated tracts were uninhabitable from cold. It must not therefore be supposed that the capacity of the country to support population was commensurate with the extent of its surface. Still the magnitude of the Peruvian empire, in the midst of an immense multitude of independent savage communities, so extremely minute, that a hundred of them might have been planted without crowding in one of its provinces, is an extraordinary phenomenon. The creating and maintaining of such an empire is a proof that the Peruvians had made no trifling progress in the useful arts and in the science of government. To keep in subjection so many remote provinces, there must have been an efficient military force, rapid means of communication, considerable revenues, and an organised magistracy capable of understanding and executing the plans of rulers, who had sufficient political skill and knowledge of human nature to adapt their institutions and arrangements to the wants, habits and character of a great

variety of dissimilar nations, spread over a territory reaching as far as from Lisbon to the banks of the Volga. It is clear that the ruling tribe, which was able to extend its dominion, and to a considerable extent its language, over a space of 2500 miles, must have possessed a marked superiority of some kind over the hordes that surrounded it. We must remember, besides, that the Peruvians lay under the disadvantage of being destitute of even such an imperfect instrument of communication as the hieroglyphic language of the Mexicans, and that they were extremely deficient in military spirit. Indeed, it is one of the most singular facts connected with the history of America, that by far the largest empire it contained was formed by the most unwarlike people in it. The dominion of the Incas was founded entirely on policy, superstition, and the arts. It could only be by the intelligence and skill which civilisation develops, that the Peruvians conquered tribes superior to themselves in courage; and it was by policy and superstition that the Incas tamed the rudeness of savage tribes, and held distant countries in subjection. Robertson justly observes, that the Peruvians "had advanced far beyond the Mexicans, both in the necessary arts of life, and in such as had some title to the name of elegant." In two points only were they inferior; in their calendar or mode of computing time, and in their want of such a substitute for writing as the Aztecs possessed in their hieroglyphics.

Agriculture was conducted with greater care and success in Peru than in Mexico. The lands capable of cultivation were divided into three shares. One was consecrated to the service of religion, the erection of temples, and the maintenance of priests; the second was set apart as a provision for the support of the government; and the third and largest share, which was reserved for the people, was parcelled out, not among individuals, but among the hamlets and villages, according to the number and rank of the inhabitants; and a new division was made every year to meet any change that might arise in the circumstances of the parties. The members of each little community went to the fields under overseers, and cultivated the land by their joint labour. The produce was distributed among the families and individuals according to their wants, while the evils of famine were provided against by storing up the corn in granaries. The Peruvians having no draught animals, and no ploughs, turned up the earth with wooden mattocks; but their skill and care were exemplified in irrigation, which they practised extensively, and in their employing as manure guano, or the dung of sea birds, which abounds on the islands near the coast. Their masonry was superior to that of the Mexicans. Like the ancient Egyptians, they understood mechanics sufficiently to move stones of vast size, even of 30 feet in length, of which specimens are still existing in the walls of the fortress of Cuzco. They had the art of squaring and cutting blocks for building with great accuracy; and they did not effect their purpose, as Robertson supposes, merely by chipping the stones, or rubbing them together so as to fit the surface of the one to that of the other, without regard to symmetry of form. It is now known that they had hard chisels, made of copper, with a mixture of 6 per cent. of tin,—a proof of considerable skill in the working of metals. With these they hewed the stones into parallelepipeds, which were disposed in "courses regular," says Humboldt, "as those of Roman workmanship." They are joined with such nicety, that the line which divides the blocks can scarcely be perceived; and the outer surface is in some cases covered with carving. The palaces or lodges of the Incas, of which there are many remains, had doors with slanting sides like the

Egyptian; sloping roofs, which, it is supposed, were covered with rushes or stone slabs; no windows, but niches symmetrically distributed.<sup>1</sup> Ancient stone structures, which are so rare in Mexico, are pretty abundant in Peru,—a fact for which we can only account by the difficulty with which the Mexicans erected buildings, in consequence of their inferiority in the art of masonry. The architecture of the Peruvians, like everything else connected with their social state, displays a remarkable uniformity, not only of style, but of plan. “It is impossible,” says Humboldt, “to examine a single edifice of the time of the Incas, without recognising the same type in all the others which cover the ridge of the Andes, along an extent of 450 leagues.”

Roads. The ancient public roads of Peru are justly considered as striking monuments of the political genius of the government. One of these extended along the sides of the Andes from Quito to Cuzco, a distance of 1500 miles. It is about forty feet broad, and paved with the earth and stones which were turned up from the soil; but in some marshy places it is formed, like the old Roman roads, of a compact body of solid masonry. A tolerably level line is preserved, by filling up hollows, cutting down small eminences, and winding round the sides of large ones. At proper distances tambos or storehouses were erected, for the accommodation of the Inca and his messengers. A similar road was made along the coast in the low country. Fissures a few yards in breadth were passed by bridges formed of beams laid horizontally; and an invention, at once bold and ingenious, afforded the means of crossing deep ravines, or the channels of rivers, which happened to intersect the route. This consisted of a suspension bridge, perfectly analogous in its principle to those with which we are familiar. It was formed of half a dozen of cables of twisted osiers, passed over wooden supports, and stretched from bank to bank; then bound together with smaller ropes, and covered with bamboos. Humboldt passed over one of these pendulous bridges, of 120 feet span; and Mr Miers crossed one of 225 feet span, over which loaded animals might travel. In low grounds the rivers were crossed on rafts with a mast and sail, which, by a particular contrivance, could be made to tack and veer. In this respect the Peruvians were a stage in advance of all the other American races, who had nothing superior to the canoe with paddles. The Peruvians manufactured a rude species of pottery: they understood the art of spinning, and, in an imperfect degree, that of weaving. They procured native gold by washing the gravel of rivers; and silver, and perhaps copper, by working veins downward from the outcrop. They knew how to smelt and refine the silver ore; and they possessed the secret of giving great hardness and durability to copper by mixing it with tin. Their utensils and trinkets of gold and silver are said to have been fashioned with neatness and even taste. On the other hand, they had no money, no knowledge of iron or glass; and they were ignorant of the mode of mortising or joining beams, and of casting arches. They had no animals fitted for draught; but the llama, a small species of camel, which they had tamed, was employed to some extent as a beast of burden.

Laws and customs. The political organisation of Peru, which was artificial in a high degree, reminds one, in some of its features, of the old system of the Saxons in England, but bears a more general resemblance to that of the ancient Egyptians. The mass of the people were in a state of servitude, except a small number, who were free; above these in rank were the Curacas, or chiefs of districts, who formed

a sort of nobility; and above the whole, the family of the Incas, the members of which, by intermarrying only with themselves, formed a numerous and distinct caste. For the purposes of police and civil jurisdiction, the people were divided into parties of ten families, like the tithings of Alfred, over each of which was an officer. A second class of officers had control over five or ten tithings, a third class over fifty or a hundred. These last rendered account to the Incas, who exercised a vigilant superintendence over the whole, and employed inspectors to visit the provinces as a check upon mal-administration. Each of these officers, down to the lowest, judged, without appeal, in all differences that arose within his division, and enforced the laws of the empire, among which were some for punishing idleness, and compelling every one to labour. It is probable that the tithings and hundreds, as in England, would lose their numerical signification in course of time, and become mere local allotments. In the hamlets and villages a person mounted a tower every evening, and announced where and how the inhabitants were to be employed next day. The taxes were paid in the produce of the fields, and magazines for receiving them were established in every district. Such is the account given by Acosta and Garcilasso of the civil institutions of Peru, which may be correct with regard to the oldest possessions of the Incas near Cuzco, where their power had been long established; but it is not probable that such a complicated system was ever fully in operation in the more distant parts of the empire.

The government of Peru was a theocracy. The Inca Government was at once the temporal sovereign and the supreme pontiff. He was regarded as the descendant and representative of the great deity the sun, who was supposed to inspire his counsels, and speak through his orders and decrees. Hence even slight offences were punished with death, because they were regarded as insults offered to the divinity. The race of the Incas was held sacred. To support its pretensions, it was very desirable that it should be kept pure and distinct from the people; but human passions are often too strong for the dictates of policy; and though the marriages of the family were confined to their own race, the emperor, as well as the other males of the blood royal, kept large harems stocked with beauties drawn from all parts of the empire, and multiplied a spurious progeny, in whom the blood of the “children of the sun” was blended with that of the “children of the earth.” Among a simple-minded and credulous people the claims of the Incas to a celestial origin seem to have been implicitly believed. They were blindly obeyed, and treated with a respect bordering on adoration, by the nobles as well as the common people. The Peruvians worshipped the sun, the moon, the evening star, the spirit of thunder, and the rainbow, and had erected temples in Cuzco to all these deities. That of the sun, which was the most magnificent, had its walls covered with plates of gold. The sacrifices consisted of the objects most prized by the people, of grain and fruits, of a few animals, and of the productions of their own industry. Sabianism, as it is the most rational of all the forms of idolatry, is also generally the most mild; and doubtless this results from the tendency which it has to fix the thoughts on the marks of beneficence and wisdom which are displayed in the works of nature. The Peruvian temples were accordingly never polluted, like those of Mexico, with the blood of human victims; and the Incas even went farther, and signalised their zeal against such horrid rites, by suppressing them in all the countries they conquered. Though their history exhibits some bloody deeds, the general character of their government

<sup>1</sup> See Humboldt's account of the ancient buildings of Callo and Cunnar, vols. i. and ii. of his *Researches*.

was the reverse of cruel. The severe punishments prescribed by their laws were rarely inflicted, and rebellion was scarcely known in their dominions. The Inca not only assumed the title of the father of his people, but the vices as well as the merits of his government sprung partly from the attempt made to construct the government on the model of paternal authority, and partly from the blending of moral and religious injunctions with civil duties. Hence the idle pretension of the state to reward virtuous conduct, as well as to punish crimes; hence too the plan of labouring in common, the extinction of individual property, the absurdities of eating, drinking, sleeping, tilling, building, according to fixed universal rules; in fine, that minute and vexatious regulation of all the acts of ordinary life, which converted the people into mere machines in the hands of an immense corps of civil and religious officers. Such a system may have served to reclaim some tribes from the savage state; but it must have stifled the seeds of improvement, and left the mass of the people more stupid and imbecile than it found them. The government was as pure a despotism, probably, as ever existed; but its theocratic character, no doubt, helped to mitigate the ferocity of its spirit. Superstition and force are the two bases on which tyranny rests in all countries; and in proportion as it is firmly seated on the one, it stands less in need of the support of the other. The Inca had so completely enslaved the minds of his subjects, and the apparatus he wielded for directing and controlling their acts was so perfect, that he was able in a great measure to dispense with those terrific examples of cruelty and bloodshed, by which the pure military despot operates on the fears of those who live under his authority.

This system of the Peruvian monarchs, by which the people were kept in a state of perpetual tutelage, merits the greater attention, because it is precisely that which the Jesuits employed, in Paraguay and other districts, to reduce the natives to a settled mode of life; and it seems, in fact, to be the only method by which a semblance of civilisation can be introduced amongst the American nations. Two things must be supposed to account for its prevalence: first, a certain amount of timidity, passiveness, and superstition, in the body of the people, implying weak passions, but not necessarily smallness of intellect; and, secondly, a few minds of a higher class, to give an impulse to the rest, and to control and regulate their acts. In the case of Peru, did these ruling intellects spring from the body of the people, and, after striking out new lights in morals and legislation for themselves, devise a complex and artificial system for establishing their power over the minds of the rest, by the help of superstition and force? or were they strangers from another country, and imbued with the principles of a higher civilisation? If we may believe the Peruvian annals, the latter was the case. About the year 1000 of our era, or perhaps a century later, Manco Capac, with his wife and sister Mama Ocello, appeared as strangers on the banks of the lake Titicaca. They were persons of majestic appearance, and announced themselves as "children of the sun," sent by their beneficent parent to reclaim the tribes living there from the miseries of savage life. Their injunctions, addressed to a people who probably worshipped the god of day, were listened to by a few, who settled around them, and founded Cuzco. By degrees, other tribes were induced to renounce their wandering habits. Manco Capac instructed the men in agriculture and the arts, and Mama Ocello taught the women to spin and to weave. Laws, institutions, and religious rites, were added. The form of a civilised society arose, which was gradually extended by persuasion or conquest,—the Incas having always planted

their arts and religion wherever they established their authority. Huayna Capac, the twelfth in succession from the founder of the dynasty, occupied the throne when the first party of Spaniards visited Peru in 1527, and the empire was then still in a state of progress. There is, however, little doubt that some advance in civilisation had been made in times before the Incas.

Such is the account which the Peruvians give of the origin of their civilisation, which we should be disposed to reject as a fable, if there were not peculiar circumstances which give it some credibility. First, their institutions, taken in the mass, do not present what may be called the American type. The mild and paternal character which they display, the injunction to "love one another" raised to the rank of a positive precept, the preference of the useful arts to war, all breathe a spirit, not only foreign to the genius of the American tribes, but exactly opposed in character to anything which a native self-taught legislator was likely to produce. Secondly, the artificial and systematic form of the Peruvian institutions renders it improbable that they were developed by the natural action of political causes, but strongly favours the idea, that they were framed by a few designing heads, as an instrument to tame and govern a patient, feeble, and credulous people of rude or savage habits. A small number of Jesuits were led, by a sagacious study of the savage character, to devise a system extremely similar in its nature, which worked admirably. These missionaries were the Manco Capacs of Paraguay; and, like the Incas, might, in the course of two or three centuries, have extended their theocracy over as large a space as Peru, if their situation had permitted them to employ force. Thirdly, a million of native Peruvians yet survive, the living descendants of those who built the temples of Cuzco; and their extreme stolidity, apathy, and feebleness of character, sufficiently testify that the chances were nearly as great against a legislator like Manco Capac arising amongst them, as against the Jews in the time of Augustus producing a being like Jesus Christ. They have the weakness and passiveness which fit them to receive an impression from superior directing minds; but they discover no trace of the intelligence, energy, and originality which must have been united in the persons who planned and carried into effect the political system of the Incas. We admit that oppression may have degraded their character, but it cannot have entirely changed it.

If, then, the civilisation of Peru was exotic, whence was it derived? To us it appears most probable, that the legislators of Peru were either Chinese, or persons who had received at second-hand a knowledge of the arts and institutions of China; and our opinion is grounded on traits of resemblance in the manners, laws, arts, and institutions of the two nations, which, in our opinion, are too numerous, striking, and peculiar, to be the effect of chance. We shall mention some of the most prominent.

1. The first and most obvious resemblance is in the singularly artificial frame of society in both countries. In China, as in Peru, the legislation is *directive* as well as punitive, and is distinguished by that minute and elaborate system of regulation, inspection, and control, which interferes with the most trifling actions of ordinary life, and reduces the mass of the people to the condition of automata, moved and guided in everything by the rulers. China, says Mr Barrow, is a great school, in which the magistrates are the masters, and the people the scholars. It might be more correctly compared to a large monastic establishment, in which each person has his place and his duty assigned to him, and all his acts directed by superiors, whose wisdom and authority he is not permitted to question. The Chinese have the same immense multitude

Foreign  
legislators  
and  
teachers.

Peruvians  
and Chi-  
nese com-  
pared.

of civil officers which the Peruvians had, and the same chain of subordination from the emperor down to the petty constable. In China this system was undoubtedly the growth of many centuries; but it was too artificial to occur to the thoughts of a cacique, educated amongst a tribe of savages on the sides of the Andes. 2. In China as in Peru, the emperor assumes the title of the "father of his people;" and his government is modelled upon this figure of speech. He affects to be sprung from progenitors who descended from heaven like the children of the sun, and he unites the character of supreme pontiff with that of temporal prince. There are vestiges, too, of the worship of the heavenly bodies in China.<sup>1</sup> 3. The Chinese emperor extends an ostentatious patronage to agriculture, by celebrating an annual festival in its honour, on which occasion he proceeds to the field in great pomp, and takes a part in the labour of cultivating the ground with his own hands. This singular custom existed in Peru, where the Incas went through an annual ceremony perfectly similar. How foreign was such an institution to the spirit of the American tribes! 4. In China agriculture is in a rude state, and exhibits proofs of intelligence and skill only in two things—the use of manures, and a laborious system of irrigation. Precisely the same circumstances characterised the agriculture of Peru. 5. The internal taxes of China, like those of Peru, are paid in kind (maize, rice, silk, cotton, &c.), and stored in public magazines or granaries. 6. The Chinese government maintained public roads, even in those provinces where neither carriages nor beasts of burden were used, of course for the use of pedestrians, and storehouses or places of refreshment were built upon them at proper distances. The Peruvians constructed roads on precisely the same plan, and for the same purposes; and this was done by no other people in America. 7. The Chinese do not inter the bodies of the dead, but lay them on the ground and raise a tumulus or conical heap of earth over them. Such was also the practice in Peru. The only barbarously cruel rite practised in Peru, that of immolating the Inca's domestics at the obsequies of their master, was brought into China by the Tartars. Its existence is an anomaly in each case, for the genius of both nations was peaceful and mild. 8. The architecture of the Chinese displays little taste, but is distinguished by two peculiarities—the power shown of cutting and moving immense masses of stone, and the uniformity of style which pervades their structures, of every size and description. "All the buildings," says Mr Barrow, "from the meanest hut to the viceroys' palace, are upon one plan." Humboldt remarks the same adherence to a single model among the Peruvians, and the walls of Cuzco show that they were acquainted with the method of moving stones of prodigious size. The Chinese were fond of covering their walls with carving, and examples of the same practice occur in Peru. If any of the Peruvian buildings had remained entire with their roofs on, it would perhaps have been found, that the type or primary architectural form employed in the two countries was not very dissimilar, and some allowance should be made for the circumstance, that Peru must have borrowed her models from China 700 or perhaps 1000 years ago. 9. The Peruvians made coarse pottery, and all the world knows that this is an art in which the Chinese excel. The Peruvians were the only American nation who had made any progress in the art of fusing and alloying metals, in which the Chinese have long been distinguished by their skill. 10. The

Peruvians had dramas and dramatic spectacles. Whence could a people so uninventive have derived the idea of such entertainments, if not from China, where they have been long familiar to the people? There were mimics and buffoons in Mexico, but nothing, we believe, to which the term drama could be applied. 11. But perhaps the most remarkable coincidence is found in an invention entirely confined to the two countries. We have described the suspension bridges made of ropes, employed by the Peruvians in crossing deep ravines. Now, it is singular that bridges of the very same description, some of chains, and some of ropes, are found in the south of China, and nowhere else except in Thibet, which has interchanged arts and customs with China from time immemorial. This single fact we would consider as a proof of communication between the two countries. The Peruvians made their ropes of twisted osiers, and the Chinese had ropes also of this description. 12. From what people nearer than the Chinese could the Peruvians borrow the idea of rafts with a mast and sail? These rafts, supporting covered huts, may be considered as literal copies of some that are used in China; and the peculiar mechanism employed in lieu of a rudder is no doubt borrowed from the paddles attached to the Chinese boats, fore and aft. 13. The Chinese in ancient times made use of quipus or knotted cords to facilitate calculation. Is it not probable that this invention had passed from them to the Peruvians, the Mexicans, the Kaluschi, and other American nations who employed it? It would be easy to trace similar analogies in many other customs, laws, and institutions of the two nations. Both had nunneries or religious societies of women, who lived under a vow of celibacy; both had a class of literary men (the Haravecs and Amautas, or poets and philosophers, in Peru), patronised by the government; both divided the year into twelve months, and placed the beginning of it in January (a coincidence the more remarkable, as the year of the Mexicans and other northern nations consisted of 18 months); both were strangers to the use of milk, cheese, and butter.<sup>2</sup> These facts may suffice, for we have not room for lengthened inquiries, neither are we anxious to press our argument beyond its proper limits. Our position is, not that the Peruvians are descended from the Chinese, but simply that Peru had been inoculated with civilisation by persons who derived their ideas from China. If it be asked why these persons did not import from China the use of letters, the method of casting arches, and many other arts practised there, our answer is, that no individual, and still less any casual assemblage of individuals such as the purposes of trade or navigation might bring together, possesses a knowledge of every art and science which exists in his country. How many men are there in England at this day, who could not even carry the knowledge of the alphabet to another country? We must remember, too, that all the arts existing in China do not exist in every province of it, and have not always existed in those provinces where we now find them.<sup>3</sup> As to the means of communication, it is evident that the trade-wind renders Peru almost unapproachable from Eastern Asia, between the parallels of 30° N. and 30° S. latitude.

<sup>2</sup> Sir John Barrow is our authority for this fact, which is the more remarkable, as the Mongols, the neighbours and conquerors of the Chinese, had the use of all the three articles immemorially.

<sup>3</sup> The uniformity and unchangeableness of customs in China have evidently been much exaggerated. The empire is formed of an assemblage of small states, conquered one after another, each of which must have had its peculiar laws, manners, and superstitions; and common sense tells us, that to blend these into one perfectly homogeneous mass, must have required a much longer period than has elapsed since the empire attained its present magnitude. It would be easy, too, to find instances of the Chinese having changed their customs, both in matters of business and matters of domestic economy.

<sup>1</sup> See accounts of the temples at Pekin dedicated to the heavens, the north star, the moon, the earth, &c., and of the festival kept at the summer solstice, like the grand solar festival in Peru.

But beyond these limits the west winds prevail, and hence China, in point of facility of access, is nearer to Peru than the Society or Marquesas Islands. The Chinese have long exposed themselves to the casualties of a maritime life, in vessels of large size, provisioned for many months; and at this day they perform voyages of 3000 or 4000 miles, to Ceylon and Polynesia.

The Quichua language, or that of Peru, was spread, by the care of the Incas, over all the countries which they conquered, so far at least as to be understood, if not spoken, by the great variety of tribes subject to their sway. It is understood at present as far as Santiago del Estero, 1200 miles of direct distance south-east from Cuzco. This single fact proves both the long duration of their power, and the efficiency of their internal administration. It is said to be the most rich, polished, and harmonious of the South American languages, abounding in vowel sounds, but wanting those corresponding to the Spanish consonants *b, d, f, g, l, x, v*. Like all the other American tongues, it wants terms for abstract and universal ideas, such as *time, space, being, substance, matter, body*, and even such as *virtue, justice, liberty, gratitude*. There are five dialects of the Quichua, which are spoken in Peru proper, and in Quito, New Granada, and a considerable part of La Plata, and not only by the aborigines, but by many Spaniards of the higher classes. The Peruvians had no alphabetic writing. They possessed a very rude species of hieroglyphics, of which little use was made, and the quipus or knotted cords of various colours, which last were originally employed simply as aids to calculation, but latterly as records of facts, laws, &c. Each quipu required a verbal commentary. About ten years ago a copy of an old MS. was discovered, which contained an account of the Maya alphabet of Yucatan—the only alphabet yet known to have existed in America.

The Peruvians of the aboriginal Quichua race are of a copper colour, with a small forehead, the hair growing on each side from the extremities of the eye-brows; they have small black eyes, a small nose, a moderately sized mouth, with beautiful teeth; beardless chin (except in old age), and a round face. Their hair is black, coarse, and sleek, the body well proportioned, the feet small, the stature rather diminutive. Their intellectual qualities, according to M. Ulloa, are of the lowest order. The most prominent trait in their character is an imperturbable and incurable apathy. Though half-naked, they are as contented as the Spaniard in his most splendid raiment. Gold and silver have so little influence over them, that the greatest recompense will not induce them to perform the slightest service voluntarily. Neither power nor dignity moves them, and they receive with the same indifference the office of alcalde and that of executioner. They are habitually slow in their motions, and extremely indolent. When employed at any piece of labour, if the master withdraws his eye for a moment, they cease to work. They are timid, shy, secretive, and always grave, even in the dances, which are their favourite pastime. The love of intoxicating liquors is deeply rooted in their nature. They prepare a fermented beverage called chicha from maize, by a process known to them before the conquest, and at their festivals drink till their senses fail them, day after day. This vicious habit, however, is common to all the American nations, and is confined to the men, for the women are in general strictly sober. The Peruvians are a gentle and mild people; they are fond of their dogs, and breed up hogs, geese, and chickens, for which they have so tender a regard, that they will often neither kill nor sell them. Their huts, says Mr Stevenson, consist of stones laid upon one another without any cement or mortar, thatched over with long grass or straw, affording

no defence from either the wind or the rain. One small room contains the whole family; their bed a sheep-skin or two; their furniture one or two earthen pots. The principal food of the Peruvians is maize; but they raise also potatoes, wheat, beans, tomatoes, yucas, pumpkins, and other vegetables. Christianity, imposed upon them dogmatically, by priests who take no pains to enlighten them, has scarcely gained admission to their understandings, and has no hold on their affections. They attend divine service from the dread of chastisement, and give an outward assent to whatever they are taught, but without any real religious impression being made upon their minds. They meet death with the same stupid indifference as the ordinary accidents of life, and rather decline than seek the assistance of a priest in their last hours. It ought not to be forgotten, however, that the intellectual torpor which the Peruvians display may be attributed in part to the deadening and debasing effects of three centuries of brutal oppression. They still cherish in secret a strong veneration for their ancient faith and their native government, which displays itself even in the large towns. The story of Manco Capac (whom, since numbers of our countrymen appeared in Peru, they affect to call an Englishman) and Mama Ocello, the wealth, power, and beneficence of the Incas, are still fresh in their memories, and are handed down from father to son with a degree of fond admiration which three centuries of humiliation and misfortune seem only to have rendered more intense. The barbarous murder of the Inca Atahualpa by Pizarro is annually represented in the form of a tragedy. "In this performance," says Mr Stevenson, "the grief of the Indians is so natural, though excessive, their songs so plaintive, and the whole is such a scene of distress, that I never witnessed it without mingling my tears with theirs. The Spanish authorities have endeavoured to prevent this exhibition, but without effect. The Indians in the territory of Quito wear black clothes, and affirm that it is mourning for their Incas, of whom they never speak but in a doleful tone."

The oppression of the *mita*, or forced labour in the mines, with the introduction of the small-pox and the use of spirituous liquors, has destroyed prodigious multitudes of the Indians since the conquest. What their number was before that event it is impossible to tell; but, judging from the extent of the Inca's dominions, he probably had not less than three or four millions of subjects. A pretended Spanish account, assigning a population of eight millions to Peru shortly after the conquest, is known to be fictitious. An official estimate in 1862 made the number of Indians in Peru amount to 1,600,000, being three-fourths of the entire population.<sup>1</sup>

In Chili there were several tribes who possessed nearly all the arts known to the Peruvians, but were distinguished from them by a finer physical constitution and an unconquerable spirit. When the Spaniards arrived, Chili, according to Molina, was inhabited by fifteen tribes independent of each other, who were spread over the country on both sides of the Andes, from latitude 30° to the Strait of Magalhaens. They all spoke dialects of one language, which is described as rich, harmonious, abounding in compound words, and having, like the other American tongues, very complicated grammatical forms. It has no affinity to the Quichua or Peruvian. The inhabitants of the plains are a stout people, of middle stature; those

<sup>1</sup> In this account of the Peruvians we have chiefly followed Garcilasso, Acosta, Frezier, and Ulloa, of whose statements a copious digest is given by Prevost in the 13th volume of his *Histoire Générale des Voyages*. We have also taken some facts from Humboldt's *Recherches*, Balbi's *Ethnographical Atlas*, and W. B. Stevenson's *Narrative of Twenty Years' Residence in South America*, a useful work, although the author has shown rather too great an anxiety to exalt the character of the Indians.

of the mountains are tall; and one tribe, the Tehuels or Patagonians, surpass in size every other nation in the world. All the tribes inhabiting the plains, except those of the extreme south, now make use of horses. The complexion of the Chilian tribes is, like that of the other American nations, a reddish brown; but one tribe is said to be of a clear red and white. They do not paint their bodies. The Chilians lived partly by hunting, but chiefly by agriculture, before they had any intercourse with Europeans. They cultivated maize, magu, guegen, tuca, quinoa, the potato, pumpkins, and some species of pulse; and to these they added, as food, the flesh of the bizcacho, and of the llama or Araucanian camel, of whose wool they are said to have manufactured cloth. Like the Peruvians, they understood the use of manure, practised irrigation with considerable skill, and turned up the ground with a wooden spade or mattock. They boiled their grain in earthen pots, or brayed it into meal after roasting it in hot sand; of the meal they made puddings or bread, which they knew how to leaven, and various species of fermented drink. They had gold, silver, copper, tin, and lead, procured probably by washing; but they seem to have had few or no edge-tools of metal, those found being almost always of basalt. They made baskets and mats, extracted salt from sea-water, and were able to give various dyes to their cloths. They used *quipus* or knotted cords for calculation, and, according to Mr Stevenson, for the transmission of intelligence and for recording events. They lived in villages formed of houses standing at a distance from one another, under hereditary chiefs, but whose power was limited. It is remarkable that the Chinese mode of catching wild ducks on the rivers; by covering the fisher's head with a gourd, was practised in Chili.

The Araucanians, the most intelligent, improved, and warlike of the Chilian tribes, occupy about 200 miles of the sea-coast, between the 37th and 39th parallels. They are of ordinary stature, but vigorously formed; bold, hardy, hospitable, faithful to their engagements, generous to a fallen enemy, ardent, intrepid, and enthusiastic lovers of liberty. Their vices are drunkenness, and a contempt of other nations, springing from pride. Their government, in the regularity of its form and its sub-division of authority, has an outward resemblance to the Peruvian; but the spirit of the two systems differs as widely as the genius of the two nations. Araucania contains four tetrarchies, under four *toquis* or princes, who are independent of one another, but confederated for their joint security against foreign enemies. Each tetrarchy is divided into five provinces, ruled by five chiefs called *apoumen*; and each province into nine districts, governed by as many *ulmen*, who are subject to the apo-ulmen, as the latter are to the toquis. These various chiefs (who all bear the title of ulmen, as our nobility of all orders are barons) compose the aristocracy of the country. They hold their dignities by hereditary descent in the male line, and in the order of primogeniture. The supreme power of each tetrarchy resides in a diet or great council of the ulmen, who assemble annually in a large plain, like the Poles and Germans in old times; but as the people are all armed, and have a high love of liberty, no resolution of the diet is of any avail if it has not their hearty concurrence. The chiefs, indeed, are little more than leaders in war; for the right of private revenge, which is fully admitted, limits their authority in judicial matters; and they receive no taxes. Their laws are merely primeval usages. The Araucanians can raise altogether 6000 or 7000 men, besides a body of reserve. When war is declared by the great council, messengers bearing "arrows dipt in blood" are sent to all parts of the country

to summon the men to arms. Unlike many barbarous nations, which are immovably attached to their ancient customs, the Araucanians were not slow in copying the military arts and tactics of the Spaniards. Their troops now consist of infantry and cavalry; the former armed with pikes or clubs, the latter with swords and lances. The infantry are formed into regiments of ten companies, each company containing a hundred men. When they take the field, they carry parched meal with them for provisions; they station sentinels, send out scouts, and have advanced guards preceding their main body. When necessary for their security, they dig ditches, and plant stakes along their sides, and throw up mounds of earth. They advance to battle in lines, well formed, and fight with intrepidity. Their history affords a brilliant example of what a brave nation, animated by an enthusiastic love of liberty, can accomplish under the greatest disadvantages. After resisting the best troops and the best generals of Spain for two hundred years, they at last compelled their proud enemies to acknowledge their independence. The Araucanians were indebted for their success to a deliberate species of courage, to which even the bravest of the North American tribes are strangers; and they combined with it a degree of sagacity and intelligence which led them to adapt their mode of fighting to the new circumstances in which they were placed. Experience having taught them the inefficiency of their old missiles when opposed to musket balls, they soon laid aside their bows, and armed themselves with spears, swords, or other weapons fitted for close combat. Their practice was to advance rapidly within such a distance of the Spaniards as would not leave them time to reload after firing. Here they received without shrinking a volley, which was certain to destroy a number of them, and then rushing forward in a close column, fought their enemies hand to hand. In this way they gained many victories, and impressed the Spaniards with such a respect for their courage that an individual of that nation made their achievements the subject of an epic poem. Combining the moral, intellectual, and physical qualities of the Araucanians, they were certainly the finest native race in the New World. They had nearly all the germs of civilisation which belonged to the Mexicans and Peruvians, without the ferocity of the former, the apathy of the latter, or the slavish habits common to both; and without having their minds stupified by that grovelling superstition which the rulers of these two nations seem to have considered as the only secure foundation of their authority. In true courage, in manliness and energy of character, they take precedence of all the American nations.

The Araucanians believe in a supreme being, and in many subordinate spirits, good and bad. They believe also in omens and divination, but they have neither temples nor idols, nor religious rites; and discover upon the whole so little aptitude for the reception of religious ideas that the Catholic missionaries who have settled among them have had very little success in imbuing their minds with a knowledge of Christianity. They believe in a future state, and have a confused tradition respecting a deluge, from which some persons were saved on a high mountain. They divide the year into twelve months of 30 days, which have significant names, and add five days by intercalation. They esteem poetry and eloquence, but can scarcely be induced to learn reading or writing. Chess, a game of oriental origin, is said to have been known among them from time immemorial; and it may be further observed, that the numbers 5 and 9, employed in their geographical and civil divisions, are favourite numbers in China.

The other Chilian tribes are all much behind the Arau-

canians in civilisation; but some, as the Puelches and the Tehuels, surpass them in strength and stature. Part of them live on horse flesh, part by keeping sheep and cattle, and part by hunting. Some of these tribes paint their faces. With regard to the height of the Patagonians, M. Lesson, an eminent French naturalist, has collected the authorities on the subject in a note published by Balbi in his *Ethnographical Atlas*; and they appear to us to remove every rational doubt as to the fact of a race of men existing there whose average stature is about six feet, and among whom men seven feet high are perhaps more frequently to be met with than among an equal number of men in any other country. They have large heads, but their hands and feet are small, and they are not strong in proportion to their tall stature. They ride on horseback, and hunt the huanaco or the ostrich with a sling, which they cast so as to entangle the animal's legs. They dwell in tents, and lead a wandering life.

Of the numerous nations that inhabited Brazil there is only one to which we can afford any special notice in this article. The Guaranis have at one time formed a numerous people, which seems to have been spread over a larger surface than any other now existing in America. Tribes, or remnants of tribes, whose relationship to the Guaranis is attested by the strong evidence of their language, are found diffused over the wide space between the Orinoco and the embouchure of the Plata, or more than the half of South America. They are met with among the Andes of Peru, in the province of Chiquitos, in Matto Grosso, in Paraguay, in Minas Geraes; and the Omaguas, in the republic of Ecuador, who, from their nautical habits, and the influence they obtained on the upper part of the Amazon, have been called the Phœnicians of the new world, are believed to be of the same race. They constituted the bulk of the native population of Brazil when the Portuguese gained possession of it, but were divided into many distinct tribes, quite independent of one another, and living, not in contiguity, but mixed with other nations. They are of low stature, two inches shorter than the Spaniards, according to Azara; of a square form, fleshy, and ugly. Their colour has a strong shade of the copper red, while that of the other Brazilian tribes inclines generally to the tawny or black. Their character, like their physical form, resembles that of the Peruvians. They are patient, torpid, silent, downcast in their mien, mild, and passionless. Nearly all the Indians whom the Portuguese have civilised or converted belong to this race. It is difficult to account for their dissemination through the southern continent, amidst nations much more brave and powerful than themselves. May we suppose that, like the subjects of the Incas, they had been, at one time the dominant tribe of an extensive empire, which derived its force from union and civilisation? But if such a state did exist, its date cannot be very ancient; for the identity or close resemblance of the dialects spoken by the scattered portions of the Guaranis shows that their dispersion from a common point did not happen at a very remote period.<sup>1</sup> Yet no memorial of its existence survives, either in traditions or monuments. The supposition, therefore, that the Guarani tribes are the remnants of a once powerful and united people, is scarcely admissible; and Azara thinks it more probable that they have crept gradually from north to south. Their dispersion is the more remarkable, as they are not a wandering but an agricultural people. They live in the woods, or in small open spaces in the forests; cultivate maize, beans, gourds, yams, mandioc; and eat also wild honey, and the flesh of monkeys and various small quadrupeds.

The Indians whom the Jesuits civilised and collected into communities in the celebrated settlements of Paraguay belonged chiefly to the nation of the Guaranis. These missionaries are said to have borrowed the plan of the theocracy which they established here from that which the Incas had introduced into Peru. There is no doubt that the spirit of their system was the same; and, considering that they were precluded from any other means of extending and supporting their authority than persuasion, their success was remarkable. The settlements were commenced about 1610, and were gradually extended over the country watered by the Parana and Uruguay, between the 27th and 30th degrees of south latitude, till the order of the Jesuits was suppressed in 1767. The plan of the government may be called *parochial*, for it was administered entirely by the parochial clergy. The Indians were collected into villages. Each village had its church and its curate, who was assisted by one, two, or more priests, according to the number of Indians under his charge. The curate and assistant priests were nominated, not by the Spanish authorities, but by the father superior, also a Jesuit, who exercised a vigilant superintendence over the whole. Indians were appointed in each village with the titles of regidores and alcaldes; but they were merely instruments in the hands of the curate and his assistants, in whom all power was lodged. The curate gave his whole attention to religious offices, saying mass in the church, and visiting the sick; while the assistant priests managed all secular matters, directing the labour of the Indians who cultivated the ground, and training others to the crafts of the weaver, mason, carpenter, goldsmith, painter, and sculptor; for the fine arts were by no means neglected. Private property did not exist. The produce of the labour of the community was stored in magazines, from which each family was supplied according to its wants, special provision being made for aged persons, widows, and orphans. The surplus was sold by agents at Buenos Ayres, and the proceeds employed in paying the taxes to the king, in procuring ornaments for the churches, and various articles which the colonists could not manufacture for themselves. The religious instruction was of the most simple kind; but the service of the church was conducted with a well-trained choir, a pompous ceremonial, and every accessory calculated to strike the senses. The punishments were mild; and they were always accompanied with such admonitions as a parent would address to a child whom he was chastising. Crimes, in truth, were rare. The Indians, who regarded their spiritual chiefs with the veneration due to beneficent beings of a superior order, scarcely felt humbled in confessing their misdeeds; and offenders may have solicited correction, as Raynal says, for the quieting of their consciences. The incursions of the Portuguese compelled the Jesuits to take means for repelling force by force. All the male Indians of the proper age were accordingly armed with muskets, and disciplined as a militia. In 1732, according to Dobrizhoffer, the thirty villages or parishes under the care of the missionaries contained a population of 141,000 souls. The Jesuits had another establishment of the same kind among the Chiriguas, a branch of the Guaranis, in the province of Chiquitos, containing 30,000 or 40,000 Indians; a third, of smaller size, in the province of Moxos; a fourth in California; and probably others. After the suppression of the order, all these were committed to the care of friars of other descriptions; and we believe they have universally fallen into a state of decay. The social system established in Paraguay was the most effectual ever contrived for reclaiming the Indians from their savage mode of life; but even its success shows how hopeless the attempt is to raise the American tribes to

<sup>1</sup> Dr Prichard's *Researches*, vol. ii. p. 487.

the rank of thoroughly civilised nations. The Jesuits were able to introduce settled habits and a slight knowledge of religion and the arts among the Indians only by means of the personal ascendancy they acquired over them. It was a few superior minds gaining the respect and confidence of a horde of savages, then employing the influence they acquired to lead them as children; giving them such portions of instruction as taught them to trust implicitly in their guides, working alternately on their fears, their pride, their kind affections, but never fully revealing to them the springs of the machinery by which they were governed. The incurable indolence of the savages rendered it necessary to prescribe the labour as task-work, and to carry it on under the constant inspection of the missionaries. The plan of cultivating the ground in common, and of storing the produce in magazines, out of which the wants of each family were supplied, was resorted to as a check upon their improvident habits. In short, the eye and the hand of the missionaries were everywhere; and the social system was held together entirely by their knowledge and address. When these were withdrawn, the fabric soon fell into ruins, and the Indians relapsed into their idolatry and savage habits.

Other races  
of Indians.

To complete our general view of the aboriginal races, a few particulars remain to be mentioned. Many of the tribes who inhabit the Pampas of South America make use of horses. Dobrzhoffer enumerates eight equestrian tribes in the province of Chaco, on the west side of the river Paraguay, who are generally distinguished by tall and vigorous forms, and a bold and active character. The Abipones and Mbayas are the most celebrated of these. The woods of Brazil are too dense for equestrians; but horses are used by a few hordes in the great plain of the Mississippi and in the north of Mexico. The American tribes in general either kill their prisoners or adopt them; but a few retain them as slaves, and compel them to work. The Guayeurus of Brazil are an example. The food of different tribes is extremely various. Maize, beans, pumpkins, and mandioc are raised in small quantities by some; natural fruits, berries, bulbous roots, and bananas are gathered by others. Those who dwell on the sides of rivers live greatly on fish; in the plains, buffaloes, horses, and sheep are killed. In the forests of Brazil, monkeys, pigs, armadillos, pacas, agoutis, and tapirs are the favourite food; but birds, turtles, deer, and the coati are also taken; and in an emergency the Indians do not scruple to feed on serpents, toads, and lizards, the larvæ of insects, and other disgusting substances. Salt is used where it can be easily obtained, and some season their food with capsicum. Some roast their meat, others boil it; and not only several savage tribes, but even the civilised Peruvians, ate their flesh raw. The Ottomaques, a tribe near the Orinoco, eat a species of unctuous clay; this strange diet, which no doubt owed its introduction to the stern monitor famine, is not extremely rare in Brazil, and Captain Franklin found the same food in use among an Indian tribe near the Frozen Ocean. The clay is stated by that traveller to have a milky and not disagreeable taste. A great proportion of the tribes in Brazil and the basin of the Orinoco, and some in other parts of America, indulge in the horrid banquet of human flesh. Shame, in our sense of the term, is nearly a stranger to the breasts of these savages. In the warm regions of Brazil men and women go entirely naked, except in the neighbourhood of the Portuguese settlements, where some wear a band of cloth round the loins. In such situations, where the want of shelter is little felt, their dwellings are often nothing more than a sort of arbour formed by interlacing the open space between two or three trees with twigs, and cover-

ing it with leaves so as to form a screen on the windward side, while it is left entirely open on the other. The manufacture of bows and arrows, war-clubs, baskets, mats (which, swung from a tree, serve them both as seats and hammocks), and in some cases a coarse pottery, comprises the sum of their practical skill in the arts. It has long been the practice of bands of Portuguese, consisting chiefly of outlaws and vagabonds, to make marauding expeditions among the Indians living near the great rivers, and to carry them off and sell them clandestinely for slaves. This infamous trade is carried on in despite of the orders of the government, which has issued many decrees for the protection of the Indians, and, besides employing missionaries to convert them, enjoined the governors of provinces to furnish them with hoes and other agricultural implements. Wherever the negroes are introduced in great numbers, as in the Capitánias of Santo Paulo and Rio Janeiro, and in the whole of the West India islands, the aborigines rapidly disappear, the former being more intelligent, more tractable in their habits, and more active and industrious. The negroes are indeed a superior race to the Indians; and the existence of one or two hundred blacks, as slaves, among some thousands of the Cherokees, does not detract from the accuracy of this opinion. Missions for the conversion of the Indians have been supported for more than two centuries by the governments of Spain and Portugal. They are thinly spread over those parts of Mexico, La Plata, Peru, Brazil, and Colombia, which are still occupied by the savages; but there are extensive districts in all these provinces in which they have never been established, owing to the fierce character of the tribes, or the remote and inaccessible nature of the country. A mission consists in general of one or two friars or priests, who settle among the savages, learn their language, and, besides teaching them the elements of Christianity, always endeavour to instruct them in the more simple and useful arts, and to train them to settled habits. We believe that many of these establishments have been abandoned, owing to the failure of the funds with which they were supported; and that the success of the others has been extremely trifling. The late revolutions in those countries, by liberating the Indians from their ancient state of tutelage under the whites, have in many cases broken up the little settlements which the missionaries had formed. This has been the result even in Brazil, where the political changes have been least felt.

Owing to the fanaticism of the Spaniards a large proportion of the manuscripts of the natives were destroyed, so that now we are unable to acquire so full and accurate a history of the more civilised nations as we might otherwise have done. The literature which still exists, together with the numerous remains of cities, temples, roads, bridges, and other works of art, testify to the general truth of the historical narratives. However obscure they may now be, or however difficult the reconciliation of statements, it seems clear they have been founded on facts. As in the case of other histories, there is much error and tradition, mingled with truth, which renders their correct interpretation difficult. Amongst some of the nations we know that historians were appointed by the government, and that such historians were severely punished if they ventured to tamper with the truth wilfully. The best connected account of these histories, so far as concerns the nations of Central America, is that given by the Abbé Brasseur de Bourbourg.<sup>1</sup> If we credit the native accounts, the earliest traces of civilisation originated in Yucatan and the neighbouring districts, a region which is amongst the most fertile in the New World.

Traditi  
history  
Central  
Americ

<sup>1</sup> *Histoire des Nations civilisées du Mexique et de l'Amérique centrale, durant les siècles antérieurs à Christophe Colomb.* 4 tomes. 8vo. 1857-59.

It is stated that many centuries before the Christian era, Votan, the oldest of the American legislators, established himself in the region watered by the rivers Tabasco and Usumasinta. It is near the sources of this latter river, in the highlands of Vera Paz, that cities of civilised Indians still exist, according to travellers who have recently visited the adjoining districts. However this may be, this river was the principal highway into the interior of Central America for the earliest civilised tribes, as it is now for the existing natives. Near the mouths of the rivers mentioned the ground is scarcely above the level of the sea, and is for the most part a recent alluvial formation. During the rainy season it is covered with water, and all intercourse between village and village takes place by water. Just where the land acquires a slight rise, Palenque, said to be the oldest city in Central America, was founded. At this time, according to the tradition, the low land was occupied by a lake. Votan, it seems, came from some foreign land, and found the whole of the country from Darien to California occupied by a barbarous people, who used the skins of wild beasts for clothing, caverns and huts made with branches for shelter, and wild fruits and roots, with raw flesh, for food. Votan announced to these people a knowledge of the Supreme Deity, who was at first worshipped as the God "of all truth." At first no temples or altars were dedicated to him, and it was not until long after that Nezahualcoyotl erected a teocalli, or "house of God," as it means in the Mexican language, and dedicated it "to the unknown God." At a later period the religious ideas were considerably debased. In Votan's time there seems to have been but one language prevalent over a large area, and this language was probably the Maya, which is the stock of many of the languages formerly in use among the natives, and is still the language of Yucatan. The people apparently formed tribes differing somewhat in manners, the most prominent of which tribes are referred to as the Quinames or giants. Votan and his companions arrived in large ships, wore long flowing garments, and spoke the Nahuatl language. These strangers married the daughters of the country, and established a settled form of government. According to one document, the year 955 B.C. is assigned to these events; but it is quite impracticable to give any trustworthy fixed date. Votan, it is said, wrote an account of the origin of the Indians, and of their immigration into America. He attempted to prove that they were the descendants of Imos, of the race of Chan, or the serpent. Votan made four voyages to his original country, and described the route he followed. On one of these voyages he visited the dwelling of the thirteen serpents, as also the ruins of an old building which had been erected by men for the purpose of reaching heaven. The people who lived in its vicinity told him it was the place where God had given to each family its particular language. Allusion is also made by him to certain mysteries like those of Egypt and Greece, of which traces were still discoverable amongst the civilised nations of America. On returning from his first voyage to his native country he found the people at Palenque had attempted to usurp his authority and overturn his power. Thereupon he parted his monarchy into four divisions. One of these had for its capital the town of Tulha, the ruins of which may be seen near Ocosingo in Chiapa. Votan also is the reputed founder of Tsequil, which was afterwards called Ghowel, and the site of which is now occupied by a suburb of Ciudad Real. Some time, possibly not many years, after Votan, Zamna appeared in Yucatan. He introduced the Maya civilisation, founded the town of Mayapan, and called the country Maayha, or land without water, a term well applied to the extremity of the peninsula of Yucatan, where rivers are almost absent.

Mayapan was once the capital of Yucatan, and in Zamna's time the sea covered the country to within a short distance of it. He lived to a great age, and during the later years of his life dwelt on the sea-coast, and was buried at this place. The spot became the site of a large temple erected to his honour, which was visited by pilgrims from great distances. A town sprung up around it called Itzamal, which is believed to correspond with the modern Isamal, now about 30 miles distant from the sea. The region to seaward is reported to be geologically very recent as land, and the remarkable absence of names of any antiquity in a country where almost every locality has its appellation is some confirmation of the traditions. The architectural character of the oldest towns also lends some support to the considerable antiquity claimed for them. The forest-covered ruins of Mexico and Central America present so many different architectural styles that it seems very probable they were built at different periods and by different people. Those which appear to be the oldest, and which are most uniform in style, are the substructures in Mayapan, some of the buildings in Tulha, many of those in Palenque, and others which occur in the country of the Lacandons.

The names of the successors to Votan are mentioned, but without details. One of the last of the dynasty was Chinax, in whose reign mention is made of the Nahuatl people. Not long after his death, this people, who were called Nahoa or Toltecs, obtained the dominion of the country, and the throne was occupied by Nahoa princes. They originally came from Huehue-Tlapallan (but where this country was situated is not known), having been induced to leave it in consequence of a revolution. This event seems to have occurred shortly before the Christian era. The journey to America from their native country was a long and painful one, and indicates that seas and lands intervened between them. The traditions report it to be in the far east, and that the first comers filled seven ships and disembarked at Tampico, near the mouth of the Panuco. The leader of the band bore the title of Quetzalcohuatl, and was the first known by that name. They then coasted along the shore as far as Tamoanclia, which place was evidently somewhere near the mouth of the Tabasco. In this district there was a tradition in the time of the Spaniards that twenty illustrious chiefs from the east landed there many centuries before, who had long flowing garments and large beards, of whom the principal was Cukulean, a name which has the same meaning as Quetzalcohuatl. Quetzalcohuatl and his comrades soon obtained possession of the capital of the country, Xibalba, which is believed to be the same as Palenque. Their success induced others of the Nahoa nation to join the first colonists, and their power gradually spread over a large portion of Central America. The strangers, however, met with considerable resistance from the princes of Xibalba, who compelled the Nahoa to leave their country and disperse themselves over the surrounding region. This dispersion is stated to have occurred in A.D. 174. Before this date, the lunar calendar, so prevalent among the civilised nations of America, was introduced. It was one of these parties of Nahoa that established itself in Mexico, and founded many of the more important cities. They were called Olmeques, and were led by Olmecatl and Xelhua. The latter was one of Quetzalcohuatl's companions, and was once shipwrecked along with him. In order to commemorate his delivery he erected the great pyramid of Cholullan. Before the arrival of the Olmeques the valley of Mexico was inhabited by the Quinames or giants, and they continued to dwell in the mountains around for centuries after they had been driven from their native valley. The Totonacs, Mixtecas, and Othomis were the contemporaries, or possibly the

predecessors, of the Olmeques. The first mentioned people erected the pyramids of the Teotihuacan, or the City of the Gods, near Mexico. These tribes spoke a language quite distinct from the Nahuatl. The Totonacs placed the cradle of their race at Chicomoztoc, which was said to be far to the north; but the Othomis seem to have been in possession of the land from time immemorial. According to the traditions of the Quiches and other nations of North America, they originally came from Tulan. They allude to several places of this name. One was in the region of the setting sun and beyond the sea; and another, from which the Quiches came, was also in the direction of the setting sun and was apparently situated in California. In the descriptions given of the migrations from the more distant Tulan, which seem to have occurred at frequent intervals, each migration consisting of a moderate number of people, the difficulties and hardships are prominently noticed. They pointedly allude to the intense cold, to the long dark night, and to the sterility of the country, which allusions seem to point to travels in Arctic regions. The travellers were reduced to such extremities as to be obliged to suck juicy woods in order to sustain life. The name Chichimecs, which means suckers of maguey, given to the invading hordes from the north, may have some connection with this traditional fact. Chicomoztoc has been identified by some with the extensive ruins near the Rio Gila, in California. The history of these early nations is somewhat obscure, but it may be gathered from the preserved records that the worship of the sun and the practice of human sacrifice had nearly or wholly superseded the earlier and purer religions. Towards the end of the 7th century we first hear of the Chichimecs invading Mexico from the north. This name is a general one given to all invading hordes from the north, and is similar to that of barbarians applied to the people who invaded the Roman empire. The first invasion was by the Chichimecs-Cullhuas, headed by Mixcohuatl Mazatzm. They commenced their march, or rather progress, from Chicomoztoc about 635, and reached the valley of Mexico about 40 years after. After many years' fighting the Toltec empire was established in about 686; and from this period we enter upon more detailed and trustworthy historical ground. At first the government of the Toltecs was republican and theocratical, but it soon became monarchical, and Nahuotzin was elected the first king. The most illustrious of his successors was Topiltzin Ceacatl Quetzalcohuatl, during whose reign the Toltec empire arrived at its most flourishing condition. According to tradition, the Toltecs were taller and of larger build than the existing Indians, were great runners, and were as white as Europeans. They carried many of the arts to a high state of perfection, such as weaving, building, jewellery, and making ornaments with the feathers of birds. There were astrologers and poets, sorcerers and philosophers and orators. They were well acquainted with the medical properties of plants, and were in the habit of recording in books their observations on diseases. Quetzalcohuatl's reign was for the most part one of prolonged peace, but this peace was disturbed by the religious party who advocated human sacrifice, a practice which he used every effort to abolish. The rebellion becoming very formidable, Quetzalcohuatl left the country with a few chosen attendants, and founded a new Toltec empire on the plain of Huitzilapan, which corresponds with the one on which La Puebla now stands. This occurred in 895. The town of La Puebla stands on the site of the old Huitzilapan, and at the time of Quetzalcohuatl's arrival it was said that the pyramids of Cholullan had existed from time immemorial, and had been built by the giants. According to this legend, the country was inhabited by giants, all but seven of whom were either destroyed by a

great inundation or turned into fishes. These seven took refuge in a cave, and when the waters abated, one of them, named Xelhua, went to Cholullan, and built the famous pyramid to commemorate his escape. Quetzalcohuatl built a temple here, which he dedicated to the "creator of light," and around this temple sprang up Cholullan, or the "town of the exile." His disciples carried the Toltec civilisation into Oaxaca. After having reigned at Cholullan about ten years, during which period his subjects enjoyed all the blessings of peace, he was attacked by enemies again. Huemac had ascended the throne which he had vacated, and being jealous of Quetzalcohuatl's power and prosperity, he suddenly resolved to march with his army against Cholullan. In order that the town might be spared the horrors of a siege, Quetzalcohuatl informed his priests of his intention to leave the place and to visit other countries. Accordingly he proceeded to the mouth of the Coatzacoalco river, then entered a boat with four companions, and nothing more was heard of him. Huemac finding his enemy had escaped, wreaked his vengeance on Cholullan, and took up his residence there with a view to subjugating the surrounding districts. He also re-established the practice of human sacrifice. During Huemac's absence from his kingdom of Tulan, Nahuotl was elected king in his stead. A battle took place between the rivals, which resulted in the defeat and subsequent death of Huemac and the establishment of Nahuotl's power. His reign lasted for fifteen years, and as he was one of Quetzalcohuatl's disciples, he governed according to similar principles, so that the reign was a prosperous one. His death occurred in 945. After this a series of disasters broke over the country, and these, with constant civil war, weakened the power of the empire in Anahuac. This soon became known to other nations, and led to the Chichimecs-Teotenancas leaving their homes in Texas and New Mexico to make an irruption upon the valley of Mexico. This occurred between 1041 and 1047. The internal discord continued, and the disorder was increased by the uprising of the sect of Ixcuinames, the devotees of which practised the most abominable rites. In the midst of this corruption another horde of barbarians, the Teo-Chichimecs, poured down from the north, and took possession of the country. The Toltec power rapidly declined, and the last king of the empire was Huemac Ateopanecat, who after his dethronement lived for some years at Chapultepec, and died there in 1070.

According to the Guatemalian traditions, four individuals of the Tutul-Xius, a nation speaking a Nahuatl language, left their country of Tulapan, to the west of Zuyua, in A.D. 174, and arrived the same year at Chacnouitan, which seems to be the name for some place in Yucatan. In 258 another migration of Tutul-Xius occurred, the new colony being established in the province of Zyan-Caan, which is believed to be the district around Chetumal Bay. About the end of the 10th century, it is stated that a venerable personage arrived in Yucatan, called Cukulcan, who retrieved the falling fortunes of the Tutul-Xius. According to the *Ablé Brasseur de Bourbourg*, this personage was no other than the Ceacatl Quetzalcohuatl whose departure from the Coatzacoalco river has already been mentioned. After reigning here ten years, he voluntarily abdicated the throne and left the country. According to a Mexican legend he went to Tlapallan, and died there. His successor transferred the capital of the Tutul-Xius from Mayapan to Uxmal, a town which seems to have been founded some centuries before, but which first rose to importance at this period, or near the end of the 10th century. Numerous temples and public buildings were erected, the ruins of which are now so abundantly met with in Yucatan. Artificial ponds or zonotes were constructed; and the number and magnitude of these indicate a large number of

towns as well as a thickly-populated country. At the present day they have all the appearance of being natural ponds, and indeed were long considered to be such, notwithstanding the repeated assertions of the Indians that they had been built by their ancestors, until chance led to the discovery that the maddy floor of one was entirely composed of flat stones, the interstices between which were stopped with a kind of clay not known in the neighbourhood. The centre was occupied by four artificial wells, the walls of which were formed of polished stones. Further research led to the discovery of numerous other zonotes. After the final fall of the Toltec empire there commenced the great movement of the northern tribes towards the south, a movement which continued throughout the 11th, 12th, and 13th centuries. The movement consisted of a succession of migrations, and its starting-point appears to have been in New Mexico and California, which region was evidently the seat of a semi-civilised empire. Amongst these invading tribes was one which subsequently rose to high importance. The Aztecs, or Mexicans proper, were living at Atzlan in the 11th century, a country which was surrounded by water, and where their usual occupation was as boatmen and carriers of wood. Other tribes also lived in this region, which is believed to be that of Lower California. The Aztecs commenced their journey towards Mexico in 1090. In 1116 they reached Chicomoctoc, and in 1177 they entered Anahuac. Settlements were gradually established in the valley, towards which peoples of various nations converged from the south as well as the north. The numbers of the Aztecs were slowly augmented by fresh arrivals; but it was not until 1325 that they were able to lay the foundations of Mexico-Tenochtitlan, and thus to inaugurate their assumption of power. In 1464 the empire of the Tutul-Xius was overthrown. The Mexican empire had, however, acquired large proportions, and was conducted with a magnificence and splendour scarcely equalled by any other court in America, and this empire continued up to the time of the Spanish conquest.

The discovery of a continent so large that it may be said to have doubled the habitable world, is an event so much the more grand and interesting that nothing parallel to it can ever occur again in the history of mankind. America had of course been known to the barbarous tribes of eastern Asia for thousands of years; but it is singular that it should have been visited by one of the most enterprising nations of Europe five centuries before the time of Columbus without awakening the attention of either statesmen or philosophers. Iceland was discovered about 860, and colonised by the Norwegians in 874. About 50, or, according to other accounts, 100 years later, the same people planted colonies in Greenland. Into the disputes respecting the situation of these colonies we have not room to enter. Sir Charles Giesecke, a good authority, states that their ruins exist near the southern point of the peninsula. It is obvious that the same adventurous spirit which enabled these northern mariners to discover the southern extremity of the country, would not permit them to stop short without visiting what is now known to be the most habitable part of it—the western coast; and the fact has been established by an inscription in *runic* characters found on a stone four miles beyond Upernavik, at the 73d parallel, intimating that “Erling the son of Sigvat, and Enride Oddsoen, had cleared that place and raised a hillock on the Friday after Rogation day.” The marking of the date is indistinct, but it is supposed by Professor Rask, the translator, to be either 1135 or 1170; and the *runic* characters show at any rate that it was anterior to the Reformation, when this mode of writing was prohibited.<sup>1</sup> Whoever looks at the map of Greenland, and reflects on the fact

that the Norwegians must have been ascending through Davis' Straits as high as the latitude mentioned, annually, perhaps for two or three centuries, will admit that, with half the spirit of enterprise which had carried them so far, the discovery of some portion of the west coast of these straits was almost unavoidable. Now, the position and direction of this coast once known, it required no great effort to trace it southwards to Labrador and Newfoundland. We mention these particulars because Mr Murray, one of the few who have denied the discovery of America by the Norwegians, grounded his disbelief chiefly on the hypothesis that the colonies and the navigation of that people at the period alluded to were confined to the east coast of Greenland.

In 1001 an Icelander, sailing to Greenland, was driven away by a tempest far to the south-west, where he saw a level country covered with wood. The wind abating, he turned his course homeward, and on his arrival gave such a flattering account of the country he had seen as induced Lief, the son of the founder of the Greenland colony, to undertake a voyage thither. Lief and Bjorn, who sailed together, first reached a rocky island, to which they gave the name of Helluland; then a low country, thickly wooded, which they called Markland; and some days afterwards they found trees loaded with fruits on the banks of a river. They spent the winter in the country; and one of them, who was a German, having found wild vines growing, they called it Vinland. They had some intercourse and traded for furs with a people who came in leathern boats, and were called *Skrælings*, from their dwarfish size. A colony was planted, and remained for many years in the country, the situation of which is indicated by a fact casually mentioned, that the sun remained nine hours above the horizon at the shortest day. This indicates the 41st parallel of latitude; and the actual latitude of Rhode Island, the country which every collateral circumstance would lead us to fix upon as the seat of the colony, is from 41° to 42°. The *Skrælings* were of course the Esquimaux.<sup>2</sup> The *vine* appears to be the fox grape (*Vitis vulpina*), which grows wild in that part of America. Only a few unimportant particulars respecting the settlement are preserved; but it was probably abandoned or destroyed, like the Greenland colonies, of which it was an offset. The account, though meagre, is distinct and consistent. Its authenticity can scarcely be disputed; and it is almost equally obvious that the country it refers to under the name of Vinland is in the vicinity of Rhode Island. A conclusion resting on such strong grounds scarcely requires to be supported by the high authority of Humboldt and Malte-Brun. That the colony disappeared, and that the discoveries made were not prosecuted farther, are not circumstances which will shake the credit of the narrative in the minds of those who know the numerous reverses which befell the early colonies in New England and other parts of America. The hostilities of the *Skrælings* was no doubt the principal cause of the abandonment of the colony. The Norsemen describe Vinland as a rich country, with a delightful climate. Helluland, Markland, and Vinland, were no doubt regarded as countries either connected with or similar to Greenland, the flattering descriptions of which, given by the first discoverers were sadly belied by later experience.<sup>3</sup> The interest excited by the obscure accounts

<sup>2</sup> See the curious work of Torfaeus called *Vinlandia Antiqua*, Hafn, 1705; and the valuable *Antiquitates Americane*, published at Copenhagen in 1837. Also Humboldt's *Cosmos*, vol. ii. p. 233, Sabine's transl. 1848.

<sup>3</sup> M. Rafn, a Dane, who was much engaged in researches respecting these early voyages, announced that he had ascertained, from original documents, various facts previously unknown; among others, that America (first discovered in 985) was repeatedly visited by the Icelanders in the 11th, 12th, and 13th centuries; that the embouchure of the St Lawrence, and in particular the bay of Gaspé, was their principal station; that they had penetrated along the coast as far south as Carolina; and that they introduced a knowledge of Chris-

<sup>1</sup> Ferussac, *Bulletin des Sciences Historiques*, Juillet 1828.

of these countries was probably such as the announcement of a new island eastward of Spitzbergen would produce at the present day. No reasonable doubt can exist, however, that the north-eastern portions of America (considering Greenland as a distinct country) were familiarly known to the Norwegians in the eleventh century.

The obscure allusions of Aristotle, Plato, and Seneca, to a country hid in the Western Ocean, must have derived fresh importance from the discovery of the Canary Isles, Madeira, and the Azores in the early part of the fifteenth century. The love of maritime adventure was excited by these events; and among the active spirits who were attracted to nautical life by the career of distinction which was then opened up, was Christopher Columbus. Our limits do not permit us to enter into details respecting this great man, an outline of whose life will be found under the proper heading. He had received a learned education, and the study of the geographical systems then in vogue impressed him with a strong conviction that a voyage to India by a course directly westward was quite practicable with the degree of nautical science which his contemporaries possessed. From the old and imperfect maps of Ptolemy he was led to believe that the parts of the globe known to the ancients embraced 15 hours, or 225 degrees of longitude, which exceeds the truth by more than one-third. The discovery of the Azores on the west side had lengthened the space by one hour; and the accounts gleaned by Marco Polo in Asia induced him to think that the isles connected with this continent stretched out so far to the eastward that their distance from Europe could not be great. Columbus was, however, without the fortune necessary to fit out ships; and when he attempted to interest some of the princes of those times in his project, he encountered neglects and difficulties which would have exhausted the patience of any mind less ardent than his own. At length, after many delays and discouragements, Ferdinand and Isabella of Spain supplied him with three small vessels, two of them only half-decked; and in this little armament, accompanied by 120 men, he set sail from the port of Palos on the 3d of August 1492. He proceeded first to the Canary Isles, where he was detained three weeks in repairing one of his vessels. On leaving these isles he entered on a region of ocean where all was mystery. The trade-wind, however, bore him steadily along, and the labour of the ships proceeded cheerfully, till the increasing length of the voyage, the failure of prognostics which had from time to time kept alive the hopes of the crew, and various circumstances interpreted by their superstition as evil omens, produced a mutinous spirit, which all the address and authority of Columbus would not have been able to quell had the discovery of land happened one day later than it did. Columbus, says Humboldt, on sailing westward of the meridian of the Azores, through an unexplored sea, sought the east of Asia by the western route, not as an adventurer, but according to a pre-conceived and steadfastly-pursued plan. He had on board the sea-chart which the Florentine astronomer Toscanelli had sent him in 1477. If he had followed the chart, he would have held a more northern course, along a parallel of latitude from Lisbon. Instead of this, in the hope of reaching Zipangu (Japan), he sailed for half the distance in the latitude of Gomera, one of the Canary Islands. Uneasy at not having discovered Zipangu, which, according to his reckoning, he should have met with 216 nautical miles more to the east, he after a long debate yielded to the

opinion of Martin Alonzo Pinzon, and steered to the south-west. The effect of this change in his course curiously exemplifies the influence of small and apparently trivial events on the world's history. If Columbus, resisting the counsel of Pinzon, had kept his original route, he would have entered the warm current of the Gulf Stream, have reached Florida, and thence perhaps been carried to Cape Hatteras and Virginia. The result would probably have been to give the present United States a Roman Catholic Spanish population, instead of a Protestant English one, a circumstance of immeasurable importance. Pinzon was guided in forming his opinion by a flight of parrots towards the south-west. Never, says the Prussian philosopher, had the flight of birds more important consequences. It may be said to have determined the first settlements on the new continent, and its distribution between the Latin and Germanic races. It was on the 12th of October that the western world revealed itself to the wondering eyes of Columbus and his companions. What a triumph for this extraordinary man, who had treasured in his breast for twenty years, amidst neglect, discouragement, and ridicule, the grand truth which his own incomparable skill, wisdom, and firmness had now demonstrated in the eyes of an incredulous world! The spot which he first touched was Guanahani, or Watling Island, as was suggested by Muñoz in 1793, and proved by Mr R. H. Major in 1870. After spending nearly three months in visiting Cuba, Hispaniola, and other isles, he returned to Spain. He made three other voyages, and in the second coasted along a part of South America, which he rightly judged to be a continent from the volume of water poured into the sea by the Orinoco. But he died ignorant of the real extent and grandeur of his discoveries, still believing that the countries he had made known to Europe belonged to that part of Eastern Asia which the ancients called India. Hence the name of West Indies which the tropical islands and part of the continent have ever since received.

We should extend this article to an unreasonable length were we to describe in detail the discoveries and settlements made by the several nations of Europe in America. We shall therefore confine ourselves to a very brief chronological notice of the more important events.

1495. The first place in which the Spaniards established their power was the large island of Hayti or Hispaniola, which was inhabited by a numerous race of Indians of a mild and gentle character, a third part of whom are said to have perished within two or three years after the Spaniards conquered them.

1497. John Cabot discovered Newfoundland June 24th, and coasted along the shores of North America to Florida.

1498. Columbus first saw the mainland, May 30.

1500. Cabral, a Portuguese, visited the coast of Brazil, and discovered the mouth of the Amazon. It was probably colonised before 1515. In 1500, too, Cortereal touched at Labrador.

1508. Vincent Pinzon is said to have entered the Rio de la Plata. It was in the same year that the Spaniards, finding the aborigines too weak for the labour of the mines in Hayti, first imported negroes from Guinea, and thus laid the foundation of a traffic which continued to disgrace the civilisation of Europe for three centuries.

1511. Diego Columbus conquered the island of Cuba with 300 soldiers, of whom he did not lose one.

1513. Balboa crossed the Isthmus of Darien with 290 men, and discovered the South Sea.

1519. Hernando Cortes sailed from Cuba with 11 ships and 550 men, and landed on the coast of Mexico, which had been discovered in the previous year. The conquest of the empire was finished in 1521 by 950 Spaniards, assisted by a vast number of the Indians of Tlascala.

tianity among the natives. The announcement was contained in a letter addressed to a person in Washington, and published in Nile's Register (Baltimore), in November 1828. But M. Rafn afterwards found reason to change his opinion as to the site of the Icelandic colony, and he latterly considered that it was at the mouth of the River Taunton, which falls into the sea in Narraganset Bay, at the north end of Rhode Island.

1531. Peru invaded by Pizarro, and conquered in little more than one year, with a force of 1000 men.

1535. Jacques Cartier, a Frenchman, discovers the Gulf of St Lawrence.

1535. Mendoza, a Spaniard, with 2000 followers, founds Buenos Ayres, and conquers all the country as far as Potosi, at which silver mines were discovered nine years after.

1537. Cortes discovers California.

1541. Chili conquered; Santiago founded; Orellana sails from the sources of the Rio Napo down the Amazon to the Atlantic.

1578. New Albion, on the north-west coast of America, discovered by Sir Francis Drake.

1586. The Spaniards found St Thomas' Island, in Guiana.

1587. Davis' Straits and Cumberland Islands discovered by John Davis.

1604. De Monts, a Frenchman, founded the first settlement in Nova Scotia, then called Acadie.

1607. After many ineffectual attempts during more than twenty years, the first permanent settlement of the English in North America was made this year, on the banks of the James River, in Virginia.

1608. Quebec founded by the French, who had had a small neglected colony in Canada from 1542.

1611. Newfoundland colonised by the English; a Dutch colony established at Hudson's River.

1614. New York founded.

1618. Baffin penetrates to the 78th degree of latitude, in the bay which bears his name.

1620. The first English colony established in New England at Plymouth. It was in 1619 that the first negroes were imported into Virginia. They were brought by a Dutch vessel.

1635. A French colony established in Guiana.

1655. Jamaica conquered by the English.

1664. The Dutch colonies on Hudson's River capitulate to the English.

1666. The Buccaneers begin their depredations on the Spanish colonies.

1682. William Penn establishes a colony in Pennsylvania. La Salle takes possession of Louisiana in the name of the French king.

1698. A colony of 1200 Scots planted at Darien. In the following year the settlement was attacked by the Spaniards, and abandoned.

1733. Georgia colonised by the English.

1760. Canada and all the other French settlements in North America conquered by the English.

We must pause at this point to give a very short account of the colonial system introduced by the principal European nations who occupied extensive tracts of the new world. The English settlements extended from the 31st to the 50th degree on the east coast, and were divided into 15 or 16 provinces. The colonists had carried the love of liberty characteristic of their countrymen with them; and after many struggles with their British rulers, all the provinces, with one or two exceptions, were permitted to enjoy a form of government extremely popular. The executive power was vested in a governor appointed by the king. He was assisted by a council, which sometimes conjoined the functions of a Privy Council and a House of Peers. The people were represented by a House of Assembly, consisting of persons chosen by the freeholders in the country parts, and the householders or corporations of towns. The governor could levy no money without the consent of the House of Assembly: the British parliament, however, claimed, but scarcely ever exercised, the privilege of imposing taxes upon the colonists

without consulting them. Against this assumption of power the local legislatures always protested as an infringement of their rights. The vessels of foreign states were not permitted to trade with the colonies; but the colonists were allowed to trade in their own ships with one another, with the mother country, and, to a limited extent, with foreign states. Their taxes, which were always small, were all consumed in defraying internal expenses; and, compared with any other people in the new world, they enjoyed an unexampled degree of commercial and political liberty. It was the growing prosperity of the colonies and the increasing debt of the mother country, which induced the British ministers, for the first time, in 1764, to attempt raising a revenue in America, for purposes not colonial. The experiment was made by imposing a stamp-duty on newspapers and commercial writings. The sum was trifling; but the Americans, far-sighted and jealous of their rights, saw in it the introduction of a principle which deprived them of all security for their property. The people declared themselves against it as one man, in local assemblies, and by petitions and publications of all kinds. The ministers became uneasy, and repealed the tax; but, as a salve to the pride of the mother country, a declaratory Act was passed, asserting her right "to bind the colonies in all cases whatsoever." The idea of raising a revenue in America was not renounced, but another mode was to be tried. Duties were laid on glass, colours, paper, and tea, and were met by an opposition in the colonies still more zealous and determined. The British ministers, irritated, but wavering in their purpose, dropped all the taxes but that on tea, and commenced at the same time a series of alarming innovations. They closed the port of Boston, changed the charter of the province, placed judges and juries on a footing to render them more subservient to the views of the government, and introduced a strong military force to overawe the people. On the other side, the colonists passed resolutions not to import or consume any British goods, and hastened to supply themselves with powder and arms. Blood was at length shed in April 1775, at the village of Lexington; and in the following year the American Congress published their celebrated declaration of independence. We shall not enter into the details of the war, which was closed in 1782. Suffice it to say that, on the part of the Americans, it rested on high grounds; it was a war to vindicate a principle—for the practical grievance was admitted to be slight; and it was conducted with a regard to humanity of which there are few examples in history.

The Spanish possessions in America before the revolution formed nine distinct governments, all constructed on the same plan and independent of one another. Four of these, of the first rank, were vice-royalties, viz., Mexico, Peru, La Plata, and New Granada; and five were captain-generalships, viz., Yucatan, Guatemala, Chili, Venezuela, and the island of Cuba. The government was vested in the viceroy or captain-general, who was held to represent the king, and to enjoy all his prerogatives within the colony. But in these countries, as in others where the supreme power is apparently unlimited, it was indirectly restrained by the influence of the courts of justice, corporations, and other public bodies. The royal audiencias or supreme courts, composed of Spaniards nominated by the crown, had extensive judicial powers, and were independent of the viceroys. The cabildos or municipalities, and the fueros or corporations (similar to our guilds), also possessed considerable privileges, which derived security and importance from long prescription. Lastly, the clergy, who were numerous and rich, necessarily possessed great influence among a supersti-

tious people. The vices naturally inherent in the colonial system existed in full force in the Spanish American dominions. There was tolerable security for all classes except the miserable Indians, who were regarded and treated precisely as beasts of burden, out of whose toil and sufferings a provision as ample as possible was to be extracted, first to supply the wants of the royal treasury, and next to provide for and satisfy the cupidity of a shoal of do-nothing public officers and priests. Edicts were indeed issued for the protection of the Indians, and persons appointed to enforce them; but these were feeble correctives of the evils rooted in the system, and not unfrequently increased their weight. The Indians, after the conquest, were at first slaves; they paid a capitation tax to the crown, and their labour was entirely at the disposal of their lord. This system was modified from time to time; but all the changes introduced down to the revolution did not release them from their state of vassalage. They still continued liable, in a less or greater degree, to the performance of compulsory labour, under the orders of persons against whom they had no protection. This was an enormous grievance; but, what was equally bad, being held incompetent in law to buy or sell, or enter into any pecuniary engagement beyond the value of a few shillings, without the agency of white men, the swarm of public functionaries had an unlimited power of interfering in their concerns, of vexing, harassing, and plundering them, under the forms of law. The memoir of Ulloa, long buried amidst the Spanish archives, with various other documents published since the revolution, depicts acts of extortion, perfidy, cruelty, and oppression practised upon the Indians which have rarely been paralleled. Men rose to affluence in offices without salaries; and the priests rivalled the laymen in the art of extracting money from those whom they ought to have protected. As the sole aim of the Spaniards in the colonies was to enrich themselves, so the government at home made all its acts and regulations subordinate to the grand object of raising a revenue. Spain retained in her hands the whole trade of the colonies, and guarded her monopoly with the most severe penalties. The price of all European commodities was enhanced three, four, or six fold, in America. The colonists were not allowed to manufacture or raise any article which the mother country could supply; they were compelled to root up their vines and olives; and for a long period one colony was not even permitted to send a ship to another. To support such a system it was necessary to keep the people in profound ignorance, and to cherish prejudices and superstition. The schools were extremely few, and permission to establish them was often refused, even in towns where the Spaniards and Creoles were numerous. The importation of books, except books of Catholic devotion, was rigorously prohibited. Even the more grave and dry sciences, such as botany, chemistry, and geometry, were objects of suspicion. And the more effectually to crush all mental activity, natives of America could rarely obtain leave to go abroad, to seek in foreign countries what was denied them in their own. On the other hand, the priests, sharing in the spoil, filled the minds of the people with childish superstitions, as a means of confirming their own power, and employed the terrors of religion to teach them patience under oppression. To create a race of servants devoted to its purposes, the court bestowed all offices, from the highest to the lowest, on natives of the peninsula exclusively. The wisdom of the plan seems questionable, but that it was adhered to with wonderful pertinacity is certain. "It was the darling policy of Spain," says Mr Ward, "to disseminate through her American dominions a class of men distinct from the people in feelings, habits, and interests,

taught to consider themselves as a privileged *caste*, and to regard their own existence as intimately connected with that of the system of which they were the principal support." With all those means and appliances, it is extraordinary that Spain should have been able to uphold for three centuries a system in which the interests of so many millions of human beings were so habitually and unrelentingly sacrificed. It was the course of events, much more than its own inherent weakness, which ultimately caused its subversion.

After the seizure of Ferdinand and the elevation of Joseph Buonaparte to the throne of Spain, orders were dispatched to all the colonies with the view of securing their obedience to the new dynasty. The men in office were generally disposed to submit, but the treacherous conduct of the French excited a universal hatred of their cause among the people; and when the regency established in Spain presented the semblance of a patriot government, the loyalty of the Americans blazed forth, and poured large contributions of money into the hands of Ferdinand's adherents. The weak and suspicious conduct of the regency, however, and its subserviency to the grasping spirit of the merchants of Cadiz, at length alienated the colonists, and roused them to take measures for their own security. But the diversity of views and interests among the colonists rendered the course to be adopted a matter of some delicacy. Ferdinand, being a prisoner, was, politically speaking, a nonentity. Napoleon's brother was clearly an usurper, odious to, and rejected by, the mass of the Spanish people. The regency, shut up in Cadiz, without troops or revenue, was but a phantom; and the little power it had was so employed as to raise doubts whether its members were not secretly in league with the enemy. In these circumstances, when the only government to which the colonists owed allegiance had fallen into abeyance, the wisest course they could have pursued was to declare themselves independent. This would at once put a stop to the machinations of France, which they dreaded, and prevent the regency from compromising or sacrificing their interests by its weakness or treachery. The Spaniards, however, who occupied all public situations, were averse to a change which they foresaw must lead to the downfall of their power. This was perfectly understood by the other classes; and in the first movements which took place in the different colonies nothing was said derogatory to the supremacy of Spain, though independence was clearly aimed at. By spontaneous efforts of the people "juntas of government" were formed, at Caracas in April 1809, at La Paz in Upper Peru in July, at Quito in August, at Santa Fe and at Buenos Ayres in May 1810, and at Santiago in Chili in September the same year. In 1810, also, the first insurrection broke out in Mexico. The colonists unluckily had been too long the slaves of superstition and tyranny to be fit for conducting so bold an experiment; and after a struggle, which was generally short, but almost everywhere bloody, the juntas were all put down except in Colombia and Buenos Ayres. But in the stir and tumult of the contest old prejudices had received a shock, and the seeds of political change had struck their roots too deep in the soil to be eradicated. A desultory war was carried on for six years between Buenos Ayres and Upper Peru, with little advantage on either side. At length, in 1817, the former state, which had assumed the style of an independent republic four years before, sent an army across the Andes to Chili, under General San Martin, and defeated the Spaniards at Chacabuco. A second victory, gained at Maipo in April 1818, led to the entire subversion of the Spanish power in this colony. The war was now transferred to Peru, where the Spaniards continued

to lose ground, till the decisive battle of Ayacucho put an end to their power in December 1824. Rodil and Olaveta, with the obstinacy of their nation, held out for some months longer, when every chance of success was gone; but after the surrender of Callao in January 1826, the Spanish flag no longer waved on any spot in the land of the Incas.

In New Granada and Venezuela the struggle was more bloody, variable, and protracted than in any other part of South America. As this portion of the dominions of Spain was comparatively easy of access, and from its central position was in some measure the key to the whole, she made immense efforts for its preservation. No less than ten thousand troops were sent out to it within the course of one year. The patriots, on the other hand, possessed advantages here, in the greater intelligence of the population, and the easy intercourse with the West Indies. From 1809, when juntas were established in Caraccas and Quito, to the surrender of Porto Cabello in 1823, the vicissitudes of the war were numerous and extraordinary. The patriots were repeatedly on the eve of a complete triumph, and as often the state of their affairs seemed nearly hopeless. But the spirit of resistance never was entirely subdued. The cause was rooted in the hearts of the people, and was insensibly gaining ground even during its reverses. To attempt the faintest outline of the military operations would lead us beyond our proper limits. It is enough to state that the decisive victory of Carabobo, gained by the patriots in 1819, gave them an ascendancy which they never afterwards lost; but the Spaniards, according to their custom, continued to maintain the contest as long as they had a foot of land in the country, and were only finally expelled in 1823.

In Mexico the revolutionary movement began at Dolores in 1810, and soon wore a very prosperous appearance; but the weakness or false pride of the Creoles, who were cajoled into the ranks of their oppressors the old Spaniards, armed against the patriots those who should have been their firmest supporters, and by one or two mischances the force of the independent party was ruined in November 1815, when Morelos, their able leader, was taken prisoner and executed. For six years after this period many guerilla bands maintained themselves in the provinces, and greatly annoyed the Spaniards; but they did not act in concert, and no congress or junta professing to represent the Mexican people existed. Even during this interval the desire for independence was making great progress among the population; but the establishment of a constitutional government in Spain in 1820, and its extension to the colonies, gave a new aspect to the affairs of Mexico. The viceroy Apodaca, while outwardly yielding obedience to the new system, was silently taking measures to effect its overthrow; but he mistook the character of the agent he employed. This person, the celebrated Iturbide, turned his own arms against him, proclaimed a constitution under the name of "the three guarantees," and put an end to the dominion of Spain in 1821, almost without bloodshed. Iturbide, who had nothing in view but his own aggrandisement, called a congress, which he soon dissolved after getting himself proclaimed emperor. His usurpation kindled a spirit of resistance. He was exiled in 1823, made a new attempt on the liberties of his country in 1824, was taken prisoner, and expiated his crimes by a military death within a few weeks after he landed.

Guatemala was the last portion of the American continent which threw off the Spanish yoke. In 1821 the persons in office assembled and formed a junta. Divisions arose, which were fomented by the intrusion of a Mexican army sent by Iturbide. This force, however,

was beaten, and an elective assembly called, which declared the country independent, and established a constitution in July 1823. Spain now retains none of her possessions in the new world but Cuba and Porto Rico.

The government of Brazil was conducted by the Portuguese on a system extremely similar to that of the Spanish colonies. The monopoly which the mother country retained of the commerce of the colony was equally rigorous; the restrictions on its internal industry as severe; and the same means were employed to keep the people in a state of pupillage and ignorance. Down to 1806 a single printing-press had never existed in Brazil. In 1807, when the emperor Napoleon had resolved to possess himself of Portugal, and if possible to get the royal family into his power, the king, seeing no other means of escaping from the clutches of his enemy, embarked with his suite in several ships, and sailed for Brazil, where he arrived in January 1808. He was received with joy by the colonists, who anticipated great benefits from his residence, of which they were not disappointed. One by one the fetters of colonial dependence fell off. Within a few months printing-presses and newspapers were established, the ports were opened to the trade of all nations, and the people were invited and encouraged to prosecute all those branches of internal industry from which they had till now been interdicted. To crown and secure these advantages, Brazil was declared an independent kingdom in 1815, subject to the crown of Portugal, but entitled to its separate administration and its own laws. The revolutionary spirit pervading the Spanish colonies now found its way into Brazil, and produced an insurrection at Pernambuco in 1817. It was soon subdued, but received a new impulse from the constitutional systems suddenly introduced into Spain and Portugal in 1820. To quiet the popular feeling, it was announced that the Portuguese constitution would be extended to Brazil. Before this had been done, however, the old king had sailed for Europe, leaving his son Dom Pedro to rule in his absence. The people now discovered, or believed, that the object of the king was to degrade Brazil again to the rank of a colony, and to restore the old system in all its rigour. Meetings were held, and resolutions adopted to maintain the independence of the country at all hazards; and the patriots, gaining confidence by degrees, called loudly for the establishment of a legislature, and besought Dom Pedro to put himself at the head of the independent government. Ambition or policy induced Pedro to listen to the solicitation: in 1822 he was proclaimed emperor, and had his own title and the independence of Brazil acknowledged by his father three years afterwards. A representative system was at the same time introduced. An unlucky war now arose with Buenos Ayres, which weakened both countries; but it was at length terminated in 1828 by the recognition of the disputed territory as an independent state under the title of the Banda Oriental.

Having finished this brief notice of the series of revolutions which broke the fetters of America, we shall now give a very short sketch of the new political order of things which has arisen out of these changes, referring for a detailed account of the several states to the articles appropriated to them in the different volumes of the present work.

America, with its islands, embraces at present (1874) twenty-one independent states, and various colonies belonging to six European powers. The former are—1. The United States of North America; 2. Brazil; 3. Mexico; 4. Venezuela; 5. Colombia; 6. Ecuador or Quito; 7. Peru; 8. Bolivia or Upper Peru; 9. Chili; 10. La Plata, or the Argentine Republic; 11. Uruguay; 12. Paraguay;

Portuguese colony Brazil.

Empire Brazil.

Existing Political Divisions.

13. Patagonia; 14. Costa Rica, 15. Mosquitia; 16. Guatemala; 17. Honduras; 18. Nicaragua; 19. San Salvador; 20. Hayti; 21. San Domingo. The colonies belong to Britain, Denmark, Sweden, Holland, France, and Spain. Patagonia is merely the geographical name of a district of Chili, occupied by independent tribes of Indians; Mosquitia, or the Mosquito coast, is a small Indian state ruled by a native king; and Hayti is a negro republic proclaimed in 1867. For detailed accounts of these various states and colonies we refer to the articles under the proper heads. At present we must confine ourselves to a brief notice of the more important ones.

The United States were colonised a century later than Spanish America; but their brilliant and rapid progress shows in a striking light how much more the prosperity of nations depends on *moral* than on *physical* advantages. The North Americans had no gold mines, and a territory of only indifferent fertility, covered with impenetrable woods; but they brought with them intelligence, industry, a love of freedom, habits of order, and a pure and severe morality. Armed with these gifts of the soul, they have converted the wilderness into a land teeming with life and smiling with plenty; and they have built up a social system so pre-eminently calculated to promote the happiness and moral improvement of mankind, that it has truly become the "envy of nations." The republic is bounded on the north by Canada, on the south-west by Mexico, and on the other sides by the sea. At present (1874) it consists of thirty-seven states, with one *district* and eleven *territories*, which latter will be converted into *states* as soon as each acquires a sufficient population. The extent of the country, including the Indian lands stretching west to the Pacific Ocean, over which it claims a right of pre-emption, embraces 3,603,844 square miles of land. The agriculture of the United States partakes to some extent of a tropical character. The sugarcane is cultivated in Louisiana, Florida, and other states as far north as the latitude of 31½°. Cotton is raised in all the south-east states S. of the 37th parallel, and tobacco chiefly in the middle states. Wheat succeeds in the middle and northern states, and maize thrives in every part of the Union. Agriculture is conducted with considerable skill; but the "high farming" practised in England would not pay in America, where money is of much value and land of little. Scarcely any portion of the soil is rented in the United States: the farmers are almost universally proprietors; and when their property is extensive, which rarely happens, it is soon broken into small occupancies under the law of equal division. The advance the Americans have made in manufactures may be judged of from the fact that in 1870, according to the census then taken, there were upwards of

35,000 operatives employed in 969 cotton factories, and 77,870 in 1938 manufactories of woollen goods. The iron industries gave employment to upwards of 140,000 hands, the iron produced in the country reaching nearly two millions of tons. In the useful arts generally America is on a level with France and England. The internal commerce of the United States is conducted with extraordinary spirit. The amount of capital expended on roads, canals, harbours, bridges, and other public works, is very great. The length of the lines of railway open for traffic now exceeds 70,000 miles, and is rapidly increasing. The extent of the foreign trade of the country, and the amount of its shipping, place it next to Great Britain in the list of commercial nations.

The population of the United States in 1870 was } by census.....	38,558,371
In 1800 it was .....	5,308,483
Increase in 70 years.....	33,249,888

Since 1800 the rate of increase has been remarkably uniform at nearly 3½ per cent. per annum. In 1871 the

number of immigrants was 346,938, of whom 198,843 migrated from the British Isles, 107,201 from Germany, 6030 from China, and the remainder from British North America, Sweden, Norway, France, Austria, Italy, Switzerland, Denmark, and Russia.

Slaves were first introduced in 1619. In 1775 slavery was abolished in Rhode Island; in 1780 Massachusetts abolished it; then numerous northern states followed, and in December 1865 slavery was abolished throughout the United States. By subsequent amendment of the constitution all negroes were admitted to all the privileges of citizenship. Thus it was enacted on March 30, 1870, that "no discrimination should be made in the United States among the citizens of the United States in the exercise of their elective franchise, or in the right to hold office in any state, on account of race, colour, nativity, property, education, or creed." Every person born or naturalised in the United States is recognised to be a citizen thereof.

The American government is a pure representative democracy in which the people are recognised as the fountain of all power; and the sole object of all its mechanism is to give effect to their deliberate opinions. The federal government and the governments of the separate states are constituted on the same plan. The legislature consists in every case of two bodies, a House of Representatives chosen for one or two years, and a Senate for a period varying from two years to six—all chosen by popular election, except in the case of the Federal Senate, which is elected by the legislatures of the thirty-seven states. The President holds his office for four years, but is occasionally re-elected for four years more.

The characteristic facts in the condition of America are the non-existence of titles, of privileged classes, of corporations in our sense of the term, of a landed aristocracy, of mendicancy except to a very limited extent, and of an endowed church; the cheapness and efficiency of its government, the universality of education, the omnipresence of its periodical press, the high feeling of self-respect which exists in the very humblest classes, and the boundless spirit of enterprise which pervades all classes of society. The higher classes are less polished than in England, the middle are perhaps less carefully instructed; but the American people, taken collectively, are at least as well educated and have as much intelligence and manliness of character as any other nation in the world.

In 1867 the territory formerly known as Russian America was purchased by the United States, and called Alaska. It occupies the north-west corner of the continent, and extends along the coast as far south as Mount Elias, where it is bounded by British Columbia and the southern end of Prince of Wales Island, in 54° 40' N. It comprises an area of about 570,390 square miles. Furs and fish are the most valuable commodities. Sitka is the capital. It is situated on an island in 57° 2' 45" N. and 135° 17' 10" W. It has a population of over 2000 persons. The Yukon river, which is about 2000 miles long, flows through the territory.

British North America is bounded on the south by the United States, on the north by the Arctic Ocean, and on the west by Alaska. In 1867 the provinces of Ontario (formerly Upper Canada), Quebec (formerly Lower Canada), Nova Scotia, New Brunswick, Manitoba (formerly Hudson's Bay Territory), and British Columbia, were united under the title of "The Dominion of Canada," while Newfoundland and Prince Edward Island still remained independent. The executive power is vested in the sovereign of the British empire, but is carried out by a Governor-General and Privy Council. The Parliament consists of a Senate and a House of Commons. The senators are nominated for life

by the Governor-General, and are 75 in number. The members of the House of Commons are elected by the people in the proportion of one member for each 17,000 souls. The seat is retainable for five years, and each member is allowed a salary and travelling expenses. Ottawa is the capital of the Dominion. According to the latest census, taken on April 3, 1871, the area and population of the several provinces are as under:—

	Area, square miles.	Population.
Ontario .....	121,260	1,620,842
Quebec.....	210,020	1,191,505
Nova Scotia .....	18,660	387,800
New Brunswick .....	27,105	285,777
Manitoba.....	2,891,734	111,963
British Columbia.....	213,000	50,000
	<hr/>	<hr/>
	3,481,779	3,647,887
Newfoundland (1869).....	40,200	146,536
Prince Edwards Island (May 1871)	2,173	94,021

In 1871 the Dominion had 2854 miles of railway open, 1173 miles in preparation, and 3000 miles for which concessions had been granted by the government. A line has been projected to extend from Lake Superior to the Pacific Ocean.

Brazil is the largest state in South America, and enjoys the greatest combination of natural advantages. It is bounded on the south, west, and north, by La Plata, Paraguay, Uruguay, Bolivia, Peru, Ecuador, Colombia, Venezuela, and Guiana. Embracing an area of 3,100,000 English miles, it is nearly as large as Europe, and is capable of supporting a much greater population. Its climate is probably cooler and more salubrious than that of any other extensive tropical country; and every part of its soil is rich and fruitful, as its magnificent forests and the exuberance and boundless variety of its vegetable productions attest. Its commercial advantages are admirable. No country in the new world has the same facilities for carrying on intercourse with Europe and with all its neighbours. The Amazon, with its numerous branches, the Parana, the Tocantins, the St Francisco, and other streams, supply the most remote parts of the interior with easy means of communication with the sea. Brazil possesses iron, copper, and probably all the other metals; but her mines of gold and diamonds are remarkably rich. Her most valuable productions for exportation are cotton, sugar, coffee, hides, tobacco, vanilla, dyewoods, aromatic plants, timber, &c. Her commerce is much greater than that of all the Spanish colonies put together. The Brazilians are lively, irritable, hospitable, but ignorant, superstitious, and rather inclined to indolence. Their acquisition of independence in 1822, however, worked like a charm, and produced an extraordinary change in their industry, opinions, and modes of thinking. There are numerous schools, but although the education is gratuitous, they are not well attended. The advance literature has made will be allowed to be great when it is remembered that printing was unknown in the country in 1807. According to the constitution introduced by Dom Pedro, the legislature consists of a Senate of 52 members, who hold their places for life, and a House of Congress of 107, elected by the people for four years; upon the acts of both of which bodies the emperor has a negative. The members of the lower house are chosen by elections of two stages. The householders of a parish meet and appoint one elector for every thirty of their number, and the electors thus chosen meet in districts and choose the deputies. The members of both houses receive salaries. The executive power is invested in the emperor assisted by a ministry and a council of state.

The population of Brazil amounted to 3,671,558, according to returns published in 1848, and procured probably for the purpose of taxation. This was exclusive of the wander-

ing Indians. In 1823 it was estimated at 4,000,000 by Humboldt. M. Schœffer carries it to 5,700,000, and an estimate for 1867 makes it 9,858,000, comprising 8,148,000 free persons, and 1,674,000 slaves. The census taken in 1872 gives a population of 10,095,978, including 1,683,864 slaves.

Brazil, unlike the Spanish American provinces, has remained, subject to its ancient sovereign; and its government, from being colonial, has become imperial and independent, without any violent revolution. The result has been greatly in favour of the peace and prosperity of the country. See BRAZIL.

The portion of South America next to the isthmus includes the states of Venezuela, Colombia, and Ecuador. From 1820 till 1831, when a separation took place, it formed one state under the name of Colombia; which name has recently been assumed by the republic long known as New Granada. The territories of these three states are bounded on the south by Peru, on the south-east and east by Brazil and Guiana, on the other sides by the sea, and embrace an area of 1,020,000 square English miles. The soil is fruitful and the climate salubrious, except along the coast and in a few other low situations. The eastern part consists chiefly of the llanos or steppes of the Orinoco, which are very hot; the western, of the mountain ridges of the Andes, which support tracts of table-land where the blessings of a temperate climate are enjoyed, and the cerealia of Europe can be successfully cultivated. The tropical vegetation extends to the height of 4000 feet; from 4000 to 9000 is the region where wheat, barley, and leguminous plants thrive. Above the level of 9000 feet the climate becomes severe; and at 15,700 feet vegetation ceases. The situation of Colombia is highly favourable for commerce. It has excellent ports on both seas; and being mistress of the isthmus of Panama, it has superior facilities for establishing a communication from the one to the other. The Orinoco and the Amazon afford the inmost districts of Venezuela and Ecuador the advantages of water carriage to the ocean. The Cassiquiare, an intermediate channel, by which the Orinoco bifurcates or connects with the Amazon (a remarkable hydrographical phenomenon), is within the limits of Venezuela. The territory contains much gold and silver—the former in alluvial deposits: it has mines of copper and mercury also, with platinum, iron, and coal. Its tropical productions are similar to those of Brazil; but it has as yet cultivated few articles for foreign markets, and its exports are inconsiderable. The civilised population of this country is chiefly located in the districts near the coast, and in the high valleys or table-land of the Andes. Its amount, according to the *Statesman's Year-Book*, is—

Venezuela.....	1,564,433
Colombia.....	2,794,473
Ecuador.....	1,300,000
	<hr/>
	5,658,906

It is always of importance to know in what proportions the different races are blended, but on this subject we have only approximate data. In Colombia the whites form about half of the population, the Indians about one-third, and the negroes about one-tenth, the remainder being of mixed blood. In Venezuela the whites form about one-third, the Indians about one-thirtieth, and Zamboes (from Indians and negroes) about one-half. In Ecuador the proportions are, roughly—whites one-sixth, Indians nearly one-half, negroes one-thirteenth.

All the three states are republican. See VENEZUELA, COLOMBIA, and ECUADOR.

The Argentine Republic, or La Plata, is, in point of natural advantages, the second state of importance in South

Argentina Republic, or La Plata. America. It is bounded on the west by Chili; on the north by Bolivia; on the east by Paraguay, Brazil, Uruguay, and the sea; and on the south by Patagonia. It embraces an area of 515,000 square miles if we include Tucuman, Salta, Santiago del Estero, and Jujuy, which scarcely acknowledge its authority. Nearly the whole territory of this republic consists of open plains destitute of timber, called *pampas*, extending from the Atlantic and the river Paraguay to the Andes. The eastern part of these plains exhibits a vigorous growth of herbage, intermixed with a forest of gigantic plants, 9 or 10 feet high, which have been called thistles, but are now known to be artichokes; in the middle they are covered with grass; and the western division, which extends to the foot of the Andes, consists of barren sandy plains, thinly sprinkled with shrubs and thorny trees. The openness and dryness of the country, however, render it healthy; and by the Parana, the Paraguay, and their branches, it possesses a great extent of natural inland navigation. It has mines of gold, silver, copper, lead, and probably iron; but its mineral riches have been greatly diminished by the separation of Potosi, Cochabamba, La Paz, and other provinces now forming part of Bolivia. The force of this republic lies almost entirely in the wealth, intelligence, and commercial spirit of its capital, Buenos Ayres, which contains 150,000 souls, including a large proportion of foreigners. A small number of *estancias*, or grazing farms, are sparingly diffused over its boundless plains, the proprietors of which keep multitudes of horses and mules, flocks of sheep, and vast herds of cattle; the latter being chiefly valued for their skins. These people are a bold, frank, hardy, half-civilised race, who live isolated in the wilderness, and scarcely acknowledge any government. The census of 1869 gives a total population of 1,736,922. See ARGENTINE REPUBLIC; and for the two small states formed out of the north-eastern portion of its territory, see PARAGUAY and URUGUAY. Entre Rios, formerly a separate state, is now a province of La Plata.

Chili. Chili extends along the coast of the Pacific from 24° to 56° of south latitude: its length is 2270 miles; its breadth varies from 40 to 200; and its surface, exclusive of Araucania, which has an area of 88,000 sq. miles, is estimated at 130,977 English square miles. The country consists properly of the western slope or declivity of the Andes, for the branches of the mountains running out in tortuous directions from the main trunk reach to the sea-shore. It enjoys an excellent and healthful climate; severe cold is unknown in the inhabited parts, and the heat is seldom excessive. The useful soil bears a small proportion to the entire surface of the country, consisting merely of the bottom of the valleys. It has rich mines of gold, silver, and copper in the northern provinces; but very few of them can be worked in consequence of the absolute sterility of the adjacent country. Its two northern provinces, occupying 450 miles of the coast, are nearly perfect deserts. The soil continues extremely dry, and yields nothing without irrigation, till we reach the latitude of 35°; and it is believed that not one-fiftieth part of the country is fit for cultivation. But south of the river Maule the land is covered with fine timber, and bears crops of wheat and other grain without the aid of any other moisture than what is supplied by the atmosphere. This is in truth the fine and fruitful part of Chili; and the project was once entertained of selecting its chief town, Concepcion, for the seat of the government. Chili has no manufactures, and is unfavourably situated for commerce. It has no navigable rivers, while its mountainous surface is an obstacle to the formation of roads; but nevertheless it has now upwards of 500 miles of railway opened. A representative constitution was established in Chili in 1833. An enumeration dated 1869 makes the population, exclusive of Araucania (with 70,000 aborigines), 1,938,861. See CHILI.

Peru may be regarded as a continuation of Chili, consisting of the western declivities of the Andes, from the 4th to the 22d degree of south latitude, with the addition of a considerable tract on the east side of the mountains, between the 4th and 15th parallels. There are few countries in the world which have a more singular physical character than the western part of Peru. It is a belt or zone of sands, 1240 miles in length and from 70 to 600 in breadth, with inequalities of surface which might be called mountains if they were not seen in connection with the stupendous background of the Andes. This long line of desert is intersected by rivers and streams, which are seldom less than 20 or more than 80 miles apart, and on the sides of which narrow strips of productive soil are created by means of irrigation. These isolated valleys form the whole habitable country. Some of the large rivers reach the sea; the smaller are either consumed in irrigating the patches of cultivated land or absorbed by the encompassing desert, where it never rains, where neither beast nor bird lives, and a blade of vegetation never grew. No stranger can travel from one of these valleys to another without a guide, for the desert is trackless; and the only indications of a route are an occasional cluster of bones, the remains of beasts of burden that have perished. Even experienced guides, who regulate their course by the stars, the sun, or the direction of the wind, sometimes lose their path, and they almost inevitably perish. Of a party of 300 soldiers thrown ashore by a shipwreck in 1823 on one of these desert spaces, nearly a hundred expired before they reached the nearest valley. Ignorance and wonder have been busy with this singular region: legends are current, which tell that descendants of the ancient Peruvians have lived in some of these mysterious valleys, hid from the knowledge of their merciless invaders, since the days of the Incas. We have no reason to believe that more than one acre in a hundred of maritime Peru will ever be available for the sustenance of mankind. The country has two advantages—its mines of the precious metals, and a temperate and delightful climate, in consequence of the absence of rain and the fogs which intercept the solar heat. It can never be rich in the proper sense of the term, or make much progress in the improvements which depend upon a dense population. Like Chili, it has no navigable rivers—and nature has deprived it of the means of forming good roads. There are indeed few countries in the world whose natural advantages have been so much overrated as Peru; and it requires little sagacity to discover that its future career cannot correspond with its past celebrity. The districts east of the Andes, which have a hot climate accompanied with a rich soil, will ultimately be the most valuable part of the country; but their secluded situation and want of communication with other countries must keep them long in a backward state. The government is republican. Peru comprehends a surface of 502,760 square miles; the capital, Lima, contained in 1862 a population of 121,370. In that year a rough calculation was made which gave 3,199,000 as the entire population of the republic. It was also estimated that the proportions of races were:—

Indians.....	57 per cent.
Mixed races.....	23    "
Spaniards, Negroes, Chinese, &c.....	20    "

Bolivia, or Upper Peru, lies eastward of Lower Peru, and is bounded on the south by the Argentine Republic, and on the north and east by Brazil. It is of an irregular form, and comprehends a space of 473,300 square miles. The climate is pleasant and healthful, the soil is generally dry, and in the eastern parts, as well as the elevated table-land, its aridity produces barrenness. Nature, however, as a compensation for its other disadvantages, has bestowed upon it some of the richest mines in the world. The country was erected

into an independent state only in 1826, and named Bolivia in honour of its liberator Bolivar. It has a small strip of barren territory on the shores of the Pacific Ocean, between the 22d and 25th parallel; but it is, properly speaking, entirely an inland country, and more deficient in the means of communicating with foreign nations than any other state in America. See BOLIVIA.

Guatemala or "Central America" originally occupied all the narrow part of the continent from the 83d to the 94th degree of west longitude, extending 800 miles in length, and covering a space of 130,000 square miles. The surface of the country is hilly, and in most parts mountainous; the climate warm and very moist. The mineral wealth of the country is not great; but this is compensated by the richness of its soil and its excellent commercial position. It was a federal republic, but its five provinces have now become independent states. Humboldt estimated the population of the five states at 1,600,000. According to a statement furnished to Mr Thomson, a former British envoy by the government, it was 2,000,000; while the most recent of the estimates made by the resident officials give a total of 2,335,019, viz. :-

Guatemala (1865).....	1,180,000
St Salvador (1870).....	434,520
Honduras.....	250,000
Nicaragua.....	350,000
Costa Rica.....	120,499
	2,335,019

The proportions of the different races have been estimated as follows :-

	Humboldt.	Thomson.
Whites and Creoles.....	20 per cent.	20 per cent.
Mixed classes.....	23    "	40    "
Indians.....	52    "	40    "

Mexico is the most populous and powerful of all the new states erected in America since the commencement of the present century. Previous to the war with the United States it embraced an area of 1,600,000 square miles, which was reduced to 1,030,442 by the cession of the northern provinces in 1848. About three-fourths of the surface consists either of mountains or table-land, raised from 5000 to 10,000 feet above the sea. Owing to this extraordinary elevation, even those parts of the country which lie within the torrid zone (the low ground on the coast excepted) enjoy a dry, cool, and salubrious atmosphere; but this advantage is counterbalanced by the insufficient supply of moisture and the rapid evaporation resulting from the same cause, which render the soil generally rather arid, and in many parts absolutely barren; by the smallness of the rivers and the almost entire absence of inland navigation; and by the obstacles which the steep and rugged ascents from the coast present to land-carriage. The republic is, besides, almost destitute of ports on the Atlantic side. Mexico is extremely rich in the precious metals; and there are few regions upon which nature has lavished so great a variety of vegetable productions, or where plants fitted to the coldest and the hottest climates may be seen so nearly in juxtaposition. The low ground on the east coast is admirably adapted for raising sugar; and no country is more favourably situated for growing the other great articles of West India produce—coffee, cotton, cocoa, indigo, and tobacco. The raising of *bread-stuffs*—as they are termed by the Anglo-Americans—wheat, maize, and barley, with potatoes, the cassava root, beans, pumpkins, fruit, &c.—for domestic consumption, will necessarily be the chief branch of industry on the table-lands. The mines have never employed above 30,000 labourers; and their superior productiveness depends chiefly on two circumstances—the great abundance of the ore, which is only of poor quality, and the comparative facility with

which they can be worked owing to their being generally situated in fertile districts, where provisions, wood, and all materials can be easily procured.

Mexico has had her full share of the ignorance and superstition which belonged to Spain; and these evils, with her internal dissensions and her rapacious, immoral, and intolerant clergy, are great obstacles to her improvement. That excessive inequality of fortune which corrupts both extremes of society has been nowhere in the world more prevalent than in Mexico. Individual proprietors possessed immense tracts of land and boundless wealth, while all the great towns swarmed with beggars, and thousands fell a sacrifice to famine from time to time. The Mexican constitution, which is federal and almost a literal copy of that of the United States, was established in 1824. The distinction of *castes*, which was maintained in the greatest rigour under the colonial system, has now disappeared, and power and office are open, not only legally but practically, to men of all colours. The African blacks formed an extremely small proportion of the Mexican population at all times; and since the revolution slavery has ceased. The number of inhabitants was estimated at 6,800,000 by Humboldt in 1823, and classed as follows:—

	Numbers.	Proportions.
Whites.....	1,230,000	19 per cent.
Mixed races.....	1,860,000	27    "
Indians.....	3,710,000	54    "

Mr Ward states that very few of the whites, so called, are free from a mixture of Indian blood; and now when the odious distinctions founded on complexion are abolished, they readily acknowledge it. Mr Ward estimated the population at 8,000,000 in 1827. In 1869 that of Mexico with its present boundaries was stated to be 9,176,082. See MEXICO.

Hayti, called formerly Hispaniola and St Domingo, was a colony belonging partly to France and partly to Spain till 1791, when the blacks rose in arms, killed a number of whites, and expelled the rest. The attempts of England in 1793, and of France in 1801, to conquer the island, both failed, and Hayti has at length been acknowledged as an independent state by all the great powers, including France. The island, which contains about 28,000 square miles, is remarkably fertile; but its climate, like that of the West Indies generally, is rather unhealthy. The population, which before the revolution was estimated at 600,000, is now said to amount to 900,000 or 1,000,000, and it is almost entirely composed of blacks and mulattoes. The island formed one state till 1844, when the eastern or Spanish portion revolted, and established its independence. It is now the republic of "Dominica," ruled by a president, while the western portion, retaining the name of Hayti, was formed into an empire under Faustin I.; but in 1867 a republican constitution was proclaimed. After long negotiations, the French government agreed in 1838 to acknowledge the independence of Hayti on condition of the latter paying 60,000,000 of francs by small annual instalments continued for 30 years. The money was destined chiefly to indemnify the French proprietors who were chased from the island in 1791. Nothing has been paid of late years.

The multifarious nature of the subject prevents us from attempting any description of the West India colonies, insular and continental. The islands have been variously denominated, but the most convenient division seems to us the following:—1. The Great Antilles, comprehending Cuba, Hayti, Jamaica, and Porto Rico; 2. The Small Antilles, extending in a semicircle from Porto Rico to the coast of Guiana; 3. The Bahama Isles, about 500 in number, of which, however, only a small number are inhabited. The British colonies are 18 in number, viz., 16 *insular*—Jamaica, Antigua, Barbadoes, Dominica, Grenada, Montserrat, Nevis, St Kitts, St Lucia, St Vincent, Tobago,

Tortola, Trinidad, Bahamas, Bermuda, Falkland Island ; and 2 *continental*—British Guiana and Honduras. The colonies contained a population of 1,228,967 in 1871, of whom probably four-fifths were persons of colour.

The Spanish colonies are Cuba and Porto Rico. Cuba has an area of 45,883 square miles, and in 1867 the population was 1,414,508. Porto Rico has an area of 3530 square miles, and in 1866 a population of 646,362 persons. In 1867 there were upwards of 700,000 slaves in these two colonies.

In August 1872 the Spanish government issued a decree ordering that arrangements should be made for the gradual emancipation of the slaves ; and in December 1872 a bill was laid before the Spanish Cortes for the abolition of slavery in Porto Rico in 1873 ; so that probably slavery will soon be extinct throughout the whole of America.

The French colonies in the West Indies include Martinique, Guadeloupe, and some smaller isles ; and on the continent, Guiana. According to a recent authority the population of these colonies was 318,934.

The Dutch have Surinam on the continent, with the islands of Curaçoa, St Eustatius, and St Martin.

In 1870 the population of the islands was 35,482, and of Surinam 59,885, occupying an area of 2812 geographical square miles. Slavery has ceased since July 1863, when the Dutch government compensated the owners for 44,645 slaves.

The Danes have the small islands of Santa Cruz and St John, containing a population of 24,698 in 1860, of whom most are freed slaves, and St Thomas, which had in the same year a population of 13,463. St Bartholomew, another of the Lesser Antilles, belongs to Sweden.

The problem of making a grand highway for travel and traffic from the Atlantic to the Pacific, either across the breadth of the American continent or by taking advantage of the narrow isthmus that joins its northern to its southern portion, has been the subject of many schemes since its western as well as its eastern shores have been inhabited by enterprising nations, skilled in commerce and in mechanical arts. It is interesting to remark that, whereas the hope of sailing to India by a westward route was the motive which guided the navigators of the 15th century to the discovery of America, the means of internal communication for this part of the earth, and the geographical exploration of its remote extremities, have been more recently advanced by the desire of finding a path in this direction to the Asiatic resorts of mercantile activity. Arctic voyagers were at first invited to the icy seas of high latitudes by the dream of a north-west passage to China and the East Indies. It was a passage by sea from the Atlantic to the Pacific which Sir John Franklin went to seek in his last expedition in 1845, but which Captain Maclure effected in 1856, though by an opposite course from Behring's Strait to Baffin's Bay. But it is scarcely possible that this route along the north coasts of America should ever be habitually frequented by mariners going to and fro between the two oceans. At the opposite extremity of the continent arrangements have lately been made to substitute a shorter way to the Pacific for that round Cape Horn by improving the navigation of the Strait of Magalhaens, which separates Tierra del Fuego from the south portion of the mainland. The project of cutting a canal through the central American isthmus has often been discussed. There can be no doubt of the practicability of a system of inland navigation from the Atlantic coast by the river San Juan to Lake Nicaragua, and thence by a canal to the neighbouring Lake Managua or Leon, with a short artificial channel of exit to the Pacific. A different route, of combined river and canal navigation, has more recently been proposed, which would cut off the whole of the isthmus from the body of South America—entering the uppermost part of that mainland

by the river Atrato from the Gulf of Darien, ascending this river 150 miles, then following up the course of the Napipi or the Bajaya, tributaries of the Atrato—crossing the coast range of hills by a canal with several locks, and descending to the Pacific either in Limon Bay or in the Gulf of Cupica. But these projects could be adapted only to the admission of vessels of smaller size than such as in the present day are commonly employed for commercial traffic between distant regions of the world. In spite of the grand example of the Suez Canal, it seems likely that, in a country tolerably productive of wealth and capable of supporting population, the more profitable means of providing for a through traffic will be found in railroads, which serve also for the accommodation of intermediate districts. In this class of undertakings North America has of late years displayed a wonderful degree of active enterprise. The line of 60 miles from Aspinwall, near Chagres, across the neck of land, which is there so narrow, to Panama, on the Pacific side, though situated in the territory of a Spanish republic, was constructed by citizens of the United States, expressly for the traffic between New York and San Francisco. But since that first opening of a gateway of communication with California, Australia, or China, for the travellers and merchandise of the Atlantic states or of Europe, the whole breadth of the continent where it widens, in latitudes between 35° and 45° N., all belonging to the United States, has been traversed by a continuous railroad system. The middle link of this system is the Union Pacific Railway, 1600 miles long, from Omaha, on the Missouri, in the state of Nebraska, through that state, up the course of the Platte river, and through Wyoming, Idaho, Utah, and Nevada, crossing the summits of three great mountain ranges from 7000 feet to 8250 feet high, and meeting the Central Pacific Railway of California. This line was through a barren desert for several hundred miles, in the arid uplands of Idaho and the salt plains of Utah; but its construction has served to bring the commercial cities of the Atlantic and of the Pacific within six or seven days' journey of each other. Three or four rival projects of railways across the width of the United States, or extensions of the existing railway system westward from the Mississippi and Missouri, have been taken up with some promise of their realisation. The one which offers the greatest advantages is that designed to ascend the long and broad valley of the Arkansas river, and to cross the Rocky Mountains with a southerly inclination into New Mexico, opening up the Rio Grande and San Juan country, which is said to be very rich, and thence passing on to the Grand Cañon of the Colorado, and to the Nevada mining district. Near the northern frontier of the United States territory, where it borders on the British Dominion of Canada, another continental line from east to west is now in progress—that is, from the western extremity of Lake Superior, through Minnesota, Dakotah, and Washington, to Puget Sound, just below Vancouver Island. But the work of this kind that will be most interesting to many of our readers is that undertaken in 1871 by the government of the Canadian Dominion. By the extension of the Dominion beyond the Rocky Mountains to include British Columbia, and the incorporation of the vast territories of the Hudson's Bay Company, nearly the whole of North America above the 49th parallel is united in one grand British colonial province, and the Canadian Pacific Railway will do much to promote a compact union between the widely-scattered communities of Her Majesty's subjects on this great continent. The line will proceed from a port on the northern shore of Lake Superior, westward to the Red River settlement, near Lake Winnipeg, now forming the province of Manitoba ; and will thence be conducted up the valley of the river Saskatchewan to the foot of the Rocky

Mountains, which it will cross by the Yellowhead Pass, to descend along the Thomson and Fraser rivers, in British Columbia, till it finally reaches the coast of the Pacific Ocean, possibly connecting Vancouver Island with the mainland by a bridge over the narrowest part of the straits. In connection with the Grand Trunk and other railways of Canada, supplemented by the Intercolonial Railway between Lower Canada, New Brunswick, and Nova Scotia, this new western line will afford the most direct and expeditious means of transit across North America, and will probably become the favourite route for mails and passengers and light traffic from Europe to China. It will open a country which abounds in mineral wealth, especially of iron, coal, and copper; while the Saskatchewan valley, and the belt of fertile soil lying at the base of the Rocky Mountains (where the climate, as far north as Fort Dunvegan on the Peace river, is not more severe than that of Toronto, though in latitudes beyond 56° N., nearly thirteen degrees above that place), are capable of sustaining an agricultural population. The progress of railroad construction in North America, stimulating and assisting the development of industrial resources with amazing rapidity, is a feature of high importance in the most recent phases of the world's civilisation. Its average rate of advance in the United States alone, during the five years preceding January 1873, was nearly 6000 miles annually of new railway; and the aggregate length of railway lines in the Union, all completed and in actual working, was then computed at 71,000 miles. British America, as we have seen, will not be left deficient of similar appliances for its internal improvement.

A great auriferous deposit was discovered in Upper California in the end of 1847, just before its formal cession to the United States. It is situated in the valley of the Sacramento river, and its principal branch the Joaquin, and is believed to extend over a range of country 200 miles in length, or more. The gold is found in its virgin state in small grains in three different situations—*first*, in sand and gravel beds; *secondly*, among decomposed or disintegrated granite; and *thirdly*, intermixed with a friable talcose slate standing in vertical strata, and containing white quartz, interlaminated or in veins. The largest pieces of gold are found in and near the talcose slate rocks, over which the streams flow; but the finer particles and scales have been carried down by the water to the lowest part of the valleys. It was known before that gold existed in the country; but the wonderful richness of the deposit was only discovered in 1847, in making a mill-race on American Fork, a small branch of the Sacramento. It soon became widely known, and attracted multitudes of persons, first from the neighbouring districts, and by and by from all parts of the world. The population, which was estimated at 15,000 in 1848, had increased to 92,000 in 1850, and in 1870 was found to be 560,247.

Humboldt gave the following estimate of the entire population of America in 1823:—

	Number.	Proportion.
Whites ..	13,471,000	38 per cent.
Indians.....	8,610,000	25 "
Negroes	6,433,000	19 "
{ Slaves, 5,000,000 }		
{ Free, 1,433,000 }		
Mixed races .....	6,428,000	18 "
	<hr/> 34,942,000	

Bollaert made the following estimate for 1863:—

	Number.	Proportion.
Whites .....	38,074,423	52 per cent.
Indians.....	11,014,710	15 "
Negroes.....	12,122,030	17 "
Mestizoes.....	6,031,000	16 "
Mulattoes.....	4,037,440	
Zamboes.....	1,563,230	
	<hr/> 72,842,833	

What will be the number of the inhabitants of the new continent two or three centuries hence, and of what races will it consist? Setting aside the negroes, to simplify the question, and the Indians, who will gradually disappear, it is evident that the soil of America is destined to be occupied by two races, who may be designated as the Anglo-Saxon and the Spanish-Indian. In the latter the Indian blood greatly predominates, for the Creoles or pure progeny of the Spaniards probably do not constitute more than 20 per cent. of the population, while the civilised Indians may amount to 50, and the Mestizoes to 30.

The whites in the United States were in 1850 .....	19,500,000
The population of British America.....	2,500,000
	<hr/> 22,000,000

The population of Spanish and Portuguese America, exclusive of slaves, was in round numbers..... 20,000,000

The Anglo-Saxon population in America increases at 3 per cent. annually, and doubles its numbers in 25 years.

Its amount in 1850 was .....	22,000,000
In 1875 it will be.....	44,000,000
In 1900.....	88,000,000
In 1925.....	176,000,000

A population of 176,000,000 spread over the territories of the United States and Canada would only afford an average of 40 persons to each square mile, about 1-7th part of the density which England now exhibits, and could occasion no pressure. But let us suppose the rate of increase after 1925 to fall to 2 per cent., the period of doubling will then be 35 years.

In 1960 the number will be.....	352,000,000
In 1995 do. do. ....	704,000,000

Suppose the rate again to decline to 1½ per cent., which scarcely exceeds that of England and Prussia, the period of doubling will then be 50 years.

In 2045 the number will be.....	1,408,000,000
In 2095 do. do. ....	2,816,000,000

Let us now compare with this the growth of the Spania-Indian population, doubling its numbers in 75 years.

Its amount in 1850 was.....	20,000,000
In 1925 it will be.....	40,000,000
In 2000 do. ....	80,000,000
In 2075 do. ....	160,000,000
In 2095 (interval of 20 years).....	200,000,000

It hence appears that, supposing both races to have free space for expansion, the Anglo-Saxon population in 220 years from the present time will amount to 2816 millions, while the Spanish-Indian population will only have multiplied to 200 millions, or *one-fourteenth part* of the other. It will be shown by and by, on probable grounds, that the new continent, if fully peopled, could support 3600 millions, and there would consequently be room enough for both; but long before this density is attained the two races will inevitably come into collision. In new settlements, where the best lands are invariably first occupied and the inferior neglected, the population is always thinly diffused. The Anglo-Saxons will therefore crowd to the richer fields of the south, while millions of acres of their own poorer lands are still untenanted; for we may rest assured that before cultivation is extended to the third-rate soils on the north side of the boundary, means will be found to appropriate the first-rate soils on the south side. These may be acquired by purchase like the lands of Louisiana, or by conquest like those of New Mexico and California, but in one way or another they will be acquired. Nearly forty years ago M. de Tocqueville calculated that along the great space from the Gulf of Mexico to the Canadian lakes the whites were advancing over the wilderness at an average rate of 17 miles per annum, and that enlightened observer was powerfully impressed by the grandeur and solemnity of this deluge of men, for ever swelling and flowing onward,

to the west, the south, and the north, as "driven by the hand of God." Since he wrote the rate of progress has perhaps doubled, and every year will quicken its pace. If, then, we take a glance at the state of America at any future period, say 220 years hence (A.D. 2095), we must take the ratio of increase of the two civilised races as the prime element of our calculation. We may assume that the whole continent, from Behring's Straits and Hudson's Bay to Cape Horn, will be divided between the two races in some such proportion as their rate of growth indicates—it may be 10, 15, or 20 to 1. Supposing them to maintain a separate existence, the weaker race will probably be driven, like the Welsh before the English, into the mountainous and inhospitable regions. On the other hand, it is possible, and not improbable, that the smaller population may be absorbed into the mass of the greater, be incorporated with it, and adopt its language. The result, like other things in the womb of time, may be modified by causes yet unseen; but in whatever shape it may present itself, there is little risk in predicting that the Anglo-Saxon race is destined by its superior intelligence and energy to rule the New World from end to end. American statesmen now speak of the whole continent as the heritage of their people.

Paradoxical as the fact may appear, we are satisfied that the new continent, though less than half the size of the old, contains at least an equal quantity of useful soil and much more than an equal amount of productive power. America is indebted for this advantage to its comparatively small breadth, which brings nearly all its interior within reach of the fertilising exhalations of the ocean. In the old continent, owing to its great extent from east to west, the central parts, deprived of moisture, are almost everywhere deserts; and a belt round the western, southern, and eastern shores, comprises nearly all that contributes to the support of man. How much fruitful land, for instance, is there in continental Asia? If we draw a line from the Gulf of Cutch (near the Indus) to the head of the Yellow Sea, we cut off India and China, with the intervening Birman empire and the southern valleys of Thibet; and this space, which comprises only about one-fifth of the surface of Asia, embraces five-sixths of its productive power. Arabia, Persia, Central Thibet, Western India, Chinese and Independent Tartary are deserts, with scattered patches of useful soil not amounting to the twentieth part of their extent. Siberia, or Northern Asia, is little better, owing to aridity and cold together. Anatolia, Armenia, the Punjab, and a narrow strip along the western shores of the Pacific Ocean, north as far as the 60th parallel, compose the only valuable agricultural territory beyond India and China. Europe, which is merely the western margin of Asia, is all fruitful in the south; but on the north its fruitfulness terminates at the 60th or 62d parallel. Africa has simply a border of useful soil round three-fourths of its sea-coast, with some detached portions of tolerably good land in its interior. Of the 31,000,000 of square miles which these three continents occupy, we cannot find, after some calculation, that the productive soil constitutes so much as one-third, and of that third a part is but poor.

Now, in estimating the useful soil in America we reject—1. Most of the region north of the latitude of 53°, amounting to 2,600,000 square miles; 2. A belt of barren land about 300 miles broad by 1000 in length, or 300,000 square miles, lying on the east side of the Rocky Mountains; 3. A belt of arid land of similar extent situated on the east side of the Andes, between 24° and 40° of south latitude; 4. The desert shore of Peru, equal to 100,000 square miles; 5. An extent of 100,000 square miles for the arid country of Lower California and Sonora; and 6. An extent of 500,000 square miles for the summits of the Andes and the south extremity of Patagonia. These make an aggregate of 3,900,000

square miles; and this, deducted from 13,900,000, leaves 10,000,000 square miles as the quantity of useful soil in the New World.

The productive powers of the soil depend on two circumstances, heat and moisture; and these increase as we approach the equator. Now, it appears that the productive or rather nutritive powers of the soil will be pretty correctly indicated by combining the ratios of the heat and the moisture, expressing the former of these in degrees of the centigrade scale. Something, we know, depends on the distribution of the heat through the different seasons; but as we do not aim at minute accuracy, this may be overlooked.

Latitude.	Inches of Rain.	Mean Heat.	Product.	Ratio.
60	16	7	112	4
45	29	14	406	15
0	96	28	2688	100

Thus, if the description of food were a matter of indifference, the same extent of ground which supports four persons at the latitude of 60°, would support 15 at the latitude of 45°, and 100 at the equator. But the food preferred will not always be that which the land yields in greatest abundance; and another most important qualifying circumstance must be considered—it is labour which renders the ground fruitful, and the power of the human frame to sustain labour is greatly diminished in hot climates. We shall therefore consider the capacity of the land to support population as proportional to the third power of the cosine (or radius of gyration) of the latitude. It will therefore stand thus in round numbers:—

Latitude,	0°	15°	30°	45°	60°
Productiveness,	100	90	65	35	12½

In England the density of population is about 389 persons per square mile; but England is in some measure the workshop of the world, and supports, by her foreign trade, a greater population than her soil can nourish. In France the density of population is about 177; in Germany it varies from 100 to 200. On these grounds, we may assume that the number of persons which a square mile can properly sustain without generating the pressure of a redundant population is 150 at the latitude of 50°, and 26 is the sum which expresses the productiveness of this parallel. Then taking, for the sake of simplicity, 35 as the index of the productiveness of the useful soil beyond 30° in America, and 85 as that of the country within the parallel of 30° on each side of the equator, we have about 4,000,000 square miles, each capable of supporting 200 persons, and 5,700,000 square miles, each capable of supporting 490 person. It follows that if the natural resources of America were fully developed it would afford sustenance to 3,600,000,000 of inhabitants, a number nearly five times as great as the entire mass of human beings now existing upon the globe!

## AMERICAN LITERATURE

## I.—INTRODUCTORY.

The literature of the United States, while still half our own, is pervaded, to a degree not easily estimated, by a foreign element. The relationship between Englishmen and Americans, making them ignorant of their mutual ignorance, operates against the soundness of their judgment on each other's work. Community of speech, which ought to be a bond of union, is often a medium of offence; for it dispenses with a study of the language, and in studying a language we learn something also of the habits and social histories which are reflected in, and serve to interpret, distinctly alien literatures. Facility of travel, making it easy to acquire first impressions, is a temptation to such hasty estimates as many of the most accomplished Americans have formed of England, and many of the most accomplished Englishmen have formed of America. The least satisfactory works of some of their foremost writers, as Mr Hawthorne's *Old Home* and Mr Emerson's *English Traits*, are those associated with their transatlantic experiences. But of the mistakes on both sides, ludicrous and grave, we have had perhaps the larger share. Few Americans have ever so misconceived a British statesman as we misconceived Mr Lincoln, or gone so far astray in regard to any crisis of our history as we did in reference to the moving springs and results of their Civil War. The source of this greater ignorance lies not so much in greater indifference as in greater difficulty. England is one, compact and stable. The United States are many, vast, various, and in perpetual motion. An old country is a study, but a new country is a problem. Antiquity is brought to our firesides in the classics, till Athens and Rome

"To us are nothing novel, nothing strange."

We are more familiar with the Acropolis than with the Western Capitol—with Mt. Soracte than with the Catskills. Our scholars know more about Babylon than about Chicago. Dante immortalises for us the Middle Age; Plantagenet England is revived in Chaucer; the inner life of modern England has a voice in Tennyson and the Brownings. Where is the poet who will reveal to us "the secrets of a land," in some respects indeed like our own, but separated in other respects by differences which the distance of 3000 miles of ocean only half represents; which, starting on another basis, has developed itself with energies hitherto unknown in directions hitherto unimagined? Who will become the interpreter of a race which has in two centuries diffused itself over a continent, the resources of which are not more than half discovered, and which has to absorb within itself and harmonise the discordant elements of other races for whom the resources of the Old World are well-nigh exhausted? *Caret vate sacro*; but it does not want poetical aspirations as well as practical daring:

"This land o' ourn I tell ye's gut to be  
A better country than man ever see;  
I feel my sperit swellin' with a cry  
That seems to say, 'Break forth and prophesy.'  
O strange New World, that yet wast never young,  
Whose youth from thee by gripin' want was wrung,  
Brown foundlin o' the woods, whose baby bed  
Was prowled round by the Injun's cracklin' tread,  
An' who grew'st strong thru' shifts an' wants an' pains,  
Nursed by stern men with empires in their brains."

## II.—CONDITIONS AND CHARACTERISTICS OF AMERICAN LITERATURE.

The number of writers who have acquired some amount

of well-founded reputation in the United States is startling. The mere roll of their names would absorb a great part of the space here available for an estimate of the works which best represent them. Mr Griswold informs us that he has in his own library more than 700 volumes of native novels and tales; his list of "remarkable men" is like Homer's catalogue of ships. Almost every Yankee town has indeed its local representatives of literature, reflecting in prose or verse the impulses and tendencies of the time. But while America has given birth to more than a fair proportion of eminent theologians, jurists, economists, and naturalists, hardly any great modern country, excepting Russia, has in the same number of years produced fewer works of general interest likely to become classical; and Bishop Berkeley's prophecy of another golden age of arts in the Empire of the West still awaits fulfilment. This fact, mainly attributable to obvious historic causes, is frankly recognised by her own best authors, one of whom has confessed—"From Washington, proverbially the city of magnificent distances, through all its cities, states, and territories, ours is a country of beginnings, of projects, of designs, of expectations." The conditions under which the communities of the New World were established, and the terms on which they have hitherto existed, have been unfavourable to Art. The religious and commercial enthusiasms of the first adventurers to her shores, supplying themes for the romancers of a later age, were themselves antagonistic to romance. The spirit which tore down the aisles of St Regulus, and was revived in England in a reaction against music, painting, and poetry, the Pilgrim Fathers bore with them in the "Mayflower," and planted across the seas. The life of the early colonists left no leisure for refinement. They had to conquer nature before admiring it, to feed and clothe before analysing themselves. The ordinary cares of existence beset them to the exclusion of its embellishments. While Dryden, Pope, and Addison were polishing stanzas and adding grace to English prose, they were felling trees, navigating rivers, and fertilising valleys. We had time, amid our wars, to form new measures, to balance canons of criticism, to discuss systems of philosophy; with them

"The need that pressed sorest  
Was to vanquish the seasons, the ocean, the forest."

The struggle for independence, absorbing the whole energies of the nation, developed military genius, statesmanship, and oratory, but was hostile to what is called polite literature. The people of the United States have had to act their Iliad, and they have not had time to sing it. They have had to piece together the *disjecta membra* of various races, sects, and parties, in a παντοπόλιον πολιτειῶν. Their genius is an unwedded Vulcan, melting down all the elements of civilisation in a gigantic furnace. An enlightened people in a new land, "where almost everyone has facilities elsewhere unknown for making his fortune," it is not to be wondered that the pursuit of wealth has been their leading impulse; nor is it perhaps to be regretted that much of their originality has been expended upon inventing machines instead of manufacturing verses, or that their religion itself has taken a practical turn. One of their own authors confesses that the "common New England life is still a lean impoverished life, in distinction from a rich and suggestive one;" but it is there alone that the speculative and artistic tendencies of recent years have found room and occasion for development. Our travellers find a peculiar charm in the manly force and rough adventurous spirit of the Far West, but

the poetry of the pioneer is unconscious. The attractive culture of the South has been limited in extent and degree. The hothouse fruit of wealth and leisure, it has never struck its roots deeply into native soil. Since the Revolution days, when Virginia was the nurse of statesmen, the few thinkers of America born south of Mason and Dixon's line—outnumbered by those belonging to the single State of Massachusetts—have commonly migrated to New York or Boston in search of a university training. In the world of letters at least, the Southern States have shone by reflected light; nor is it too much to say, that mainly by their connection with the North the Carolinas have been saved from sinking to the level of Mexico or the Antilles. Whether we look to India or Louisiana, it would seem that the tropical sun takes the poetic fire out of Anglo-Saxon veins, and the indolence which is the concomitant of despotism has the same benumbing effect. Like the Spartan marshalling his helots, the planter lounging among his slaves was made dead to Art by a paralysing sense of his own superiority. All the best transatlantic literature is inspired by the spirit of confidence—often of over-confidence—in labour. It has only flourished freely in a free soil; and for almost all its vitality and aspirations, its comparatively scant performance and large promise, we must turn to New England. Its defects and merits are those of the national character as developed in the Northern States, and we must seek for an explanation of its peculiarities in the physical and moral circumstances which surround them.

When we remember that the Romans lived under the sky of Italy, that the character of the modern Swiss is like that of the modern Dutch, we shall be on our guard against attributing too much to the influence of external nature. Another race than the Anglo-Saxon would doubtless have made another America; but we cannot avoid the belief that the climate and soil of America have had something to do in moulding the Anglo-Saxon race, in making its features approximate to those of the Red Indian, and stamping it with a new character. An electric atmosphere, and a temperature ranging at some seasons from 50° to 100° in twenty-four hours, have contributed largely to engender that restlessness which is so conspicuous "a note" of the people. A territory which seems boundless as the ocean has been a material agent in fostering an ambition unbridled by traditionary restraints. When European poets and essayists write of nature, it is to contrast her permanence with the mutability of human life. We talk of the everlasting hills, the perennial fountains, the ever-recurring seasons. "Damna tamen celeres reparant coelestia lunæ—nos ubi decidimus"—In the same spirit Byron contemplates the sea and Tennyson a running stream. In America, on the other hand, it is the extent of nature that is dwelt upon—the infinity of space, rather than the infinity of time, is opposed to the limited rather than to the transient existence of man. Nothing strikes a traveller in that country so much as this feature of magnitude. The rivers like rolling lakes, the lakes which are inland seas, the forests, the plains, Niagara itself, with its world of waters, owe their magnificence to their immensity; and by a transference, not unnatural although fallacious, the Americans generally have modelled their ideas of art after the same standard of size. Their wars, their hotels, their language, are pitched on the huge scale of their distances. "Orphaned of the solemn inspiration of antiquity," they gain in surface what they have lost in age; in hope, what they have lost in memory.

"—That untravelled world whose margin fades  
For ever and for ever when they move,"

is all their own; and they have the arena and the expecta-

tions of a continent to set against the culture and the ancestral voices of a thousand years. Where Englishmen remember, Americans anticipate. In thought and action they are ever rushing into empty spaces. Except in a few of the older States, a family mansion is rarely rooted to the same town or district; and the tie which unites one generation with another being easily broken, the want of continuity in life breeds a want of continuity in ideas. The American mind delights in speculative and practical, social and political experiments, as Shakerism, Mormonism, Pan-tagamy; and a host of authors, from Emerson to Walt Whitman, have tried to glorify every mode of human life from the transcendental to the brutish. The habit of instability, fostered by the rapid vicissitudes of their commercial life and the melting of one class into another, drifts away all landmarks but that of a temporary public opinion; and where there is little time for verification and the study of details, men satisfy their curiosity with crude generalisations. The great literary fault of the Americans thus comes to be *impatience*. The majority of them have never learnt that "raw haste is half-sister to delay;" that "works done least rapidly, art most cherishes." The makeshifts which were at first a necessity with the Northern settlers have grown into a custom. They adopt ten half measures instead of one whole one; and, beginning bravely, like the grandiloquent preambles to their Constitutions, end sometimes in the sublime, sometimes in the ridiculous.

Many of the artistic as well as many of the social peculiarities of the United States may doubtless be traced to their form of government. After the most obvious wants of life are provided for, Democracy stimulates the production of literature. When the hereditary privileges of rank have ceased to be recognised, the utility, if not the beauty, of knowledge becomes conspicuous. The intellectual world is spurred into activity: there is a race in which the prize is to the swift. Everyone tries to draw the eyes of others by innumerable imperfect efforts with a large insignificant sum total. Art is abundant and inferior: whitewashed wood and brick pass for marble, and rhythmical spasms for poetry. It is acknowledged that the prevailing defect of Aristocratic literatures is formality; they are apt to be precise and restricted. A Democratic literature runs the risk of lawlessness, inaccuracy, and irreverence. From both these extremes the Athenian, the Florentine, and the Elizabethan classics were preserved by the artistic inspirations of a flexible tradition. The one is exemplified in the so-called Augustan ages of letters, in the France of Louis XIV. and the England of Queen Anne, when men of genius, caring more to perfect their style than to establish truth, more to captivate the taste than to stir the passions, moved with clipt wings in a charmed circle of thought. The other has its best illustration in the leaders of our own romantic schools, but its most conspicuous development in America; a country which is not only democratic but youthful without the modesty of youth, unmellowed by the past and untrammelled by authority, where the spirit of adventure is unrestrained by feelings of personal loyalty—where order and regularity of all kinds are apt to be misnamed subservience—where vehemence, vigour, and wit are common, good taste, profundity, and imagination rare;—a country whose untamed material infects the people, and diverts them from the task of civilisation to the desire of conquest.

American literature is cramped on another side by the spirit of imitation. It has been in great measure an offshoot or prolongation of our own. As English sculptors study at Rome and Naples, the most prominent Western artists in every department have almost invariably inaugurated their careers by travelling in Europe, and writing descriptions of the foreign lands where they have found their richest intel-

lectual culture. They have sought the sources, the themes, the rules, and the sanctions of their art in the Old World, and their highest ambition, like that of all colonists, has hitherto been to receive a favourable verdict, not from the country of their birth, but from that of their ancestors. Even Franklin—in some respects an American of the Americans—was in philosophy a practical disciple of Locke, as Jefferson was of the French Revolution. "The literary genius of Great Britain," says De Toqueville, "still darts its rays into the recesses of the West. . . . The small number of men who write are English in substance, and still more in form." Of the great number of men who have written in America since the date of this criticism, only a few have written much to confute it. Washington Irving, who, in the course of four distinct visits, spent much of his life in Europe, only escapes from the influence of Addison in his *Knickerbocker* and Dutch sketches. On land at least, Cooper—though in many respects an original writer—everywhere remembers Scott. As in the works of the Scotch novelist, the semi-barbarous feudal spirit is represented in conflict with modern law, in those of the American the enterprise of New England is struggling against the ruggedness of nature and a savage life. The writers of the last thirty years have been making strenuous, sometimes spasmodic, efforts after originality, but they are still affected by transatlantic associations. In the style of Mr Motley we cannot help observing the stamp of Carlyle. The Transcendental movement begun by Emerson is admitted to have derived its first impulse from *Sartor Resartus*; and among the eccentricities that mark its followers none is more remarkable than their mania for German and Oriental quotations. The tyranny which five centuries' load of classics, in the same tongue, exercises over the mind of a nation not yet a century old is very much strengthened by the non-existence of an international copyright, which leads to the intellectual market being glutted with stolen goods. As long as a publisher in Boston or New York can republish a good book written in Edinburgh or London without paying for it, he is likely to prefer an undertaking which involves no risk and comparatively no outlay, to another which involves both; that is, the republication of the English to the first publication of an American book; for the English book has already attained its reputation, and its popularity in America is secured, while the American book, for the copyright of which he has to pay, has, except in the case of a few authors, still to win its spurs. If the people of the United States had spoken a language of their own, it is probable they would have gained in originality; as it is, they are only now beginning to sign their intellectual declaration of independence,—a fact confessed among the latest words of their own greatest prose artist:—"Bred in English habits of thought as most of us are, we have not yet modified our instincts to the necessities of our new modes of life. Our philosophers have not yet taught us what is best, nor have our poets sung to us what is most beautiful in the kind of life that we must lead, and therefore we still read the old English wisdom, and harp upon the ancient strings."

### III.—EARLIER AMERICAN LITERATURE.

We may trace the influence of the foregoing controlling facts or tendencies, subject to various phases of personal power, through the three great periods under which Anglo-American history obviously falls:—The Colonial, the Revolutionary, and that of the 19th Century.

1. *The Colonial Period.*—Little of interest in the world of letters has come down to us from the 17th century in the West. Sandys's *Ovid*, translated on the banks of the James River, dedicated to Charles I., and published 1626,

is worthy of note as the first contribution to English literature from America. About the same date the Welsh Puritan Vaughan sent home his *Golden Fleece* from Newfoundland, and Captain Smith gave to the world his descriptions of Virginia. But the earliest verse that has a real claim to be regarded as American is a doggerel list, by an anonymous author, of New England's annoyances, which, if we remember the date—a generation after Spenser had celebrated "the Indian Peru" in his *Faery Queen*—will confirm our view of the backwoodsman's want of leisure for "polishing his stanza:"—

"The place where we live is a wilderness wood,  
Where grass is much wanting that's fruitful and good.

\* \* \* \* \*  
If fresh meat be wanting to fill up our dish,  
We have carrots and pumpkins, and turnips and fish;  
We have pumpkins at morning and pumpkins at noon,  
If it was not for pumpkins we should be undone."

A little later we have a Puritan version of the Psalms, the worst of many bad; and about 1650 the poems of Anne Bradstreet and Benjamin Thomson, worthy of mention, but scarcely readable. In prose are relics of the sermons and controversies of Roger Williams and John Cotton and Eliot, the apostle of the Indians, with the ponderous *Magnalia* and witch denunciations of Cotton Mather. The main literary event of the century was the foundation (1636) of Harvard University. Yale College followed at a long interval, and subsequently Princeton College, and Brown University (Rhode Island). In all new countries industrial and commercial interests are at first the strongest. The febrile activity produced by fear of a sterile future leaves little room for speculative imagination. But in the New World, colonised in part by adventurers, in part by religious refugees and enthusiasts, another influence was from the first at work. When her solitudes began to give place to cities, the brains of her people were expended on the farm or the exchange with a zeal materially modified by the spirit and formulae of the faith which led the founders of the Northern States across the sea, and continued to infuse a religious element into their enterprises. This element, which elevated the settlers of New England above ordinary emigrants, adding to their strength and giving a faster dye to their morality, was yet, in its original form, no more favourable to freedom or variety of thought than the industrialism by which it was surrounded. But it begat and fostered the Puritan theological literature which was concentrated in the massive yet incisive treatises and discussions of Jonathan Edwards of Connecticut—(1703–1758)—who, if not, as asserted by American panegyrists, "the first man of the world during the second quarter of the 18th century," was yet, by the clear vigour of his thought and the force of its expression, one of the foremost figures of that era. An estimate of his rank as a theologian belongs to a distinct branch of the history of American literature. It is enough here to refer to the testimony of all competent judges as to the singular lucidity of his style, and to that of his contemporaries as to the fervour of his eloquence and the modest simplicity of his life. Passages of his occasional writings, as the description of his future wife, evince a grace and sweetness of temper not always associated with the views of which he was and remains the most salient English advocate. A slightly junior contemporary of Edwards, the exponent *κατ' ἐξοχήν* of the other—that is, the secular side of early American life—was destined to see the end of one and play a prominent part in opening another era of his country's history. Benjamin Franklin, as long as Utilitarian philosophy endures, will be a name to conjure with. It is *clarum et venerabile*, though its owner was endowed with as little as possible for a great man of the "faculty divine." Franklin's autobiography, the details of which

need not find place here, is as romantic as the life of an unromantic person can be. The incidents of the young candle-moulder—the printer's apprentice—the ballad-monger wisely discouraged by the wise paternal criticism, "Verse-makers are generally beggars"—the runaway, eating rolls on the Philadelphia street—his struggling life in London with Ralph of the *Dunciad*—his return, "correcting the erratum" of his infidelities by marriage with his old Pennsylvanian friend—his success as a printer, economist, statesman, and diplomatist—his triumphs in natural and political philosophy, clenched in Turgot's line, adapted from Manilius—

"Eripuit cælo fulmen, sceptrumque tyrannis"—

his examination before the House of Commons, resulting in the repeal of the Stamp Act, when Lord Chatham spoke of him as one who was "an honour not to England only, but to human nature"—his signature of the Declaration of Independence—his ministry in France and popular triumph with Voltaire, who said, "Je n'ai pu résister au désir de parler un moment la langue de Franklin"—the acclamations of shouting multitudes on his return home—Mirabeau's announcement of his death (in 1790, in his eighty-fourth year) to the Assembly—"the genius which has freed America, and poured a flood of light over Europe, has returned to the bosom of the divinity"—are elementary facts of schoolboy history. They are the records of the successive stages of the greatest success achieved in modern times by the genius of common-sense, integrity, and industry indomitable. Franklin's experiments and physical discoveries form a chapter in the history of science; but half of his fame even in this field is due to the precision and clearness of the manner in which they are announced. "The most profound observations," says Lord Jeffrey, "are suggested by him as if they were the most obvious and natural way of accounting for phenomena." The same literary merit characterises the financial pamphlets and treatises which first brought him into celebrity. Both are marked by the same spirit,—the love of the Useful, which was his passion through life. Franklin follows Bacon, to an extreme opposed to that of the Platonists, in decrying abstractions. Archytas is said to have apologised for inventing the arch. Franklin is ashamed to have wasted time over pure mathematics in his "magical squares." His aim is everywhere to bring down philosophy, like the lightning, from heaven to earth, "*illustrans commoda vite*." His ethics—those of Confucius or the Seven Sages, modified by the experience and the circumstances of a later age—are embodied in the most famous of popular annuals, *Poor Richard's Almanack*, in which for twenty-six years he taught his readers (rising to the number of 10,000) "the way to be healthy and wealthy and wise," by following simple utilitarian rules, set forth in plain incisive prose and rhyme, rendered attractive by a vein of quaint humour and the homely illustrations always acceptable to his countrymen. The same train of thought appears in the "Whistle," among the letters from Passy, where his persistent deification of thrift appears side by side with graceful compliments to Mesdames Helvetius and Brillon, records of the aftermath of sentiment that often marks a green old age. Franklin remains the most practical of philosophers in perhaps the most practical of nations.

2. *The Revolution Period.*—It has been often remarked that periods of political national crisis are more favourable to the preparation than to the actual production of literature. Wordsworth's assertion, that poetry is the outcome of emotion recollected in tranquillity, applies with slight modification also to artistic prose. The demands of instant action cast the reflective powers into abeyance, but a

stormy era is the seed-time of a later harvest. There is only one exercise of the imagination that it directly stimulates—that of the orator; and the conditions of his success, save in a few instances, make a drain on his posthumous reputation. In reading even the greatest speeches of the past, divested of the living presence which gave them colour and force, we find it difficult to account for the effect which they are known to have produced. They are the ashes or the fossils of genius. Little that is of permanent literary value is left us of the harangues that were the trumpet-calls of patriotism during the American Revolutionary War. The triumphs of Patrick Henry, who Orators. "wielded at will that young democracy," are commemorated in the judicious biography of Wirt, but few of his orations are accurately preserved; and of the speeches of James Otis, which were compared to "flames of fire," we have mainly a tradition. His pamphlet (1762), entitled *A Vindication of the conduct of the House of Representatives*, is considered to contain the germ of the Declaration of Independence. Among other considerable efforts of eloquence, those of Fisher Ames are worthy of note as being directed in great measure against the excesses of democracy. The master-minds of the era were the states- Statesmen men and jurists, who fought for the free soil, sunk the deep foundations, and reared the superstructure of the new Commonwealth. The history of American law is a distinct theme. It must suffice here to mention, as claiming recognition in the field of letters, Washington himself, in his Washington. clear and incisive though seldom highly-polished correspondence; his biographer John Marshall, chief justice of Marshall. the supreme court from 1801 to 1835, one of the early pilots of the state, who left behind him a noble and stainless name, and laid down the first principles of that international code afterwards elaborated by Wheaton; Madison, John Jay, the elder Adams, and Alexander Hamilton. Hamilton, during the war Washington's "most confidential aid," afterwards the presiding genius of the movement represented by the *Federalists*, the organ of the anti-democratic party. To this he contributed three-fourths of the material, marked, as are all his papers and speeches, by originality of thought, breadth of view, and purity of style. As secretary of the treasury, he became perhaps the greatest of financiers. The general judgment of his countrymen acquiesces in the terms of the tribute paid to his memory by Guizot. "He must be classed among the men who have best known the vital principles and fundamental conditions of a government worthy of its name and mission." Of Hamilton's numerous historical sketches, the most celebrated is his letter to Colonel Laurens giving an account of the fate of Major André, in which refinement of feeling and inflexible impartiality of view are alike conspicuous. The great and unhappily the bitter anta- Jefferson. gonist of the Federalists is one of the most conspicuous figures in the history of American thought. Thomas Jefferson (1743-1826), President from 1801 to 1809, is the representative in chief of the revolutionary spirit of his age and country. While his rival compeers stood firmly on the defensive against the encroachments of an arbitrary government, his desire was, in politics as in speculation generally, to break with the past. Inspired with patriotic zeal by Patrick Henry's denunciations of the Stamp Act, he came forward prominently in 1769 as a member of the Colonial Assembly of Virginia. In 1776 the main part of the responsibility of drawing up the Declaration of Independence fell upon him. In 1784 he was appointed minister of the congress in Paris, where he spent the greater part of six years, and brought back an admiration for those phases of the French Revolution from which the more temperate judgments of Hamilton and Fisher Ames had recoiled. He threw himself heart and soul into

the arms of the Democratic party, and in the constitutional struggle that ensued his keener sense of the direction in which popular sympathies were tending, with the weight of his half physical energies, gave him the ascendancy over the wider knowledge and more far-seeing intellects of his adversaries. Jefferson might be termed the Danton of the West, but his forte lay not so much in oratory as in political management and incisive vivacity. More perhaps than any other great statesman of his age, he aspired to be an author, to which title the best passages in his *Notes on Virginia*, his *Autobiography*, and *Correspondence*, give him a fair claim. His descriptions of scenery in the first are always pleasing and generally graphic. His sketches of Continental society are lively, and his occasional flights of fancy, as the dialogue between the head and heart, at least ingenious. His religion and ethics were those of his friend Tom Paine and the *Encyclopédie*.

The age of the Titans in transatlantic history abounds in minor literati, whose light effusions, mainly satirical or descriptive sketches in prose and verse, throw a somewhat dim and ragged lustre over its graver page. The bulk of these obvious reflections of the manner and thought of Butler, Pope, and Swift, or of Gay, Prior, and Shenstone, are a penance to wade through, and scarce claim remembrance for their authors. A few stand out conspicuously by the celebrity of the names with which they are associated, or a certain raciness and approach to originality in their style. Of these the chief are:—The social caricatures of Judge Brackenridge (who, though born in Scotland, lived in America from infancy), and his doggerel but vigorous lines on Bunker's Hill; the once popular humorous lyric entitled *McFingal*, by J. Trumbull, also the author of *The Progress of Dulness*, in the Hudibrastic metre which seems to have been used by imitators to show how intolerable it is in any but the original hands; the more flowing but on the whole commonplace odes of Philip Freneau, including his patriotic hymns to Washington, with the more musical lyrics the "Wild Honeysuckle" and the "Indian Death Song," and his prose entitled *Advice to Authors*; the political satires of Mercy Warren, authoress of *Things necessary to a Woman* (the obvious model of the more modern squib, *Nothing to Wear*), and of a *History of the Revolution*, remembered only as being the first in date; the patriotic rhapsodies of Phillis Wheatley, interesting as the production of a young negress brought from Africa in 1761, and soon afterwards sold in Boston to the mistress from whom she took her name; Francis Hopkinson's *Battle of the Kegs* and his *Pretty Story*—a burlesque closely fashioned after Arbuthnot's *John Bull*—his *New Roof*, meaning the American constitution, and his satire on the pedantry of the sciences entitled *The Sull Box*; Joel Barlow's *Hasty Pudding*; the humorous *Wants of Man*, by Quincy Adams, more prominent as a statesman than as a poet; and on a similar but higher platform the best of too large a volume of verses, in which the "Triumph of Infidelity" (after the manner of Cowper), the "Conquest of Canaan," and "Columbia," are the leading pieces, by the amiable theologian Dr Timothy Dwight. Dwight's prose descriptions, as that of the Notch of the White Mountains and the evening on Lake George, are superior in grace to his efforts in rhyme.

The ballad literature of the revolution days is said to have attracted the attention of Lord Chatham, less probably from its intrinsic merit than from its faithful though rough embodiment of the sentiment that not only moved over the surface, but penetrated the depths of the national life. The anonymous popular literature of a country is the best "abstract and brief chronicle of the time" in which it is produced. The songs current in America during this era, inspired by the same spirit and pitched in the same key, are historically interesting and artistically monotonous. They celebrate in rude verse the achievements of native heroes, like "Bold Hawthorne;" or ridicule, like "Jack Brag," the British Lion; or, like the "Fate of Burgoyne," the overthrow of vaulting ambition; or, as in "Wyoming Massacre," bewail the fate of the fallen; or, as in "Free America," celebrate with schoolboy huzzahs the triumph of the good cause. Among the very rude national anthems of the West, "Yankee Doodle" is remarkable as having been an old Dutch catch adapted into an English satirical chant, and adopted, with conscious or unconscious irony, by the American troops. "Hail Columbia," which as a poetical production takes even a lower rank than "Rule Britannia," was a somewhat later production by Joseph Hopkinson (1793); and the "Star-Spangled Banner" of Francis S. Key is associated with the traditions of the second British war. As inspired with the spirit of the 18th, though belonging in date to the early years of the 19th century, we may mention in advance the "Pilgrim Fathers" of J. Pierpont, Woodworth's "Old Oaken Bucket," "Home, Sweet Home," by J. H. Payne; the humorous burlesque of J. G. Saxe, "Miss MacBride;"

and the verses of the great painter and creditable romancer Washington Allston, with the refrain "We are one."

English philology and literature were during this period represented by the famous Lindley Murray, and Noah Webster (1758–1843), the author of the best dictionary of our language that has appeared since Johnson's. In natural science, the two Bertrams; Alexander Wilson the ornithologist; and Audubon, the literary glory of Louisiana, whose descriptions of animate nature rival those of Buffon, are illustrious names.

#### IV.—THE LITERATURE OF THE NINETEENTH CENTURY.

##### *Prose Writings.*

1. In a rapid estimate of the literature of this prolific age we can only signalise its contributions to the several branches of physical and mental science. The United States have during the last two generations been justly proud of the names of Morton and Schoolcraft in ethnology, of Bowditch in mathematics, of Sullivan and Dana in chemistry and mineralogy. Their classical scholarship, which hardly competes with that of England, has yet been fairly maintained by Everett, Felton, Woolsey, Anthon, and Robinson. Dr Marsh is an accomplished English scholar, while Professor Whitney is a learned and accurate philologist, whose researches in Sanscrit are well known and appreciated by European Orientalists. The metaphysical schools of Locke and Reid are nowhere better represented than in America by Dr Bowen and Dr N. Porter. The place of Marshall as a jurist has been worthily filled by Chief-Justice Kent and Judge Story; the latter of whom ranks, by virtue of his essay on classical studies and his graceful descriptions of natural scenery, among the most accomplished of the numerous professional men who have in the New World devoted their leisure hours to lighter literature.

The inhabitants of the United States have always been noted for remarkable fluency, sometimes a super-fluency of speech. The early years of the century were illustrated by the fiery zeal of Randolph and the practical force and occasional impassioned eloquence of Henry Clay. The great political controversies inherited from the preceding age found their most conspicuous popular exponents in two leading minds laying claim to diverse kinds of greatness, and destined to be in almost incessant antagonism. John C. Calhoun, the most illustrious representative of the Southern States, of whose rights, real or imaginary, he was during his life the foremost champion, was by education and choice a professional statesman. Secretary of War in 1817, and Vice-President of the Commonwealth in 1825, he resigned the latter office on occasion of the dispute about the tariff law in 1832, to become the leader of the Opposition; and in vindicating the attitude of South Carolina was the first to lay the strands of the future Secession war. The most accomplished modern apologist for slavery, it is probable that he only hastened the conflict between opposing principles which was sooner or later inevitable. Calhoun's eloquence, as attested by his auditors and the numerous speeches and papers preserved in the six volumes of his published works, was notable for its earnestness and gravity, the terse polish of its manner, for philosophic generalisations and analytical dialectic. His prevailing sincerity and candour have made his memory respected by those farthest removed from him in sentiment and opinion. Daniel Webster, on the whole the grandest orator of the New World, was during the greater part of his career the champion of Massachusetts and the assertor of her policy. His defence of that State in the Senate (1830) against General Hayne of Carolina, and his oratorical duel with Calhoun (1838), resulting in the temporary overthrow of the doctrine of nullification, are among the most

Minor writers.

Ballad literature.

remarkable triumphs of debate in history. Some of his pleadings on criminal trials have an almost terrible power. But his literary genius and richness of illustration found freer scope in his famous appeal for the Greeks in 1824, his great speech (1820) on the second centennial anniversary of the landing of the Pilgrims, or his address (1825) on laying the corner-stone of Bunker Hill monument. Webster's eloquence, everywhere solid, massive, and on great occasions glowing with a lurid light, is not the mere record of half-forgotten strifes; it is "vital in every part," and belongs to the permanent literature of his country, in whose political arena he was during his life perhaps the most powerful actor. The art of making commemorative speeches, technically called "orations," has been cultivated in North America to excess. The great master in this species of composition was Edward Everett, distinguished by his early association with Lord Byron in Greece, the high dignities—governor of Massachusetts, minister to the court of St James's, and president of Harvard—to which he attained, and by the variety of his accomplishments. Mr Everett was for ten years a useful member of Congress. In his literary work he displayed an almost fatal fluency, having contributed to the "North American Review," of which he was for some time editor, upwards of a hundred articles in the space of a few years. These articles are inevitably of unequal merit, but they everywhere evince the ripe scholarship of a highly cultivated mind. The volume by which he is best remembered—twenty-seven Orations—published in 1836, is marked by the same characteristics. Discoursing on a wide range of subjects—among which the refrains are America and Greece, the "Mayflower," the Progress of Discovery, Patriotism, Reform, the Republic, Concord, Lexington, and the inevitable Bunker Hill—these speeches are always able, but seldom inspiring; carefully elaborated and richly adorned, they are the production of the first of rhetoricians rather than a genuine orator.

Among the remaining lawyers and statesmen, remarkably numerous in the States, who have in the course of their professional careers made highly creditable contributions to literature, it may suffice to mention H. Swinton Legaré of Charleston, at one time a student of law at Edinburgh, a prominent speaker in the House of Representatives, afterwards President Tyler's attorney-general, who published in the *Southern Quarterly* and *New York Reviews* a series of masterly criticisms mainly relating to Greek and Roman literature; J. P. Kennedy of Baltimore, a successful barrister and Congressman, also a vigorous essayist and author of some remarkably lively sketches of country life and manners in the Old Dominion; Richard H. Wilde, of Georgia, in which State, after surmounting unusual difficulties with remarkable perseverance, he rose at the bar to be attorney-general, author of the song entitled the "Lament of the Captive," and of a *Life of Tasso*, displaying great research and occasionally subtle criticism, written after two years' residence in Europe; and, taking higher rank as an author, Richard Dana, a barrister of the early years of the century, and adherent in politics of the old Federalist party in the state. Dana became known in the world of letters as the author of a Fourth of July Oration in 1814, and somewhat later as the contributor to the *North American Review* of appreciative and discriminating criticisms of the English lake poets. In 1827 he published his fantastic ghost-story of the "Buccaneer" and other poems, to which he continued to add at intervals. Many of his minor verses are characterised by remarkable grace, but they want original force. Among contemporary politicians, Mr Wendell Phillips is the only one who can be called a great orator; the ease and energy of his style at its best being rarely surpassed. But the speeches of Mr Sumner are eloquent, and his arrangement of facts converging to clench his argument is often masterly.

2. HISTORY, as the reflection of philosophy on the statesmanship and the struggles of the past, seldom comes very early in national literature. The 18th century in America supplied, in letters, journals, and contemporary chronicles, material for more elaborate and comprehensive treatment in the 19th at the hands of George Bancroft, a leading Democrat, who held the post of representative of his country in Great Britain from 1816 to 1819. His great work—

three volumes of which are devoted to the Colonisation and seven to the Revolutionary period—published at intervals between 1834 and 1874, has been generally accepted as the standard history of the United States up to this time. The book is written for the most part in a sufficiently vigorous style; somewhat defective, however, in elegance, and characterised by a certain monotony and want of ease, which detracts from the pleasure of the reader. Bancroft's statements of matters of fact are generally reliable; but his comments are moulded even more than is usual by the foregone theories of a political partisan. The rival history of Richard Hildreth, which appeared in six volumes, issued in rapid succession (1849–53), while marked by the same Puritan tone, is even more severe in its judgments. The style is more animated, but more prone to the *torva voluptas* of false rhetoric. The keynote of the sentiment which pervades Mr Hildreth's book is to be found in his keen abolitionist views, previously expressed in a juvenile work of the author, *The White Slave*. One of its merits is its appreciation of the Federalists, and especially of the genius and character of their leader, Hamilton. Of the host of national biographies in which the West abounds, Sanderson's *Lives of the Signers*, the historical sketches of G. C. Verplanck, Wirt's *Patrick Henry*, and the stupendous series edited and largely written by Jared Sparks, may be signalised. Nearly one-half of the works of the most classic American prose writers of the generations previous to our own are historical or biographical. Washington Irving's *Conquest of Granada*, and his lives of *Columbus*, the *Followers of Mahomet*, *Goldsmith*, and *Washington*, if not the most original, are among the most interesting of his works—accurate in their leading estimates, and marked by the usual smoothness and even flow of his style. Irving contemplated a continuation of the record of the early relations of Spain to the New World, but, with his wonted generosity, abandoned the theme on hearing that the task had been assumed by worthy hands. The works of William H. Prescott, the most artistic historian to whom the United States have hitherto given birth, are remarkable from the difficulties under which they were produced, and for the well-deserved success which they have achieved. This success is due in part to the genius and indomitable industry of the writer, in part to the steady concentration of his powers on the arduous undertaking of which he had at an early age-formed a just estimate. In a diary of 1819 (that is, in his twenty-third year) he allows ten years for preliminary studies and ten more for the execution of his task—a notable example to his countrymen, nine-tenths of whose literary performances will prove ephemeral, less from lack of ability in the writers than from an utterly inadequate sense of the time and toil that every true Muse demands of her votaries. *Ferdinand and Isabella*, given to the world in 1838, was written while Mr Prescott was, owing to an accident at college, almost wholly deprived of his sight. His authorities, in a foreign tongue, were read to him by an assistant, and by aid of a writing-case for the blind he scrawled the pages of his great work. It soon attained a European as well as an American fame, and superseded all other records of the period of which it treats. No such comprehensive view of Spain at the zenith of her greatness has ever appeared in English. The proportion of its parts and the justice of its estimates are universally acknowledged; while hypercriticism of the style—graceful, correct, and sufficiently varied—can only point to the occasional possibility of greater condensation. Among the most notable of the descriptions, which can seldom be detached from the whole into which they are woven, we may refer to the return of Columbus and the contrasted characters of Queen Isabella and Elizabeth. The *Conquest of Mexico*,

written with somewhat improved sight, followed in 1843; that of *Peru* in 1847. These have attained an even wider popularity than their precursor, owing to the more condensed romance and greater novelty of their themes. They are "open sesame" to an old world of wonders, real, and yet from its strangeness invested with half the charms of fairyland. Few passages of fiction are so enthralling to the youthful reader as the story of Nezahualcoyotl, king of Tezucuo, the life and exploits of Montezuma, the night retreat from the Aztec capital, or the account of the sun-worshippers in the Golden City. Both works are dramas in which our sympathy is divided between the chivalry of Spain in her hey-day and the poetical traditions and innocent patriotism of a vanished race. But their author has never, in the midst of his "Claude-like descriptions" and charmingly vivid narratives, allowed himself to forget that he is writing history. Boys read his Mexico and Peru as they read the Arabian Nights; critics can point to few flaws in the accuracy of the author's judgment. *Philip II.*, Mr Prescott's latest work, has similar excellencies in dealing with a less attractive theme. John Lothrop Motley, a distinguished ambassador in foreign courts, and author of the best existing history of Holland, is Mr Prescott's only more recent rival. Less faultless, he is more strikingly original; and the greater complexity of the theme, which he has made his own, calls for the exercise of even higher powers. The *Dutch Republic*, which appeared in 1856, at once arrested attention by its evidence of careful and long research, comprehensive grasp, rich pictorial power, and the enthusiasm which, only here and there interfering with the impartial judgment of the author, gives colour and life to the work. Mr Motley's style, even to minute turns in his sentences, bears the impress of the influence of Carlyle. The very titles of his chapters, especially in the first volume, seem transferred from the *French Revolution*. Such are "Sowing the Wind," "The Harvest Ripening," "The First Whirlwind," "The Taciturn against King, Cardinal, and Elector," &c. From the same source he may have caught some of his hero-worship, which, however, by the choice of a worthy object, he has done much to vindicate. The *Dutch Republic*, precluded by the overture of a masterly and vivid historical survey, is a drama, which facts have made highly sensational, of the most terrific struggle against temporal and spiritual despotism that, within the same space of years, modern times have seen. It is divided, not inappropriately, though perhaps with some regard for effect, into a prologue and five acts, to each of which in succession the name of the Spanish governor for the time is attached. The portraits of those emissaries, particularly those of Granvelle of Arras and Duchess Margaret of Alva, Don John of Lepanto, and Alexander of Parma, are drawn with bold strokes and in lasting colours. Behind the scenes, director of the assailing forces, is the evil genius Philip himself, to whose ghastly figure, writing letters in the Escorial, our attention is called with a wearisome, if not affected, iteration of phrase; while the presence of the great champion, like that of Achilles in the *Iliad*, is felt at every crisis retrieving the retreat and urging on the victory. The most horrible chapter of modern history—that of the Inquisition—is unfolded with a power that brands its records into the memory of the reader; and amid a throng of scenes of pageantry and pathos we may refer to those of the resignation of Charles V., Egmont's triumph at St Quentin and his death, the misery of Mook Heath, the siege of Leyden, and the hero's death. The *United Netherlands* (1867-69) is a continuation of the same history in the same spirit; but, as regards style, a somewhat calmer and more matured composition. The most thrilling chapters in those four

later volumes are the siege of Antwerp—which compares with that of Syracuse in Thucydides—and that on the wreck of the Armada, unsurpassed in vividness and vigour by either Froude or Kingsley; to which we should add the episodes of the battle of Ivry and the skirmish at Zutphen, with one of the most eloquent tributes ever paid to the genius and character of Sir Philip Sidney. Of the other full-length pictures, which, with the campaigns of Parma, Spinola, and Maurice, and the intrigues of England and France, divide the interest of the book, are those of Queen Elizabeth (whose habitual treachery, real meanness, and shallow pretences to magnanimity are exposed, as afterwards by Mr Froude), Henry of Navarre, St Aldegonde, the Earl of Leicester, and the great Barneveld, who, with the Prince of Nassau, divides our sympathy at the close of the book. Since the death of Lord Macaulay no equally solid and valuable contribution has been made to historical literature. As supplementary in some measure to the volumes of Mr Prescott, we may mention here the *History of Spanish Literature* by his coadjutor Geo. Ticknor, incomparably the best, the most comprehensive, most critical, and most interesting work which exists on the subject.

Of other contributions to literary criticism, from which, owing to their superabundance, it is hard to select, those of George S. Hillard, one of the most highly cultured writers in New England; of Henry T. Tuckermann, author of *Thoughts on the Poets*, an elegant but sentimental essayist; of E. P. Whipple, a critic who, according to Mr Griswold, combines "the strength of the *Areopagitica* with the liveliness of the *Spectator*" (!); of Margaret Fuller D'Ossoli, a precocious linguist, translator of Eckermann's *Conversations with Goethe*, herself a brilliant conversationalist and somewhat cloudy transcendentalist and advocate of the superiority of women to men; the always lively reviews of Mr Lowell, with numerous papers in the *North American* and *Atlantic Reviews*,—may be referred to. To these we should add the discriminating "Essays on recent English Poets" contributed to *Scribner's Monthly* by E. C. Steedman.

3. POLITE LITERATURE, of any excellence, in the lighter branches is, in the West, almost wholly a growth of the present century. The most widely and justly celebrated of transatlantic authors in this field, during its earlier half, was the amiable and versatile Washington Irving. Of his numerous writings, we have referred in last section to those which are directly historical. The rest fall under two heads, according as they are concerned mainly with American or with European themes. On the same principle on which Agassiz, and Follen, and Paine, even Berkeley and Priestley, have been claimed by the United States, Irving is associated with the progress of English literature; for in virtue of his Scotch parentage, and in the course of four distinct and extended visits to Europe—1803-6, 1815-20, 1827-32, and 1841-46—he may be said to have become half an Englishman. His style is in the main that of the essayists of Queen Anne, modified by the humour of Charles Lamb; and many of his most effective sketches of life, manners, and society relate to the eastern hemisphere. Such are his *Histories*, the *Tales of a Traveller*, *Bracebridge Hall*, *Newstead and Abbotsford*, the *Alhambra*, and half of the *Sketch Book*. In reference to those works—the best passages of which are classical—a French critic has said that Irving describes all countries but his own in the style of Addison. In others, however, and these the earliest and latest of his works, he treats of national legend and scenery in a manner peculiar to himself. His first literary efforts, which resulted in the series of papers entitled *Salmagundi*, were gently satirical descriptions of the features of society in American cities. The *History of New York*, by "Diedrich Knickerbocker," in point of pure originality his masterpiece, is one of the richest farragoes of fact, fancy, and irony that have ever issued from the press. In later life, his *Tour of the Prairies*—*The Adventures of Bonneville*, and *Astoria*, are instinct with the spirit of western discovery and adventure.

In this, as in other points of view, versatility and grace are his prevailing characteristics. He belonged historically to both worlds, and was equally at home in each; he reflected the quiet philosophy of the *Tatler* and *Spectator*, adding to it the pathos which dims the eye of the reader over his "Wife," and "Widow and Son," and "Broken Heart," and "Pride of the Village." He started the vein of burlesque that has run through his country's literature, but under the restraints of taste and temperance that have unfortunately been often discarded. The even grace of his manner often leads hasty critics to do scant justice to the range of his sympathy. His manly but gentle style is at home in Spanish history, English essay, and American legend; in the *Alhambra* and among the slopes of "Sleepy Hollow," where, as in the famous "Rip Van Winkle," we have some of the earliest models of amusement with grave faces and the melancholy parties of pleasure that are, under various forms of buffoonery, still typical of American humour. Associated with Irving in his *Salmagundi*, the name of J. K. Paulding deserves a distinct place for the humorous vigour of his character sketches, and his vivid pictures of early colonial life, in the *Dutchman's Fireside* and *Westward Ho!* where the features of the contest between the new settlers and the aborigines are brought before us in clear relief. His apologue of "Bull and Jonathan," and the thirteen good farms over which they squabbled—founded on Swift's *Tale of a Tub*—presents us, in a satire which lies on the border of irony and a rougher form of wit, with an early American view of the relations between his own and the mother country. Some of the same themes have been handled with superior richness of illustration and force by the greatest, with one exception, of transatlantic novelists—J. Fenimore Cooper (1789–1851)—a man remarkable no less for the somewhat defiant independence of his character, which led him to defend his countrymen in Europe, where he travelled from 1827–33, and to assail their foibles in America, than by the marked originality of his genius. His first considerable work, *The Spy*, appeared in 1821, and from its fresh treatment of a patriotic theme obtained a European reputation. His second, *The Pioneers* (1823), with a vivid representation of the scenery of the author's early life, introducing for the first time his ever-recurring hero the famous Natty Bumppo, or Leather-Stocking, established his place as a new actor on a crowded stage. Then followed *The Pilot*, in which he first asserted his claim to an empire since indisputably made his own among novelists—that of the sea; and somewhat later *The Last of the Mohicans* and *The Prairie*, in which he asserted a similar sway over the "gardens of the desert" and the hills of the remoter West. While abroad he wrote his *Red Rover* and *The Bravo*—a graphic tale of Venice, and flung on the aspersors of his country the *American in Europe*. Shortly after his return he issued his satirical assault on newspaper editors and other delinquents—his *Homeward Bound*, which led him into several actions for libel, in which he claims to have been almost invariably successful—*The Pathfinder*, and *The Deerslayer* (1840–41). The latter, perhaps the best of the Leather-Stocking series, completes the list of his great novels; to which must be added another important work—*The History of the American Navy*—published in 1839. There is a certain severity about Cooper's genius, showing itself in a hardness in his style, which restricts the range of his readers. He wastes perhaps too many words on descriptions, is exhaustive where he might have been suggestive, and his plots are apt to be deficient in interest—*The Red Rover* conspicuously excepted. But, deducting the echoes of Scott, to which we have referred, he is American to the core; he needs no slang or affectation to establish his originality, but moves on his own way with

something like disdain of comment. His best descriptions—as, for example, those of the prairie on fire, of the "Ariel" among the shoals, of the capture of the whale and the panther in *The Pioneers*, of the last sea-fight in *The Rover*, of the regatta in *The Bravo*—are unsurpassed. His ships move over the seas like things of life. His hunters traverse the prairies with a sense of possession. His best characters are few; but Natty Bumppo, Bob Yarn, Nightingale, Long Tom Coffin, Hetty Hunter, and Brand Merideth are undying creations. The earliest American romancer of note, Charles Brockden Brown (1771–1810), who came before the world (1797) in *Alecwin, a Dialogue on the Rights of Women* (first of a mob of tracts on the same theme), set the example on his side of the Atlantic of that love of the anomalous, fantastic, and horrible, represented on our own by Beckford, Walpole, and Godwin, and later by Mrs Radcliffe and Mrs Shelley. His main works—*Wieland, Ormond, Arthur Mervyn, and Edgar Huntly*—are unmistakably the productions of a man of genius. None are wanting in passages of thrilling interest, striking situations, and subtle analysis of character. But they dwell too prevalently on the night-side of nature—on such themes as insanity and somnambulism, and all the repulsive anatomy of mental disease. Brown's account of the yellow fever in *Arthur Mervyn* may be compared with the corresponding narratives in Thucydides, Lucretius, and Defoe; and Wieland's confession of the murder of his wife (a favourite subject of Western fiction) is hideously vivid; but the author's plots as a whole are wanting in method, his bursts of passion are dulled by intervening tediousness, and his style deformed by pedantic circumlocutions. Brown must be credited with considerable originality of conception, and blamed for introducing a morbid vein of thought. His influence is apparent in two novels of Richard Dana—to whom we have before referred—*Tom Thornton* and *Paul Felton*, in which a more graceful style is employed with almost equal vigour to illustrate similar monstrosities of character on the basis of incidents almost equally unnatural. Of the same school are many of the sketches of Charles F. Hoffmann, as "Ben Blower's Story" of being immured in a steam-boiler, and the "Flying Head;" but alongside of these are others, as his "Winter in the West," "Romance of the Mohawks," and "Adirondacks," that are steeped in the fresh atmosphere of the green fields and hills. Hoffmann is also the author of three deservedly popular songs, "Myrtle and Steel," "Sparkling and Bright," and "Rosalie Clare." The influence of those writers, along with that of a profounder analyst, the French Balzac, is apparent in the works of the most morbid genius the modern world of letters has known. In the regions of the strangely terrible, remotely phantastic, and ghastly, Edgar Allan Poe reigns supreme. For clearness of style, aptness of illustration, and subtlety of thought, he distances in this field all his predecessors except Balzac, who in the mental dissecting-room is his only master. But while the Frenchman deals with anomalous realities, the power of the American consists in making unrealities appear natural. One of his great charms is his perpetual interest. Confining his imagination within limited bounds of space, he is never dull, save in his acridly jealous criticisms and miserable attempts at humour. Criticism would hardly strike a line from the longest and perhaps the most thrilling of his narratives, that of "Arthur Gordon Pym." In fictitious verisimilitude it is only equalled by De Quincey's "Flight of the Kalmuck Tartars." With the "Adventure of Hans Pfaall" in his balloon, and the "Descent into the Maelstrom," it is the obvious source of the ingenious pseudo-scientific romances of Jules Verne, which have lately attained so wide a popularity. Poe's most hideous tales, as "Thou art the

Man," "The Black Cat," "The Premature Burial," "The Pit and the Pendulum," "The Cask of Amontillado," "The Tell-Tale Heart," are redeemed by their literary merits and their reference, under the form of grotesque circumstances, to dominant fears and passions of mankind. In the "Fall of the House of Usher," "The Domain of Arnheim," "William Wilson," and "Ligeia," a more purely poetic or deeply psychological element is added to the horror. In the "Murders of the Rue Morgue," "The Mystery of Marie Roget," "The Purloined Letter," and "The Gold Bug," he is on the border-land between romance and reality, and seems to prove himself in potentiality the prince of all detectives. We shall have to refer to him again as a poet. The super-subtlety of Balzac and Poe appears with higher qualities in the works of the greatest of New England romancers, on the whole the most artistic of American prose writers, Nathaniel Hawthorne. Of his style it is impossible to speak too highly; for without any of the defects often found in the writings of his countrymen, it has a healthy flavour of nationality. It is accurate and strong, terse and yet full, rich and yet simple, harmonious, varied, and suggestive. These excellencies of form give a fascination to his most ordinary themes as to his descriptions of scenery and works of art. The only modern pictures of Italy comparable to those of Rome and her sculptures in *Transformation* are Ruskin's *Venice* and the finest stanzas in the fourth canto of *Childe Harold*. But Hawthorne's scenery can seldom be disentangled from the mood of mind in which he views it, and which constantly associates it with some remoter purpose or underlying allegory. Amid the din of voices in the Custom-house or half-buried in the mosses of his Manse, walking along the Appian Way or gliding down the Assabeth, he dwells among strange visions. The sea-shore tells him secrets of the past, and the prattling village is full of a present sympathy. But the features of nature, and life, and character which he loves to draw are peculiar. They are for the most part sombre and mysterious; not with the sort of mystery that attends unprecedented events and unnatural marvels, but with the mystery which he finds underneath the current of common lives. One of his prevailing thoughts is, things are not what they seem—he is so fond of peering beneath the surface of existence, that in his pages it almost loses its ordinary reality; he tries so constantly to look through life that he scarcely takes time to look at it. The highest art of all is that which comprehends both aspects, and, seeing the face of nature as it is, also penetrates to its hidden meanings. Hawthorne, on the other hand, weaves his fictions, to borrow a phrase from himself, in "the moonlight of romance;" and while he admits that materials for a better book than he has written "lie scattered on the page of life open before him, he has seldom stooped to gather them."

"Moonlight," he repeats in his preface to the *Scarlet Letter*, "moonlight in a familiar room, falling so white upon the carpet and showing all its figures so distinctly, making every object so distinctly visible, yet so unlike a morning or noontide visibility, is a medium the most suitable for a romance writer to get acquainted with his illusive guests. The room becomes a neutral territory, somewhere between the real world and fairyland, where the actual and imaginary may meet, and each imbue itself with the nature of the other."

Hawthorne has sometimes abandoned this neutral territory, and given us a few short sketches which show that he is eminently capable, when he chooses, of illustrating and characterising common things; such, among his minor tales, are "The Old Apple Dealer," "Little Annie's Preamble," "A Rill from the Town Pump," "Sights from a Steeple," "The Village Uncle," that well-named "Buds and Bird Voices," and "The Seven Vagabonds," the most humorous and genial of his lighter pieces. His prevailing

themes are drawn on a border-land or twilight between two worlds, half real and half ideal; fairy tales, in which human beings are the fairies, and are made to point morals of their own histories. He haunts us, as he himself was haunted, by problems. Of the five volumes of his minor sketches, three at least are filled with allegories—riddles, some of them hard to read, and open to doubtful because double interpretations. "The Great Stone Face" is a noble piece of writing, apart from the lesson it is intended to convey. "Drowne's Wooden Image" and "The Artist of the Beautiful" are in themselves "beautiful exceedingly." The exquisite pathos of "Lily's Guest" and "Edward Fane's Rosebud" lies on the surface. "Lady Eleanor's Mantle" tells its own story in a parable of the Nemesis of pride; but in "Roger Malvin's Burial," "The Wedding Knell," "Young Goodman Brown," and others, the meaning is either more intricate or more remote. Hawthorne's longer works are all conceived in the same spirit. Their incidents are comparatively few, and might have easily been condensed into one of his shorter tales; which in their turn might easily have been expanded into elaborate romances—what a consummate story, for instance, might have been reared on the basis of "Rappaccini's Daughter!" His forte lies in the analysis of character and situations, rather than the dramatic arrangement of events. "To live in other lives, and to endeavour to learn the secret which was hidden even from themselves," is the purpose set before himself by a character which in one of those romances nearly represents the author. Everywhere he seems to be carrying out this purpose, operating upon some three or four characters, and removing them—as he tells us in the introduction to *Blithedale*—a little from the highway of ordinary travel to a theatre where these creatures of his brain may play their phantasmagorical antics without exposing them to too close a comparison with the actual events of real lives. A small group of figures is thus made to work out some problem of life, or at least to throw by their ideal actions a light on some puzzle in the author's mind. The great question over which, in one form or other, he perpetually broods, is the nature of evil—the effect of sin and error on the soul—and their relation to virtue and human progress. In the *Blithedale Romance*, for instance, his theme is that the exaggeration of good may turn to evil. This almost painfully minute anatomy of four lives, relieved by passages of delicate description and a few scenes of thrilling power, is designed to show the blighting effects of a one-sided idea, even though it assumes the guise of a benevolent impulse, when it overrides private and personal claims. In *Transformation, or the Romance of Monte Beni*, a conception in some respects the converse of this, is wrought out of richer materials; and we are taught to appreciate the possibilities of good that there may be in evil, by the effect which an impulsive crime has in inspiring a simple instinctive nature with a stronger life. The *Scarlet Letter*, which is at once the most solid and the subtlest of the author's works, illustrates the fatal influence which a single sin exerts on all the persons whom it involves; but unlike the *Blithedale Romance*, which is a dismal tragedy, it ends with a magnificent triumph of expiation. The *Scarlet Letter* appears to us to be the best analytical novel of this century, the nearest approach to it in artistic finish and psychological penetration being Goethe's *Elective Affinities*. The *House of the Seven Gables* has more variety, and mixes humour with its pathos; but the web of this last romance, which has for its moral the malign influences which may be transmitted from one generation to another, is woven of thinner threads. Hawthorne's Protean genius is a power in American thought. His influence as a teacher and an artist is still crescent among the contemporaries from

whom he has lately passed. His symbolic yet real characters—Hester and Pearl by the forest brook; Dimmesdale by the scaffold, with the red morning upon his brow; the dead Judge sitting with his watch; the Cleopatra of Brook Farm plunging in the pool; Miriam and Hilda, and Donatello the Faun—are stamped in letters of fine gold on the pages of his country's literature, and the music of his quiet sentences yet lingers on the ear of strangers as of friends. But his name remains as a warning as well as an example. In one sense he was a patriot, glorying in the great deeds of his country's past. Of this feeling the "Gray Champion" and "Howe's Masquerade" give sufficient evidence. At the close of the last he writes, as we may fancy with a grim Puritan smile: "On the anniversary night of Britain's discomfiture the ghosts of the ancient governors of Massachusetts still glide through the portals of the Province House." But as a politician he wrecked himself with the democratic party. He looked upon slavery as "one of those evils which Providence does not leave to be remedied by human contrivances." He had no sympathy with the abolitionists, and at least a half sympathy with the planters. "As regards human progress," he wrote, "let them believe it who can;" and in the preface to his last completed work, as his excuse for laying the scene in Italy,—“There is in our country no shadow, no ambiguity, no mystery, no picturesque and gloomy wrong.” “Romance and poetry, ivy, lichens, and wall-flowers, need ruin to make them grow.” Hawthorne lived to see the beginning of what he could only regard as ruin: he did not live to see his country rising stronger after a great struggle with a gloomy wrong.

Oliver Wendell Holmes, the accomplished physician of Harvard, better known as a humourist and author of occasional verses, has contributed to psychological romance two remarkable volumes: *Elsie Venner* and *The Guardian Angel*. The former, and more striking of the two, is a weird tale of destiny, dwelling upon the idea of transmitted qualities in a manner which suggests comparison with *The House of the Seven Gables*; but Holmes's story has a more incredible plot, the chief character being a sort of sprite, having mysterious relations to the animal world, a snake-charmer, herself half a snake (as Donatello in *Transformation* is half a faun), like the Lamia of tradition and Keats, but endowed with the graces of Undine. The vigorous sketch of the hero Langdon, with which the book opens, is impaired by the somewhat obtrusive manner in which he is vaunted as a type of the blue-blooded or Brahmin caste of New England. The same pathological treatment of human nature pervades *The Guardian Angel*, which turns partly on mysterious physical and psychical affinities. The *Margaret* of Sylvester Judd, a Unitarian clergyman of Maine, belongs, by virtue of some of the problems with which it deals, to the category of metaphysical novels. This work of decided genius, to which a just tribute is paid by Mr Lowell in his *Fable for Critics*, has hardly attained the popularity it merits, owing to the slender character of the plot, and the frequency of the dissertations by which the author endeavours to impress his own views of society, art, and religion. But it is a powerful picture of the more ideal sides of New England life; the character of Margaret and Chilion are permanent types, and the whole book is extremely fresh and original. The most genuine successor of Hawthorne is Theodore Winthrop, who left a counting-house in New York for an adventurous life, and fell at Great Bethel in 1861 in his thirty-third year. His best novel, *Cecil Dreeme*, teems with life-like characterisation, bathed in a poetic element of mystery; and *John Brent*, the next in merit, is a graphic sketch of romantic incidents in the Far West, drawn from his own experience.

Of tales evincing talent there is a plethora; they lie on the shelves of the libraries "thick as the leaves on Vallombrosa." Among those worthy of note are the pictures of Southern society by W. G. Simms, whose fertile brain is said to have produced fifty volumes in twenty years; *The Bee Hunter*, and other narratives of the south-west, by T. B. Thorpe of Baton Rouge; John Neal's *Rachel Dyer* and *Ruth Elder*; the classical romances of Ware, *Zenobia* and *Probus and Julian*; Mrs E. O. Smith's *Indian Reminiscences*; *The Linwoods*, *Hope Leslie*, and other philanthropic tales of New England, by Miss Sedgwick; Mrs Lydia Child's *Hobomok*, and her *Philothea*, a romance of Pericles and Aspasia, somewhat too sentimental in its style, and not free from anachronisms; with the anti-slavery pictures represented by Mrs Stowe's *Uncle Tom*, a book which, inspired by ordinary talent and written in an earnest spirit, owed its success to the air of simple narration which pervades it, and its having the aggressive strength of a political pamphlet appearing at the right time in harmony with the passion on one side of an impending struggle. The light but graceful and often incisive sketches of N. P. Willis take a somewhat higher rank. A rapid writer, but at his best a brilliant colourist, his fertile fancy has been employed in almost all the countries of Europe, and in his own, in prose and verse, with more than average success. His *Pencilings by the Way* and *People I have Met* are among the most agreeable of books for a leisure hour; his descriptions are always interesting as well as accurate, and his characters, grave and gay, are generally life-like. His picture of the Indian girl, Nunn, in the *Dickings of Adventure*, is fascinating and vivacious enough to be worthy of a higher artist.

Books of TRAVEL, among which those of Mr Willis hold a respectable place, superabound in the literature of the West. Nine-tenths of the literary men of America have crossed the Atlantic, and nine-tenths of those who have done so have published their impressions of the Old World, with every variety of good and bad taste, from the *Old Home* to the *Innocents Abroad*. After that of his birth, an American author's travels are the first essential of his being. We may next predict his praise of Italy, his half satirical half envious view of England, and his wonder at the Pyramids. Of the multifarious descriptions of Europe to which this habit has given birth, the worthiest of note are those of Hawthorne and Emerson, of Story and Cheever, and Curtis's *Nile Notes*. In the "Lotus Eating" of the last named we have pleasing reminiscences of the watering-places of his own country. But the most interesting records of western scenery are those of Fremont; Winthrop's *Canoe and Saddle*, and *Life in the Open Air*; and the numerous remarkable "Excursions" of Emerson's leading pupil, H. D. Thoreau—his "Maine Woods," "Cape Cod," and "Merrimack;" with the vacation voyage to Cuba of the younger Dana.

4. A leading feature of transatlantic literature is its HUMOUR. Humour is a word of many meanings: it begins on the low level of any laughter-provoking absurdity, and rises, as in the speeches of Lear's Fool, to a tragic height. In the Greek classics it shows itself in the Rabelaisian exuberance of Aristophanes or in the Socratic irony: in the English we have an even more subtle appreciation of the curiosities of character, and a deeper sense of the contradiction or conflict between the higher and lower phases of human nature. In Sterne and Fielding, as in Ben Jonson, we have every man in his humour. As developed in America, this quality of the mind seldom penetrates to the under-currents of life; its insight is clear but not profound; it relies mainly on exaggeration, and a blending of jest and earnest which has the effect of singing comic words to a sad tune, or telling a preposterous story with a grave face. Mr Lowell makes us laugh by his description of a negro "so black that charcoal made a chalk mark upon him," and of a wooden shingle "painted so like marble that it sank in the water." Mr Browne (Artemus Ward) excited the same sort of laughter by his remark in pointing to a hill daubed on his canvas, "the highest part of this mountain is the top." In both cases there is a surprise, excited in the one by a falsehood plausibly pretending to be the truth, in the other by a truism asserting

itself as a novelty. Similarly, when the latter writer, among his anecdotes of the conscription, tells us that "one young man who was drawn claimed to be exempt because he was the only son of a widowed mother—who supported him," the amusement is all in the unexpected turn of the last three words. In contradistinction to this, the humour of Don Quixote, of Falstaff, of Uncle Toby, of Major Bath, of the Vicar of Wakefield and Sir Roger de Coverley, of Major Pendennis and Bishop Blougram, consists in its truth. What these people do or say never surprises us. It is absurd as a great part of human life is absurd, and, laughing at them, we feel we are laughing at something in ourselves. The best recent instances of this higher kind of humour which American literature affords are to be found in Washington Irving, in Mr Lowell's *Biglow Papers* (to which, as a considerable national poem, we shall have to revert), in passages of Mr Longfellow's *Kavanaugh*, in Mr Hawthorne's *Seven Gables* and *Seven Vagabonds*, and in the prose and verse of Dr Holmes. In his three pleasant volumes, *The Autocrat*, *The Professor*, and *The Poet at the Breakfast Table*, there is much that might have been omitted, more that should have been compressed. They contain too many jokes, good, bad, and indifferent, and are tainted here and there with what we must be excused for regarding as New England slang. But they are pervaded by a genial glow of kindly sympathy, and they exhibit, with a quaint mannerism—not without its attractions—personages, and situations, and sentiments which we recognise as at once odd and real. Dr Holmes's works have frequent reflections of Montaigne and Burton, and the *Noctes Ambrosianæ*; he mixes pathos and whimsicality after the manner of Lamb and Sterne. His humorous verses, the best known of which, "Daily Trials," "Evening, by a Tailor," and the "Music-grinders," inevitably recall the drolleries of Hood. His genius has, nevertheless, an original vein, less mellow, but at its best as genuine as that of his older masters. Several of the miscellaneous papers, essays, and periodicals belonging to the earlier years of the century, as *Salmagundi*, *The Talisman* of Bryant and Verplanck, *The Olipodiana* of W. G. Clarke, and the *Sparrow Grass Papers*, are frequently enlivened by sparkles of wit and evidences of keen discrimination. In others we trace the germs of a vicious style which threatens to degrade the lighter literature of the States. The *Charcoal Sketches* of Joseph Neal—which might be entitled Comicalities of the Mississippi—are among the earliest examples of the habit of playing with slang terms characteristic of his successors. An author who relies for effect on giving his imaginary personages such nicknames as "Dawson Dawdle," "Peter Ploddy," "Tippleton Tipps," and "Shiverton Shanks," is more likely to be the cause of wit in others than the source of humour himself. During the last generation in America the anxiety to be national has led many of her minor authors to make themselves ridiculous. To avoid walking like Englishmen, they have gone on all-fours; to escape the imputation of Anglo-Saxon features, they have painted their faces with ochre and put ear-rings through their nostrils; forsaking the speech of Addison and Steele, they have expressed themselves in an unseemly jargon of strange tongues. Of this mocking-bird humour the most legitimate form is that of the *Biglow Papers*, where the New England dialect is employed with effect to give voice to the sentiments of that district of the country during the national struggle, on one side of which it took the lead. A similar justification may be put forward in behalf of the Californian peculiarities, which are perhaps not too prominent in the often really humorous pieces of Bret Harte. The mixture of two dialects in the *Breitmann Ballads* is a bolder licence, though for the best of these Mr Leland

may plead the wide-spread use of the mongrel speech, and the original success of a drollery which has only become tiresome from his not knowing when his readers have had more than enough of it. The parodies of Mr Browne (Artemus Ward) are open to the same criticism. The writer was a man of wit and talent, and therefore his writings are amusing. They are good specimens of the worst style of satire: for the wit that relies on bad spelling is almost as false as that which consists in bad language. In vindication of the "Showman," it must, however, be observed that his sarcasm is generally directed against mean or ridiculous things. But his example has paved, for those who have caught the trick of his phrase and who are unrestrained by his good feeling and good sense, an easy descent to the lowest form of light literature—that which panders to the vice of moral scepticism and thrives on the buffoonery of making great and noble things appear mean or ridiculous. The names of those who habitually feed on mental garbage should be left to sink into the oblivion from which they have unfortunately emerged. It is painful but necessary to observe that some of the more considerable writers and thinkers of the New World are apt to condescend on occasion to this burlesque way of writing. American light literature bristles in puns which are at best the "a-b abs" of wit. Of these, Mr Lowell (a severe critic of everything English) has made the worst—"Milton is the only man who has got much poetry out of a cataract—and that was a cataract in his eye." Mr Leland, the next worst, in his book of travels—"If a thing of beauty be a jaw for ever, as the American said of his handsome, scolding wife, then the donkey boys of Cairo are the most jaw-ous and beautiful creatures; for the sound of their voices drieth not up." Eccentricities of this sort, with the graver irreverences which intrude themselves even into the pulpits of the West, should be universally discredited as blasphemies against the first principles of taste. They are as "flat, stale, and unprofitable" as the contortions of a wearied clown. True humour—as ever in our classics—must go hand-in-hand with seriousness; it must never forget that behind the comic there is a tragic element in human life. The mere "farce" is contemptible, because it is as unnatural as the expression of a countenance distorted by a continual grin. In forgetfulness of this lies the greatest danger of the recent literature of America, and we can only trust to the higher intellectual instincts and tendencies of the age to detect and resist it.

5. NEW ENGLAND TRANSCENDENTALISM.—Religion, the Theolog first motive power of thought in America, has continued to flow, both in its old channel—that of the orthodox Puritanism which came down from Eliot and Edwards through Dwight to Hodge and the Princeton Essays—and in another, that of the new forms of faith advocated by W. E. Channing, and with gravely heterodox modifica- Channing tions by Theodore Parker. Criticism of Channing's theological position is apart from our purpose here. He claims notice in a review of literature by the vigour of his conceptions and his graceful and correct expression of them. His earliest considerable essay, the *Moral Argument against Calvinism*, one of the best known of his numerous controversial works, indicates by its title his prevailing attitude. He relied through life on a priori moral arguments, and employed them as his engines of attack against all persons, institutions, or practices that offended his rigid sense of justice or his enthusiastic benevolence—e.g., Napoleon I., War, and Slavery. A generous indignation against wrong, and keen practical sense of the duties of life, are more conspicuous in his writings than speculative power; but his insight into the political position of parties and the probability of future

conflicts is remarkable. Though at variance with the older creeds of Christendom, Channing's writings are everywhere marked by a reverential spirit, and not unfrequently by a touch of asceticism inherited from the Puritan days, whose abstract doctrines alone he proposed to modify. On the other hand, he admired the higher forms of Art, and in his eloquent essays on *Self-culture* anticipated much that has been said more recently by Emerson. He loved beauty as well as virtue for itself, and his style, except on rare occasions, is free from the defects of taste so frequent in the writings of his contemporaries. His reviews of Milton and Fenelon abound in passages—as the picture of religious peace in the latter—which exhibit the delicacy and the breadth of his sympathies. Theodore Parker—unlike Channing—assails the whole basis of the old theology, and frequently errs from arrogance and impetuosity. He had, perhaps, a more powerful but a less highly cultivated mind. He was a pupil of the transcendental movement of New England, to which, because of its influence on literature and its association with the most original thinker of the New World, we must accord some space.

In the early years of this century the mental philosophy of the West, beyond that which was a handmaid to the Calvinistic theology, was limited to commentaries on Locke and Brown and the eclecticism of Cousin, when the republication of *Sartor Resartus*, and the works of the German idealists which it introduced, gave life and voice to a new intellectual world. Ideas which filter slowly into English soil and abide there for a generation, flash like comets through the electric atmosphere of America. Coleridge and Carlyle were hailed as prophets in Boston while their own countrymen were still examining their credentials. The rate of this transformation was surpassed by its thoroughness. The converts put their teachers to the blush; and in recoil from solid Scotch psychology and practical materialism, rushed to the outer verges of idealism, mysticism, and pantheism. Their quarterly magazine, the *Dial*, during the space of four years represented their views throughout four volumes of miscellaneous merit. The *Dial* is a pantheon from which only Calvinists and Utilitarians are excluded, where the worshippers, Parker, Fuller, Alcott, and a host, meet and sing hymns to Confucius, Zoroaster, Socrates, Goethe, Tieck, and Richter, set to German music; and pass from antiquated laudations of Homer and Shakespeare to friendly recognitions of new heresies; from thoughts on labour to puffs of poetasters; from Hindoo mythology and Chinese ethics to 19th century truisms about progress and union, prudence and humanity; from soaring among the heights of a modern religion of beauty to raking among the tangled roots and dead leaves of a second-hand Orientalism. But those vapours of idealism might have soon faded into the light of common day, had not all their best aspirations been concentrated and vitalised by Mr R. W. Emerson. His first oration, delivered at Cambridge thirty-five years ago—the refrain of which is the independence of American literature—is referred to by recent critics as a landmark in the annals of their country. In this discourse—as in the six volumes through which the author enforces the same conceptions—there is scarce anything of which, taken separately, we need fail to trace the pedigree. Fichte had many years before spoken in the same strain of the vocation and nature of the scholar; the view of science comes from Swedenborg and Schelling; and the dignity of labour from Carlyle. The originality, as is the case with the author's whole system of thought, is in the combination—which, it may be, is the only kind of originality now possible. His position, as far as it is tenable, illustrates the fact that the divisions of philosophy are being continually altered as old systems form affinities with new

beliefs and historical conditions. Mysticism in the New World has been combined with the opposite extravagances of Mount Lebanon and Oneida Creek, but it has been distinguished from idealism proper by its exaltation of emotion above reasoning. Mr Emerson, defining transcendentalism as “the saturnalia of faith,” differs from the older mystics in his absolute rejection of all external authority, his almost arrogant confidence in the sufficiency of the inner light, and his new American preference for the active to the passive sides of life. He has an historical sympathy with the unsatisfied aspirations of all ages, with the day-dreams of restlessness in search of rest that inspired the quest of the Sangreal, and led the monks to Christianise the eastern Nirvana; that laid out Brook Farm in Massachusetts, and gave Novalis and Newman back to the fold of Rome: but he will not be drawn by them into any church with walls. All religions are to him “the same wine poured into different glasses.” He drinks the wine, and tries to shatter the glasses. His unflinching scepticism pierces the armour of all definite dogmas, while he entrenches himself behind an optimism like that of Spinoza. Mysticism has in the main been fatalistic. As a developed system, its natural home is in the East; where the influence of great uniformities of soil and climate have only in recent years been partially counteracted by the conquering activities of an energetic race. Beneath her burning sun and surrounded by her tropic vegetation, the mass of men were overwhelmed by a sense of their insignificance, and this feeling of subjugation was intensified by absolute forms of government. The same listlessness which permitted a secular and priestly despotism, led its victims to welcome the idea of a final absorption of their individuality. Their philosophical ambition was to pass into the framework of a gigantic nature, to be “rolled round the earth's diurnal course with rocks and stones and trees.” There is a relic of this spirit in the *ἀρραβία*, *ἀπάθεια*, and *ἡρεμία*, which are the aims at once of the Epicurean and Stoic systems; but the doctrines of passive obedience had been banished from Greece as early as the overthrow of the Pythagorean institute. They revived in the dark and middle ages, when the church took upon itself the task of legislating for the intellect; and even the precursors of the Reformation were possessed with an almost oppressive sentiment of resignation. The reproduction of the Oriental spirit in America, in so far as it is genuine and not the mere expression of a love of far-fetched quotations, may be attributed to external influences in some respects comparable to those which weighed on the inhabitants of ancient India. In the Western, as formerly in the Eastern World, nature still struggles to assert her old supremacy, and threatens to domineer over men's minds by the vastness of her empire. But in other respects the conditions are reversed. In place of stagnation and uniform although magnificent decay, we have to deal with the manifold progress of 19th century civilisation in a land where every one is more or less inspired by the resolve of the modern mariner with an ancient name to “sail beyond the sunset” in pursuit of fresh adventures; where the energies of the individual are in constant, and in the long run triumphant, struggle with all that tends to restrict the full sweep of his arm or to retard the freest activities of his mind. Where every moon sees new forests felled, new rivers crossed, new fleets built, new tribes amalgamated, new discussions raised, and new problems solved, mysticism, if it exist at all, must take on a form very different from that handed down from the East of 3000 years ago to the Alexandrians, and transmitted to the European ages of implicit faith by the pseudo Dionysius. Mr Emerson strikes the key-note of the difference when he writes, “Feudalism and orientalism had long enough thought it majestic to do nothing; the modern

majesty consists in work." Retaining from the mystics his belief in the supremacy of the higher emotions, he substitutes for a religious creed an idealised view of modern physical science. His combination of stern practical rectitude with an ideal standard is his point of contact with Puritanism. A chivalric nobility, in which beauty and goodness are blended, is at once the goal, the sanction, and the motive of his ethical system. Praise of the virtue which, transcending all prudence and disdaining all consequences, is its own reward, is the refrain of his moral monologue. His severe censure of Goethe's artistic indifferentism recalls the age when the Bible and theological commentaries were regarded as the sum of honest literature. He writes of our great dramatist in the spirit of the men who closed the theatres: "He was the master of the revels to mankind"—a sentence far removed from the spirit of modern art-worship. But those which follow, protesting against the opposite extremes of austerity, indicate his divergence on the other side from the old faith of New England.

Mr Emerson is, we believe, most widely known in this country by his *Representative Men*: by no means the most satisfactory of his works. A series of generally acute criticisms, pervaded by no well-marked ethical idea, it leaves on the mind a somewhat indefinite impression. Its categories are not exhaustive, and it is difficult to determine on what principle they are chosen; but it serves as an interesting point of comparison with the corresponding lectures of the great English advocate of hero-worship, to the suggestions of which it probably owes its existence. Mr Carlyle, whose whole faith is centred in strong individualities, adopts the view of history which practically resolves it into a series of biographies. Mr Buckle, caring little for persons, and confiding rather in general laws, resolves biography into history. Mr Emerson on this question steers a middle course. He believes in great men, "to educate whom the state exists, with the appearance of whom the state expires;" but he regards them as inspired mouthpieces of universal or national ideas rather than as controlling forces. Their mission is not so much to regulate our action as to "fortify our hopes." Possessed of a larger share of the Over Soul which "makes the whole world kin," they apprehend and explain phenomena which have hitherto passed unheeded; but their indirect services are the best. Their examples, more weighty than their acts or discoveries, are perpetual encouragements. The great man is an encyclopædia of fact and thought; the belief born in his brain spreads like a current over humanity, and he becomes for a time the golden key to the ill-defined ideal of the multitude. But his career should rouse us to a like assertion of our liberties. We ought not to obey, but to follow sometimes by not obeying him. Our author accepts the position upheld by Aristotle and popularised by Macaulay, that different forms of government are adapted to different social conditions; but maintains that the tendency of modern times, attaching more weight to the equality of persons and less to the inequalities of property, is towards Democracy, with which and the industrialism of his age he has in the main a cordial sympathy. He believes in collective wisdom as the best check on collective folly, and, allowing that the state exists for its members, he thinks they can act best in union when all are subject to the fewest external restraints. He differs from Thoreau and others of his disciples in having no share in their selfish isolation. His best essays, woven of two curiously intersecting threads, present us with a unique conjunction of shrewdness and idealism. There never was a mystic with so much of the spirit of the good farmer, the inventor, or the enterprising merchant.

As regards form, Mr Emerson is the most unsystematic of writers. The concentration of his style resembles that

of a classic, but, as with others who have adopted the aphoristic mode of conveying their thoughts, he everywhere sacrifices unity to riches of detail. His essays are bundles of loose ideas tacked together by a common title, handfuls of scraps tossed down before his audience like the contents of a conjuror's hat. He delights in proverbs and apt quotations; he exaggerates like an American, loves a contradiction for itself, and prefers a surprise to an argument. His epigrams are electric shocks. He sacrifices everything to directness. His terse refinement of phrase and trenchant illustrations are his charm. His ideas are on the scale of a continent; his sentences are adapted for a cabinet of curiosities—bits of mosaic work, sweeping generalisations given in essences. His style, armed with points like the bristles of a hedgehog, wants repose. This feature is conspicuous in the *English Traits*, where his estimates of men and things, frequently felicitous and generally racy, are often marred by an unpruned violence. His eye is keen, but its range is narrow, and he is ignorant of the fact. Unconsciously infected by the haste which he condemns, he looks at other nations through the folding telescope of a tourist. His representations of our leading writers and statesmen seldom rise above the level of Mr Willis's *Pencilings by the Way*. His taste is constantly at fault, and an incessant straining after *mots* often leads him into caricature. His judgments of those whose lives and writings do not square with his theories are valueless; and in dealing with foreign languages he betrays the weakness of his scholarship.

One qualification for a good critic is a well-defined artistic standard, another is the dramatic capacity of placing himself for the time in the position of the person who is being criticised. Mr Emerson has neither of these. With the spirit of a fearless inquirer, he unfortunately blends so much presumption as to feel an absolute indifference regarding the opinions of others; and this in excess constitutes a moral as well as an artistic defect. Thought is free, and the expression of it ought to be so; but when our thought wanders very far from that of the majority of the wise and good, we are bound to watch it, to sift its conclusions, and to state them moderately. Mr Emerson's thought does wander far, and it runs fast; he does not know what moderation in expression means, and his almost childish love of contradiction perpetually, and often justly, provokes offence. He rides rough-shod over the most cherished convictions, or waves them aside with a complacent smile and a sort of divine impudence. Every claim of authority he receives as a challenge to his personal rights, and he stabs the bull Apis, in utter disregard of the historian's warning. His impatient *anticipationes nature* detract from his reliability in matters of detail, while by a similar carelessness he repeats and contradicts himself with equal frequency. His soundest judgments relate to the men around him, of whom he is at once the panegyrist and the censor. All that is weak and foolish in their mode of life he condemns, all that is noblest and most hopeful he applauds.

Mr Emerson has left his mark on the century; to use a favourite phrase of his own, "he cannot be skipped." Even where his results are least satisfactory, his intense suggestiveness is the cause of thought in others; and as one of the "genetic" powers of modern literature, his fertilising influence will survive his inconclusive speculations. His faults are manifest: a petulant irreverence, frequent superficiality, a rash bravery, an inadequate solution of difficulties deeming itself adequate, are among the chief. But he is original, natural, attractive, and direct—limpid in phrase and pure in fancy. His best eloquence flows as easily as a stream. In an era of excessive reticence and cautious hypocrisy he lives within a case of crystal where

there are no concealments. We never suspect him of withholding half of what he knows, or of formularising for our satisfaction a belief which he does not sincerely hold. He is transparently honest and honourable. His courage has no limits. Isolated by force of character, there is no weakness in his solitude. He leads us into a region where we escape at once from deserts and from noisy cities; for he rises above without depreciating ordinary philanthropy, and his philosophy at least endeavours to meet our daily wants. In every social and political controversy he has thrown his weight into the scale of justice, on the side of a rational and progressive liberty; and his lack of sympathy with merely personal emotions is recompensed by a veneration for the ideal of the race which recalls the beautiful sentiment of Malebranche: "When I touch a human hand I touch heaven."

### Poetry.

Half the literary men and all the literary women of this century in America have written verses; most of them are respectable and many are excellent. But a brief review of the poetry of the West must dwell on the works of four or five authors who most clearly and saliently express the main tendencies of their nation. It must suffice here to name as familiar, or worthy to be so, the graceful *vers de société* of Holmes, especially his "Punch Bowl" and "Old Ironsides;" the patriotic chants of James Percival; the sparkling fancies of J. R. Drake's "Culprit Fay;" the fashionable satires of Halleck; the lyrics and romances of the great traveller and prolific author, J. Bayard Taylor; the well-balanced stanzas of Hillhouse; the plays of Conrad and Bird: "Woodman, spare that Tree" and the "Whip-poor-Will," by G. P. Morris; A. B. Street's "Settler," and "Forest Walk;" and, pre-eminent among female minstrels, Mrs Sigourney, whose blank verse descriptions of nature approach those of Bryant; the youthful prodigies, Lucretia and Maria Davidson; and Maria Brooks, authoress of the richly imaginative southern romance of *Zophiel*, whom Southey, her friend and admirer, pronounced to be "the most impassioned of poetesses." We proceed to review the position of the really great poets of the United States, as representing somewhat different manners and modes of thought.

1. THE EUROPEAN SCHOOL.—Of these, in our judgment, Mr Longfellow is still the first. His works are free from the defects that stamp the national literature of his country. He has none of the uncouth power and spasmodic exaggeration of his contemporaries. He is all grace, polish, and sweetness. His prose masterpiece, "Hyperion," is the key-note of his minor poems. The source of their inspiration is "Outre Mer" among feudal towers, Flemish towns, and Alpine passes. Like Irving in the variety of his culture and superior in genius, his imagination is Teutonic rather than American. He lingers in Nuremberg, Bruges, and Prague; and chooses for his emblem of life's river, not the Ohio, nor the Hudson, nor the Assabeth, but the "Moldau's rushing stream." His "New England Tragedies" are perhaps his least successful efforts, partly because dramatic literature has seldom yet flourished in American soil, and partly because his sympathy with the ruder age is not keen enough to enable him to vitalise it. Mr Longfellow has given us the best translations in the world from Swedish, German, Spanish, and Italian authors, and many of his best verses are avowedly suggested by proverbs or sentences, or bits of old romance. A few words from an old French author give him the burden of the "Old Clock on the Stairs;" a leaf out of Mather's *Magnalia Christi* is rhymed into the "Phantom Ship;" the ballad of the Count Arnaldos sets him dreaming over the secret of the sea; a verse of Euripides is the key-note to his "Voices of the Night;" a few lines from Goethe gather

up the essence of the "Psalm of Life." In the New World, but not of it, he dwells with almost wearisome fondness on the word "old." Volumes of old days, old associations that we cannot buy with gold, quaint old cities, old poets and painters, sweet old songs, old haunted houses, dear old friends, the grey old manse, Nature the dear old nurse, dear old England,—on phrases and thoughts like these his fancy broods. American verse is frequently rough-hewn and audacious, sometimes obscure and pedantic; its novelty is often more striking than its truth. Every sentence that Longfellow has penned is as clear as crystal and as pure as snow. He wears his weight of learning lightly as a flower; and though he cannot create, he cannot touch without adorning. He seldom gives us thoughts absolutely new, but he puts our best thoughts in the best language. Critics react against his popularity, and complain of his want of concentration and the conventionality of his epithets (a fault more rare in his later volumes); but his place as the laureate of women and children and gentle men is unassailable; and there are seasons when we prefer his company to that of the grand old masters, when we seek an anodyne rather than a stimulant—

"His songs have power to quiet  
The restless pulse of care."

Longfellow's command of verse alone proves him to be a genuine poet. There are passages in the "Arsenal," the "Occultation of Orion," the "Building of the Ship," and the "Household Poems" unsurpassed in melody by any in contemporary English verse. The introduction to "Hiawatha," the closing lines of "Evangeline," and some of the character sketches which preface the "Tales of the Wayside Inn," have a music equally attractive and more decidedly original. The highest flights of Longfellow's imagination are in the strangely-confused old-world story of the "Golden Legend," but the work on which his fame most securely rests is "Hiawatha." This poem, in which a series of idylls are strung together on the thread of an idea common to Indian and Scandinavian legend, has that exhilarating flavour of nationality wanting in many of the author's works, and it yields to none of them in artistic finish. The monotony of the verse is like that of a bird's song which has only two or three notes, and yet from its everlasting freshness never palls upon the ear. Most modern attempts to reproduce old ballads put new wine into old bottles; but the American poet has thrown himself as completely into the spirit of aboriginal western life as he has into that of Gothic paganism in the "Challenge of Thor." Like Chibiabos the musician he is at home among the pine-groves and the prairies and "the great lakes of the Northland;" and

"All the many sounds of Nature  
Borrow sweetness from his singing."

Longfellow's descriptions charm us more than they astonish. Inferior in luxuriance to those of "Enoch Arden," in intensity to those of "Locksley Hall," in subtlety to Browning's Italian pictures, they are superior in simplicity. If they do not adorn Nature as a mistress with the subjective fancies of a lover, they bring her before us as a faithful nurse, careful for her children. In "Evangeline" the poet follows the wheels of the emigrant's waggon over

"Billowy bays of grass, ever rolling in sunshine and shadow;"  
and

"Over them wander the buffalo herds and the elk and the  
roebuck."

Hiawatha speaks of Nature with the familiarity of an inhabitant; there is no trace of the grandiose style of the tourist. In the best episodes of the volume—as the account of the hero's childhood and his friends—of the wooing of Minnehaha—of the son of the evening star—of

the ghosts and the famine—the parable of human life, with its incidents of birth, love, and death—of civilisation and decay—is told in a narrative of child-like tenderness as well as masculine grasp. He who runs may read it, and yet the whole is lit up by an imagination like an aurora borealis. A recent New York critic ridicules the European view of "Hiawatha" as an American poem. It is true that the feverish ardour of Wall Street has no place in its pages; but it is none the less manifestly transatlantic and *sui generis*. In celebrating Red Indian life, it inevitably discloses some of the features of the race which has come into close contact with that life. The New Zealand myth about the strength of the dead enemy passing into his conqueror applies here. Mr Dixon has dwelt very justly on the extent to which the aborigines of America have communicated their spirit to the pioneers before whom they have given way. Hiawatha sings of the decadence of a primitive people in strains that recall by their pathos the old British legends of the death of Arthur, but has also a prophetic side; from the meeting-point of two races it looks before as well as after.

More devoid of national sentiment and local colouring are the remarkable verses of Edgar Allan Poe, to whom we have before referred as a romancer. If the aim of poetry be to astonish or to fascinate, Poe takes a high rank among poets. According to Wordsworth's definition of the art, he has hardly a place among them at all. He teaches nothing, and living in one world writes in another. All we know of the personality of most of the authors we have named adds to the charm of their works. Regarding Poe's career it is otherwise. The vain and captious jealousy of his criticism is as repulsive as his graver defects. It has been said that he is the greatest of American writers in verse. This is an exaggeration of his powers only surpassed by his own exaggeration of them. It is true, however, that by pure intensity of delirium he now and then takes a flight beyond that of any other Western poet. His "Politian" is perhaps the stupidest fragment of a play that exists. But in his lyrics the fervour of his sympathy with himself makes artistic recompense for his want of sympathy for others. The passion of "Annabel Lee" is at a white heat, and is pervaded by a true pathos. The class finish of the best of his verses is unsurpassed, and his musical cadences give a charm even to those which are comparatively meaningless. The "Raven" is at the worst a marvellous piece of mechanism; and the same delicacy of touch is everywhere visible in the rushing lines of "Annie," "Eulalie," "Ulalume," "Lenore," and the "City in the Sea." The purity of those poems is one of their most remarkable features. By the side of the author's life, they are like nuns in the convent of a disorderly city; but they are at the same disadvantage—their isolation gives them an air of unreality. The "banners, yellow, glorious, golden," of his fancy "float and flow" on the roof of an imaginary palace.

2. SCHOOL OF AMERICAN SCENERY AND ADVENTURE.—The French critic M. De Tocqueville remarks that, in democratic communities, where men are all socially insignificant, poetry will be less apt to celebrate individuals, but will incline to dwell on external nature or on the ideas which concern mankind in general. It will be either descriptive or abstract. The works of Mr Bryant, the earliest considerable American poet, help to vindicate the generalisation. His "Thanatopsis," written in his 19th year, is perhaps the masterpiece of his sombre contemplative imagination. The reason why the author has never surpassed this effort of his youth is to be found partly in the cast of his mind, characterised by a narrow greatness, and partly in the fact that, during the major part of his life he has been constrained to "scrawl strange words with the barbarous pen" as the editor of a daily newspaper: a fact

to which, at the close of his "Green River," he makes a touching reference. Mr Bryant has lived in thronging cities, an honest and energetic politician; but in his leisure hours his fancy has roamed to breezy hills and valleys and the undulating sea of the prairies. The perpetual autumn of his writings is peculiar. He has written smoothly in various measures, but he is never lively. An American Alastor, he loves "the air that cools the twilight of the sultry day" better than morning "clad in russet vest." In the beautiful verses on the "Death of the Flowers" his ear catches a dirge in the wind

"The south wind searches for the flowers whose fragrance late  
he bore,  
And sighs to find them in the wood and by the stream no  
more."

The high rank grass of the meadow is to his eye the garniture of the graves of a race represented by his "Disinterred Warrior." His "Evening Wind," "Forest Hymn," "Monument Mountain," "The Burial Place," and "The Past," are set to the same slow music, and pervaded by the thought of life as the avenue of death. If we compare his "Address to a Waterfowl" with Wordsworth's or Shelley's "Skylark," we appreciate the monotony of his mind, which is like that of Cowper without Cowper's occasional vivacity. Mr Bryant stands on a high level, but the space he covers is limited; he has no touch of humour, and only the distant pathos of prevailing melancholy. Master of his position where he is at home in the woods, he loses his inspiration when he draws near his own cities. His nature-worship has a parallel in the feeling which animates some of the most graphic passages in New England prose; as when Emerson writes—

"At the gates of the forest, the surprised man of the world is forced to leave his city estimates of great and small, wise and foolish. The knapsack of custom falls off his back with the first step he makes into these precincts. Here is sanctity which shames our religions, and reality which discredits our heroes. . . . We have crept out of our crowded houses into the night and morning. . . . The incommunicable trees begin to persuade us to live with them, and quit our life of solemn trifles. Here no history or church or state is interpolated on the divine sky and the immortal year."

The whole life and writings of the morbidly eccentric Thoreau genius H. D. Thoreau are a comment on the results of this one-sided spirit. It pervades half the volumes of Theodore Winthrop, a manlier though less original mind. It has taken possession of the poetic advocate of Far Western and wild Indian life, Joaquin Miller, whose "Songs of the Sierras" in their best passages add to Bryant's descriptive power more of the fire of adventure, finding expression in the quicker pulse of the verse. But the lyrics of this writer, though the vehicle of national thought, bear the mark of foreign influence. Their cadences are echoes of Mr Swinburne. The impulse which made captive the "Scholar Gipsy," which the hero of "Locksley Hall" welcomes and then rejects, is a leading feature of Western literature. Imaginative and ardent minds, oppressed by what Mr Arnold calls "this strange disease of modern life," try to escape from the region of the real drama into that of the ideal lyric—"arva, beata petamus arva, divites et insulas,"—and have now and then endeavoured to convert it into an actual idyll, as when Thoreau buried himself in a log hut by Walden lake, or Theodore Winthrop, leaving his ledgers in New York, scoured over the crags of Oregon; or Horne, with his "Orion" still unsold, was found mining in a quarry of New South Wales. But this *emigré* spirit, when put into practice, ultimately cures itself: a poet soon tires of working with his hands for a livelihood. The aspirations of Clough's "Bothie" are stifled by the *vitiosæ curæ* of a hard life, or terminate in the catastrophes of a fanaticism, such as Hawthorne has branded with his genius in the *Blithedale Romance*. The philosophical refugees

find that the solitude they desired charms only by its contrast with the civilisation they have left; as the beauty of the sea is its contrast with the shore. But this wandering impulse, strong in the ancient Greek and the modern English race, has colonised and civilised the world: it is especially strong in the Anglo-American. The very restlessness which makes his cities so noisy bid him long for a remoter rest, and this longing acts in conjunction with more material demands to drive him across the Mississippi, and pioneer the way to the Pacific.

3. TRANSCENDENTAL AND ECCENTRIC SCHOOL.—The freshness which breathes through Mr Emerson's essays reappears in his poems: but they are seldom so successful as his prose. Apart from the obscurity of their matter, which is great—for he has chosen verse as the vehicle of his remoter mysticism—they are defaced by frequent mannerisms and incongruities: most of them are wanting in melody, many in syntax. The writer seems to trust to providence for his rhymes, and changes his metres at will. Nevertheless, his genius has a lyric side, and the imaginative sympathy with nature which makes his prose poetical, prevents his verse, even when awkward, from becoming prosaic. The rippling of rivers, the sigh of the pine, the murmur of the harvest, and the whirr of insects pervade and give life to his descriptions. A morning light is thrown over his happiest pages, and some of his quieter reflective pictures are not unworthy of the author of the "Excursion." Interleaved between the gold-dust of Alexandrian rhapsody there are pieces that speak of a love that is neither "initial," "dæmonic," nor "celestial," but human. Of these, "The Dirge," "In Memoriam," "The Farewell," the lines "To J. W.," "To Ellen," and the "Threnody," are the most conspicuous. The prevailing tone of the greater part of Emerson's poetry is cheerful. Unlike those of Bryant, his "woodnotes" are those of the spring.

"Thousand minstrels wake within me,  
Our music's on the hills,"

is the perpetual refrain of the exulting worshipper of nature. His lines entitled "Good-bye, proud World," breathe the hermit-like spirit of Quarles or Andrew Marvell; but the Puritanism of older days has here assumed another shape. There are other pieces relating to the intercourse of men with each other showing a keen observation of common life and sound worldly wisdom, in neat quatrains and a few vigorous political songs. The "Hymn on Concord Monument" is strong and dignified, while the verses relating to the civil war address the nation in forcible terms both of warning and encouragement. Those practical manifestoes are the more striking from the fact that they are printed by the side of others proclaiming in transcendental enigmas the emptiness of transitory things, the fixity of fate, and the doctrine of the absorption of the individual in the infinite.

Mr Emerson was one of the first to praise the extraordinary rhapsodies of Mr Walt Whitman, which have since attracted too much attention to be passed without notice. But although this author on various occasions displays an uncouth power, his success is in the main owing to the love of novelty, wildness, and even of absurdity, which has infected a considerable class of critics and readers on both sides of the Atlantic. Mr Whitman does not write in verse; he discards not only rhyme, but all ordinary rhythm. What there is of the latter seems to come by accident in lines of various length, and arranged either on no principle or on one which we have failed to discover. "The Leaves of Grass" is redeemed by a few grand descriptive passages from absolute barbarism both of manner and matter. It is a glorification of nature in her most unabashed forms, an audacious protest against all that civilisation has done to raise men above the savage

state. The "Drum Taps," a set of generally vigorous pictures of the war, are less objectionable; the dirge on Lincoln in particular has many qualities of a noble elegy,—the imagery is rich though sometimes fantastic, and there is here and there a wild music in the composition,—but it is still defaced by pedantic words and unjustifiable, because unnecessary, novelties of phrase.

4. PATRIOTIC AND POLITICAL POETRY.—The assertion of Henri Beyle, that politics are like a stone tied round the neck of literature, must be accepted with a reservation; for if the songs make the laws, the battles often make the songs of a nation. The growth of a history on their own soil is, in the minds of most Americans, a requisite to the full development of national art. English history inadequately supplies the desired background, for they cannot associate it with what they see around them. Memories of the Revolution war have, during this century, been recalled in some stirring verses, as "Paul Revere's Ride," in Mr Longfellow's "Wayside Inn;" but the most effective national poetry has been suggested by more recent events. The "Biglow Papers," a series of metrical pamphlets, born of the last great social and political struggle of the New World, are among the most original contributions to its literature. Mr James Russell Lowell is the author of several volumes of miscellaneous verse. His earlier efforts, buoyant and vigorous, but bearing the marks of haste, display more impetuosity than power. His genius everywhere appears in contrast to Bryant's. Far from shrinking into solitary places, he loves great cities and their cries, and sets them to rhyme with hearty good-will. When he goes into the country, it is on a "day in June," to have his blood sent faster through his veins by the spring morning, and not to dream among the autumn woods of "Thanatopsis." His "Allegra," "Fountain," and "Indian Summer Reverie," are marked by the same jubilant energy and the same apparent carelessness. Mr Lowell's diffuseness is only half redeemed by his fluency. He writes *currente calamo*; and, unchecked by any spirit of reverence, contemns what he is pleased to call "the blaspheming past" and the "dotard Orient." In dealing with the forms of nature around him, he shows a keen eye and a fine sense of analogies: his images drawn from history are less successful. Few Americans know how to use the classics with reticence, and Mr Lowell's pages are infected with schoolboy commonplaces. His "Ode to Freedom," "The Present Crisis," with other semi-political and social pieces, are noble and stirring platform verse, but they will not bear analysis. His "Irene," "Requiem," and "Beggar Bard" are marked by genuine sentiment and true pathos. But the prevailing flaw of his earlier and later serious poems—as "The Cathedral," and "Under the Willows," is the confusion of inspiration with aspiration. In the "Fable for Critics," which may be compared with Leigh Hunt's "Feast of the Poets," he breaks ground on the field in which he has found his harvest. The merit of this piece lies in its candour and the general fairness of its criticisms, in the course of which "the whole tuneful herd" of American authors are reviewed with good-humoured banter. In several instances, as in the following, he shows himself alive to the defects which he shares with the majority of his countrymen—

"Neal wants balance; he throws his mind always too far,  
And whisks out flocks of comets and never a star;  
He has so much muscle, and longs so to show it,  
'That he strips himself naked to prove he's a poet."

The author's style is rapid and sparkling; his points follow one another like the sparks from a Leyden jar; his love of freedom and truth and detestation of pretence are always admirable; but his earlier poems are constantly defaced by violences.

Mr Lowell informs us that the Mexican war, which he regarded as a crime perpetrated in behalf of slavery, led to the publication, in 1846, of the first of his series of "Biglow Papers." After an interval of thirteen years, the second began to appear in 1861, and closed with the war in 1865. In his preface to those remarkable productions the author makes a successful defence of the language in which they are written. The more homely standards of the present as compared with those of the last century give countenance to his mottoes—"Unser Sprach ist auch ein Sprach," and "Vim rebus aliquando ipsa verborum humilitas affert." The essential to the use of a *patois* is that it be natural to the writer. Mr Lowell has taken pains to show that the peculiarities of the Yankee dialect are not indigenous; that the pronunciation and meanings given to familiar words, and the employment of words now unknown in England, are authorised by the example of our elder classics. We are more concerned to know that he has been happy in his use of the words and phrases in question. The popularity of his work is in this respect a voucher for his success. The rural dialect seems to suit his genius better than the English of his university. The quasi-dramatic form he has adopted confines within limits a too discursive fancy. The letters of Mr Sawin are excellent examples of the form of satire in which contemptible qualities are stripped of their varnish by the sheer effrontery of the wearer. The style of the book is more trenchant and better matured than that of Lowell's other works, and it is really humorous. The humour of the "Biglow Papers" is broad and obvious. They derive their force from the incisive expression given to the sentiments shared by the author with a large section of his countrymen; and the lines most frequently quoted owe everything to a startling directness, something bordering on irreverence. Mr Lowell's poetical powers are set on fire by political zeal, and his animosity sharpens the edge of his most effective verse. The satiric scorn of the lines put into the mouth of Calhoun, with the speeches of Garrison, Phillips, and Sumner, helped to hasten the irrepressible conflict of the contending forces in the Western Continent. The second series of the "Biglow Papers" are animated by the spirit of an uncompromising Unionist as well as that of an Abolitionist. In these the poet's patriotism glows with a deeper fervour, and his songs rise out of the battlefield "like rockets driv' by their own burnin'." The graver poetry of this volume reaches a higher standard than the author has elsewhere attained. The short rural romance entitled "The Courtin'" is one of the freshest bits of pastoral in the language. The stanzas beginning "Under the yallar pines I house," and ending "A nation saved, a race delivered," are his masterpieces.

Whittier. Mr John Greenleaf Whittier is the political lyricist *par excellence* of America; and the best of his lyrics have a verve, swing, and fire that impart to the reader a share of the writer's enthusiasm. His verse, rapid as a torrent, is perpetually overflowing its banks. No one stands more in need of the advice once given to Southey, "squeeze out the whey;" and to no works more than to his is the maxim *πλέον ἤμισυ παντός* more applicable. There are few more graceful tales in verse than those of his "Tent on the Beach." They are remarkable for their smoothness and quiet beauty of sentiment. The music of "River-mouth Rocks," "Revisited," and the "Grave by the Lake" recalls that of Longfellow's best ballads. The most striking is the "Brother of Mercy," Piero Luca, who, like Abu Ben Adhem, loves his fellow-men. The same trust in the divine love which is the sum of Whittier's ardent faith, appears in the beautiful verses entitled "The Eternal Goodness" and "Our Master." The strongest lines in the book, addressed to "Thomas Starr King," have the rare

merit of condensation. Of Whittier's national lyrics, the most powerful is "Laus Deo," the burst of acclamation suggested by the passing of Lincoln's constitutional amendment. His narrative power is best illustrated in "Maud Muller," an original and more innocent version of Browning's "Statue and the Bust," springing up in an American meadow.

#### V.—SUMMARY.

The critics of one nation must, to a certain extent, regard the works of another from an outside point of view. Few are able to divest themselves wholly of the influence of local standards; and this is pre-eminently the case when the early efforts of a young country are submitted to the judgment of an older country, strong in its prescriptive rights, and intolerant of changes the drift of which it is unable or unwilling to appreciate. English critics are apt to bear down on the writers and thinkers of the New World with a sort of aristocratic hauteur; they are perpetually reminding them of their immaturity and their disregard of the golden mean. Americans, on the other hand, are impossible to please. Ordinary men among them are as sensitive to foreign, and above all to British, censure, as the *irritabile genus* of other lands. Mr Emerson is permitted to impress home truths on his countrymen, as "Your American eagle is very well; but beware of the American peacock." Such remarks are not permitted to Englishmen: if they point to any flaws in transatlantic manners or ways of thinking with an effort after politeness, it is "the good-natured cynicism of well-to-do age;" if they commend transatlantic institutions or achievements, it is, according to Mr Lowell, "with that pleasant European air of self-compliment in condescending to be pleased by American merit which we find so conciliating." Now that the United States have reached their full majority, it is time that England should cease to assume the attitude of their guardian, and time that they should cease to be on the alert to resent the assumption. Foremost among the more attractive features of transatlantic literature is its *freshness*. The authority which is the guide of old nations constantly threatens to become tyrannical: they wear their traditions like a chain; and, in the canonisation of laws of taste, the creative powers are depressed. Even in England we write under fixed conditions; with the fear of critics before our eyes, we are all bound to cast our ideas into similar moulds, and the name of "free-thinker" has grown into a term of reproach. Bunyan's *Pilgrim's Progress* is perhaps the last English book written without a thought of being reviewed. There is a gain in the habit of self-restraint fostered by this state of things; but there is a loss in the consequent lack of spontaneity; and we may learn something from a literature which is ever ready for adventures. In America the love of uniformity gives place to impetuous impulses: the most extreme sentiments are made audible, the most noxious "have their day, and cease to be;" and truth being left to vindicate itself, the overthrow of error, though more gradual, may at last prove more complete. A New England poet can write with confidence of his country as the land

"Where no one suffers loss or bleeds  
For thoughts that men call heresies."

Another feature of American literature is its *comprehensiveness*: what it has lost in depth it has gained in breadth. Addressing a vast audience, it appeals to universal sympathies. In the Northern States, where comparatively few have leisure to write well, almost every man, woman, and child can read and does read. Books are to be found in every log-hut, and public questions are discussed by

every scavenger. During the war, when the Lowell factory girls were writing verses, the "Biglow Papers" were being recited in every smithy. The consequence is, that (setting aside the newspapers) there is little that is sectional in the popular religion or literature; it exalts and despises no class, and almost wholly ignores the lines that in other countries divide the upper ten thousand and the lower ten million. Where manners make men the people are proud of their peerage, but they blush for their boors. In the New World there are no "Grand Seigniors," and no human vegetables; and if there are fewer giants, there are also fewer mannikins. American poets recognise no essential distinction between the "Village Blacksmith" and the "caste of Vere de Vere." Burns speaks for the one; Byron and Tennyson for the other; Longfellow, to the extent of his genius, for both. The same spirit which glorifies labour denounces every form of despotism but that of the multitude. American slavery, being an anachron-

ism based on the antipathies of race, was worse than Athenian slavery. But there is no song of an Athenian slave. When the ancients were unjust to their inferiors, they were so without moral disquietude: the lie had got into the soul. Christianity, which substituted the word "brother" for "barbarian," first gave meaning to the word "humanity." But the feudalism of the Middle Ages long contended successfully against the higher precepts of the church: the teaching of Froissart held its ground against that of Langland. The hero-worship of our greatest living author is apt to degenerate into a reassertion of the feudal spirit. The aspirations of our descendants in the West point, on the other hand, to a freedom which is in danger of being corrupted by licence. But if the vulgarity of demagogic excess is restrained and overcome by the good taste and culture of her nobler minds, we may anticipate for the literature of America, under the mellowing influences of time an illustrious future. (J. N.)

AMERIGO VESPUCCI. See VESPUCCI.

AMERSFOORT, a town of Holland, in the province of Utrecht, situated 12 miles E.N.E. of the city of that name, on the Eem, which here is navigable. It contains a town-house, several churches—Protestant and Roman Catholic—a court of primary jurisdiction, a Jansenist college, an industrial and several other schools. Woollen goods, cotton, silk, glass, and brandy are the chief manufactures, and there is a large trade in corn, tobacco, and dried herrings. Amersfoort received its municipal privileges in 1249. It was taken by the Archduke Maximilian in 1483, and by the French in 1672 and in 1795. Population, 13,200.

AMERSHAM, or AGMONDESHAM, an old market town in Buckinghamshire, pleasantly situated in the valley of the Misbourn, a small tributary of the Colne, 32 miles from Buckingham, and 26 from London. It consists chiefly of a main street crossed by a smaller one; and possesses a handsome church, containing some beautiful monuments, several dissenting places of worship, a town-hall, built in 1642 by Sir William Drake, and a grammar school. It has manufactures of black lace, cotton, straw-plait, wooden chairs, flour, and beer. Edmund Waller, the poet, was born near Amersham, and sat for the borough, which sent two members to parliament until 1832. Population of parish in 1871, 3259.

AMES, FISHER, an eminent American statesman and political writer, son of Nathaniel Ames, a physician, was born at Dedham, in Massachusetts, on 9th April 1758. He studied at Harvard college, where he graduated in 1774. After practising the law for some little time, he abandoned that profession for the more congenial pursuit of politics, and in 1788 became a member of the Massachusetts convention for ratifying the constitution. In this assembly he bore a conspicuous part, and in the next year, having passed to the house of representatives in the state legislature, he distinguished himself greatly by his eloquence and sprightliness and readiness in debate. During the eight years of Washington's administration he took a prominent part in the national councils; and on Washington's retirement, he returned to his residence at Dedham to resume the practice of the law, which the state of his health after a few years obliged him to relinquish. He still continued his literary labours, and published numerous essays, chiefly in relation to the contest between Great Britain and revolutionary France, as it might affect the liberty and prosperity of America. Four years before his death he was chosen president of Harvard college, an honour which his broken state of health obliged him to

decline. He died on the 4th July 1808, admired and respected by his countrymen from the brilliancy of his talents and his private virtues. His writings, which abound in sparkling passages, displaying great fertility of imagination, were collected and published, with a memoir of the author, in 1809, by the Rev. Dr Kirkland, in one large octavo volume. A more complete edition in two volumes was published by his son, Seth Ames, in 1854.

AMES, JOSEPH, author of a valuable work on the progress of printing in England, called *Typographical Antiquities* (1749), which is often quoted by bibliographers. He was born in 1689, and died in 1759. The best editions of his work are those published with the additions of Herbert (1785-90), and of Dibdin (1810-16). These both include a life of Ames written by Mr Gough.

AMES, WILLIAM, D.D. In the Latinised form of Amesius this distinguished English theologian is now better known on the Continent than in our own country, through works that were a power in their day, and are not yet spent of their force. He was born at Ipswich, Suffolk, in 1576. He received an excellent education at the grammar school of Ipswich; and proceeded next to the university of Cambridge, where he was entered of Christ's college. From the outset, as to the latest, he was an omnivorous student. Entering half-carelessly into the church where the great Master William Perkins was the preacher, he was, under the sermon, roused and alarmed in such fashion as was not rare under so burning and intense an orator as Perkins. Like another Nicodemus he visited the venerable preacher, and was taught and comforted so as never through life to forget his interviews with the "old man eloquent." Perkins having died at a ripe old age, was succeeded by one of kindred intellect and fervour, Paul Bayne, and his friendship also was gained by Ames. He proceeded B.A. and M.A. in due course, and was chosen to a fellowship in Christ's college. He was universally beloved in the university. His own college (Christ's) would have chosen him for the mastership; but a party-opposition led to the election of a Dr Carey, who at once sought a quarrel by arraigning Ames for disapproving of the surplice and other outward symbols. Not succeeding by threats of expulsion, which were illegal and powerless, the master resorted to transparent flattery. Ames stood firm, was led to re-examine former opinions, and the result was that more absolutely than ever he decided against conformity. Nevertheless, he preached in season and out of season, and always with profound impression. One sermon became historical in the Puritan controversies. It was delivered on St Thomas' day, before the feast of Christ's

nativity, and in it he rebuked sharply Lusory Lotts and the "heathenish debauchery" of the students during the twelve days ensuing. His exposures and scathing denunciations won thunders of applause, but there were sheathed in them lightnings of wrath among the High Church party. He was summoned before the vice-chancellor and whole senate of the university. He appeared, and in presence of as brilliant an assembly as ever met in the congregation-house, defended himself triumphantly. Nonconformity, admittedly in lesser things, was regarded as excluding him from the Church of England. He left the university, and would have accepted the great church of Colechester in Essex, but the relentless bishop of London refused to grant institution and induction. Like furtive persecution awaited him elsewhere, and at last he passed over to Holland. To leave England was not so simple or easy a thing then, and Ames had to disguise himself for safety. His disguise was singularly timed, for it produced an incident that has long been worked into the very fabric of church history in England and Holland. Coincident with his arrival at Rotterdam a congress of theologians—Remonstrant and non-Remonstrant—was being held. Ames went into the meeting in his "habit of a fisherman, with his canvas slops about his body, and a red cap on his head." As the debate proceeded, the English visitor rose and craved permission to oppose Grevinchovius—a theologian long since in oblivion, but a tower of strength in heresy at that day—in Latin. The Remonstrant champion was rather taken aback at first; but jeered and flouted the plain countryman, "like another Goliath scorning David." The question was the old-new one of the "self-determining power of the human will to spiritual good, without any need of the previous efficacious operations of divine grace." Ames bore his opponent's gibes at his dress, and overwhelmed him with his logical reasoning from Phil. ii. 13, "It is God that worketh in us both to will and to do." The fisherman-controversialist made a great stir, and from that day became known and honoured in the Low Countries. Subsequently Ames entered into a controversy in print with Grevinchovius on universal redemption and election, and cognate problems. He brought together all he had maintained in his *Coronis ad Collationem Haagensem*—his most masterful book, which figures largely in Dutch church history. At Leyden, Ames became intimate with the venerable Mr Goodyear, pastor of the English church there. While thus resident in comparative privacy he was sent for to the Hague by Sir Horatio Vere, who appointed him a minister in the army of the states-general, and of the English soldiers in their service, a post held by some of the greatest of England's exiled Puritans. He married at the Hague a daughter of Dr Burgess, who was domestic pastor of Vere. On his father-in-law's return to England, Ames succeeded to his place. It was at this time he began his memorable controversy with Episcopius, who, in attacking the *Coronis*, railed against the author as having been "a disturber of the public peace in his native country, so that the English magistrates had banished him thence; and now, by his late printed *Coronis*, he was raising new disturbances in the peaceable Netherlands." It was a miserable libel. Mr Goodyear being present in the lecture-room when Episcopius vented his malice, there and then rebutted his charge against his absent friend. None the less did the controversy proceed. Ultimately Ames reduced the Remonstrants to silence. The *Coronis* had been primarily prepared for the Synod of Dort, which sat from November 1618 until May 1619. At this celebrated synod the position of Dr Ames, if an extremely honourable, was a peculiar one. The High Church party in England had induced the king to interfere and bring about his removal from the Hague, on the ground of his nonconformity; but

he was still held, deservedly, in such reverence that it was arranged he should attend the synod informally. Throughout its sittings Dr Ames appears to have been the most active and influential of the foreign divines. It is a sorrowful fact that, from 1611–12 onward, Ames was interfered with harassingly by the High Church party in England. Twice over, when chosen professor, the most envenomed opposition was led from England. He was kept from the university of Leyden; and when later invited by the state of Friesland to a professoriate at Franeker, the persecution was renewed, but this time abortively. He was installed at Franeker on 7th May 1622, and delivered a most learned discourse on the occasion on "Urim and Thummim." He soon brought renown to Franeker as professor, preacher, pastor, and theological writer. He prepared his *Medulla Theologica* for his students. His *Casus Conscientiæ* followed. Both these treatises left their mark on the thought of the century. His "Cases of Conscience" was a new thing in Protestantism. The work shows much insight into human nature, and may be favourably compared with the bulkier *Ductor Dubitantium*. Having continued twelve years at Franeker, his health gave way, and he contemplated removal to New England. But another door was opened for him. His English heart yearned for more frequent opportunities of preaching the gospel to his fellow-countrymen, and an invitation to Rotterdam gave him such opportunity. His friends at Franeker were passionately opposed to the transference, but ultimately acquiesced. At Rotterdam he drew all hearts to him by his eloquence and fervour in the pulpit, and his irrepressible activity as a pastor. Home-controversy engaged him again, and he prepared his *Fresh Suit against Ceremonies*—extrinsically having the distinction of being the book which made Richard Baxter a Nonconformist. It was posthumously published. He did not long survive his removal to Rotterdam. Having caught a cold from a flood which drenched his house, he died in November 1633, in his fifty-seventh year.

Few Englishmen have exercised so formative and controlling an influence on continental thought and opinion as Dr Ames. He was a master in theological controversy, shunning not to cross swords with the formidable Bellarmine. He was a scholar among scholars, being furnished with extraordinary resources of learning. His works, which even the *Biographia Britannica* (1778) testifies, were famous over Europe, were collected at Amsterdam in 5 vols. 4to. Only a very small proportion were translated into his mother tongue. His *Lectiones in omnes Psalmos Davidis* (1635) is exceedingly suggestive and terse in its style, reminding of Bengel's *Gnomon*, as does also his *Commentarius utriusque Epist. S. Petri*. His "Replies" to Bishop Morton and Dr Burgess on "Ceremonies" tell us that even kinship could not prevent him from "contending earnestly for the faith." (John Quick's MS. *Icones Sacre Anglicanae*, who gives the fisherman anecdote on the personal authority of one who was present; Brook's *Puritans*, vol. iii. pp. 405–8; Winwood's *Memorials*, vol. iii. pp. 346–7; Neal's *Puritans*; Fuller's *Cambridge (Christ's College)*; Sylvester's *Life of Baxter*, part i. pp. 13, 14; *Diogr. Brit.*, vol. i. pp. 172–3; Mather's *New England*, book iii.; Palmer's *Nonconf. Memorial*.; Mosheim's *Eccles. Hist.*, who mistakenly calls him a Scotsman; Hanburg, s.v.; *Collections of the Massachusetts Historical Society*, vol. vi., fourth series, 1863, pp. 576–7.) (A. B. G.)

AMESBURY, an old town in Wiltshire, on the Avon, 8 miles north of Salisbury, and 78 west of London. It is an ill-built place, with little trade. It contains an old parish church, which probably belonged to an abbey, a chapel for the Wesleyan Methodists, and a beautiful house erected by Inigo Jones for the Duke of Queensberry. Near Amesbury are Stonehenge, and Milston, where Addison was born. Population, 1169.

AMETHYST, properly, is only a variety of quartz or rock-crystal distinguished by its fine violet-blue or purple colour. This tint seems to be caused by a minute mixture of the peroxide either of iron or of manganese, and is lost when the stone is exposed to the action of the fire. It

then changes through yellow and green to colourless; and in this condition is often sold for the aquamarine or topaz. Amethyst is generally found in thick columnar masses, of short hexagonal prisms terminating in pyramids. The faces, especially in Brazilian specimens, are often marked by zig-zag or undulating lines, and the colour in many is similarly disposed, showing a peculiar internal structure in the stone. It has been proposed to name all varieties of quartz, whether coloured or uncoloured, showing this peculiarity, amethyst, but without sufficient reason. Amethyst, according to Pliny, got its name, ἀμέθυστος, from its supposed power of preventing drunkenness. Though not a true gem, it was formerly much valued as an ornamental stone, but has greatly declined in value in the present century, being obtained in great abundance from Brazil. There it is often white or yellow, and named topaz. The finest blue stones are found in Ceylon and Siberia; and less remarkable ones in many places in Europe, India, and Australia. Amethysts may be counterfeited by glasses, to which the proper colour or stain is given by mineral matter. There were fine ones made in France about the year 1690, which even imposed on connoisseurs, but with the decrease in price there is now less danger of such deceptions.

AMHERST, a district and city within the Tenasserim division of British Burmah, and within the jurisdiction of the chief commissioner of that province. The DISTRICT forms a narrow strip of land between the Indian Ocean and the mountains which separate it from the independent kingdom of Siam. It lies in 16° N. lat., 98° E. long., and consists partly of fertile valleys formed by spurs of the mountain system which divides it from Siam, and partly of a rich alluvial tract created by the great rivers which issue from them. The most important of these are the Salween river and the Houng-da-raw Khyoung. The river highways bring down inexhaustible supplies of rice to Maulmain, the chief town of the district, as also of the province of Tenasserim, and the second city in British Burmah. The district comprises an area of 15,144 square miles, of which 346 are cultivated, 4889 are capable of being brought under cultivation, and the remaining 9909 square miles are returned as uncultivable. The population in 1872 numbered 235,738 souls, occupying 38,945 houses, and consisting of 203,774 Buddhists, 15,598 Hindus, 12,279 Mahometans, and 4081 Christians. The town of Maulmain contains 53,653 inhabitants. The rainfall is very heavy, 245·85 inches being registered in 1871-72. The temperature is uniform, but not excessive, and averaged 83° at 2 P.M. throughout the month of May 1871, 80° at 2 P.M. throughout July, and the same at 2 P.M. throughout December 1871.

AMHERST TOWN, situated in the district of the same name, about 30 miles south of Maulmain. It was founded by the English in 1826 on the restoration of the town of Martaban to the Burmese, and named in compliment to the Governor-General of India who projected it. The proclamation inviting the natives to people the town was well adapted to the character and capacities of those whom it addressed. "The inhabitants of the towns and villages who wish to come shall be free from molestation, extortion, and oppression. They shall be free to worship as usual, temples, monasteries, priests, and holy men. The people shall go and come, buy and sell, do and live as they please, conforming to the laws. In regard to slavery, since all men, common people or chiefs, are by nature equal, there shall be under the English government no slaves. Whoever desires to come to the new town may come from all parts and live happy, and those who do not wish to remain may go where they please without hindrance." Shortly after its settlement the number of

houses amounted to 230, and the population to 1200. Large teak forests abound in its neighbourhood, and the timber is exported in considerable quantities. The harbour, though large and capable of accommodating ships of any burden, is difficult of access, and dangerous during the south-west monsoon. Amherst town has been eclipsed by the rapidly rising city of Maulmain, which has absorbed to itself the trade and mercantile enterprise alike of Amherst district and of the Tenasserim province.

AMHERST, a post township of Hampshire county, Massachusetts, United States. It is a picturesque village intersected by two branches of the Connecticut river. Its water-power is utilised for manufactories of machinery, edge tools, cotton goods, paper, &c.; but it is principally known as the seat of Amherst college, a valuable institution founded in 1821, mainly for the purpose of educating poor and pious young men for the ministry. The charity fund is large, and pays the tuition fees of forty or fifty students. The faculty of the college consists of eighteen professors, beside the president. The number of students in 1873 was 261. The buildings of Amherst college are situated on a hill at the southern extremity of the village. An octagonal building in advance of the line of college halls is devoted to the purposes of a museum. Some of the collections are of great value, especially those in the palæontological department. The Massachusetts Agricultural school, founded in 1863, has also its seat at Amherst. Its handsome buildings are on the edge of a rich plain from which fine views are obtained of the mountains on the west and south. There is a large farm for experiment attached to the school, which is esteemed one of the best in America. The population of Amherst in 1870 was 4035.

AMHERST, EARL (WILLIAM PITT AMHERST), born in 1773, was the nephew of Jeffery Amherst, who, for his services in America, where he was commander-in-chief at the time of the conquest of Canada, was raised to the peerage as Baron Amherst in 1776. The patent of nobility was renewed in 1788 with remainder to the subject of this notice, who succeeded to the title in 1797. In 1816 he was sent as ambassador extraordinary to the court of China, with the view of establishing more satisfactory commercial relations between that country and Great Britain. On arriving in the Peiho, he was given to understand that he could only be admitted to the emperor's presence on condition of performing the *ko-tou*, a ceremony which Western nations have always considered degrading, and which is, indeed, a homage exacted by the Chinese sovereign from his tributaries. This Lord Amherst, following the advice of Sir George T. Staunton, who accompanied him as second commissioner, refused to consent to, as Lord Macartney had done in 1793, unless the admission was made that his sovereign was entitled to the same show of reverence from a mandarin of his rank. In consequence of this he was not allowed to enter Peking, and the object of his mission was frustrated. His ship, the "Alceste," after a cruise along the coast of Corea and to the Loo-Choo Islands, on proceeding homewards was totally wrecked on a sunken rock in Gaspar Strait. Lord Amherst and part of his shipwrecked companions escaped in the ship's boats to Batavia, whence relief was sent to the rest. The ship in which he returned to England in 1817 having touched at St Helena, he had several interviews with the Emperor Napoleon (Ellis's *Proceedings of the Late Embassy to China*, 1817; McLeod's *Narrative of a Voyage in H.M.S. "Alceste,"* 1817). Lord Amherst held the office of governor-general of India from August 1823 to February 1828. The principal event of his government was the Burmese war, resulting in the cession of Aracan and Tenasserim to Great Britain. He was created Earl Amherst of Aracan in 1826. On his

return to England he lived in retirement till his death in March 1857.

AMHURST, NICHOLAS, an English poet and political writer of the 18th century, was born at Marden in Kent, and entered (1716) at St John's college, Oxford, from which he was expelled, ostensibly for libertinism and irregular conduct, but really, according to his own statement, on account of the liberality of his opinions. Retaining great resentment against the university on this account, he gave expression to his feeling in a poem published in 1724, called *Oculus Britannicæ*, and in a book entitled *Terræ Filius*. He published a Miscellany of Poems, sacred and profane; and *The Convocation*, a poem in five cantos, which was a satire on the bishop of Bangor's antagonists. But he is best known for the share he had in the political paper called *The Craftsman*, which he conducted for several years. It attained a circulation of 10,000 or 12,000 copies, and had very considerable influence in inflaming popular opinion against Sir Robert Walpole, and in bringing about the political change of 1742. Amhurst's party made no provision for him, however, on their accession to power, and their neglect is supposed to have hastened his death, which occurred at Twickenham on the 27th April 1742.

AMIANTHUS (*unstained*, from a privative, and *μαίωω*, to stain), the best known and most beautiful of the asbestos class of substances. See ASBESTOS.

AMICI, GIOVANNI BATTISTA, a celebrated designer and constructor of optical instruments, was born at Modena in 1784. While studying mathematics at Bologna, he acquired a taste for astronomical science, and devoted himself early in life to the improvement of astronomical instruments with great ingenuity and success. For the specula of his reflecting telescopes he prepared a very hard alloy, capable of receiving and retaining a fine polish, and to prevent spherical aberration he wrought the specula into an elliptical form. About 1812 he undertook the construction of a telescope with a five-foot speculum, and the gun-foundry at Pavia was put at his disposal for this purpose by the war minister of Italy, but the project was broken off, owing apparently to political complications. Amici is still better known from his microscopes. His reflecting microscopes, with ellipsoidal specula, were an improvement on all that had preceded them, and he attained still greater success in the construction of compound achromatic object-glasses. His compound microscope was the first that could be used either in a vertical or in a horizontal position. His prism, too, for the oblique illumination of objects of microscopical observation is much commended. Amici was a very diligent and skilful observer; and his intimate acquaintance with the principles of optical science enabled him to arrange his apparatus to the very best advantage. Various papers recording the results of his observations, which he read before learned societies, were published in scientific journals. They treat of the measurement of the diameters of the sun (by means of a micrometer he invented) and other astronomical subjects, the circulation of the sap in plants, the fructification of plants, infusoria, &c. After holding for some time a professorship of mathematics in Modena, he was in 1831 appointed inspector-general of studies in the duchy. A few years later he was entrusted with the charge of the observatory at Florence, where he also delivered lectures as professor of mathematics at the museum of natural history. He died in April 1863.

AMIENS, an ancient city of France, capital of the department of Somme, and formerly of the old province of Picardy, situated on the Somme, about 40 miles from its mouth, and 71 miles N. of Paris. It was once a place of great strength, and still possesses a citadel, but the ramparts

which surrounded it have been replaced by beautiful boulevards. The new part of the town is well built, but the streets of the old quarter are narrow and irregular, and are so cut up by the eleven canals into which the Somme is here divided, that Louis XI. is said to have called the town "little Venice." The most interesting object in Amiens is its magnificent cathedral, one of the finest in Europe, commenced in the year 1220 and finished in 1288, although additions to it were afterwards made. Among the other important public buildings are the Hôtel de Ville, the Chateau d'Eau, the theatre, the museum, the hospital, and several churches. The town is the seat of a bishop, of a prefect, and of the departmental courts of justice; and possesses a library containing more than 50,000 volumes, besides manuscripts, an academy of sciences, various other learned societies, a theological seminary, a lyceum, and several ordinary schools. It has many important manufactures, the chief being cotton velvets, kersycemes, woollen and linen cloths, flax, beetroot sugar, soap, leather, and paper. Amiens occupies the site of the ancient *Samarobriua*, capital of the *Ambiani*, from whom it probably derives its name. After the dissolution of the empire of the west it repeatedly changed owners, becoming for the first time a dependency of the French crown in 1185, when Philip of Alsace ceded it to Philip Augustus; and since that date it has more than once passed out of the power of the French kings. The famous treaty between Great Britain, France, Spain, and Holland, which took its name from this city, was signed in the Hôtel de Ville on March 25th, 1802. During the recent war between France and Germany Amiens fell into the hands of the Prussians on the 28th of November 1870. General Manteuffel was operating against the French army of the north, which had been formed with the view of helping the armies of Paris and of the Loire to effect a junction, and thus raise the siege of the capital. The French, however, were defeated in a battle in front of Amiens, which was fought on the 27th of November, along a line stretching from Saleux to Marcelean, and extending, it is said, more than four leagues. They retreated northward in the direction of Arras, and Amiens surrendered on the following day, after a very slight demonstration of force on the part of the Prussians. Peter the Hermit was born at Amiens about 1050. Population (1872), 63,747.

AMIOT, PÈRE JOSEPH, a learned Jesuit missionary to China, was born at Toulon in 1718. In 1750 he arrived, along with two others of his order, at Macao, from which, on a favourable answer to a petition being received from the emperor Kien-Lung, he removed to Peking in the autumn of the following year. He continued to reside in the capital until his death in 1794, devoting himself almost exclusively to the study of Chinese and Manchoo-Tatar literature. The results of his labours were communicated at frequent intervals to Europe in works which did more than had ever been done before to make known to the Western world the thought and life of the farthest East. Many of his statements, however, are not trustworthy, and his works are practically superseded by those of others who entered the field later. His *Dictionnaire Tartaromanchou-Français* (Paris, 1789) was a work of great value, the language having been previously quite unknown in Europe. His other writings are to be found chiefly in the *Mémoires concernant l'histoire, les Sciences, et les Arts de Chinois* (15 vols. 4to, Paris, 1776-91). The *Vie de Confucius*, which occupies the twelfth volume of that collection, is very complete and accurate.

AMLWCH, a town of Anglesey, North Wales, situated on a rising ground on the north coast of the island, 15 miles from Beaumaris. It owes its importance almost entirely to the copper mines of the Parys Mountain; before

the discovery of the ore in 1768 it was a small hamlet of some six houses. At one time the mines produced 3000 tons of metal annually, but in recent years the quantity has greatly diminished. The harbour has been cut out of rock at considerable expense, and is protected by a break-water. A branch of the Chester and Holyhead Railway terminates in the town. Amlwch, which is associated with Beaumaris, Holyhead, and Llangefni, in returning one member to parliament, had a population of 2968 in 1871.

AMMAN, JOHANN CONRAD, a physician, and one of the earliest writers on the instruction of the deaf and dumb, was born at Schaffhausen, in Switzerland, in 1669. In 1687 he graduated at Basle, and commenced the practice of his profession at Amsterdam, to which he had to flee on account of his religious views. He first called the attention of the public to his method of training the deaf and dumb in a paper which was inserted in the *Philosophical Transactions*, and which appeared in a separate form in the year 1692, under the title *Surdus Loquens*. It was again issued, with much additional matter, in 1702 and 1728, under the title *Dissertatio de Loquela*. In this work, which Haller terms "*vere aureum*," he develops, with great ability, the mechanism of vocal utterance, and describes the process which he employed in teaching its use. This consisted principally in exciting the attention of his pupils to the motions of his lips and larynx while he spoke, and then inducing them by gentle means to imitate these movements, till he brought them to repeat distinctly letters, syllables, and words. As his method was excellent, we may readily give him credit for the all but universal success to which he laid claim. The edition of Celsus Aurelianus, which was undertaken by the Weststeins in 1709, and still ranks as one of the best editions of that author, was superintended by Amman. He died about 1730.

AMMAN, JOST, an artist celebrated chiefly for his engravings on wood, was born at Zurich in June 1539. Of his personal history little is known beyond the fact that he removed in 1560 to Nuremberg, where he continued to reside until his death in March 1591. His productiveness was very remarkable, as may be gathered from the statement of one of his pupils, that the drawings he made during a period of four years would have filled a hay-waggon. A large number of his original drawings are contained in the Berlin collection of engravings. The genuineness of not a few of the specimens to be seen elsewhere is at least questionable. A series of copperplate engravings by Amman of the kings of France, with short biographies, appeared at Frankfort in 1576. He also executed many of the woodcut illustrations for the Bible published at Frankfort by Feierabend. Another serial work, the *Panoplia Omnium Liberalium Mechanicarum et Sedentariarum Artium Genera Continens*, containing 115 plates, is of great value. Amman's drawing is correct and spirited, and his delineation of the details of costume, &c., is minute and accurate. He executed too much, however, to permit of his reaching the highest style of art. Paintings in oil and on glass are attributed to him, but no specimen of these is known to exist.

AMMAN, PAUL, a physician and botanist, was born at Breslau on the 30th August 1634. In 1662 he received the degree of doctor of physic from the university of Leipsic, and in 1664 was admitted a member of the society *Naturæ Curiosorum*, under the name of *Dryander*. Shortly afterwards he was chosen extraordinary professor of medicine in the above-mentioned university; and in 1674 he was promoted to the botanical chair, which he again in 1682 exchanged for the physiological. He died on the 4th February 1691. Paul Amman seems to have

been a man of acute mind and extensive learning; but a restless and irritable disposition led him to engage too much in controversy, and to indulge in railery in his writings to a degree which the nature of the subjects hardly warranted.

Amman's principal works were—*Medicina Critica, seu Centuria Casuum in Facultate Lipsiensi resolutorum variis Discursibus aucta*; *Parænesis ad Docentes occupata circa Institutum Medicarum Emendationem*; *Irenicum Numæ Pompilii cum Hippocrate*; *Supplex Botanica, et Manufactio ad Materiam Medicam*; and *Character Naturalis Plantarum*.

AMMANATI, BARTOLOMEO, a celebrated Florentine architect and sculptor, was born in 1511, and died in 1592. He studied under Bandinelli and Sansovius, and closely imitated the style of Michael Angelo. He was more distinguished in architecture than in sculpture. He designed many buildings in Rome, Lucca, and Florence, an addition to the Pitti palace in the last-named city being one of his most celebrated works. He also planned the beautiful bridge over the Arno, known as *Ponte della Trinita*—one of his celebrated works. The three arches are elliptic, and though very light and elegant, have resisted the fury of the river, which has swept away several other bridges at different times. Ammanati's wife, daughter of Giov. Antonio Battiferri, an elegant and accomplished woman, published a volume of poems of considerable merit.

AMMIANUS, MARCELLINUS, a Roman historian of the 4th century, was born in the city of Antioch, in Syria. In his youth he was enrolled among the *protectores domestici*, or household guards, which proves him to have been of noble birth. In the year 350 he entered the service of Constantius, the emperor of the East, and, under the command of Ursicinus, a general of the horse, he served during several expeditions. According to his own modest account, it appears that he acquired considerable military fame, and that he deserved well of his sovereign. He attended the Emperor Julian in his expedition into Persia, but it is not known that he obtained any higher military promotion than that which has already been mentioned. He was either in the city or in the vicinity of Antioch when the conspiracy of Theodorus was discovered, in the reign of Valens, and was an eye-witness of the severe tortures to which many persons were subjected by the emperor on that account. But his lasting reputation was not to be acquired from military service. He left the army and retired to Rome, where he employed himself in writing a history of the Roman empire, comprising a period of 282 years. Though a Greek by birth, he wrote in the Latin language; but, according to the remark of Vossius, his Latin shows that he was a Greek, and also a soldier. His history extended from the accession of Nerva to the death of Valens; and the work was originally divided into thirty-one books. Of these the first thirteen have perished, and the eighteen which remain commence with the seventeenth year of the reign of Constantius, and terminate at the year 378. But there are several facts mentioned in the history which prove that the author was alive in the year 380. Of this number are the accession of Theodosius to the Eastern empire, the character of Gratian, and the consulate of Neothorius. The style is harsh and redundant, as was to be expected from the author's education and military life; but the work is valuable as a source of information for the period of which it treats. Gibbon appears to give a correct estimate when he says that Ammianus is "an accurate and faithful guide, who composed the history of his own times without indulging the prejudices and passions which usually affect the mind of a contemporary." From the respectful manner in which he speaks of pagan deities, and of the advantage of heathen auguries in foretelling future events, it is evident that Ammianus was a

heathen. The favourable account which he gives of the religion, manners, and fortitude of Christians, is the result of his candour and impartiality as an historian. The work of Ammianus has passed through several editions, of which the best are the Leyden edition of 1693, by Gronovius, and those of Leipsic, published in 1773 and 1808. The latter was edited by Wagner and Erfurdt.

AMMIRATO, SCIPIO, an Italian historian, born at Lecce, in the kingdom of Naples, on the 27th September 1531. His father intending him for the profession of law, sent him to study at Naples, but his own decided preference for literature prevented him from fulfilling his father's wishes. Entering the church, he resided for a time at Venice, and afterwards engaged in the service of Pope Pius IV. In 1569 he went to Florence, where he was fortunate in securing the patronage and support of Duke Cosmo I. It was at the suggestion of this prince that he wrote the work by which he is best known, his *Istorie Fiorentine* (1600). In 1595 he was made a canon of the cathedral of Florence. He died in 1601. Among the other works of Ammirato, some of which were first published after his death, may be mentioned discourses on Tacitus and histories of the families of Naples and Florence.

AMMON, the name of an Egyptian deity, called by the ancient Egyptians *Amen* or *Anun*, and one of the chief gods of the country. His name meant the hidden or concealed god, and in this respect was analogous to *Hapi* or *Apis*, which conveyed the same idea. He was the local deity of Thebes or Diospolis, and supposed by the Greeks to be the same as Zeus or Jupiter. His type was that of a man wearing on his head the red crown *teshr*, emblem of dominion over the lower world or hemisphere, surmounted by the sun's disc to indicate his solar nature, flanked by two tail feathers of a hawk, also symbolical of his relation to the gods of light. Ammon was not one of the oldest deities of Egypt, for his form and name do not appear till the eleventh or Diospolitan dynasty, when the kings of that line assumed his name, and built a sanctuary to him at Medinat Habu. From this period the monarchs of Thebes introduced his name into their titles, and the worship of Amen became the predominant one of ancient Egypt; and the embellishment of his shrine and enrichment of his treasury were the chief object of the policy of the Pharaohs. Victory and conquest were the chief gifts he offered to his adorers; and he is often seen leading up the conquered nations of the north and south to the monarchs whom he endows with power and victory. In this character Amen is often represented holding the Egyptian scimitar *khepsh*. In his celestial character his flesh was coloured blue, that of the heaven. He is said to have been called on some monuments the son of Hapimaa (or the Nile); but in the hymns addressed to him the title of self-engendered is applied to him, and he was one of the self-existent deities. His principal titles are—lord of the heaven, king of the gods, substance of the world, and resident on the thrones of the world, eternal ruler,—appellatives of his celestial and terrestrial functions. He was also lord of heaven and earth, streams and hills, and as a demiurgos, the creator of beings. The hymns addressed to him designate him as the sole or only god, in terms applicable to one god who alone exists, who moulds and governs the world. At one time an attempt was made to identify him with the solar orb. Considered as the active, intelligent, and pervading spirit of the universe, he transfuses the breath of life into the nostrils of kings and other persons. In his solar characters, Ammon was allied with Ra, and called Amen Ra, or Amen Ra Harmachis, or “the sun in the horizon,” Amen being considered one of the forms of the sun itself. The worship of the celestial Ammon prevailed chiefly at Thebes, where,

with the Mut, or “mother” goddess, and his son Khonsu or Chons, he formed the Theban triad, and the sacred name of Thebes was “the abode of Amen.” Besides Thebes, his worship has been found at Siuah in Lybia, at Beit Oually, and at Meroe in Ethiopia, marked respect being shown to his worship by the later Ethiopian monarchs. At Philæ and Debud his name also appears as one of the dominant deities. In the representations at Hermonthis he assists at the birth of Har-pa-Ra; and in the scenes of the passage of Ra, or the sun, through the hours of the night, the gigantic arm of Amen strangles the serpent Apophis, “the great dragon” of Egyptian mythology, the spirit of darkness, who warred against the gods of light. Another of the types of Amen represents him as the reproductive power of nature, still in the human form, but mummied, and holding—instead of the usual sceptre, *uasm*, or so-called *kukupha* sceptre—the whip *nekhekh*. In this type he was supposed to be Amen the father and Horus the child of the triad, which then consisted of Amen, Ament, or the female Ammon, and Harka. His titles in this character are *Amen-ka-mut-f*,—Amen, “the husband of his mother,” considered as the final avatar of the god, the alpha and omega, the oldest and youngest of created beings. He is, considered in his youthful character, called *Harnekht*, or “the powerful Horus,” and identified with *Khons*, the local god of Chemmo or Panopolis. As Horus he is called the “son of Isis,” but this is clearly a later fusion of the two myths. In the inscriptions it is said “he has tall plumes,” and in the esoterical explanations of the seventeenth chapter of the *Ritual*, these plumes are explained by “his two eyes,” or Isis and Nephthys, who are seen accompanying Horus in certain scenes. This type of Amen was not usually exhibited, but brought out on the occasion of his festival, called the manifestation of Khem, one of the oldest fêtes of Egypt. This type of Amen is principally found at the Ruan, or valley of El Hammamat, on the way to Coptos; and at Wady Halfa, where a temple was erected to him by Amenophis III. As the god of the reproductive powers of nature, the kings of Egypt are seen hoeing the ground before him, or offering various coloured calves and gazelles to him. A great festival in his honour is represented at Medinat Habu, where his statue is carried by twenty priests, and Rameses III. cuts down before him the corn which has just ripened for the sickle. The negroes of Arabia, or else the *Regio Barbarica* of later geographers, appear as assistants at this festival. Another type of Amen connected him with the god Khnum or Chnouns, the spirit of the waters. In this relation he has the head of a ram instead of the usual human one. Khnum was one of the demiurgi, and creator of mankind, whom he had made as a potter out of clay on the wheel, as also Osiris and Horus. Sometimes the type of Khnum bears the name of Amen; and with the ram's head he was worshipped in the Oasis of Ammon, as also up the Nile at the cataracts, Syene, Elephantine, Beghe, Beit Oually, and Meroe. It is this type of Amen with which the later Greek and Roman writers were most familiar; and Rameses II., as the son of Amen, assumes the ram's horn, which Alexander the Great adopted at a later date. The worship of Khnum was older than that of Amen, as it appears on the Pyramids and at the Wady Magaresh, but became less important, and finally fused into that of Amen. Although it has been supposed that the worship of Amen came from Meroe, it is now known that the Ethiopian civilisation was comparatively of much more recent date than the Egyptian, and that it was implanted in Ethiopia by the conquests of the Pharaohs, and subsequently adopted by the later rulers of Meroe; and that the statements of Herodotus, that it was brought from thence to the Oasis of Ammon are incorrect, the existing temple at the Oasis

not being older than the Persian rulers of Egypt, while the worship of the god at Thebes dates from a much older epoch. The later chapters of the *Ritual*, added at the time of the twentieth dynasty, which contain the mystic names and appellatives of the god in the language of the negroes of Punt, are also of too late a date to throw any light on the origin of Amen, which appears prior to the Hykshos, when the Egyptian princes were driven to the south. The sheep was sacred to the god, and the inhabitants of Thebes in consequence abstained from it; but it is said they annually sacrificed a ram to Amen, and dressed the figure of the god in the hide of the animal. The reasons assigned by classical authorities for this action, as well as for the astronomical meaning of his horns, are not confirmed by monumental evidence. On the conquest of Egypt Alexander the Great called himself the son of Ammon, and his portraits wear the ram's horn. In this he had only imitated the Pharaohs of the nineteenth dynasty. Amen is only mentioned by the Hebrew prophets in speaking of Diospolis as the city of No or No Amon.

Jablonski, *Panth. Egypt.*, i. 160–184; Birch, *Gallery of Antiq.*, pt. i. 1; Wilkinson, *Manners and Customs*, iii. 313, iv. 246, ff.; Goodwin, *Trans. Soc. Bibl. Arch.*, ii. pp. 353–9; Herodotus, ii. 42, 54; Diodorus, iii. 72; Jer. xlv. 25; Nah. iii. 8. (S. B.)

AMMON, CHRISTOPH FRIEDRICH VON, a distinguished theological writer and preacher, was born at Baireuth in January 1766, studied at Erlangen, held various professorships in the philosophical and theological faculties of Erlangen and Göttingen, succeeded Reinhard in 1813 as court preacher and counsellor at Dresden, retired from these offices in 1849, and died May 21, 1850. He sought to establish for himself a middle position between rationalism and supernaturalism, inclining, however, decidedly to the former. He declared for a "rational supernaturalism," and contended that there must be a gradual development of Christian doctrine corresponding to the advance of knowledge and science. He was a man of great versatility and extensive learning, and a very voluminous author, his principal work being the *Fortbildung des Christenthums zur Weltreligion*, in 4 vols. (Leipsic, 1833–40). *Entwurf einer rein biblischen Theologie* appeared in 1792 (second edition, 1801), and *Summa Theologica* in 1803 (other editions, 1808, 1816, 1830). Von Ammon's style in preaching was terse and lively, and some of his discourses are regarded as models of pulpit treatment of political questions.

AMMONIA ( $\text{NH}_3$ ), sometimes called the *Volatile alkali*, or *Alkaline air*, was known to the alchemists in aqueous solution. Priestley first separated it in the gaseous state in 1774. Scheele in 1777 discovered that it contained nitrogen, and its true composition was ascertained by Berthollet about 1785. Ammonia occurs in the atmosphere as carbonate and nitrate, in sea-water, and in many mineral springs. Iron ores and many clayey soils contain it in small quantity, and sal-ammoniac and ammonia alum are found as minerals in volcanic districts. Carbonate of ammonia is obtained in large quantity by the putrefaction of the urine of animals, or the dry distillation of animal matter. Ammonia is obtained from its salts by the acting of slaked lime or solutions of potash or soda, and is freed from water by passing over quicklime or solid potash, and finally collected over mercury. It is a colourless gas, of a pungent smell, and alkaline taste and reaction. It does not support combustion or respiration, and is feebly combustible. It is remarkably soluble in water, 1 volume dissolving nearly 700 of the gas. It may by the action of a low temperature and great pressure be changed into the liquid or solid state. The gas is easily decomposed into its elements by a succession of electric sparks, or by passing it over red-

hot iron or platinum wire. The aqueous solution in presence of finely divided platinum and atmospheric air is converted into nitrite of ammonia; and conversely, the oxides of nitrogen, mixed with excess of hydrogen and passed over platinised asbestos, are changed into ammonia. Nitrogen and hydrogen have not by any process been induced to combine so as to yield this compound directly, unless in very small quantity. For theoretical relations of ammonia, salts, &c., see CHEMISTRY.

AMMONIAC, SAL ( $\text{NH}_4\text{Cl}$ ), the earliest known salt of ammonia, now named *chloride of ammonium*, formerly much used in dyeing and metallurgic operations.

The name *Hammoniacus sal* occurs in Pliny (*Nat. Hist.* xxxi. 39), who relates that it was applied to a kind of fossil salt found below the sand, in a district of Cyrenaica. It was similar in appearance to the *alumen scissile*, and had a disagreeable taste, but was useful in medicine. The general opinion is, that the sal-ammoniac of the ancients was the same as that of the moderns; but the imperfect description of Pliny is far from being sufficient to decide the point. The native sal-ammoniac of Bucharica, described by Model and Karsten, and analysed by Klaproth, has no resemblance to the salt described by Pliny. The same remark applies to the sal-ammoniac of volcanoes. Dioscorides (v. 126), in mentioning sal-ammoniac, makes use of a phrase quite irreconcilable with the description of Pliny, and rather applicable to rock-salt than to our sal-ammoniac. Sal-ammoniac, he says, is peculiarly prized if it can be easily split into rectangular fragments. Finally, we have no proof whatever that sal-ammoniac occurs at present, either near the temple of Jupiter Ammon, or in any part of Cyrenaica. These circumstances induce us to conclude that the term *sal-ammoniac* was applied as indefinitely by the ancients as most of their other chemical terms. It may have been given to the same salt which is known to the moderns by that appellation, but was not confined to it.

Some derive the name *sal-ammoniac* from Jupiter Ammon, near whose temple it is alleged to have been found; others, from a district of Cyrenaica called Ammonia. Pliny's derivation is from the sand (*ἄμμος*) in which it occurred.

Whether our sal-ammoniac was known to the ancients or not, there can be no doubt that it was well known to the alchemists as early as the 13th century. Albertus Magnus, in his treatise *De Alchymia*, informs us that there were two kinds of sal-ammoniac, a natural and an artificial. The natural was sometimes white, and sometimes red; the artificial was more useful to the chemist. He does not tell us how it was prepared, but he describes the method of subliming it, which can leave no doubt that it was real sal-ammoniac. In the *Opera Mineralia* of Isaac Hollandus the elder, there is likewise a description of the mode of subliming sal-ammoniac. Basil Valentine, in his *Currus Triumphalis Antimonii*, describes some of the peculiar properties of sal-ammoniac in, if possible, a still less equivocal manner.

Egypt is the country where sal-ammoniac was first manufactured, and from which Europe for many years was supplied with it. This commerce was first carried on by the Venetians, and afterwards by the Dutch. Nothing was known about the method employed by the Egyptians till the year 1719. In 1716 the younger Geoffroy read a paper to the French Academy, showing that sal-ammoniac must be formed by sublimation; but his opinion was opposed so violently by Homberg and Lemery, that the paper was not printed. In 1719 M. Lemaire, the French consul at Cairo, sent the Academy an account of the mode of manufacturing sal-ammoniac in Egypt. The salt, it appeared, was obtained by simple sublimation from soot. In the year 1760 Linnæus communicated to the Royal

Society a correct detail of the whole process, which he had received from Dr Hasselquist, who had travelled in that country as a naturalist. This account is published in the 51st volume of the *Philosophical Transactions*, 1760, p. 504. Almost the only fuel used in Egypt is the dung of cattle. The dung of black cattle, horses, sheep, goats, &c., which contains the sal-ammoniac ready formed, is collected during the first four months of the year, when the animals feed on the spring grass, a kind of clover. It is dried, and sold to the common people as fuel. The soot from this fuel is carefully collected and sold to the sal-ammoniac makers, who work only during the months of March and April, for it is only at that season of the year that the dung is fit for their purpose.

The composition of this salt seems to have been first discovered by Tournefort in 1700. The experiments of the younger Geoffroy in 1716 and 1723 were still more decisive, and those of Duhamel, in 1735, left no doubt upon the subject. Dr Thomson first pointed out a process by synthesis, which has the advantage of being very simple, and at the same time rigidly accurate, resulting from his observation that when muriatic gas and ammoniacal gas, both as dry as possible, are brought in contact with each other, they always combine in equal volumes.

The first attempt to manufacture sal-ammoniac in Europe was made, about the beginning of the 18th century, by Mr Goodwin, a chemist of London, who appears to have used the mother ley of common salt and putrid urine as ingredients. The first successful manufacture of sal-ammoniac in this country was established in Edinburgh by Dr Hutton and Mr Davy, about the year 1760. It was first manufactured in France about the same time by Baumé. Manufactories of it were afterwards established in Germany, Holland, and Flanders.

Chloride of ammonia is now manufactured in large quantity from the crude carbonate of ammonia obtained in gas-works, or from the destructive distillation of animal matter. This salt is changed into chloride by the addition of hydrochloric acid or the mother liquor of salt-works, called *bittern*, containing the chlorides of calcium and magnesium. When hydrochloric acid is not easily got for neutralisation, the crude gas liquor is transformed into sulphate, and this is mixed with an equivalent quantity of common salt. During the subsequent evaporation the sulphate of soda separates in hard granular crystals, which are apt to adhere to the sides of the boiler. The liquor is agitated to prevent this adhesion taking place, and assist in the separation of the sulphate of soda. The sulphate of soda is removed by drainers as it is formed, and the mother liquor boiled up to the crystallising point, and run off into coolers. The crystals of impure muriate of ammonia are dried carefully and subsequently sublimed.

Sal-ammoniac occurs usually in the form of a hard, white cake, opaque, or only slightly translucent. Its taste is cooling, saline, and rather disagreeable. It dissolves in 2.72 parts of water at 18°·7 C. with great reduction of temperature, and in about an equal weight of water at the boiling-point. The feathery crystals it forms are found on microscopic examination to be masses of cubes or octahedrons; their specific gravity is about 1.5. When exposed to a moist atmosphere, the salt gradually absorbs water, and deliquesces, though very slowly, becoming slightly acid. When heated, it sublimes unaltered in a white smoke, having a peculiar smell, very characteristic of sal-ammoniac. If a cold body be presented to this smoke, the sal-ammoniac condenses on it, and forms a white crust. When thus sublimed, it has the property of carrying along with it various bodies, which, when heated by themselves, are perfectly fixed.

For the other ammoniacal salts see CHEMISTRY.

AMMONIACUM, or AMMONIAC, a gum-resinous exudation from the stem of a perennial herb (*Dorema ammoniacum*) belonging to the natural order Umbelliferae. The plant grows to the height of 8 or 9 feet, and its whole stem is pervaded with a milky juice, which oozes out on an incision being made at any part. This juice quickly hardens into round tears, forming the "tear ammoniacum" of commerce. Lump ammoniacum, the other form in which the substance is imported, consists of aggregations of tears, frequently incorporating large quantities of the fruits of the plant itself, as well as other foreign bodies. In order to free lump ammoniacum from these impurities, it has to be melted and strained, operations which depreciate its therapeutical value. Ammoniacum has a faintly fetid unpleasant odour, which becomes more distinct on heating; externally it possesses a reddish yellow appearance, and when the tears or lumps are freshly fractured they exhibit an opalescent lustre. It is chiefly collected in the province of Irak in Persia; but some quantity is also produced in the Punjab, and comes to the European market by way of Bombay. Its composition, according to Hagen, is—resin, 68.6; gum, 19.3; gluten, 5.4; volatile oil and water, 2.8; extractive, &c., 3.9. Ammoniacum is closely related to assafoetida, not only in the plant yielding it, but also in its therapeutical effects. It may be used as a substitute for assafoetida, although, containing a much smaller proportion of volatile oil, its effect is less powerful. Internally it is used in conjunction with squills in bronchial affections; and in asthma and chronic colds it is found useful. It is, however, more used externally in the form of plasters, as a discutient or resolvent application in indolent tumours, affections of the joints, &c.

African ammoniacum is a totally different substance, though often confounded with the real gum-resin, which is produced only in the East. It is the product of an unknown plant growing in North Africa, and occasionally shipped to our markets from Morocco. It is a dark-coloured gum-resin, possessed of a very weak odour and a persistent acid taste. A considerable commerce in it is carried on between Mogador and Alexandria, where it is in demand for purposes of fumigation.

AMMONITES, called also very frequently *the children of Ammon*, a people allied by descent to the Israelites, and living in their vicinity, sprung from Lot, Abraham's nephew, by the younger of his daughters, as the immediately adjoining people, the Moabites, were by the elder (Gen. xix. 37–38). Both peoples are sometimes spoken of under the common name of the children of Lot (Deut. ii. 19; Ps. lxxxiii. 8); and the whole history shows that they preserved throughout the course of their national existence a sense of the closest brotherhood. The original territory of the two tribes was the country lying immediately on the east of the Dead Sea and of the lower half of the Jordan, having the Jabbok for its northern boundary; and of this tract the Ammonites laid claim to the northern portion, the "half mount Gilead" (Deut. iii. 12), lying between the Arnon and the Jabbok, out of which they had expelled the Zamzumim (Judg. xi. 13; Deut. ii. 20, 21; cf. Gen. xiv. 5), though apparently it had been held, in part at least, conjointly with the Moabites, or perhaps under their supremacy (Num. xxi. 26, xxii. 1; Josh. xiii. 32). From this their original territory they had been in their turn expelled by the Amorites, who were found by the Israelites after their deliverance from Egypt in possession of both Gilead and Bashan, that is, of the whole country on the left bank of the Jordan, lying to the north of the Arnon (Num. xxi. 13). By this Amorite invasion, as the Moabites were driven to the south of the Arnon, which formed their northern boundary from that time so the Ammonites were driven out of Gilead

across the upper waters of the Jabbok where it flows from south to north, which henceforth continued to be their western boundary (Num. xxi. 24; Deut. ii. 37, iii. 16). The other limits of the *Ammonitis*, or country of the Ammonites (*Ἀμμωνίτις χώρα*, 2 Mac. iv. 26), there are no means of exactly defining. On the south it probably adjoined the land of Moab (but *cf.* Ewald, *Gesch. Israels*, ii. 266); on the north it may have met that of the king of Geshur (2 Sam. xiii. 37); and on the east it probably melted away into the desert peopled by Amalekites and other nomadic races.

The chief city of the country, called Rabbah, or Rabbath of the children of Ammon, *i.e.*, the metropolis of the Ammonites (Deut. iii. 11), and Rabbathammana by the later Greeks (Polyb. v. 7, 4), whose name was changed into Philadelphia by Ptolemy Philadelphus, a large and strong city with an acropolis, was situated on both sides of a branch of the Jabbok, bearing at the present day the name of Moiet or Nahr Amman, the water or river of Ammon, whence the designation "city of waters" (2 Sam. xii. 27; *cf.* Burekhardt, *Syria*, p. 361). The ruins called Amman by the natives are extensive and imposing. The country to the south and east of Amman is distinguished by its fertility; and ruined towns are scattered thickly over it, attesting that it was once occupied by a population which, however fierce, was settled and industrious (see Burekhardt, *op. cit.*, 357, *cf.* Lindsay, *Holy Land*, 5th ed., p. 279), a fact indicated also by the tribute of corn paid annually to Jotham (2 Chron. xxvii. 5). The Israelites on their journey out of Egypt to the land of promise were forbidden to meddle with the territory of Ammon as of Moab (Deut. ii. 19); and it seems to indicate that friendly relations subsisted at first between this people and the chosen nation, that after the latter had conquered and slain Og, the giant king of Bashan, the enemy of both, his bedstead was placed in Rabbah (Deut. iii. 11). Like Moab, however, the Ammonites beheld with jealousy the rising greatness of Israel. They joined the former in hiring Balaam to curse them (Deut. xxiii. 4); and thenceforward their history, so far as known, reveals a spirit of bitter hostility against the people of Jehovah—shown in invasions repeated and violent, and cruelties the most outrageous and unsparing (Judg. x. 8; Amos i. 13). They could not forget that the Gileadite portion of the inheritance of Israel had once been their possession, nor cease to press their claim for its recovery (Judg. xi. 13). We find them joined first with Moab (Judg. iii. 12), and then with the Philistines (Judg. x. 7, 8), in the invasion and oppression for lengthened periods of the land of their enemies. Subdued by the prowess of Jephthah, they began again to act on the offensive in the days of Saul, laying siege to Jabesh-Gilead (1 Sam. xi. 1). David offered his friendship to the king of Ammon, but his offer was rejected with contumely and outrage, for which a terrible vengeance was exacted in the capture and overthrow of their metropolis, and the deliberate slaughter of the people (2 Sam. x.) They were united with Moab against Judah in the days of Jehoshaphat (2 Chron. xx. 1); they paid tribute to Uzziah and Jotham (2 Chron. xxvi. 8, xxvii. 5); and with the neighbouring tribes helped the Chaldean monarch against Jehoikim (2 Kings xxiv. 2). When, after the destruction of Jerusalem, the poor remnants of the Israelites were gathered together under the protectorate of Nebuchadnezzar, it was by the instigation of a king of Ammon that Gedaliah, the ruler appointed over them, was murdered, and new calamities were incurred (Jer. xii. 14); and when Jerusalem was to be rebuilt, the foremost in opposing the patriotic Jews were a Moabite and an Ammonite (Neh. ii. 10, 19; iv. 1-3). True to their antecedents, the Ammonites, with some of the neighbouring tribes, did their utmost to resist and check the revival of the Jewish power under Judas Maccabæus (1 Macc. v. 6; *cf.* Jos. *Ant. Jud.* xiii. 8, 1). The last historical notice of them is in Justin Martyr (*Dial. cum Tryph.* § 119), where it is affirmed that they were still a numerous people. The Ammonites are repeatedly mentioned under the form Bit-Amman, *i.e.*, house of Amman, in the inscriptions of Nineveh among the tributaries of the kings of Assyria (Schrader, *Keilinschriften und d. A. T.* 52). The names of their kings, so far as known,—in Scripture, Nahash, Hanun, Baalis, or Baalim (2 Sam. x. 2; Jer. xl. 14); in Assyrian, Puduilu (*cf.* Pedahel (Num. xxvii. 28), Basa (*cf.* Baasha, 1 Kings xv. 33), and Sanib (of less obvious analogy),—testify, in harmony with other considerations, that their language was Semitic, closely allied to the Hebrew; and this fact is now placed beyond question by the discovery of the Mesha-stele, presenting the language of the Moabites, and doubtless that also of the brother tribe (see MOABITES). Their national deity, Moloch or Milcom (see MOLOCH), was worshipped with cruel rites,—a circumstance tending to foster that fierceness of character which distinguished this people throughout their history.

AMMONIUS, surnamed HERMLÆ, or the son of Hermias, studied at Alexandria, along with his brother Heliodorus,

under the neo-Platonist Proclus during the latter part of the 5th century A.D. He was afterwards the head of a school for philosophy; and among his scholars were Asclepias, John Philoponus, Damascius, and Simplicius. Although a neo-Platonist, Ammonius appears to have devoted most of his attention to the works of Aristotle. Commentaries on some of these are all that remains of his reputedly numerous writings. Of the commentaries we have—1. One on the *Isagoge* of Porphyry, published at Venice, 1500, fol.; 2. One on the *Categories*, Venice, 1503, fol., the authenticity of which is doubted by Brandis; 3. One on the *De Interpretatione*, Venice, 1503, fol. Of each of the commentaries there are several Latin translations, and the three have been published in a collected form, with a Latin translation, Venice, 1546, 3 vols. 8vo. They are also printed in Brandis' *Scholia* to Aristotle, forming the fourth volume of the Berlin *Aristotle*. The special section on fate has been published separately by Orelli, *Alex. Aphrod. Ammonii et al. de Fato quæ supersunt*, Zurich, 1824. A life of Aristotle, generally ascribed to Ammonius, but with more accuracy to John Philoponus, is often prefixed to editions of Aristotle. It has been printed separately, with Latin translation and *Scholia*, at Leyden, 1621, and again at Helmstädt, 1666. Other commentaries on the *Topics* and the first six books of the *Metaphysics* still exist in manuscript. Of the value of the logical writings of Ammonius there are various opinions. Prantl, perhaps the highest recent authority, speaks of them with great but hardly merited contempt (*Geschichte der Logik*, i. 642). (For list of his works, see Fabricius, *Bibliotheca Græca*, v. 704-707; and also Brandis, *Memoirs of the Berlin Academy*, 1833.)

AMMONIUS, surnamed SACCAS, or "The Sack Carrier," from the fact of his having been obliged in the early part of his life to gain his livelihood by acting as a porter in the market, lived at Alexandria during the 2d century A.D., and died there 241 A.D. Very little is known of the events of his life. He is said by Porphyry to have been born of Christian parents, and to have belonged originally to their faith, from which he afterwards apostatised. Eusebius (*Church History*, vi. 19) denies this apostasy, and affirms that Ammonius continued a Christian to the end of his life. It is clear, however, that Eusebius is referring to another Ammonius, a Christian who lived at Alexandria during the 3d century A.D. Ammonius, after long study and meditation, opened a school for philosophy in Alexandria. Among his pupils were Herennius, the two Origenes, Longinus, and, most distinguished of all, Plotinus, who in his search for true wisdom found himself irresistibly attracted by Ammonius, remained his close companion for eleven years, and in all his later philosophy professed to be the mere exponent of his great master. Ammonius himself designedly wrote nothing, and the doctrines taught in his school were, at least during his life, kept secret, after the fashion of the old Pythagorean society. Thus, while all the later developments of neo-Platonism are in a general way referred to him as their originator, little is known of his special tenets. From the notices of Hierocles, a scholar of Plutarch, in the early part of the 5th century A.D., preserved in Photius, we learn that his fundamental doctrine was an eclecticism, or union of Plato and Aristotle. He attempted to show that a system of philosophy, common to both and higher than their special views, was contained in their writings. He thus, according to his admirers, put an end to the interminable disputes of the rival schools. What other elements Ammonius included in his eclectic system, and in particular how he stood related to the Jewish and Christian theosophies, are points on which no information can be procured. Few direct references to him exist, and even

these are not of unquestionable authority. He undoubtedly originated the neo-Platonic movement, but it cannot be determined to what extent that philosophy, as known to us through Plotinus and Proclus, represents his ideas. Eusebius (*Church History*, vi. 19) mentions some Christian works by Ammonius. As Porphyry expressly tells us that Ammonius the philosopher wrote nothing, Eusebius must be referring to the later Christian of the same name. To this later Ammonius belongs the *Diatessaron*, or *Harmony of the Four Gospels*, sometimes ascribed to the philosopher. (See Fabricius, *Bibliotheca Græca*, v. 701, 713; and Zeller, *Phil. d. Griechen*, 2d ed., iii. 2, 398, note 6.) On Ammonius the philosopher, besides general works on the Alexandrian school and the history of philosophy, see Rösler, *De Commentitiis Philosophiæ Ammoniacæ Fraudibus et Noxis*, Tübingen, 1786; and Dehaut, *Essai Historique sur la Vie et la Doctrine d'Ammonius Saccas*, Brussels, 1836.

AMMUNITION in its general sense comprises not only the powder and projectiles employed in guns of all classes, but also all stores directly connected with artillery fire, such as friction-tubes, fuses, percussion-caps, and rockets.

Gunpowder, as manufactured in England, consists of 75 parts of saltpetre, 15 parts of charcoal, and 10 parts of sulphur, reduced to a fine powder and mechanically mixed together, pressed into a cake, and granulated to a size varying according to the purpose which it is designed to fulfil. In cannon, a large grain is necessary for regular and thorough burning, a fine powder choking up the interstices, and so preventing the flame from finding its way through the entire charge. On the other hand, a large grain is blown out of a small piece before it is burnt to the centre. For the very heavy guns recently introduced into the British service powder formed into "pellets" or "pebbles" has been adopted, by which the pressure of the gas is kept up till the shell leaves the muzzle, without being at any instant excessive and likely to injure the gun. Modified forms of powder and gun-cotton have been employed experimentally as the charges of guns.

For heavy guns or cannon the charge is carefully weighed and made up in a serge cartridge sewn with worsted, which entirely consumes in firing—any residue left ignited in the bore being liable to cause explosion when the cartridge of the succeeding round is rammed down on it, and so to blow off the arms of the gunner using the sponge stave. The shell or other projectile employed is forced home on the cartridge (*vide* fig. 1) in muzzle-loading guns. In breech-loaders the shell is introduced first, and pressed into the shot chamber, beyond which it can only pass by the "lands" of the rifling cutting into the lead coat, which is effected by the explosion of the charge. The cartridge is pressed forward against the base of the projectile.

Rifled guns—that is, guns constructed to impart rotation to the projectiles they discharge—have superseded smooth-bored cannon in the armaments of all civilised nations; elongated projectiles, which are impeded by the resistance of the air much less than spherical ones, being in all cases employed. Fig. 1 shows a section of the bore of the

FIG. 1.—1, wrought-iron coils; 2, steel; 3, copper studs; 4, worsted braids.

muzzle-loading gun, whose projectiles are made to rotate

by means of gun-metal studs which fit in the spiral grooves of the bore. The following kinds of projectiles are fired from rifled cannon in the British service:—Common shell, Shrapnel shell, Palliser shell and shot, and case-shot. Light balls, carcasses, and spherical shells are discharged from smooth-bored mortars. The two last mentioned, as well as spherical Shrapnel, round shot, grape, and case, are fired from smooth-bored guns.

*Common shell* for rifled guns are simply hollow elongated projectiles filled with powder, which is fired by the action of a fuse, and bursts the shell with great violence, acting in walls or earth into which it has penetrated like a small mine, the largest shells, which are twelve inches in diameter, containing nearly 37 lb of powder. Gun cotton, nitro-glycerine, and other substances, have been tried for bursting purposes, but it has been found very difficult to prevent premature explosion from the sudden shock of discharge of the gun. Picrate of potash, or "picric powder," has been recommended as stronger than gunpowder and quite safe, but it is not as yet adopted. Common shells are generally fired at earthworks, buildings, and wooden ships. When carried, as in English men-of-war, filled and fused with percussion fuses, they can be discharged as rapidly as shot. The most terrible instance of their use in history is the entire destruction of the Turkish frigates by the Russian fleet at Sinope on November 30th, 1853. At the battle of Sedan in 1870 the Prussians made such havoc among the crowded French troops that the ground became covered with "heaps of flesh and rags;" and a similar result was produced by the fire of mortars concentrated on the Russian troops in the Redan at the termination of the siege of Sebastopol. The slaughter in the two last named instances is, however, to be attributed to the concentration of fire on masses of men rather than to the description of shell used, for the showers of bullets ejected by Shrapnel shell would have struck many more men, although the ghastly spectacle of dismembered human bodies would not have been exhibited.

*Shrapnel shell* are hollow projectiles containing bullets and a very small bursting charge. Fig. 2 exhibits the construction of the Boxer Shrapnel shell for the 40-pounder breech-loading Armstrong gun, and is a good specimen of this class of projectile. The shell follows the usual course of flight up to within about 100 yards of the object, when the time fuse, if properly set, fires the bursting charge, and opens the shell by splitting it along certain grooves forming lines of least resistance. The bullets and fragments then continue their course in the form of a shower of missiles. This class of shell was designed for smooth-bore guns by General Shrapnel. It was used with great effect during the Peninsular war, especially in clearing the breach and ramparts of St Sebastian of defenders, over the heads of the English storming party, who drew back into the ditch for a time. The projectile has never been understood and thoroughly taken up by foreign powers, and has never been used to full advantage on service. In skilful hands it is capable of producing results far beyond any that have as yet been achieved.

FIG. 2.—2, copper parts; 3, gun metal; 4, wrought-iron or mild steel; 5, lead; 6, paper.

The *Armstrong segment shell* fulfils the same general purpose,—that is to say, it is designed to sweep down bodies

of troops, but it opens rather more suddenly, segments of iron taking the place of lead and antimony bullets, which segments being built up in a ring with the bursting charge in the centre, are dispersed more widely when the shell opens than the bullets of the Shrapnel. The segment shell consequently is rather suited for the action of a percussion fuse on striking the head of a column of men, or the ground close in front of it. In this way results have been obtained which are out of all proportion to anything that has ever occurred in actual service. At Dartmoor in 1869 the average number of hits for every segment shell fired during the series of experiments, including failures of all kinds, was 17.1. The meaning of this estimate may be appreciated by applying it to some action. For example, at Waterloo the English artillery fired 9467 rounds. On the Dartmoor scale this would give 161,885 casualties. This result shows that after making the most liberal deductions for the peculiar circumstances of war, appalling effects might be produced by modern artillery with segment or Shrapnel shells.

*Palliser shell and shot* are projectiles made with specially hard and rigid heads, with the object of piercing the sides of armour-clad vessels. The form of the head, which is termed "ogival," is seen inside the gun in Fig. 1. A point of this shape causes the resistance of the plate to fall on the shell as an increasing pressure, acting inwards towards points distributed along the axis, rather than as the full sudden blow that would be experienced by a round shot. This enables *chilled iron* to be used, which has great hardness and crushing strength, but is very brittle. Sir W. Palliser first proposed chilled projectiles; subsequently mottled iron projectiles with chilled heads have been used. Sir J. Whitworth has obtained great results with flat-headed projectiles of a special quality of steel, which have been made to penetrate iron plates at an angle even more oblique than 45°. Solid and hollow shot, as well as shell, have been employed against plates. The shot, having thicker sides or walls, have some advantage in penetration. Shells, by their explosion, destroy wood backing better than shot, when the front plating is not too thick for them to penetrate. They are charged with powder through a filling hole in the base of the shell, closed with a strong screw plug. No fuse is required, impact against thick iron being sufficient to explode the bursting charge of a shell without any fuse. The greatest penetration that has yet been obtained in armour was achieved by the 35-ton Woolwich gun (termed the Woolwich "infant"), at Shoeburyness on June 20th, 1872, the head of a Palliser projectile passing entirely through 18½ inches of iron and 12 of teak, a thickness of armour exceeding that of any iron-clad vessel afloat.

*Solid shot* have gradually disappeared since the introduction of rifled guns, and the reasons are obvious. A round shot fired from a smooth-bored gun, after its first graze, continued to ricochet in a straight line; it produced, therefore, a considerable moral effect, and on smooth ground was actually formidable. A rifled shot, on the other hand, is violently deflected after each graze, from the fact that it is rotating rapidly as it touches the ground, and this, coupled with its liability to bury itself, detracts greatly from its efficiency. Shells for any rifled gun may be made of such length as to bring them to the *same weight* as the corresponding shot, which was not the case with smooth-bore projectiles, they being all of one *size* instead of one *weight*. In short, Palliser shell with thick walls (fired as hollow shot) excepted, the only projectiles of the shot class now employed with rifled guns are *case shot*. Owing, however, to the fact that the charge of a rifled gun varies from ¼th to ½th the weight of the projectile, while in smooth-bored guns it was sometimes as great as ¾d that of the shot, the effect of rifled case is comparatively weak. At any time

the range of case shot hardly exceeds 300 yards, while its efficiency depends on the ground along which it bounds being hard and level. Each shot consists of a number of balls enclosed in a thin metal cylinder, which breaks up in the gun, the balls scattering from the muzzle, but sweeping the ground with great effect under favourable circumstances. *Grape* differs only in the balls being larger. At the battle of Friedland, at the bridge of Lodi, and at Sebastopol, grape and case were fired with great effect.

*Time and percussion fuses* have been mentioned. *Time fuses* are those which open a shell at any given time, whether in the air or during penetration. Fig. 2 shows the "Boxer 9-second fuse" for breech-loading guns, fixed in the shell. On the shell moving, the hammer in the head, by its inertia, shears a copper wire, fires a detonating patch of composition beneath it, and lights the fuse composition. This burns until it reaches the point at which a hole is bored in the fuse, when it flashes down the channel shown on the left side of the cut, and fires the powder primer and bursting charge of loose powder. The action of this fuse therefore depends on its correct boring and regular burning. A *percussion fuse* is one that acts on impact or graze. Fig. 3 shows the Pettman general service fuse. On the first movement of the shell, the detonating ball A, and the plugs above and below it, by their inertia, crush the lead cap C, and shear the copper pin above F. During flight the ball becomes detached from the upper or steady plug B, and on impact is fired by its momentum against the part in front of it. The steady plug itself has also a ring of detonating composition, DD, which, should the plug fail to escape from the detonating ball, and so hold against it, is thrown

FIG. 2.—1, copper parts; 2, gun-metal; 3, lead.

against the little plain ball E. The flash in either case acts down the tube F, and fires the bursting charge of the shell. This fuse is made not to explode against a wave, being chiefly used for sea service. It acts both with smooth-bored and rifled guns. For land service more sensitive ones are employed to explode on graze.

Friction tubes are copper tubes driven with melted powder, and pierced from end to end. A friction bar in the head is rubbed against patches of detonating composition by pulling a lanyard, which hooks into a loop at the end of it. The tube is entered in the vent of a gun, which is thus fired by pulling the lanyard.

For mitrailleuses and breech-loading small arms, lead bullets or lead and tin bullets, fixed in central-fire cartridges, are used. The cases are made of sheet brass, with a thick base disc containing a cap chamber, cap, and anvil. Fig. 4 shows the Boxer-Heury ammunition for the Martini-Henry rifle. These metal-cased cartridges are not liable to explode in store, even from the firing of a small charge of powder confined inside the same packing-case with them. They admit of a very rapid rate of firing. The Gatling mitrailleuse has discharged 657 rounds in two minutes at Shoeburyness. The Martini-Henry rifle has fired 25 rounds in a minute.

FIG. 4.—1, sheet brass; 2, copper; 3, wrought iron; 4, paper; 5, 6, mill-board; 7, bees'-wax.

Rockets are projectiles containing composition which, as it burns, generates sufficient gas to drive forward the rocket by an action resembling that of the recoil of a gun. Of rockets there are three kinds: first, war rockets, with iron cases, introduced by Sir W. Congreve, and subsequently

brought by Mr Hale to the form shown in Fig. 5. Congreve rockets were kept point first by sticks screwed into their bases, which acted on the principle of the feathers of an arrow. The Hale rocket is kept point first by rotation, caused by the gas escaping from the vents pressing against the curved shields. The second class of rockets are signal rockets, made of paper, and containing stars, which throw a bright light in falling. The third class are the rockets used to carry a line and establish communication between a wrecked vessel and the sea-shore. (C. O. B.)

FIG. 5.

AMNESTY (*ἀμνηστία*, oblivion), an act of grace by which the supreme power in a state restores those who may have been guilty of any offence against it to the position of innocent persons. It includes more than pardon, inasmuch as it obliterates all legal remembrance of the offence. It is chiefly exercised towards associations of political criminals, and is sometimes granted absolutely, though more frequently there are certain specified exceptions. Thus in the case of the earliest recorded amnesty, that of Thrasybulus at Athens, the thirty tyrants and a few others were expressly excluded from its operation; and the amnesty proclaimed on the restoration of Charles II. did not extend to those who had taken part in the execution of his father. Other celebrated amnesties are that proclaimed by Napoleon on 13th March 1815, from which thirteen eminent persons, including Talleyrand, were excepted; the Prussian amnesty of 10th August 1840; and the general amnesty proclaimed by the Emperor Francis Joseph of Austria in 1857. The last Act of amnesty passed in Great Britain is 20 Geo. II., c. 52, which proclaimed a pardon to those who had taken part in the second Jacobite rebellion.

AMOL, or AMUL, a town of Persia, in the province of Mazanderan, about 12 miles above the mouth of the Heraz, a river which flows into the Caspian Sea. It is not walled, and is now a place of no great importance, but in and around it there are ruins and ancient buildings which bear witness to its former greatness. Of these the most conspicuous is the magnificent mausoleum of Seyed Quam-u-deen, king of Sari and Amol, who died in 1378. At Amol there is a bridge of twelve arches over the Heraz, and the bazaars of the town are large and well supplied. The population is about 40,000, but a great number of these leave the city in summer to tend their flocks.

AMONTONS, GUILLAUME, a celebrated French experimental philosopher, was the son of an advocate who had left his native province of Normandy and established himself at Paris, where the subject of this notice was born on the 31st August 1663. The exertions of genius frequently take a particular direction from accidental circumstances. A severe illness with which Amontons was afflicted in his early youth had the effect of rendering him almost entirely deaf, and consequently of secluding him in a great measure from the ordinary intercourse of society. Being compelled by this accident to depend for his enjoyments on the resources of his own mind, he began to take great pleasure in the construction of machines of various kinds, and in the study of the laws of mechanics, a path of inquiry which he pursued through life with unremitting ardour and distinguished success. One of the first objects which engaged his attention was the discovery of the perpetual motion,—an attempt which, though necessarily unsuccessful, was productive of greater advantage to him than it has usually been to those who have pursued that vain chimera. Amontons devoted himself particularly to the improvement of instruments employed in physical experiments, a subject which requires the finest applica-

tions of mechanical principles, and which till that time had not met with a due share of attention. In 1687, before he had attained his 24th year, he presented to the Academy of Sciences an hygrometer of his own invention, which was received with approbation by that learned body. In 1695 he published the only work which he has given to the world. It was dedicated to the Academy, and entitled *Remarques et Expériences Physiques sur la Construction d'un Nouvel Clepsydre, sur les Baromètres, les Thermomètres, et les Hygromètres*. After Huyghens's beautiful application of the pendulum to the regulation of the motion of clocks, any attempt to revive the clepsydra, an incommodious instrument, and not susceptible of much accuracy, might seem to subject its author to the imputation of not sufficiently appreciating the great importance of a discovery which has so completely changed the face of astronomical science; but the object of Amontons was to produce an instrument capable of measuring time on board ship, in circumstances where the motion of the vessel rendered such timekeepers as were then known useless. The machine which he constructed is said to have been extremely ingenious, and probably differed entirely from those of the ancients, among whom the clepsydra was in common use. In 1689 Amontons was admitted into the Academy of Sciences, the Memoirs of which he enriched with many important contributions. The first paper which he presented after his admission was one on the theory of *friction*, a subject then involved in great obscurity, and on which his inquiries tended to throw considerable light. After that appeared in succession descriptions of a new thermometer, and of numerous experiments made with the barometer relative to the nature and properties of air,—a detailed account of all which is given in the history of the Academy. In the course of these investigations he found that the boiling point of water varies with the pressure of the atmosphere, a discovery made almost contemporaneously in England by Dr Halley. By his countrymen he is generally regarded as the inventor of the telegraph; and he had the honour of exhibiting the methods by which he proposed to accomplish the object in view before some members of the royal family. It appears, however, from a paper read by Dr Hooke to the Royal Society in 1684, that that ingenious philosopher had brought the telegraph, in theory at least, to a state of far greater maturity than Amontons, and nearly 20 years earlier. The experiments of the latter were made about the year 1702. It may be regarded as a curious fact in the history of inventions, that although the great importance of telegraphic communication is obvious, and the method of accomplishing it was clearly explained by Hooke, and its practicability demonstrated by Amontons, it continued to be regarded as of no practical value, and was not regularly applied to useful purposes till nearly a century afterwards, at the time of the French Revolution. Amontons died in 1705, aged 42.

AMOOR, AMOUR, or AMUR, a large and important river of eastern Asia, formed by the confluence of the Argun and the Shilka, at a place called Ust Strelkoi, in 53° 19' N. lat. and 121° 50' E. long. Both these rivers come from the south-west: the Argun, or Kerulen as it is called above Lake Kulon, through which it flows about half-way between its source and Ust Strelkoi, rises near Mount Kentei, in 49° N. lat. and 109° E. long.; the Shilka is formed by the union of the Onon and the Ingoda, both of which rise in the Kingan mountains, not far from the source of the Argun. The Amoor proper flows at first in a south-easterly direction for about 800 miles, as far as 47° 42' lat.; it then turns to the north-east, and after a total course of over 1600 miles discharges itself into the Sea of Okhotsk, opposite to the island of Saghalien. Its principal tribu-

taries from the south are the Songari, which the Chinese consider to be the true head river of the Amoor, and the Ussuri; from the north it receives the Zeya, the Bureia, the Gyrin, and the Omogun. The climate of the valley of the Amoor varies very much in different parts: in the upper portion of its course there are long and cold winters and short summers; as the river descends into more southern latitudes the rigour of the climate relaxes, and the heat becomes almost tropical; the vegetation is rich and luxuriant, and large forests of oaks, limes, and elms replace barren larches and firs; while on the lower Amoor the cold again to a certain extent prevails, and at the mouth the river is ice-bound for more than half the year, a circumstance which greatly impairs its otherwise admirable facilities for navigation. The river is abundantly stocked with fish, and the mountains near it are believed to contain iron and gold. The Amoor became known to the Russians in 1639, and they resolved to annex it to their empire along with the territory through which it flows. In 1651 a party of Cossacks, under a bold leader named Khabaroff, built a fort at Albazin, about 100 miles below Ust Strelkoi. Many sanguinary conflicts between the Chinese and the Russians followed. Albazin more than once changed owners; but at last, in 1689, a treaty was concluded, by which the river Gorbiza or Kerbeche became the easterly limit of the Russian empire on the Amoor, the boundary stretching from the source of the Gorbiza, along the Yablonnoi mountains, to the Sea of Okhotsk. This state of matters continued till 1847, when the Russians again began to make preparations for the conquest of the Amoor valley. In 1850 and the three succeeding years, expeditions were sent up the river, and the towns of Nikolaevsk, Marinsk, and Blagovchenk were founded; in 1854 a powerful flotilla sailed down from Ust Strelkoi to the mouth of the river. A large and very important tract was added to the Russian empire by the cession in 1858 of the whole left bank of the Amoor and the right bank below the Ussuri, and the further cession in 1860 of all the territory between the Ussuri and the Eastern Sea.

AMORITES, a powerful people, widely spread through the Promised Land before the settlement of the Israelites, belonging to the Canaanitic stock, according to Gen. x. 16, though some think they belong rather to the pre-Canaanitic inhabitants of the Jordan basin (see Knobel, *Völkertafel*, 201, sq., who refers them to the Shemitic race of Lud). In all probability there were incorporated among them the remnants of the older tribe of the Rephaim. Their name, "the high ones," has by Ewald (*Gesch. Israels*, i. 315), after Simonis (*Onomasticon*, s.v.) been interpreted highlanders, or inhabitants of the heights, as Canaanites is supposed to mean lowlanders, or inhabitants of the plains (cf. Num. xiii. 29; Deut. i. 44; Josh. v. 1, x. 6). Others call this in question, and find an explanation rather in the tallness of stature by which they seem to have been distinguished (Num. xiii. 32, 33; Amos ii. 9, cf. Kurtz, *Gesch. d. Alt. Bundes*, i. § 45; Pusey, *Minor Prophets*, 174, n.)

That this people had a certain preponderance among the Canaanitic tribes is shown by their name often standing in Scripture for Canaanites in general (Gen. xv. 16; Josh. xxiv. 18; Jud. vi. 10). Their principal seat on the west of the Jordan was the mountains of Judah and their southern slopes,—to the whole of which mountainous region, indeed, the name the Mount of the Amorites is applied (Gen. xiv. 7, 13; Num. xiii. 29; Deut. i. 7, 20, 44; Josh. xi. 3; Jud. i. 36). We hear of them also at Gibeon, north-west of Jerusalem (2 Sam. xxi. 2), at Ajalon, west of Gibeon, and in the northern part of the Philistine plain (Jud. i. 34, 35), and in the land of Ephraim (Gen. xlvi. 22). On the east of Jordan, after having driven back the Ammonites and Moabites, they occupied the whole of Gilead and Bashan, from the Arnon, the northern limit of Moab, as far as Mount Hermon, forming in this region at the epoch of Moses two powerful kingdoms,—that of Sihon, whose capital was Heshbon, the more southerly; and that of Og, whose capital was Ashtaroth, the more northerly (Num. xxi. 21–35; Deut.

iii. 8, 10; iv. 48). It was with this east-Jordanic section of the Amorites that the Israelites first came into conflict. After these had been subdued, and after the Israelites had crossed the Jordan and had begun to capture the Canaanitish towns, five of the most powerful of the Amorite kings of the western section formed a confederacy to oppose the advancing host (Josh. x. 5, sq.) When this combination had been overthrown, a final attempt at resistance was made by the more northerly portion of the Canaanites, under the auspices of Jabin, king of Hazor; and in the united forces, which were overthrown at the waters of Merom, Amorites were included (Josh. xi. 3). Those of this and the other tribes of the Canaanites who survived the conquests of Joshua, either gradually became mingled with the Philistines and others of the neighbouring nations, or they continued to live among the Israelites in the condition of tributaries and slaves (Josh. xi. 22; Jud. i. 34, 35; 1 Kings ix. 21; 2 Chron. viii. 8).

In old Egyptian literature mention is frequently made, from the time of Sethos I., of an Asiatic people called the Amar or Amaor, whom Egyptologists agree in identifying with the Amorites (Bunsen, *Egypt's Place*, vol. iii. 212). There is as yet less agreement in regard to the position of their country. Brugsch is of opinion that the people in question are located in the north of Syria, on the banks of the Orontes (see his *Geog. Inschriften*, Bd. ii. 21; *Hist. d'Égypte*, 132, 187). The later researches of Chabas, however, have rendered the interpretation on which this view depends very doubtful, and shown that in all probability their territory lies, in entire harmony with the representations of Scripture regarding the Amorites, on the west of the Dead Sea and south of the land of Judah (Chabas, *Études sur l'Antiquité*, 267, f.; *Recherches*, 44, 107.) Among the towns of the Amaor are mentioned Dapur and Kodesh, evidently to be identified with the scriptural Debir and Kadesh.

The language, &c., of the Amorites will be more conveniently considered under CANAANITES.

AMORPHISM (from *a* privative, and *μορφή*, form), a term used in chemistry and mineralogy to denote the absence of regular structure in a body. Glass, resin, coal, albuminous substances, &c., are amorphous, exhibiting uniformity of properties in every direction: they have no planes of cleavage, as crystals have; they conduct heat equally in all directions; and they do not show double refraction unless in a *constrained* state. Amorphism is not peculiar to one kind of substances, for the same molecules may exist either in the amorphous or the crystalline state. Thus charcoal or lamp-black is the amorphous form of the diamond; sulphur and phosphorus, when slowly cooled, assume a crystalline arrangement, but when rapidly cooled are perfectly homogeneous—the suddenness of transition from the liquid or fused state giving no time for definite arrangement of particles.

AMOS (not the same as Amoz, the father of Isaiah) was an inhabitant of the district of Tekoa, a fortified town (2d Chron. xi. 6) among the hills of the south of Judah, where a breed of stunted sheep and goats, prized, however, for their wool and hair, found a scanty pasturage (Amos i. 1). Possibly he was a common day labourer; certainly he was far from wealthy, as the Jewish commentators would have him; for though he is called a "nōkēd" (*loc. cit.*), like one of the kings of Moab (2 Kings iii. 4), he tells us himself that he was glad to combine this employment with that of a dresser of sycamore fruit (vii. 14). He may thus be contrasted, as the peasant prophet, with Isaiah, the prophet of the capital and the court. It does not, however, follow that Amos was devoid of such cultivation as could then be had. Distinctions of rank were not, among the primitive Semitic races, coincident with those of culture; it is enough to refer to the pre-Mohammedan Arabs, whose poetry has been so accurately reproduced by Rückert. And in the case of Amos there is evidence in his own works that he was well acquainted with the literature of his day. It is true that he boldly admits the irregularity, from an official point of view, of his prophetic ministrations—"No prophet I, and no prophet's disciple I" (vii. 14); but his discourses are not only full of references (sometimes dubious) to the book of Joel and the Pentateuch, but framed, however

imperfectly, on a genuine artistic plan. This is unmistakably the case in the discourse contained in i. 3-ii. 16; but with greater or less correspondence to the course of thought in the remainder of the book. Thus, according to Ewald (who aims, it is true, at an unattainable precision), chapters iii. and iv. consist of five strophes—iii. 1-8, iii. 9-15, iv. 1-3 (incomplete), iv. 5-11, iv. 12, 13; chapters v. and vi. of a prologue (v. 1-3) and four strophes—v. 4-6, 8, 9; v. 7, 10-17; v. 18-27; vi. 1-10; with a sort of epilogue in vi. 11-14. And the great critic De Wette goes so far as to declare that no Hebrew prophet has shown an equal regard for clearness and harmony of proportion. (Comp. Dr Pusey, *Minor Prophets*, p. 152.)

The date of the first public appearance of Amos cannot be ascertained. From the heading of the book (i. 1), which, though not by the prophet himself, has the air of a genuine tradition (Ewald, *Die Propheten*, i. 123), we learn that he "saw"—that is, prophesied—"two years before the earthquake." This earthquake is referred to again in Zech. xiv. 5, and, as some think, in passages of Joel and other prophets. It seems, therefore, to have constituted an era in popular tradition, but is of no significance for chronology, as has been well shown by Dr Pusey (*Minor Prophets*, p. 148). More to our purpose is the former part of the heading, which limits the prophetic career of Amos to the twenty-five years that Uzziah and Jeroboam II. were contemporary—*i.e.*, 810-784, according to the common chronology; 775-750, according to the Assyrian. (Comp. Schrader, *Die Keilinschriften und das Alte Testament*, p. 120.) He flourished, therefore, in the greatest age of Hebrew prophecy. He seems to have been younger than Joel, to whose prophecy he makes several references, and more or less senior to Hosea and Isaiah. This view is fully borne out by the gradual emergence of the Assyrians on the prophetic horizon. Altogether absent from Joel's prophecy, they are but vaguely alluded to in Amos, and first mentioned by name in Hosea and Isaiah.

It was while "following the flock" (vii. 14, 15) that Amos received a prophetic impulse to leave his home and preach in the sister country. The circumstances are on several accounts worthy of notice. They indicate—1. A distinction between Hebrew prophecy, in its mature stage, and non-Hebrew—*viz.*, that the former is not dependent on a special artificial training; 2. That though his writings are included in the prophetic canon, Amos did not consider himself officially a prophet (which has a bearing on the great controversy of Daniel); and 3. That prophets of the higher or spiritual order did not recognise the revolt of the first Jeroboam (comp. ix. 11; Hos. iii. 5). But the prophecies of Amos had a wider scope than the destiny of Israel. They show a dim presentiment of the philosophy of history, and of the reproductive power of revolutions. Accordingly, Syria, Philistia, Phœnicia, Edom, Ammon, Moab, and Judah were successively rebuked by the inspired messenger. But the chief blame fell upon Israel, whose unparalleled prosperity under Jeroboam II. had developed the germs of vices inconsistent with the religion of Jehovah. The denunciations of Amos produced a powerful impression. He was expelled with contumely by Amaziah, a priest of the reactionary image cultus at the frontier town of Bethel (vii. 10-17).

It is not to be supposed that the discourses of Amos were delivered exactly as they stand. This view is precluded by their elaborate literary character, and by the allusions to the prophet's experience in Israel in ii. 12, v. 10, 13. He probably put them together, with the addition of a grand Messianic epilogue, after his return to Tekoa. There has never been a doubt of their genuineness. The text is good, but there are a few corrupt passages.

Some of the characteristics of Amos have been already

mentioned. The tradition that he was a stammerer (based on an absurd etymology of his name), and the statement of Jerome that he was "imperitus sermone (sed non scientiâ)," only prove the incapacity of the ancients for literary criticism. The simplicity of his style is that of the highest art. He delights in abrupt short clauses, but they are linked together by the closest parallelism. And the supposed rusticity of his dialect is deduced from the spelling of only five words, analogies to which may be traced in the great poem of Job. All that we can admit as probable is, that the native force and talent for observation displayed by this prophet were derived from his early converse with nature on the wild hills of Judah. His imagery, in fact, from its freshness and appropriateness (comp. ii. 13; iii. 5, 12; iv. 2, 9; v. 19; vi. 12; ix. 9), almost reminds us of Dante, and entitles him to as high a place in the history of literature as in that of theistic religion. (r. k. c.)

AMOY, a city and seaport in the province of Fo-kien, China, situated on the slope of a hill, on the south coast of a small and barren island of the same name, in 24° 28' N. lat. and 118° 10' E. long. It is a large and exceedingly dirty place, about 9 miles in circumference, and is divided into two portions, an inner and an outer town, which are separated from each other by a ridge of hills, on which a citadel of considerable strength has been built. Each of these divisions of the city possesses a large and commodious harbour, that of the inner town, or city proper, being protected by strong fortifications. Amoy may be regarded as the port of the inland city of Chang-chu, with which it has river communication; and its trade, both foreign and coastwise, is extensive and valuable. In 1870, 560 vessels, exclusive of Chinese junks, entered the port, of an aggregate burden of 224,436 tons; of these, 315, of 150,171 tons, were British. The chief articles imported were sugar, rice, raw cotton, and opium, as well as cotton cloths, iron goods, and other European manufactures; their value was £1,915,427. In the same year, 554 vessels, of 226,911 tons, cleared the port, including 314 British, of 150,826 tons; the chief exports were tea, porcelain, and paper, and their value was £1,144,046. It is not possible to give the statistics of the trade that is carried on by means of Chinese junks, but it is said to be large; and the native merchants are considered to be among the wealthiest and most enterprising in China. Amoy was captured by the British in 1841, after a determined resistance, and is one of the five ports that were opened to British commerce by the treaty of 1842; it is now open to the ships of all nations. The population of Amoy is estimated at 250,000.

AMPÈRE, ANDRÉ-MARIE, the founder of the science of electro-dynamics, was born at Lyons in January 1775. He took a passionate delight in the pursuit of knowledge from his very infancy, and is reported to have worked out lengthy arithmetical sums by means of pebbles and biscuit-crumbs before he knew the figures. His father began to teach him Latin, but left this off on discovering the boy's greater inclination and aptitude for mathematical studies. The young Ampère, however, soon resumed his Latin lessons, to enable him to master the works of Euler and Bernouilli. In later life he was accustomed to say that he knew as much about mathematics when he was eighteen as ever he knew; but his reading embraced nearly the whole round of knowledge,—history, travels, poetry, philosophy, and the natural sciences. At this age he had read the whole of the *Encyclopédie*, and with such interest and attention that he could repeat passages from it fifty years after. When Lyons was taken by the army of the Convention in 1793, the father of Ampère, who, holding the office of *juge de paix*, had stood out resolutely against the previous revolu-

tionary excesses, was at once thrown into prison, and soon after perished on the scaffold. This event produced such an impression on the susceptible mind of Ampère, that he continued for more than a year in a state little removed from idiocy. But Rousseau's letters on botany falling into his hands, the subject engrossed him, and roused him from his apathy. His passion for knowledge returned. From botany he turned to the study of the classic poets, and to the writing of verses himself. About this time (1796) an attachment sprang up, the progress of which he naively recorded in a journal (*Amorum*). In 1799 he was happily married to the object of his attachment. From about 1796 Ampère gave private lessons at Lyons in mathematics, chemistry, and languages; and in 1801 he removed to Bourg, as professor of physics and chemistry, leaving his ailing wife and infant son at Lyons. His wife died in 1804. After two years' absence he returned to Lyons, on his appointment as professor of mathematics at the Lyceum. His small treatise, *Considérations sur la Théorie Mathématique du Jeu* (Lyons, 1802), in which he successfully solved a problem that had occupied Buffon, Pascal, and others, and demonstrated that the chances of play are decidedly against the habitual gambler, attracted considerable attention. It was this work that brought him under the notice of M. Delambre, whose recommendation obtained for him the Lyons appointment, and afterwards (1805) a subordinate position in the Polytechnic School at Paris, where he was elected professor of analysis in 1809. Here he continued to prosecute his scientific researches and his multifarious studies with unabated diligence. He was admitted a member of the Institute in 1814. It is on the service that he rendered to science in establishing the relations between electricity and magnetism, and in developing the science of electro-magnetism, or, as he called it, electro-dynamics, that Ampère's fame mainly rests. On the 11th of September 1820 he heard of the discovery of Professor Oersted of Copenhagen, that a magnetic needle may be deflected by a voltaic current. On the 18th of the same month he presented a paper to the Academy, containing a far more complete exposition of the phenomenon, which he had in the interval investigated by experiment, and showing that magnetic defects can be produced, without magnets, by aid of electricity alone. In particular he showed that two wires connecting the opposite poles of a battery attract or repel each other according as the currents pass in the same or in opposite directions. According to the theory of magnetism which Ampère's subsequent investigations led him to adopt, every molecule of magnetic matter is acted on by a closed electric current, and magnetisation takes place in proportion as the direction of these currents approaches parallelism. The whole field thus opened up he explored with characteristic industry and care. He anticipated the invention of the electric telegraph, having suggested in 1821 an apparatus of the kind with a separate wire for each letter. Late in life he prepared a remarkable work on the classification of the sciences, which was published after his death. In addition to this and one or two works of less importance, he wrote a great number of memoirs and papers that appeared in scientific journals. He died at Marseilles in June 1836. The great amiability and child-like simplicity of Ampère's character are well brought out in his *Journal et Correspondence*, published by Madame Chevreux (Paris, 1872).

AMPÈRE, JEAN-JACQUES-ANTOINE, the only child of the preceding, was born at Lyons, August 12, 1800. He showed an early preference for literary pursuits, and this was strengthened by his intimate intercourse with the brilliant circle to which his introduction to Madame Récamier's celebrated *réunions* admitted him. He began his literary career as a contributor to the *Globe* and *Revue*

*Française*, which Guizot conducted in opposition to the government of Charles X. After spending some time in travel, he commenced a course of lectures at the Athenæum of Marseilles in 1830, the first of which, *De l'Histoire de la Poésie*, he published. The revolution of July led to his return to Paris, where he lectured at the Sorbonne, till, in 1833, he succeeded Andrieux as professor of the history of French literature in the college of France. His lectures here, which were greatly admired, form the basis of several works, particularly of his *Histoire littéraire de la France avant le 12me Siècle*, 3 vols., Paris, 1839, 1840. Ampère was a constant contributor to various periodical publications. He wrote for the *Revue des Deux Mondes* sprightly accounts of his long journeys in Egypt and North America, as well as in various parts of Europe, which were afterwards collected under the title, *Littérature et Voyages* (2 vols., 1834). His principal work is the *Histoire Romaine à Rome* (4 vols., 1856-64), a series of papers, reprinted in part from the *Revue des Deux Mondes*, showing shrewd sense and great and varied learning, particularly on archaeological questions, and written in an attractive though often discursive style. Ampère was officer of the Legion of Honour from 1846, and in 1847 was admitted to the French Academy. He died March 27, 1864.

AMPHIARAUS, in Greek legend, a son of Oëtes and Hypermnestra, descended on the paternal side from the kingly seer Melampus, and, like his ancestor, endowed with the prophetic gift; but at the same time known for his valour in the great enterprises of his time—the expedition of the Argonauts and the hunt of the Calydonian boar. The expedition, however, on which the chief events of his life hinge is that of the Seven against Thebes, into which he was unwillingly driven by the treachery of his wife, Eriphyle (*Odyssey*, xi. 326), a sister of Adrastus, who then ruled in Sicyon, and by whom the enterprise was planned to restore Polynices to the throne of Thebes. As prince of Argos, Amphiaraus was in a position to assist greatly; but when called upon by Adrastus to take a part, he declined, on the ground that the cause was unholy, and would end fatally. His marriage with Eriphyle, however, had not only been meant to heal previous quarrels between him and Adrastus, but was to be a bond of peace for the future in this way, that she should always arbitrate between them. To secure her favour now, Polynices gave her the fatal necklace which Cadmus had once given to Harmonia, and, though warned of the consequences, Eriphyle accepted it and decided against her husband. Knowing that he would never return, Amphiaraus enjoined his son Alcmaëon, then a boy, to avenge his death upon his mother; and to his children generally he gave wise counsel. As he stepped into his chariot to depart he turned with a look of anger towards his wife, a scene which was represented on the chest of Cypselus. The assault of Thebes was disastrous to the Seven; and Amphiaraus, pursued by Periclymenus, would have fallen by his spear had not Jupiter, at a critical moment, struck the earth with a thunderbolt, and caused it to open and swallow him with his horses, Thoas and Dias, his chariot, and his charioteer, Baton. Jupiter and Apollo, it is said in the *Odyssey* (xv. 245), loved Amphiaraus dearly; yet he did not reach an old age, but fell at Thebes, through the gift accepted by his wife. After death he continued, as a deified hero, to exercise his prophetic power by giving oracles on the spot where he had sunk into the earth. In earlier times this was believed to have happened at Harna, on the way from Thebes to Potniæ, and it was there that the oracle of Amphiaraus was which Cræsus and Mardonius consulted (*Herodotus*, i. 49, 52; viii. 134). Afterwards this oracle yielded to that in the neighbourhood of Oropus, where was also a sanctuary to Amphiaraus (Jupiter Amphiaraus, as he was styled), with athletic and

musical festivals in his honour, and with a sacred enclosure (*temenos*) in which were two springs. At one of them he was thought to have risen from the lower world, and hence its water was employed for no sacred purpose. Invalids who had been cured by oracular prescriptions threw a piece of money in it. The water of the other spring was excellent to drink and to bathe in (*Ἀμφιαράου λουτρά*). The oracles were conveyed in dreams, to obtain which it was

necessary to fast for a time, then to offer sacrifice at the great altar (Pausanias, i. 34, 2), and again to sacrifice a ram and to sleep on its skin. The ruins of the temple, with inscriptions which identify them as such, exist still at Maurodilissi, in the ancient Oropia. In the derivation of his name from *ἀμφι-ἄρασμα*, the piety for which Amphiaras was celebrated is expressed. (A. S. M.)

## AMPHIBIA

LINNÆUS originally employed this term to denote a class of the Animal Kingdom comprising crocodiles, lizards and salamanders, snakes and *Cæcilia*, tortoises and turtles, and frogs; to which, in the later editions of the *Systema Naturæ*, he added some groups of fishes. In the *Tableau Élémentaire*, published in 1795, Cuvier adopts Linnæus's term in its earlier sense, but uses the French word "Reptiles," already brought into use by Brisson, as the equivalent of *Amphibia*. In addition, Cuvier accepts the Linnæan subdivisions of *Amphibia-Reptilia* for the tortoises, lizards (including crocodiles), salamanders, and frogs; and *Amphibia-Serpentes* for the snakes, apodal lizards, and *Cæcilia*.

In 1799<sup>1</sup> Brongniart pointed out the wide differences which separate the frogs and salamanders (which he terms *Batrachia*) from the other reptiles; and in 1804, Latreille,<sup>2</sup> rightly estimating the value of these differences, though he was not an original worker in the field of vertebrate zoology, proposed to separate Brongniart's *Batrachia* from the class of *Reptilia* proper, as a group of equal value, for which he retained the Linnæan name of *Amphibia*.

Cuvier went no further than Brongniart, and, in the *Règne Animal*, he dropped the term *Amphibia*, and substituted *Reptilia* for it. Meckel,<sup>3</sup> on the other hand, while equally accepting Brongniart's classification, retained the term *Amphibia* in its earlier Linnæan sense; and his example has been generally followed by German writers; as, for instance, by Stannius, in that remarkable monument of accurate and extensive research, the *Handbuch der Zoologie* (Zweite Auflage, 1856).

In 1816, De Blainville,<sup>4</sup> adopting Latreille's view, divided the Linnæan *Amphibia* into *Squamifères* and *Nudipellifères*, or *Amphibiens*; though he offered an alternative arrangement, in which the class *Reptiles* is preserved and divided into two sub-classes, the *Ornithoides* and the *Ichthyoides*. The latter are Brongniart's *Batrachia*, plus the *Cæcilia*, whose true affinities had, in the meanwhile, been shown by Duméril; and, in this arrangement, the name *Amphibiens* is restricted to *Proteus* and *Siren*.

Merrem's *Pholidota* and *Batrachia* (1820), Leuckart's *Monopnoa* and *Dipnoa* (1821), Müller's *Squamata* and *Nuda* (1832), are merely new names for De Blainville's *Ornithoides* and *Ichthyoides*, though Müller gave far better anatomical characters of the two groups than had previously been put forward. Moreover, following the indications already given by Von Bär in 1828,<sup>5</sup> Müller calls the attention of naturalists to the important fact, that while all the *Squamata* possess an amnion and an allantois, these structures are absent in the embryos of all the *Nuda*.

Müller makes an appeal for observations on the development of the *Cæcilia*, and of those *Amphibia* which retain gills or gill-clefts throughout life, which has unfortunately yielded no fruits from that time to this.

In 1825, Latreille published a new classification of the *Vertebrata*,<sup>6</sup> which are primarily divided into *Hæmatherma*, containing the three classes of *Mammifera*, *Monotremata*, and *Aves*; and *Hæmacryma*, also containing three classes—*Reptilia*, *Amphibia*, and *Pisces*. This division of the *Vertebrata* into hot and cold blooded is a curiously retrograde step, only intelligible when we reflect that the excellent entomologist had no real comprehension of vertebrate morphology; but he makes some atonement for the blunder by steadily upholding the class distinctness of the *Amphibia*. In this he was followed by Dr J. E. Gray; but Duméril and Bibron in their great work,<sup>7</sup> and Dr Günther in his *Catalogue*, in substance, adopt Brongniart's arrangement, the *Batrachia* being simply one of the four orders of the class *Reptilia*. Professor Huxley has adopted Latreille's view of the distinctness of the *Amphibia*, as a class of the *Vertebrata*, co-ordinate with the *Mammalia*, *Aves*, *Reptilia*, and *Pisces*; and the same arrangement is accepted by Gegenbaur and Hæckel. In the Hunterian lectures delivered at the Royal College of Surgeons in 1863, Professor Huxley divided the *Vertebrata* into Mammals, Sauroids, and Ichthyoids, the latter division containing the *Amphibia* and *Pisces*. Subsequently he proposed the names of *Sauropsida* and *Ichthyopsida* for the Sauroids and Ichthyoids respectively. It is proper to mention, finally, that Professor Owen, in his work on *The Anatomy of Vertebrates*, follows Latreille in dividing the *Vertebrata* into *Hæmatotherma* and *Hæmatocrya*, and adopts Leuckart's term of *Dipnoa* for the *Amphibia*.

The *Amphibia* are distinguished from the *Sauropsida* and *Mammalia* by very important and sharply-defined characters. The visceral arches of the embryo develop gills, which temporarily, or permanently, perform the respiratory function. There is no trace of an amnion, and it is still a question whether the urinary bladder, which all *Amphibia* possess, answers to the allantois of the higher *Vertebrata* or not. At any rate, it plays no part in the respiration of the embryo, nor is it an organ by which nutriment is obtained from the parent. There are two occipital condyles, and the basi-occipital region of the skull is either very incompletely, or not at all, ossified. There is no basi-sphenoidal ossification. When young, the *Amphibia* are provided with, at fewest, three, and usually four, cartilaginous, or more or less ossified, branchial arches. From *Pisces*, on the other hand, they are distinguishable only by the characters of their locomotive apparatus. When they possess median fins and limbs, these never present fin-rays; and the limbs exhibit, in full development, the type of structure which obtains among the *Sauropsida* and *Mammalia*, and differ very widely from the fins of any fish at present known. This difference obtains even among

<sup>1</sup> Brongniart's "Essai d'une Classification Naturelle des Reptiles" was not published in full till 1803. It appears in the volume of the *Mémoires présentés à l'Institut par divers Savans* for 1805.

<sup>7</sup> *Erpétologie Générale, ou Histoire Naturelle complète des Reptiles*, 1836.

the long extinct *Amphibia* of the Carboniferous epoch. In other respects, the lower *Amphibia* approach the *Chimærae*, the *Ganoidei*, and the *Dipnoi* very closely; while, in their development, they present curious approximations to the *Marsipobranchii*.

With respect to the primary subdivisions, or orders, of the class *Amphibia*, no one can doubt the propriety of the separation of the recent forms into what may be broadly termed Newts (*Urodela*); Frogs and Toads (*Anura*); and *Cæcilia* (*Peromela*) effected by Duméril; while all that is known of the organisation of the extinct *Amphibia* of the newer Palæozoic, and older Mesozoic, formations tends to show that they form a fourth natural assemblage of equal value to each of the others.

The names of *Urodela* and *Anura*, given to the first two of these divisions, are undoubtedly open to criticism; but if well-understood terms, which have acquired a definite scientific connotation, are to be changed whenever advancing knowledge renders them etymologically inappropriate, the nomenclature of taxonomy will before long become hopelessly burdened; and, to set a good example, the names of *Urodela*, *Anura*, *Peromela*, and *Labyrinthodonta* are adopted here for the four orders of the *Amphibia*, even although it be true that the *Labyrinthodonta* do not all possess the dental structure on which the name was founded; though there is reason to believe that some *Labyrinthodonts* were devoid of limbs, or peromelous; that the *Anura* are not more tail-less than are the *Peromela*; and that the tails of the *Urodela* are not more conspicuous than were those of the *Labyrinthodonts*.

The *URODELA* are *Amphibia* with elongated bodies and relatively short limbs, devoid of scales or pectoral plates, with numerous præ-caudal vertebræ, and with ampicæulous, or opisthocæulous, vertebral centra. The hyoidean arch remains connected with the suspensorium throughout life, and its cornua are large in proportion to its body. The mandible is dentigerous. There are one or two pairs of limbs, the pectoral arch and limbs being always present. The manus never possesses more than four digits. The bones of the antibrachium and of the crus remain distinct, and the tarsus is not elongated. So far as the spermatozoa are known, they are elongated filaments with a vibratile fringe. The larva develops external gills only; and, except *Siren*, none are known to possess, at any time, a horny masticatory apparatus.<sup>1</sup>

The *ANURA* have relatively short and broad bodies, and both pairs of limbs are constantly present, the hinder being the longer and stronger. There are no scales, nor pectoral plates, but ossification sometimes occurs in the dorsal integument. The vertebræ vary in character, but are usually pro-cæulous. The præ-sacral vertebræ never exceed nine in number, and the caudal portion of the vertebral column is represented by a peculiar styliform coccyx. The hyoidean arch detaches itself from the suspensorium, and almost always becomes connected with the pro-otic region of the skull. The cornua are usually slender, as compared with the broad body of the hyoid. The mandible is almost always devoid of teeth. The bones of the antibrachium and of the crus early ankylose, and the astragalus and calcaneum are much elongated. The manus has a rudimentary fifth digit. Except in *Bombinator*, the spermatozoa have flagelliform appendages, like those of ordinary *Vertebrata*. The larvæ develop first external, and afterwards internal, gills, and, so far as is known at present, are provided with deciduous horny masticatory plates. The gill

apertures are closed by the growing over them of an opercular membrane.

The *PEROMELA* have snake-like bodies, totally devoid of limbs and limb arches. In most, the integument is provided with transverse rows of imbedded cycloid scales, but there are no pectoral plates. The vertebræ of the trunk are very numerous, and are ampicæulous; those of the caudal region are very few, and are free. The hyoidean arch is attached neither to the suspensorium, nor to the skull; its cornua are very slender, and no distinct body is developed; it is followed by several slender, hoop-like, branchial arches. The mandible is dentigerous. Nothing is known of the early stages of development; but Müller discovered branchial clefts, with rudimentary branchial filaments, in young *Cæcilia*.

The *LABYRINTHODONTA* for the most part resembled the *Urodela* in the proportions of the tail and limbs to the body, but some (as *Ophiderpeton*) were serpentiform, and apparently apodal; no raniform *Labyrinthodonts* have yet been discovered. The vertebræ are ampicæulous. The mandible is dentigerous. The bones of the antibrachium and crus remain distinct, and the tarsus is not elongated. The manus and pes appear to have been pentadactyle. Three sculptured pectoral plates and a peculiar dermal armour of small scales, confined to the ventral face of the body, are present in many genera. Nothing is known of the early stages of development, but the young *Archegosauria* appear to have possessed ossified branchial arches.

In giving a sketch of the organisation of the *Amphibia*, it will be necessary to enter much more fully into the characters of the *SKELETON* than into those of the other systems of organs.

The *Vertebral Column, Ribs, and Sternum*.—Leaving the extinct *Archegosauria* aside for the present, all the *Amphibia* possess well-ossified vertebræ, the arches of which, in the adult condition (except, perhaps, in some *Labyrinthodonts*), are not separated by a neuro-central suture from the centra. The latter may be ampicæulous, as in the lower *Urodela*, the *Peromela*, and the *Labyrinthodonta*; or opisthocæulous, as in the higher *Urodela* and some *Anura* (e.g., *Pipa* and *Bombinator*); or pro-cæulous, as in the majority of the *Anura* (with the exception of the eighth vertebræ, which is usually ampicæulous; and of the ninth, which commonly has one convexity in front and two behind). In all the recent forms which have been examined, the centra and intervertebral masses contain more or less distinct remains of the notochord. The arches of the trunk vertebræ are connected by zygapophyses; the spinous processes are usually low, but attain a great relative length in the caudal region of some of the *Labyrinthodonts* (e.g. *Urocordylus*). Transverse processes are present in all the trunk vertebræ, except the atlas; they are shortest in the *Peromela*, longest in the *Anura*. In most *Urodela*, these transverse processes, at any rate in the anterior trunk vertebræ, are divided into two portions, a dorsal and a ventral, which diverge towards their free ends; or, more strictly speaking, these processes are made up of two subequal transverse processes, a dorsal "tubercular" process, and a ventral "capitular" process. Sometimes this division prevails throughout the whole length of the trunk, but, more commonly, the two transverse processes become fused into one, posteriorly.

In the long-bodied *Urodela* (*Siren*, *Proteus*, *Amphiuma*), only a small number of the vertebræ which succeed the atlas present traces of double transverse processes; further back, the coalesced transverse processes form trihedral projections, their dorsal and ventral contours converging instead of diverging, and giving a very characteristic aspect to these vertebræ.

<sup>1</sup> This circumstance appears to have been remarked only by Müller. Speaking of the larvæ of the Salamanders, he says—"Sie haben nicht den Hornschnabel der Froschlärven."—(*Beitrag zur Anat. der Amphibien*, p. 299.) Duméril and Bibron affirm the contrary (*op. cit.*, t. ix. p. 16).

In some Labyrinthodonts, the capitular and tubercular processes, divergent and subequal in some (probably the anterior) vertebræ, coalesce into one in other vertebræ; and the capitular division being shorter than the tubercular, transverse processes, like those of the middle thoracic region of the crocodiles, are thus produced.

In the *Peromela*, there is a short capitular process, but the tubercular process is represented by a mere facet placed below the prezygapophysis.

In the *Anura*, finally, the vertebræ have only a single transverse process (possibly representing the coalesced double transverse processes of the posterior trunk vertebræ of such *Urodela* as *Menopoma*), which, in some of the vertebræ, may attain a great length.

Ribs are present in a few *Anura*, in all *Urodela*, *Peromela*, and *Labyrinthodonta*; and, in the last-named and some *Urodela*, they attain as great relative dimensions as in other *Vertebrata*. But they are always vertebral ribs, no Amphibian being known to possess more than rudiments of sternal ribs. The atlas is never provided with ribs. In the *Peromela*, ribs are borne by all the other vertebræ, except the very hindmost. In the long-bodied *Urodela*, on the other hand, they are restricted to a few of the anterior vertebræ. In the other *Urodela* they are usually confined to the præ-sacral and sacral vertebræ; but, in some cases, one or two of the anterior caudal vertebræ have free ribs. The form of the proximal end of the rib corresponds with that of the transverse processes or process. Where this is double, the rib presents a fork, formed by the capitulum and tuberculum; and when the capitular and tubercular transverse processes are of equal length, the capitula and tubercula of the ribs are equal; but when either of the former is shorter than the other, the corresponding part of the rib is longer. The *Peromela* have no sternum, and that of the *Labyrinthodonta* (if they possessed any) is unknown. In the *Urodela*, the sternum never ossifies, and there is no trace of even a cartilaginous sternum in *Proteus*. In *Menobranchus*, there is a very small cartilaginous sternal plate, which sends lateral prolongations into two of the intermuscular ligaments, representing rudimentary sternal ribs.

In the Newts<sup>1</sup> the sternum becomes a broad and stout plate of cartilage, with a median, posterior, cristate, xiphoid process, and with articular surfaces on its antero-lateral margins for the reception of the coracoids. The sternum attains its highest development in the raniform *Anura*, the xiphoid process becoming elongated and dilated at its extremity, and more or less converted into bone, while calcification of the body of the sternum itself may also occur.

FIG. 1.—The first two vertebræ of *Menopoma* ( $\times \frac{3}{2}$ ).  $V_1^1$ , atlas;  $V_2^2$ , second vertebra; a, intercondyloid process of the atlas; b, the articular surfaces for the occipital condyles. The ribs of the second vertebra are not represented. A, dorsal; B, ventral; C, lateral view.

In the *Urodela*, the first vertebra always presents two slightly concave articular facets, the faces of which look outwards and forwards to adapt themselves to the occipital condyles. Between these facets, the dorsal moiety of the anterior face of the centrum gives rise to a process, which is little more than a ridge in *Proteus*, but in other genera becomes very prominent, and has a curious resemblance to the odontoid process of the axis vertebra of a bird. This "intercondyloid" process of the atlas sometimes (*Amphiuma*, e.g.) exhibits on each side, near its termination, an articular facet, which plays on a corresponding facet of the adjacent face of the occipital condyle.

Mayer (*Analekten*, p. 10) was misled by the form of this process into the supposition that the vertebra to which it belongs is not the atlas, but the odontoid, vertebra. But there is a similar process of the first vertebra in the Rays, and the relations of the vertebra to the nerves show that it is certainly not the homologue of the axis vertebra of other Vertebrates. The first spinal nerve, which has the distribution of the hypo-glossal of the higher *Vertebrata*, passes out of the spinal canal, either between the first and second vertebræ, or through a foramen in the arch of the first, in the *Amphibia*, which have no proper suboccipital nerve. This is a very curious circumstance, and requires elucidation by the study of development.

In the *Anura*, the atlas has the same general form, but the median process is either inconspicuous, as in *Rana esculenta*, or may be absent.

Among the *Labyrinthodonta*, the atlas of *Mastodonsaurus* only is known. It presents two concave facets anteriorly, separated for about half their length by a notch, which probably lodged a ligament.

The atlas of the *Peromela* has the two characteristic facets for the occipital condyles, but the intercondyloid process is absent, and the anterior margin of the arch of the vertebra projects forwards towards the corresponding margin of the occipital foramen (*Epicerium*).

In those *Urodela* which possess posterior limbs (except *Proteus* and *Amphiuma*), one vertebra, or sometimes two (*Menopoma*), are distinguished from the rest as "sacral" by having stouter ribs, the outer ends of which abut against, and are united by ligaments with, the ilia.

The *Anura* always possess a sacral vertebra (sometimes ankylosed with its predecessor or successor), the transverse processes of which are often enlarged, and sometimes greatly expanded, at their iliac ends. The characters of the sacrum of the *Labyrinthodonta* are not known.

In the *Urodela*, the anterior caudal vertebræ, except the first, have inferior arches, which, like the neural arches, are continuously ossified with the centra; and the same condition obtained in the caudal vertebræ of the Labyrinthodonts.

In the *Anura*, the caudal vertebræ are replaced by a long coccyx, consisting of an osseous style, to the dorsal aspect of the anterior end of which two neural arches are

FIG. 2.—*Menopoma*. Posterior (A) and ventral (B) views of the sacral vertebræ (S.V.); S.R.<sup>1</sup>, S.R.<sup>2</sup>, sacral ribs; IL, Ilium; IS, Ischium.

<sup>1</sup> See Parker *On the Shoulder Girdle*, pp. 63, 68.

ankylosed. The anterior face of the style usually presents two concavities (one in *Bombinator* and some other genera), which articulate with the corresponding convexities on the posterior face of the centrum of the sacral vertebra. The number of the vertebrae in the spinal column of the *Urodela* and *Peromela* varies very much. In the long-bodied *Urodela* and *Peromela* they may be very numerous.

According to Cuvier, *Cecilia* has 230; *Siren*, 99; *Amphiuma*, 75; in *Menobranchus* there are 18 præ-sacral and 25 caudal; in *Salamandra*, 15 and 26; and a similar variation appears to have obtained in the Labyrinthodonts. On the other hand, in the *Anura* the number of vertebrae (excluding the coccyx) is very constantly nine; though this number undergoes an apparent reduction, in some cases, by the ankylosis of the first and second vertebrae (*Ceratophrys dorsata*, *Pipa*, *Dactylethra*, *Breviceps*), and in others by that of the sacral vertebra with the coccyx (*Pipa*, *Dactylethra*, *Breviceps*, *Pelobates*).

In the carboniferous Labyrinthodont, *Archegosaurus*, the notochord appears to have persisted throughout life, and the ossification of the centra of the vertebrae to have gone no further than the development of bony rings, such as those with which the ossification of the centra of the vertebrae of a tadpole commences.

**The Cranium.**—The skull is always very depressed, and is usually broad in proportion to its length, though, in this respect, there is considerable variation, the skulls of *Proteus*, *Menobranchus*, and *Amphiuma* being narrow, when compared with those of *Siredon*, *Menopoma*, and the *Anura*. The occipital foramen is situated in the middle of the posterior face of the cranium, and there are always two occipital condyles. The long axis of the suspensorium, or pedicle by which the mandible is connected with the side-walls of the brain-case, varies much in its direction—passing obliquely downwards and forwards in the lower *Amphibia* and in the larval condition of all, but swinging back until it stands out at right angles to the axis of the skull, or becomes directed downwards and backwards, in the higher *Amphibia*. The suspensorium is almost immovable upon the skull, being clamped thereto by the squamosal bone, besides being, as a general rule, united with some part of the wall of the skull by synchondrosis. The "primordial skull," or chondro-cranium, usually remains, to a great extent, unossified, even in the adult. In the *Urodela*, the hyoidean arch is always connected by strong ligaments with the suspensorium; but, in the *Anura* and in the *Peromela*, it becomes completely detached from the suspensorium, and may be free (*Peromela*), or acquire a new attachment to the petriotic region of the skull in front of the *fenestra ovalis* (*Anura*).

The bones which are always present in the Amphibian skull are the exoccipital, pro-otic, parasphenoid, vomer, parietal, frontal, squamosal, premaxillary, palatine, quadrate, dentary, splenial, and angular. The basi-occipital and the basisphenoid are always absent, or are represented by mere partial calcifications of the chondro-cranium. There is always a *fenestra ovalis* closed by a stapes. The branchial arches do not exceed four pairs in number, and, in the perennibranchiate Amphibia, there are never fewer than three pairs.

The skull of the Frog (Figs. 4-7), as the most accessible

member of the group, and that, the development of which has been most carefully studied, may be taken as the starting-point from whence to follow the various modifications of the Amphibian skull. At the sides of the occipital foramen, it presents two large exoccipital ossifications (*E. O.*), which bear the prominent occipital condyles, and, in old specimens, may meet in the middle ventral line. Dorsally, however, they remain separated by a narrow tract of cartilage, which may become more or less calcified. External to the condyles, are the foramina, by which the vagus and glosso-pharyngeal nerves emerge from the cranial cavity; and, beyond these, the bones expand outwards and forwards, so as to embrace the posterior half of the *fenestra ovalis*, while above, they enclose the greater part of the posterior vertical semi-circular canal. The cartilage which incloses the summit of the arch of that canal, however, appears always to remain unossified, and its place is occupied by a groove in the dry skull (Fig. 4, *Ep.*) These ossifications, therefore, answer primarily to the exoccipitals, but, in addition, represent the opisthotic and epiotic elements. Above the *fenestra ovalis*, the wall of the otic capsule is produced outwards into a stout shelf, which forms the roof of the tympanic cavity, and corresponds with the *tegmen tym-*

member of the group, and that, the development of which has been most carefully studied, may be taken as the starting-point from whence to follow the various modifications of the Amphibian skull. At the sides of the occipital foramen, it presents two large exoccipital ossifications (*E. O.*), which bear the prominent occipital condyles, and, in old specimens, may meet in the middle ventral line. Dorsally, however, they remain separated by a narrow tract of cartilage, which may become more or less calcified. External to the condyles, are the foramina, by which the vagus and glosso-pharyngeal nerves emerge from the cranial cavity; and, beyond these, the bones expand outwards and forwards, so as to embrace the posterior half of the *fenestra ovalis*, while above, they enclose the greater part of the posterior vertical semi-circular canal. The cartilage which incloses the summit of the arch of that canal, however, appears always to remain unossified, and its place is occupied by a groove in the dry skull (Fig. 4, *Ep.*) These ossifications, therefore, answer primarily to the exoccipitals, but, in addition, represent the opisthotic and epiotic elements. Above the *fenestra ovalis*, the wall of the otic capsule is produced outwards into a stout shelf, which forms the roof of the tympanic cavity, and corresponds with the *tegmen tym-*

*pani* in man (*t.t.*) This is largely ossified in continuity with the exoccipital<sup>1</sup> posteriorly, and the pro-otic (to which in all probability it properly belongs) in front. The outer extremity of the tegmen, however, remains cartilaginous, and, in front, it passes into a curved band of cartilage, which, as it is continued backwards into the suspensorium, may be termed the "dorsal crus" of the suspensorium (Fig. 9, *c.d.*) The T-shaped squamosal bone (*Sq.*) sends a broad, flat process inwards, which rests upon the *tegmen tympani*, while its long descending process lies external to the cartilaginous suspensorium, and the posterior half of its cross-piece, or proper squamoso-zygomatic part, has the same relation to the dorsal crus of the suspensorium. The suspensorium has a second attachment to the skull, by a "ventral crus" (Fig. 9, *c.v.*), which diverges from the dorsal crus at the anterior extremity of the suspensorium, and is continued into two branches. One of these, passing outwards and forwards, becomes the pterygoid cartilage. The other (Fig. 9, *pd.*), directed backwards and inwards, may be termed the "pedicle of the suspensorium;" it becomes thickened at its inner extremity, and articulates with a facet in front of the *fenestra ovalis*, and close to the attachment of the hyoidean cornu. A thin fibrous band extends from this inferior crus to the side walls of the skull, passing between the first division of the fifth nerve in front, and the second and third divisions behind. The space between the dorsal crus of the suspensorium and the pedicle is filled, in the fresh state, with fibrous tissue, which constitutes the anterior boundary of the tympanum. It is traversed (as Dugès long since pointed out) by the posterior division of the seventh nerve, which therefore lies above the pedicle. The pro-otic ossification (*Pr. O.*) not only walls in the anterior part of the otic capsule, but extends for a short distance forwards in the side walls of the skull. Hence, the foramen of exit for the trigeminal and *portio dura* (V.) is pierced in this position of the pro-otic; and the foramen for the sixth nerve is seen at its lower margin. In front of the pro-otic, the lateral walls of the skull remain cartilaginous for some distance, and are perforated by the large optic foramen (II.) Anteriorly to the exit of the optic nerves, the side walls of the skull are formed by elongated plates of bone, which are parts of an extensive ossification of the anterior moiety of the brain-case and the posterior part of the nasal capsules, constituting the complex structure termed by Cuvier "os en ceinture," and by Dugès "ethmoide." As it takes the place of the ethmoid, presphenoid, and orbito-sphenoids, it may be termed the *sphen-ethmoid* (*S.e.*) It may be compared to a dice-box, one-half of which is divided by a longitudinal partition. This half is anterior, the longitudinal partition being represented by the ossified mesethmoid; while the posterior, undivided, half lodges the anterior portion of the cerebral hemispheres and the olfactory lobes. The front wall of this posterior cavity is perforated by the olfactory foramina; while the outer and posterior wall of each anterior, or nasal, chamber presents, where it forms the anterior and inner boundary of the orbit, a small aperture (*V*<sup>1</sup>) through which the orbito-nasal nerve passes. The exoccipitals, pro-otics, and sphen-ethmoid are ossifications which involve the chondrocranium, though they largely consist of secondary bone. The supra-occipital is represented, if at all, by a mere calcification of the cartilage, and the like is true of the quadrate, which is an ossification of the distal end of the suspensorium. The quadrate, however, very early becomes continuous with a slender style of membrane bone, the proper jugal, which applies itself to the inner face of the posterior end of the

maxilla, and thus gives rise to the quadrato-jugal (*Q.J.*) Ligamentous fibres also connect the anterior end of the zygomatic process of the squamosal directly with the pterygoid, and indirectly with the maxilla and jugal, and pass from the same process to the fronto-parietal bone, forming a fascia over the levators of the mandible, and encircling the orbit. A strong band is continued forwards, over the ascending process of the maxilla, to the alinasal cartilage of the chondrocranium.

The short premaxillæ (*Pmx.*) are united suturely in the middle line, and have stout ascending processes, which become closely connected with the "rhinal processes" by means of oval nodules of cartilage adherent to their posterior surfaces. The long maxillæ unite with the premaxillæ in front, and with the jugals behind: each sends up a short anterior ascending process towards the alinasal cartilage, with which it is united by ligament,<sup>2</sup> and further back, gives off a longer ascending process which becomes connected with the nasal bones. The palatine bones (*Pl.*) are straight, slender, and flattened. They lie transversely to the axis of the skull, behind the posterior nares, closely applied to the ventral surface of the sphen-ethmoid and of the antorbital processes of the chondrocranium. Externally they come into contact with the pterygoids and maxillæ; internally and anteriorly with the vomers. Each pterygoid (*Pt.*) is a triradiate bone, with an anterior, an inner, and a posterior, or outer, ray. The first, or anterior, process of the pterygoid (*Pt*<sup>1</sup>) is the longest, and lies, for a considerable distance, in contact with the maxilla, reaching forward to the outer extremity of the palatine. The second (*Pt*<sup>2</sup>) underlies the pedicle of the suspensorium, and comes into contact with the end of the transversely elongated, sub-auditory, portion of the parasphenoid. The third, or posterior, process of the pterygoid (*Pt*<sup>3</sup>) is prolonged, in correspondence with the backward elongation of the suspensorium, along the inner side of which it lies, as far as the articulation of the mandible.

The vomers (*Vo.*) are broad triangular plates of bone, with irregularly-notched outer edges, which are closely applied to the ventral surface of the sphen-ethmoid. Their inner edges are separated by a narrow interval, and each bears numerous teeth, set along a line which is not quite transverse to the axis of the skull. On the dorsal aspect of the skull two elongated flattened bones, united in a median suture, represent the coalesced frontal and parietals (*Fr., Pa.*), which are separate in the young frog. In front of these, also meeting in the middle line, are two triangular bones, the apices of which extend outwards to the ascending processes of the maxillæ, and which roof over the nasal capsules (*Na.*) These correspond in position and relations with the nasal and so-called "prefrontal" bones of *Sauropsida*, and perhaps with the lachrymals: for brevity's sake, they may be termed nasals.

The parasphenoid has the form of a dagger with a very wide guard and short handle. The latter lies beneath the ventral junction of the exoccipitals, while the blade extends forwards, and its point underlies the posterior moiety of the sphen-ethmoid, but does not reach the vomers. The "guard" passes outwards on each side beneath the auditory capsules, and ends by an abruptly-truncated extremity, its anterior and external angle coming into relation with the inner process of the pterygoid.

The slender, permanently cartilaginous, hyoidean cornu (*Hy.*) passes into the cartilage of the auditory capsule on the ventral side, between the *fenestra ovalis* and the articular surface for the inferior crus of the suspensorium. The *fenestra ovalis* lies in a cartilaginous interspace between the exoccipital and the pro-otic, and is filled by the oval

<sup>1</sup> Dugès (p. 37) states that the pro-otic and the exoccipital always remain distinct in *Rana esculenta*; but it is common to find them extensively ankylosed and inseparable in old frogs of this species.

<sup>2</sup> The small ossifications in this region, termed "cornets" by Dugès, were absent in the skull figured.

cartilaginous stapes (*St.*) The anterior face of this presents a concave facet, for articulation with a corresponding surface occupying the posterior half of the inner end of the *columella auris* (*C. a.*), the anterior half of which fits into a fossa in the pro-otic bone. The *columella auris* itself consists of three portions—a middle elongated osseous rod, an inner swollen and enlarged cartilaginous part, which articulates partly with the pro-otic and partly with the stapes, and an outer portion, which is elongated at right angles to the rest, fixed into the tympanic membrane, and attached by its dorsal end to the *tegmēn tympani*.

The mandible presents one cartilaginous and three osseous constituents on each side. Of the latter, one, the "Mento-Meckelian" (Parker), is a short curved rod of bone, which unites with its fellow in the symphysis, and is, in fact, the ossified symphyseal end of Meckel's cartilage, which extends thence through the length of the ramus, becoming thicker posteriorly, and furnishing the articular surface for the quadrate. The second, and largest, bony constituent of the mandible is a long membrane bone, which ensheathes the inner and under region of the outer surface of Meckel's cartilage, rising at one part into a low coronoid process. It obviously represents the angular, coronary, and splenial elements, and may be termed the *angulo-splenial* (*An.*) A small dentary element, which bears no teeth, lies over the outer face of the anterior half of Meckel's cartilage.

The hyoidean apparatus of the adult frog (Fig. 8) presents a body and two slender cornua. The body consists of a broad and thin squarish plate of cartilage, produced on each side into three processes, which may be called anterior, lateral, and posterior. The anterior process (*a*) is slender, curves outwards, and very soon divides into two processes, one short, anterior, forming a loop by its ligamentary connection with the second, or posterior, branch, which passes into the long and slender cornu of the hyoid. The lateral process (*b*) passes outwards and slightly dorsad—expanding into a broad, hatchet-shaped free extremity. The posterior process (*c*) is a mere prolongation of the postero-lateral angles of the body of the hyoid. Finally, from the middle of the posterior margin of the body of the hyoid there project two strong bony rods, wider at the ends than in the middle, which embrace the larynx, and have been termed the *thyro-hyals* (*d*).

FIG. 8.—Ventral view of the hyoid of *Rana esculenta*. *a*, anterior; *b* lateral; *c*, posterior processes; *d*, thyro-hyals.

The parieto-frontals, nasals, premaxillæ, maxillæ, squamosals, palatines, pterygoids, and parasphenoid, the dentary and angulo-opercular bones, may be removed from the frog's skull without injury to the chondrocranium, the structure of which then becomes apparent (Fig. 9).

It furnishes a floor, side walls, and roof to the brain case, interrupted only by a large space (fontanelle), covered in by membrane, which lies in the interorbital region under the parieto-frontals; and by the foramina for the exit of the cranial nerves. It consists entirely of cartilage, except where the exoccipitals, the pro-otics, and the sphen-ethmoid invade its substance. In front of the septum of the anterior cavity of the sphen-ethmoid, it is continued forward, between the two nasal sacs, as the cartilaginous septum narium, from which are given off, dorsally and ventrally, transverse alæ of cartilage, which furnish a roof and a floor, respectively, to the nasal chamber. Of these, the floor is the wider. The dorsal and ventral alæ pass into one another where the chondrocranium ends anteriorly, and give rise to a truncated terminal face, which is wide

from side to side, narrow from above downwards, and convex in the latter direction. The lateral angles of this truncated face are produced outwards and forwards into two flattened pre-nasal processes (*p. nl.*); these widen externally, and end by free edges, which support the adjacent portions of the premaxillæ and maxillæ. From the ventral face, just behind the truncated anterior end of the chondrocranium, spring two slender cartilages (*r.p.*, *r.p.*), which do not seem to have been noticed hitherto. Each of these inclines towards the middle line, and ends against the middle of the posterior face of the ascending process of the premaxilla by a vertically elongated extremity. These may be termed the *rhinal* processes. An oval nodule of cartilage is attached to the posterior face of the dorsal end of the ascending process of the premaxilla, and serves to connect it with the rhinal process. On the dorsal face of the chondrocranium, just above the point of attachment of the rhinal processes, the external nasal apertures are situated, and the outer and posterior margins of each of these apertures is surrounded and supported by a curious curved process of the cartilaginous ala—the *alinasal* process (*a.n.*) Where the sphenoidal and the ethmoidal portions of the sphen-ethmoid meet, a stout, transverse, partly osseous and partly cartilaginous, bar (*A.O.*) is given off, which is perforated, at its origin, by the canal for the orbito-nasal nerve. It then narrows, but becoming flattened from above downwards, rapidly widens again, and its axe-head-like extremity abuts against the inner face of the maxilla. The anterior angle of the axe-head is free; the posterior angle is continued back into a slender cartilaginous rod, which bifurcates posteriorly; the outer division passes into the ventral crus (*c.v.*) of the suspensorium. The inner (*pd.*) is the pedicle of the suspensorium already described. Meckel's cartilage, articulated to the free end of the suspensorium, is unossified throughout the greater part of its extent, no osseous *articulare* being developed; but, at its symphyseal end, each cartilage becomes ossified, and forms the "mento-Meckelian" element of the mandible.

FIG. 9.—Chondrocranium of *Rana esculenta*—ventral aspect. *r.p.* the rhinal processes; *p.n.l.* the prenasal processes; *a.n.* the alinasal processes, shown by the removal of part of the floor of the left nasal chamber; *A.O.* the antorbital process; *pd.* the pedicle of the suspensorium continued into *c.v.* the ventral crus of the suspensorium; *c.v.* its dorsal crus; *t.t.* the tegmen tympani; *S.E.* the sphen-ethmoid; *E.O.* the exoccipitals; *Qu.J.* the quadratojugal. II, V, VI. foramina by which the optic, trigeminal and portio dura, and abducens nerves leave the skull.

The slender cornu of the hyoid passes directly into the periotic cartilage immediately in front of, though below, the fenestra ovalis. It is unossified throughout its whole length.<sup>1</sup> With many variations in detail, the skulls of the *Anura* in general are readily reducible to the type of that of the frog. In the *Aglossa*, which differ so widely in many respects from the other *Anura*, the cranium presents some notable peculiarities. In *Dactylethra*<sup>2</sup> the skull is similar to that of the ordinary *Anura* in general form, but the nasal region is small in proportion to the orbito-temporal space. The fronto-parietals are ankylosed together, and extend forwards as far as a line drawn along the anterior edge of the antorbital

<sup>1</sup> Compare Mr Parker's full account of the structure of the skull of *Rana temporaria*, *Philosophical Transactions*, 1871.  
<sup>2</sup> This description applies especially to *D. lewis*.

processes. Here they overlap a very singular bone, consisting of two broad alæ, which lie between the anterior edge of the frontal and the external nares, and of a median portion which is continued forwards, as a narrow, flat, curved process, between the nasal chambers, being received into a sort of groove of the chondrocranium. The bone is readily raised up from the subjacent chondrocranium, of which it appears to be quite independent. At the outer end of each of its alæ, and between the antorbital process and the nasal capsule, is a small, transversely elongated, slender bone, loosely connected by fibrous tissue with the foregoing. The ethmoid is completely cartilaginous. The parasphenoid has the ordinary sword shape, except that the "guard" is extremely short; but its point extends along the base of the skull, passing between the nasal sacs, underlying their septum, and terminating close to the premaxillæ. The vomers are represented by a transversely elongated rhomboidal osseous plate, devoid of teeth, which lies between the two posterior nasal apertures, and therefore much behind the anterior end of the parasphenoid. The side walls of the cranial cavity are ossified from the antorbital process to the anterior boundary of the foramen for the fifth nerve, just in front of which they are pierced by the optic foramen. There is no palatine bone. The pterygoid, in the main, resembles that of the ordinary frogs; but, in consequence of the shortness and little backward extension of the suspensorium, the outer process passes almost directly outwards, with hardly any backward inclination. A bony plate, which extends backwards from the posterior edge of the inner and outer branches of the pterygoid, underlies the tympanic cavity and the auditory capsule, and forms the floor of the Eustachian canal. The squamosal is a short broad bone, with a long anterior process, which becomes connected, by direct articulation, with the pterygoid, and by ligament with the maxilla. The premaxillæ are small, and the maxillæ are connected merely by ligaments with the suspensorium, there being no jugal. The *columella auris* is remarkably strong, and is bent in the middle, so that its two halves form an obtuse angle; the anterior half lies against the inner face of the tympanic membrane. The posterior half runs parallel with the posterior edge of the tegmen tympani, towards the fenestra ovalis. Ligamentous fibres fix the columella firmly, though movably, to the superior margin of the tympanic cavity, where it is bounded by the squamosal. The stout cartilaginous hyoidean cornua are attached just beneath the anterior and inferior part of the margin of the fenestra ovalis. The body of the hyoid is very small, but the two "thyro-hyals" are extremely long and broad cartilages. There is no ossified "mento-Meckelian" element.

In *Pipa*, the skull is extraordinarily depressed and broad. The nasal bones are wide, flat, triangular, and quite distinct from one another, a forward prolongation of the coalesced fronto-parietals extending between the two. The parasphenoid, very broad in the greater part of its extent, and having the guard rudimentary, sends a narrow median process forwards underneath the nasal septum, as in *Dactylethra*. No trace of a vomer, or palatine bone, was to be found in the specimen examined. The pterygoid is very like that of *Dactylethra*, but its inner branch is greatly prolonged, and the floor sent under the Eustachian tube unites much more closely with the produced exoccipital. The squamosal is very small, and the place of its zygomatic process is taken by ligament. This ligament, however, unites with the pterygoid in the same way as the bony process which answers to it in *Dactylethra*. The columella is less massive than in *Dactylethra*, and the end which abuts against the tympanic membrane is imbedded in a disk of cartilage. The occipital condyles look outwards and backwards, instead of inwards and backwards, as in *Dactylethra*.

The hyoidean cornua are wanting, the thyro-hyals being large, but not so large proportionally as in *Dactylethra*.

The skulls of the URODELA present a very interesting series of modifications, leading from a condition in which the cranium retains, throughout life, a strongly-marked embryonic character, up to a structure which closely approximates that found in the *Anura*.

In *Menobranchus*, for example, the chondrocranium of the adult is in nearly the same state as that in which it

Fig. 10.

Fig. 11.

Fig. 12.

FIGS. 10, 11, 12.—Lateral, dorsal, and ventral views of the cranium of *Menobranchus lateralis*. In the dorsal view, the bones are removed from the left half of the skull; in the ventral view, the parasphenoid, palato-ptyergoid, and vomers are given in outline. The letters have, for the most part, the same signification as before. VII. p. posterior division of the seventh nerve; VII. chorda tympani; V<sup>1</sup>, V<sup>2</sup>, V<sup>3</sup>, first, second, and third divisions of the trigeminal; s. s. l. stapedio-suspensorial ligament; h. s. l. hyo-suspensorial ligament; m. h. l. mandibulo-hyoid ligament; a, ascending process of the suspensorium; p, pterygo-palatine process; q, quadrate process; o, otic process; Na, posterior nares; Mck, Meckel's cartilage; Gl (Fig. 10), the position of the glottis. Bb<sup>1</sup>, Bb<sup>2</sup>, basibranchials.

exists in a young tadpole or larval salamander (Figs. 10, 11, 12).

Instead of there being a well-developed cartilaginous brain-case, interrupted only by a dorsal fontanelle, as in the frog, both the floor and roof of the cranial cavity are formed by merely fibrous tissue, which underlies the frontal and parietal bones, and overlies the parasphenoid; and only its sides and its anterior end are bounded by cartilage.

The occipital region remains membranous in the middle line, both dorsally and ventrally, and exhibits, in the latter aspect, the remains of the notochord. The cartilaginous rods (*Tr.*), which bound the cranial cavity laterally, and represent the *trabeculae* of the embryonic vertebrate skull, are separated by a wide oval space, which occupies the whole length of the floor of the cranial chamber. Anteriorly, they converge, and, just before they do so, give attachment to the slender antorbital processes (*A. O.*) which lie behind the posterior nares. They then unite, and, becoming applied together, coalesce into a flattened narrow mesethmoid, to the anterior extremity of which the pre-maxillary bones are applied. They give off neither alinasal nor subnasal processes, and therefore furnish neither roof nor floor to the nasal chamber. Posteriorly, they become flattened from above downwards, and coalesce with the auditory capsules, and with the cartilage which extends beneath these, and gives rise to the occipital condyles (*E. O.*)

Each auditory capsule has a generally oval form, but is produced posteriorly, so as to give rise to a conical epiotic process (*Ep. O.*), which projects beyond the level of the occipital condyle. Fitted into the outer wall of each is the relatively large, conical, stapes, whence strong ligamentous fibres proceed to the posterior face of the suspensorium.

Immediately in front of the auditory capsule, the suspensorium passes by a strong pedicle (shown, but not lettered in Fig. 12) into the trabecula, and then, directed outwards, downwards, and forwards, ends in the quadrate process (*q*), with which the dorsal end of Meckel's cartilage articulates. A large process (*o*) ascends from the posterior face of the suspensorium, and applies itself to the outer and anterior face of the auditory capsule. A small and hardly perceptible elevation (*p*) is seen near the quadrate process of the suspensorium. Finally, a flat process (*a*, Fig. 11) ascends above the pedicle, and applies itself to the dorsal face of the trabecula.

On comparing this with the suspensorium of the frog, it is clear that the rudimentary process (*p*) answers to the pterygoid cartilage; and that the process *o* (the *otic* process) answers to the dorsal crus of the suspensorium. In fact, the posterior, or hypo-mandibular, branch of the seventh nerve passes back beneath this, and above the stapedial ligament, to its distribution.

The pedicle answers to the part so named (including the ventral crus of the suspensorium) in the frog, though it retains the embryonic relations to the trabecula, such as exist in the tadpole. The ascending process (*a*) lies between the orbito-nasal and the other branches of the trigeminal, the orbito-nasal passing between it and the trabecula. A similar process is very generally found in the *Urodela* (being particularly large, for example, in *Menopoma*), but appears to be represented only by fibrous tissue in the *Anura*.

Meckel's cartilage (*Mck.*, Fig. 12) is thick and deep at its articular end, but, after furnishing a surface of attachment for the elevator muscles of the jaw, it rapidly narrows, and ends in a point, at some distance from the symphysis of the dentary bones.

The hyoidean apparatus (Fig. 13) is represented, on each side, by a cartilaginous rod, subdivided into a short *hypo-hyal* (*H. h.*) and long *cerato-hyal* (*C. h.*) A strong ligament extends from the front face of the latter, below its free summit, to the suspensorium, reaching this at the same

place as the stapedial ligament, into which it is continued. From a point a little above the attachment of this ligament, another ligamentous band arises, and, crossing the former, on the inner side of which it passes, becomes attached to the angle of the mandible. It answers to the interoperculum of a fish, and has nearly the same relations as the stylo-maxillary ligament of the higher Vertebrata.

In the ventral median line, the hypo-hyals are connected only by fibrous tissue. Firmly united with this, however,

there is a median *first basibranchial* cartilage (*Bb<sup>1</sup>*), succeeded by a *second basibranchial* (*Bb<sup>2</sup>*), which is ossified, and is the only bony constituent of the hyobranchial apparatus. There are only three branchial arches. The first consists of a stout and long *cerato-branchial* (*Cb<sup>1</sup>*), bearing an equally well-developed *epibranchial* (*Ep. b<sup>1</sup>*). The second

is represented by a mere nodule of cartilage (*Cb<sup>2</sup>*), with which the expanded end of the second epibranchial (*Ep. b<sup>2</sup>*) articulates. The third and smallest epibranchial (*Ep. b<sup>3</sup>*) is articulated with the step-like broad end of the second. There is no trace of any fourth branchial arch, such as exists in tadpoles and in young salamanders; and in *Siredon*, *Siren*, *Amphiuma*, and *Menopoma*.

The most curious feature in the bony skull, or *oro-steo-cranium*, of *Menobranthus* is the presence of the prominent conical ossifications which lie external to the exoccipitals, and occupy the place of the *epiotic* and *opisthotic* bones. In possessing these elements of the skull, in so large and distinct a form, *Menobranthus* differs from all *Amphibia*, save *Proteus* and the extinct Labyrinthodonts. The parietal bones are separate from the frontals, and send, as is usual in the *Urodela*, a long process forwards on each side of the latter. In *Menobranthus*, this process is extremely long, reaching the olfactory foramen, the posterior margin of which it bounds. There are no nasal nor prefrontal bones, nor any distinct alisphenoidal, orbito-sphenoidal, or ethmoidal ossifications; of the maxilla, nothing but a rudiment appears, and this is sometimes absent. There are no jugal or quadrato-jugal ossifications. A palato-ptyergoid plate, bearing teeth on its expanded palatine portion, extends from the antorbital process to the inner face of the suspensorium, which, as stated above, has a mere tubercle in the place of a pterygoid process. The vomers are long, bear teeth along their outer edges, and diverge backwards so as to leave an interspace between their inner edges. Posteriorly, they articulate with the anterior ends of the palato-ptyergoids.

The squamosal is a long, slender, curved bone, devoid of any zygomatic process, which extends from the articular end of the suspensorium, along its outer edge, to the outer side of the epiotic. From its posterior margin it sends down a short process over the stapedial ligament.

The parasphenoid is a broad thin plate of bone, which extends from near the junction of the vomers to the occipital foramen. The distal end of the suspensorium is incompletely ossified, as a quadrate bone; and a dentary and a splenial element, both dentigerous, lie, the former

FIG. 13.—Hyoid and branchial apparatus of *Menobranthus lateralis*. *Hh.* hypo-hyal; *Ch.* cerato-hyal; *Bb<sup>1</sup>*, first basibranchial; *Bb<sup>2</sup>*, ossified second basibranchial; *Ep. b<sup>1</sup>*, *Ep. b<sup>2</sup>*, *Ep. b<sup>3</sup>*, first, second, and third epibranchials; *Gl.* glottis.

external to and below, the latter internal to, Meckel's cartilage.

The skull of *Proteus* is, in its general characters, similar to that of *Menobranchnus*, but is more extensively ossified.

In *Siren*, the skull, which has the same elongated form and forwardly directed suspensoria as in *Menobranchnus* and *Proteus*, possesses, in the epiotic region, two strong crests, which project backwards beyond the level of the occipital condyles, but are otherwise very different from the epiotics of the latter genera. The "exoccipitals" and prootics are completely fused together, even in half-grown specimens, a mere rim of cartilage being left around the fenestra ovalis. The lateral walls of the skull present ossifications extending from the exits of the orbito-nasal nerves, forwards to the mesethmoid, or internasal portion of the trabeculae, and completely encircling the olfactory foramina. But these ossifications remain distinct for a considerable time, if they ever coalesce. Each, therefore, represents half of the sphen-ethmoid of the Frog.

The flat and wide parasphenoid extends forwards to the space left by the divergence of the vomers. On the roof of the skull, each broad parietal sends forward a prolongation along the outer edge of the frontal, which reaches the antorbital process. The premaxillae have very long ascending processes, which lie upon the mesethmoid, and are received between the ends of the frontal bones. Between these ascending processes one or two elongated ossifications are situated. These were termed "nasals" by Cuvier, but their position does not accord with this determination. The horizontal, or oral, portions of the premaxillae, on the other hand, are very short and edentulous, each being coated by a thin plate of horny substance. The maxillae are rudimentary or absent. The vomers are two, flat, oval, bony plates, the ventral aspect of which is beset with parallel rows of teeth set in obliquely-disposed curved lines, the convexities of the curves being turned inwards and backwards. The vomers are in contact anteriorly, but diverge posteriorly. The posterior extremity of each abuts upon a plate of similar form, but much smaller, and bearing fewer series of teeth, which lies on the ventral side of the origin of the antorbital process, and represents the palatine bone. The aperture of the posterior nares lies just opposite, and external to, the junction of these two bones.

The suspensorium is short, thick, and completely cartilaginous. Dorsally and internally, it is attached by a stout pedicle to the trabecula in front of the auditory capsule, while its dorsal and posterior face lies against the truncated anterior face of the pro-otic. The angle formed where this face joins the outer face represents the otic process of *Menobranchnus*. There is no pterygoid process, nor any trace of a pterygoid bone. Just above the suspensorium, and seemingly connected with it, there proceeds from the anterior face of the pro-otic region of the skull, a strong, triangular, forwardly-directed cartilaginous process. From the free anterior end of this, a band of fibrous tissue passes, and, encircling the eye, is attached to the antorbital process. The squamosal is a slender curved bone, extending from the epiotic ridge to the articular end of the suspensorium, where it is widest. It exhibits only a rudiment of the well-marked process which extends towards the stapes in *Menobranchnus* and *Proteus*. The mandible presents a dentary, an angular, and a dentigerous splenial element; and the proximal end of Meckel's cartilage is ossified, giving rise to a dense nodular *articulare*. The dentary is toothless, and supports the inferior horny beak.

The cornu of the hyoid is very stout, and its ventral moiety is ossified. The much thicker dorsal moiety is cartilaginous, and its recurved dorsal end extends beyond

the extremity of the skull. At a considerable distance below its apex, a strong short ligament proceeds from its anterior face to the stapes. A broad sheet of ligamentous fibres further unites the hyoid with the lateral walls of the ear capsule, and with the posterior face of the suspensorium (hyo-suspensorial ligament); and a slender ligament (mandibulo-hyoid) proceeds from near the insertion of the hyo-stapedial ligament to the angle of the mandible. There are two basibranchials, both ossified, the posterior ending in short radiating processes; two cerato-branchials and four epibranchials.

In *Amphiuma*, the suspensoria are very little inclined forwards, and their long axes make nearly a right angle with that of the skull. The portion of the skull which lies behind a line joining the articular ends of the *ossa quadrata* is very much shorter than the region in front of it. Moreover, although the epiotic processes are prominent, the occipital condyles project far beyond them. One bone represents the exoccipital, epiotic, and opisthotic on each side. The pro-otic is large, and gives rise to the anterior moiety of a strongly-marked temporal ridge. Its exposed surface presents two fossae, divided by a nearly vertical linear elevation. The large parietals form the posterior portion of the temporal ridge, and diverge anteriorly, to be continued forwards, on each side of the frontals, to the sphen-ethmoid. The frontals, in like manner, diverge in front to receive a median ossification, which is continuous with the coalesced median processes of the premaxillae. The anterior half of each frontal is rugose, as are the exposed surfaces of the sphen-ethmoid and of the nasal bones, and the integument is firmly adherent to these rugosities. The nasals are broad and triangular. The truncated base of each lies over the nasal aperture; the inner edge articulates with the ascending process of the premaxilla; the outer edge joins first the maxilla, and then the sphen-ethmoid. The premaxillae are so thoroughly ankylosed that no trace of their primitive distinctness is to be seen. The large maxillae extend back for half the length of the skull, are firmly united with the adjacent bones, and are connected by dense ligament with the extremity of the quadrate bone. The greatly elongated vomers diverge but little; nevertheless, they come in contact only by their anterior extremities. In the rest of their extent they are separated, in front, by a median ossification representing the anterior part of the sphen-ethmoid, and, behind, by the anterior forked prolongation of the parasphenoid which embraces this ossification. The rest of the parasphenoid is broad and flat; it widens a little, in front of the auditory capsules, so as to form a rudiment of the "guard" in the frog's skull.

The osseous pterygoid is a curved plate of bone, convex inwards and concave outwards, which articulates posteriorly with the quadrate, and, in front, stops short, at little more than half the distance from its posterior end to the internal nostril. The cartilaginous pterygoid process of the suspensorium extends some way beyond it, and, widening, is attached by ligament to the maxilla. Posteriorly, the cartilaginous pterygoid is traceable, as a comparatively narrow band, on the inner side of the bony pterygoid, to the pedicle of the suspensorium, which is attached in front of the fenestra ovalis, and above the rudimentary "guard" of the parasphenoid. An ascending process passes from it between the orbito-nasal and the other divisions of the trigeminal. The otic process of the suspensorium, which is articulated with the outer face of the auditory capsule, is cartilaginous; but the rest of the suspensorium is ossified as a quadrate bone. This is, as usual, clamped to the skull by the squamosal, which is broad and expanded above, and narrow below. Behind, the suspensorium is directly articu-

lated with the styloform projection of the centre of the stapes. A very strong hyo-suspensorial ligament passes from near the distal end of the suspensorium to the cornu of the hyoid. The mandibulo-hyoid ligament is much weaker. The hyoidean apparatus presents a median basi-hyal, connected by a rounded hypo-hyal on each side, with a long and curved cerato-hyal, which is almost completely ossified. The first basibranchial is elongated and cartilaginous—the second is absent. The first branchial arch is a single elongated bone, representing the similarly coalesced cerato-branchial and epibranchial in *Menopoma*. The second cerato-branchial is small and cartilaginous. The three posterior epibranchials are simple curved cartilages; and the single branchial cleft is placed between the third and fourth epibranchials.

The skulls of the four genera, *Menobranchnus*, *Proteus*, *Siren*, and *Amphiuma*, now described, resemble one another, and differ from those of other *Amphibia*, in their elongated form; and, especially, in the relative narrowness of the facial region in front of the orbits, which, as the case of *Amphiuma* shows, arises, not from any want of development of the maxillary bones, when they exist, but from their taking a direction which but slightly diverges from parallelism with the axis of the skull. Moreover, they all possess well-marked epiotic prominences. *Amphiuma* differs widely from the other three, in the great size of its maxillary bones, in the absence of palatine bones, in the projection of the occipital condyles beyond the epiotic processes, in the ankylosis of the premaxillæ, in the presence of well-developed nasal bones, in the coalescence of the first cerato-branchial with the first epibranchial, and in the transverse direction of the suspensorium.

In most of those respects, in which *Amphiuma* differs from *Menobranchnus*, *Proteus*, and *Siren*, it approaches the Salamanders; especially if we take such forms as *Anaides* into account. On the other hand, in the entire absence of a palatine bone, and in the fusion of the first cerato-branchial with its epibranchial, it agrees with *Menopoma* and *Cryptobranchnus*.

In *Menopoma*, the skull has a broadly-rounded snout, and its posterior contour slopes forwards and outwards (without being interrupted by conspicuous epiotic prominences), in the manner characteristic of the higher *Urodela*. The small pro-otics are separated from the exoccipitals (which also represent the epiotics and episthotics), by a wide cartilaginous interspace, in which the fenestra ovalis is situated. The parietal sends a process forwards, along the outer edge of the frontal, between it and the orbito-sphenoid. This meets a curved flat bone, which bounds the orbit anteriorly and internally, and articulates with an ascending process of the maxillary bone. It may therefore be regarded as a prefronto-lachrymal. The frontals unite in a long median suture, and then, diverging, embrace the nasal bones, and articulate externally with the fore part of the ascending process of the maxillary bone, which is thus received between the frontal and the prefronto-lachrymal. The very broad parasphenoid extends from the exoccipitals to the vomers, with which it unites by a denticulated squamous suture. The wide vomers are united by a median suture, and expand in front, ending in arched edges, close behind which the teeth are set. The premaxillæ are separate and small, articulate with the arched edges of the vomers, and send up strong ascending processes to the dorsal face of the skull, where they firmly unite with the nasals. The squamosal is a flattened prismatic bone, as broad at one end as at the other, which articulates with the parietal externally, and with the quadrate internally. Like the

suspensorium, which it covers, it stands out at right angles with the axis of the skull. There is no palatine bone. The pterygoid is broader and more square than in any other *Amphibian*, in consequence of the great expansion of its internal process, which articulates by its whole length with the parasphenoid. The anterior process ends in a free pointed cartilage, directed outwards and forwards, and united with the maxilla by ligament, as in the higher *Urodela*. The external process extends to the articular end of the quadrate, as usual, and is continued thence along the cartilaginous suspensorium to its attached end.

The chondrocranium forms a complete ring of cartilage round the occipital foramen, continuous at the sides with the auditory capsules. From these the trabeculæ are continued forwards, as in *Menobranchnus*, leaving a very wide ventral fontanelle. At the anterior end of this they unite and form the mesethmoid, from which roof and floor plates of the nasal capsules are continued. The suspensorium is connected by a pedicle with the trabecula, in front of the auditory capsule, and gives off a broad ascending process, which becomes ossified continuously with the pterygoid, over the orbito-nasal nerve. A stout otic process is articulated with a facet on the antero-external region of the periotic capsule, and is further connected with it by ligamentous fibres. The quadrate ossification involves a small portion of the articular end of the suspensorium; it thence extends upwards, on the dorsal aspect of the suspensorium, gradually becoming more slender, and nearly reaches the point at which the otic process of the suspensorium articulates with the periotic cartilage.

The osseous skull of *Cryptobranchnus* is extremely like that of *Menopoma*.

In *Menopoma* the hyo-branchial apparatus presents the same general structure as that of *Siredon*, except that the second basibranchial seems to be wanting, while the first is very broad and rounded; at the same time, the epibranchial and the cerato-branchial of the first arch are represented by only one continuous cartilage.

In *Cryptobranchnus*,<sup>1</sup> however, a considerable reduction has taken place, the two posterior pairs of branchial arches present in *Menopoma* having disappeared. The second arch still presents a division into cerato-branchial and epibranchial, but the dorsal end of the latter is closely united with that of the preceding arch. It is interesting to observe, however, that the modification thus effected is quite different from that which occurs in the Salamanders, in which, in the adult state, the first branchial arch retains its two segments; while the second, reduced to its cerato-branchial, is applied against the first, at the junction of the cerato- and epi-branchial; and the second basibranchial persists as the *ossiculum thyroideum* of Von Siebold.

*Menopoma* and *Cryptobranchnus* further differ from the proper Salamanders in having the vomerine teeth disposed along the anterior edges of the expanded vomers. Unfortunately nothing is known of the larvæ of these forms, but it would seem as if, in them, the primitive vomers enlarge by extension of ossification behind, and not in front of, the originally existent teeth.

In the remaining *Urodela*, the Salamanders proper, the skull has the broadly-arched snout and the shelving posterior contour of *Menopoma*, but the vomers and pterygoids are very different.

The structure of the skull in these animals will be best understood by commencing with that of *Siredon*, which, though perennibranchiate under ordinary circumstances, is totally unlike the other so-called *Perennibranchiata* in cranial structure, and is, in fact, to all intents and purposes a larval Salamander.

An ossification on each side of the occipital foramen represents the exoccipitals, epiotics, and episthotics. In front of each of these

<sup>1</sup> See Hyrtl, "*Cryptobranchnus japonicus*," *Schediasma anatomicum*," tab. iii.

is a pro-otic, and an orbito-sphenoid. The latter is sometimes united with its fellow of the opposite side.<sup>1</sup> The skull is roofed in by pairs of parietal, frontal, prefronto-lachrymal, and nasal bones. The maxillæ are short, and are united with the ends of the suspensorium only by fibrous tissue. There is a very broad and flat parasphenoid, which extends from the inferior margin of the occipital foramen, and ends, anteriorly, by a wide, irregularly convex edge, which does not reach the vomers. The latter bones are elongated and curved, and their long axes diverge posteriorly, as in *Menobranchius*; but their anterior ends are far apart, and they lie, separated by the whole breadth of the parasphenoid, and between that bone and the premaxilla and maxilla, adherent to the ventral face of the subnasal process of the chondrocranium.

The short palatine bones are situated immediately behind, and on the inner side of, the posterior nares, but their somewhat tapering, external and posterior, ends do not articulate directly with the pterygoids. The latter are triradiate bones, with an inner process which passes towards the base of the skull; an outer, which runs down the suspensorium; and a long anterior process, which gradually diminishes in breadth forwards, and is connected only by ligament with the palatine. Three ossifications embrace Meckel's cartilage. The dentary covers its outer face throughout its whole length. The angular lies on the inner face of its posterior two-thirds, and the small dentigerous splenial is also applied to its inner face between the angular and the dentary. The chondrocranium is in much the same condition as that of *Menopoma*. There is a broad basicranial cartilage situated between the auditory capsules, and passing, at the sides and above, into a complete occipital arch. But, in front, the trabeculae, though they have increased in vertical height, remain united by fibrous tissue only, both in the floor and in the roof of the skull, which thus presents two great "fontanelles" when the parasphenoid, parietals, and frontals are removed. In front, they coalesce, each giving off, as it does so, a flat antorbital process, which is expanded at its outer end, where it supports the maxilla. Below, this process gives attachment to the palatine. By their coalescence, the trabeculae give rise to a broad internasal septum (or mesethmoid cartilage), and they expand, on each side, below, into subnasal plates, which are separated, anteriorly, by a wide notch in the middle line. The curved outer edges of these plates give attachment to the premaxilla and maxilla, and they answer to the præ-nasal processes of the chondrocranium of the frog. Between the posterior edge of each of these and the anterior edge of the corresponding antorbital process, the posterior nostril is situated; and the inferior surface of the subnasal plate gives attachment to the vomer. Superiorly, the mesethmoid cartilage expands into a very thin (alinasal) plate, which roofs in each nasal chamber, and supports the prefronto-lachrymal and nasal bones.

The suspensorium is connected, above and internally, with the trabecula of its side by a pedicle; and it has an ascending process which lies over the orbito-nasal nerve (which is therefore included between the pedicle and the ascending process) immediately after its exit from the skull. Posteriorly and superiorly, it gives off an otic process, which is articulated with the outer and front part of the auditory capsule; while, inferiorly and externally, it furnishes an articular surface to the mandible. The pterygoid process has the form of a style tapering forwards, and nearly reaching the antorbital process, with which it is connected, however, only by ligamentous fibres. The posterior moiety of Meckel's cartilage is very stout as far as the coronoid process, and then tapers rapidly to its free, pointed, symphyseal extremity.

The hyoidean and branchial apparatus is entirely fibrous and cartilaginous, none of its parts having undergone ossification. Each cornu of the hyoid is connected with the upper and posterior face of the suspensorium, and with the angle of the mandible, by ligamentous fibres—the hyosuspensorial and mandibulo-suspensorial ligaments. The cornua are not subdivided, and are united in the median ventral line by ligament. A triangular first basibranchial extends back from their junction, and is succeeded by a second, as in *Menobranchius*; but this second basibranchial is not ossified. Two cerato-branchials are attached to the posterior extremity of the first basibranchial on each side, and the anterior is, as usual, followed by a long and strong epibranchial, which supports the anterior gill. The posterior cerato-branchial supports the second epibranchial directly, and the third and fourth epibranchials indirectly.

The interesting observations of Professor A. Duméril have shown that, under certain conditions, the ordinarily perenni-branchiate *Siredon* passes into the caduci-branchiate *Amblystoma*; and this metamorphosis is accompanied by some very interesting modifications in the structure of the cranium, especially in the vomerine, palatine, and pterygoid regions. Ossification extends forwards from

the vomers beneath the præ-nasal processes, so that the series of teeth, which originally lay along the anterior margins of these bones, come to be situated at their posterior edges. At the same time they take up a direction at right angles to the axis of the skull, instead of being greatly inclined to that axis, as they are in *Siredon*, and the two sets of vomerine teeth thus form a single transverse row. Moreover, the anterior process of the pterygoid moves outwards until it comes into contact with the inner face of the maxilla. The one end of the palatine remaining attached to the vomer, the other swings outwards, in correspondence with the change of position of the pterygoid, and thus becomes directed transversely to the axis of the skull, immediately behind the posterior nostril, its teeth continuing the transverse line of the teeth of the vomers. Salamanders with the teeth thus disposed have been termed "lechriondot." The maxillary bones are larger than in *Siredon*, but the jugal arch remains ligamentous. The dorsal ends of the cornua of the hyoid retain their ligamentous connection with the suspensorium, and the ventral ends with the anterior basibranchial. The first cerato-branchial and epibranchial persist, and retain their articulation with one another. The second cerato-branchial remains, but its dorsal or outer end becomes attached to the preceding, and all the three posterior epibranchials disappear. The second basibranchial becomes detached as a Y-shaped piece, which lies in the middle line, in front of the larynx.

In all the other Salamanders, the vomers, in the adult, present the same enlargement of the part in front of the teeth, at the expense of the region behind them, as in *Amblystoma*. But the teeth rarely offer the same disposition. More commonly they form two series, inclined to one another at a more or less acute angle, open forwards, and supported upon bony plates, which appear like prolongations of the vomers, extending backwards on the ventral face of the parasphenoid. This "meccodont" arrangement is strikingly exemplified by *Salamandra maculosa*, and still more remarkably by *Plethodon* and *Anaides*, where these longitudinal series of teeth beneath the parasphenoid are commonly termed "sphenoidal" teeth. Dugès<sup>2</sup> and other observers, however, have shown that, in larval *Salamandra* and *Tritone*, the vomerine and palato-ptyergoid apparatus have, at first, the same disposition as in *Siredon*; and Dugès has described the process by which the palatine bones, becoming detached from the pterygoids, which rotate outwards, ankylose with the vomers, taking up a position beneath the parasphenoid, and more or less parallel with the axis of the skull; and it can hardly be doubted that the so-called "sphenoidal" dentigerous plates of other genera of *Salamandrida* have the same origin. If this conclusion be correct, it indicates a very curious morphological difference between the "meccodont" and "lechriondot" *Salamandrida*.

In all the *Salamandrida* the parietal bones send long processes forwards on each side of the frontals. The parasphenoid is a broad flat plate. Very often the premaxilla are ankylosed into one bone, and the bones of the periotic capsule coalesce. In some cases there are epiotic processes or ridges. Maxilla are always present, and the snout is usually broadly arched. Nasal bones, distinct from the prefronto-lachrymals, are usually present.

In the genus *Anaides* the skull is comparatively long and narrow, and the muzzle is less arched than usual. The single premaxilla, and the two well-developed maxilla, follow the semicircular curve of the broad subnasal plates, to the edges of which they are attached. The hinder free extremities of the maxilla are curved upwards, and the jugal arch is represented only by ligament. Thus far the skull is salamandrine; as it is also in the presence of distinct nasal and prefronto-lachrymal bones, in the disposition of the vomerine and so-called "sphenoidal" teeth, in the absence of an apparent palatine bone, and in the manner in which the pterygoid is produced into a long process, which becomes connected with the inner face of the maxilla. But, in the well-marked downward and forward inclination of the suspensorium, and in the strong crests into which the epiotic processes are developed, the skull of *Anaides* is very like that of *Siren*.

In the skull of *Epicrion glutinosum* (Fig. 14), which may be selected as an example of the PEROMELA, the strong occipital condyles are continued into two ossifications, which rise on to the roof of the skull, where they unite in a short suture, and, spreading out so as to embrace the parietals, are continued over the auditory apparatus, as far as the squamosal and the quadrate bones. Ventrally, no indication of any suture between these bones and the broad parasphenoid is visible; laterally, they pass forward into a continuous ossification, which constitutes the side walls of the auditory capsule, and, in front of this, is perforated by the wide foramen for the trigeminal nerve, and enters largely into the lateral wall of the cranial cavity. The parietal bone rests on the dorsal edge of this lateral ossification, which terminates, anteriorly, by an irregularly

<sup>1</sup> See Friedrich and Gegenbaur—"Der Schädel des Axolotl (*Siredon pisciformis*)" in the *Berichte der Königlichen Zoologischen Anstalt zu Würzburg*, 1849. This memoir contains an excellent account of the chondrocranium of the Axolotl.

<sup>2</sup> *Recherches*, pp. 172, 173, pl. xiv. fig. 89. Rusconi, *Observations Anatomiques sur la Sirène*, pl. vi. figs. 3 and 10.

excavated border, between which and the posterior margin of the sphen-ethmoid the cranial wall is unossified. Throughout its whole

FIG. 14.—The skull of *Epierium glutinosum*. A, dorsal; B, ventral; C, lateral, view. The letters have the same signification as before.

extent, this large ossification, which represents the exoccipitals, the elements of the petriotic capsule, and the alisphenoids, is firmly ankylosed with the parasphenoid. There is a well-developed sphen-ethmoid, similar in its general characters to that of the frog. It is very closely united, if not ankylosed, with the vomers and premaxilla. The roof of the skull is completed by two parietals, two frontals, and two large nasals, which unite in a long suture, except in front, where, for a short distance, they are separated by the ascending processes of the premaxilla. The dentigerous oral processes of these bones are short, and unite by suture with the maxilla. These send up broad plates which lie in front of and below the orbit, on the sides of the face. The canal for the suborbital tentacle perforates the maxilla in front of the orbit. Posteriorly, the maxilla unites with the squamosal, which is a broad plate firmly fixed to the quadrate, but somewhat loosely united with the frontal and parietal and with the complex occipito-otic bone. A small crescentic post-orbital bone (denoted by 1 in Fig. 14) articulates with the maxillary and squamosal, and with another bone (2), which answers very nearly to the prefrontal of a reptile. Between the nasal bone and the premaxilla, above and below, and the maxilla behind, a small bone (3) is fitted. The quadrate bone is represented by the ossification of the distal end of the suspensorium, which is inclined a little backwards. The stapes is large and well ossified. Two distinct ossifications, an angulo-articular and a dentary, are discernible in the mandible; and the second short row of teeth, inside those of the dentary, seems to indicate the existence of a splenial element.

In the LABYRINTHODONTA the skull presents the extremes of form which are met with among the *Amphibia*, from the elongation observable in *Archegosaurus*, to the short and broad form of *Melopias* and *Brachyops*. The chief characters by which the labyrinthodont cranium differs from that of its existing allies are the following:—

The occipital condyles in some genera remained long, if not permanently, cartilaginous; and one or two supra-occipital ossifications (probably membrane bones) very generally occur. The epiotics are prominent, and appear to remain permanently separate from the adjacent bones. In front of them, and articulated with the outer edges of the parietal and frontal, are two bones, which are commonly identified with the "squamosal" and "post-frontal" of the higher Vertebrata. The "post-frontal" articulates anteriorly with a large "prefrontal" bone, which bounds the dorsal and anterior contour of the orbit. The outer edges of the "squamosal" and "post-frontal" articulate with two bones, termed the "post-orbital" and the "supra-temporal." The post-orbital lies in front of the other, and contributes to the posterior margin of the orbit,—the rest of the contour of which, between the post-orbital and the prefrontal, is usually completed by a large jugal. Articulated, dorsally and internally, with the "supra-temporal," and, anteriorly, with the jugal, is a "quadrato-jugal," which sometimes extends into the articular surface for the lower jaw, and in some cases, at any rate, overlaid a quadrate ossification. There are long paired nasals, between the anterior ends of which the ascending processes of the premaxilla are received; and between these bones, the un-

usually long maxilla, and the prefrontals, distinct "lachrymal" ossifications occur.

The vomers are large, meet in a long median suture, and bear teeth. The palatine bones, also dentigerous, bound the posterior nares in front, and are elongated antero-posteriorly.

The mandible presents a dentary (probably including a splenial) element, an angular and an articular ossification.

Those surfaces of the cranial bones which were covered by the skin are usually rugose, and sculptured much in the same way as those of the crocodiles, and they frequently present symmetrically-disposed grooves, the so-called "mucous canals," which, very probably, lodged sensory apparatuses resembling the similarly-named structures in fishes—the homologues of which are found in existing *Urodela*.

The hyoid is unknown, and what appears to be traces of a branchial apparatus have been observed only in young specimens of *Archegosaurus*. Hence it is probable, not only that no known Labyrinthodonts were perennibranchiate, but that the air-breathing condition supervened early in the course of their development.

The Labyrinthodonts doubtless possessed a well-developed chondrocranium, but such a structure would necessarily perish in the course of fossilisation. The singular resemblance of the labyrinthodont skull to that of the *Peronota*, in the arrangement of the bones which bound the cavity of the mouth, and the disposition of the teeth upon them, suggests a comparison of the other cranial bones in the two groups. Starting from the nasals of *Epierium*, which may be safely identified with those of the Labyrinthodonts, the bone marked (2) in *Epierium* corresponds very closely with the labyrinthodont "prefrontal;" and that numbered (1), with the "post-orbital." No. 3 in *Epierium*, in some respects answers to the so-called "lachrymal" of the Labyrinthodonts; while the maxilla of the *Cæcilian* may be taken to represent both maxilla and jugal of the Labyrinthodont. But if this be so, the squamosal of *Epierium* corresponds with the supra-temporal of the Labyrinthodont; and a question arises as to the true nature of the "squamosal" and "post-frontal" of the latter.<sup>1</sup>

*The Limbs.*—The pectoral arch in the *Amphibia* is distinguishable into a scapular, a coracoid, and a præcoracoid region, although the extent to which these parts of the primitive cartilaginous arch become separately ossified varies very much in the different members of the group.

In *Proteus*, *Menobranchius*, *Cryptobranchus*, and *Menopoma*, ossification occurs only in the scapular region. In *Siren* and *Amphiuma* an additional broad coracoid ossification occurs, but it does not meet the scapular ossification in the glenoidal cavity. The junction, however, takes place in *Siredon* and the Salamanders. In none of the *Urodela* does any ossification appear in or upon the præcoracoid or supra-scapular cartilage.

A supra-scapular ossification exists in all known *Anura*. All but *Microps* and *Hyladactylus*<sup>2</sup> have a præcoracoid, which acquires a sheath of bony matter. The glenoidal cavity is bounded by the præcoracoid, coracoid, and scapula; and in some cases (*e.g.*, *Dactylethra*) the ossified ends of the three unite and give rise to a tri-radiate suture in the glenoidal cavity, just as the pubis, ischium, and ilium of most Vertebrata unite in the acetabulum. In *Systema gibbosum*, contrary to the usual rule, the præcoracoid is far broader than the coracoid (Parker).

In the higher *Anura*, a median piece, of very variable size, form, and consistency, extends forwards from the junction of the præcoracoids. Mr Parker considers it to be an outgrowth from these, and terms it the *omosternum*.

The long bones, both in the fore and hind limbs, consist of an axis of cartilage, sheathed in, and more or less replaced by, a diaphysis of membrane bone. The extremities of the cartilages frequently undergo calcification, and are thus converted into epiphyses. A strong crest characterises the humerus in many male *Anura*. In the latter, the radius and ulna coalesce into one bone, while in all other *Amphibia* they remain distinct.

In *Siredon*, *Cryptobranchus*, and *Menopoma*, the carpus contains eight separate cartilages, of which three—the *radiale*, *intermedium*, and *ulnare*—form a proximal row; and four *distalia*, a distal row. Between these two series lies a single *centrale*.

In *Menobranchius*, there are only six carpal cartilages—the ulnare and intermedium, and the radiale and radial distale, respectively, having apparently, as Gegenbaur suggests, coalesced.

In *Amphiuma didactylum*, the number of carpal cartilages is reduced to four, and in *Proteus* to three. In both these cases the two largest cartilages form a proximal row.

<sup>1</sup> On the structure of the skull, as of whatever else is known of the organisation of the Labyrinthodonts, the reader will find full, excellently arranged, and well-digested information in the "Report of the Committee of the British Association on the Labyrinthodonts of the Coal Measures," drawn up by Mr Miall, *British Association Reports*, 1873.

<sup>2</sup> Parker *On the Shoulder Girdle*, p. 67.

The *Salamandrida* usually have seven carpal elements. In the proximal row there are two—a radiale and a coalesced intermedium and ulnare. There is a single centrale and four distalia. These are variously ossified until, in *Triton cristatus* and *alpestris*, all are ossified.

No urodele amphibian has more than four digits in the manus, and the number may be reduced to three, or even two (*Amphiuma didactylum*). When four digits are present the number of the phalanges is usually 2, 2, 3, 2.

Among the *Anura*, Dugès and Gegenbaur have shown that *Bombinator* and *Pelobates* have eight distinct carpal bones—two in the proximal row (radiale, intermedium-ulnare), five in the distal, and one between these two rows. This last, which is the centrale, lies on the radial side of the manus, and articulates with the three radial distalia, much as the navicular bone articulates with the three cuneiformia in the mammalian tarsus. In *Rana esculenta*, there are also two bones in the proximal row, and the centrale lies on the radial side of the carpus. But there are only three bones in the distal row; one large, on the ulnar side, which bears the third, fourth, and fifth metacarpals, and two small ossicles on the radial side, which articulate with the first and second metacarpals.

There are five digits in the manus of the *Anura*; but the pollex is rudimentary, being represented only by a cartilaginous or more or less ossified style. The second and third digits usually have two phalanges each, and the fourth and fifth, three (2, 2, 3, 3).

The pectoral arch of the Labyrinthodonts is best known in *Archegosaurus*, where it presents three ossified elements, which probably answer to the coracoid, præcoracoid, and scapula. The bones of the fore-limb in the Labyrinthodonts are always weak relatively to the size of the body. There appear to have been five digits, the carpus remaining unossified.

In *Proteus*, *Menobranchus*, and *Amphiuma*, the pelvic arch is not connected with any distinctly modified sacral vertebra, and the ilium is very small. The pubes and ischia are represented by broad cartilaginous plates, which unite, and may become fused together in the middle line.

In *Menobranchus*, the pubic portion of the pelvis is continued forwards into a broad triangular median process. In *Siredon*, *Menopoma*, *Cryptobranchus*, and the Salamanders, there is a similar median process, reminding one of the omosternum in the pectoral arch of the *Anura*. It becomes bifurcated anteriorly. The ilium is always ossified; and there are ischial ossifications in all but *Proteus*. On the other hand, the pubic region always remains cartilaginous in the *Urodela*.

Hyrtil has shown that *Cryptobranchus* has no proper knee-joint, the femur being united with the tibia and fibula by a solid fibrous mass; and that, in *Menopoma*, the cavity of the knee-joint is very small.

The tibia and fibula in the *Urodela* are always separate, and the proximal elements of the tarsus are not elongated. The greatest number of tarsal elements is found in *Cryptobranchus* and *Menopoma*, which, according to Hyrtl, have three cartilages in the proximal, and five in the distal, row, while two are central. In *Siredon*, the tarsus completely resembles the carpus, but there is one more distal cartilage. The tarsus therefore consists of three proximal cartilages (*tibiale*, *intermedium*, *fibulare*), one central (*centrale*), and five distal (*distalia*). In the Salamanders, there is usually the same number and disposition of the tarsal cartilages; but more or fewer are ossified, and it is interesting to remark that the two fibular distalia sometimes become united into a "cuboid."

*Menobranchus* has two (or three) proximal, one central, and three distal tarsal cartilages; *Amphiuma*, three proximal and two distal; *Proteus*, two cartilages on the fibular, and one on the tibial side.

*Siredon*, *Cryptobranchus*, *Menopoma*, and most Salamanders have five digits in the pes; *Menobranchus*, four; *Amphiuma*, three; and *Proteus*, two. The number of the phalanges in the pentadactyle foot is usually 2, 2, 3, 3, 2. In *Siredon*, Hyrtl found 1, 2, 3, 4, 2.

In the *Anura*, the ilium is greatly elongated, and the pubes and ischia are flattened, discoidal, and applied together by their inner surfaces. The ilium and the ischium, alone, become completely ossified, and there is no præpubic process.

The tibia and fibula coalesce into one bone. Two elongated bones form a proximal row in the tarsus, and are commonly united by their epiphyseal ends (e.g., *Rana*; they remain separate in *Bombinator*). In *Rana esculenta*, the distal confluent ends of these bones (which possibly answer to the astragalus and calcaneum) present a transversely elongated articular surface, which is convex from the dorsal to the plantar side. Between this and the proximal end of the second and third metatarsals lies a discoidal, more or less calcified, cartilage. The convex distal face of this cartilage articulates with these two metatarsals. From its fibular side a strong ligamentous band passes to the proximal end of the fifth metatarsal, and a fibrous plate to the fibular and plantar edge of the fourth metatarsal, so that the band and plate are interposed between these metatarsals and the coalesced astragalus and calcaneum. On the tibial side of the discoidal cartilage lies another, which is elongated from the dorsal to the plantar side, and concave proximally, to articulate with the tibial side of the distal end of the coalesced astragalus and calcaneum. The inner or tibial face of this cartilage

articulates with the proximal end of the elongated first joint of the *calcar*. Its distal end is connected by a strong band of ligamentous fibres, within which a nodule of cartilage may be enclosed, with the proximal ends of the first and second metatarsals. The second joint of the *calcar* has the form of an ungual phalanx.

In *Bufo* and *Bombinator*, according to Gegenbaur, the *calcar* consists of only a single piece.

The pelvic arch of the Labyrinthodonts appears to have contained a well-ossified pubic element, in which respect it differs from that of all other *Amphibia*. The hind-limb, like the fore-limb, was relatively weak. The tibia and fibula are distinct. In the few cases in which the pes is preserved it is pentadactyle, with a short cartilaginous tarsus.

*The Integumentary Organs.*—In all recent *Amphibia*, the integument is remarkable for the great abundance of simple follicular glands which are distributed through it, and are sometimes all of one kind (e.g., *Proteus*), though in other cases two sorts of such glands can be distinguished (*Rana*). In many *Anura* and *Urodela*, these glandular structures attain a greater complication of structure, especially near the angle of the jaw, and constitute what are termed the "parotoid" glands. In some cases, the secretion of these glands is extremely acrid and irritating. In some *Urodela* (*Proteus* and *Siredon*), and in the tadpole, the epidermis becomes modified in relation with the termination of sensory nerves, in the head and along the body, in the region of the nerve of the lateral line, and gives rise to sensory organs of the same nature as those which are found in the lateral line and the so-called mucous sacs and canals of fishes.<sup>1</sup>

In a few *Anura*, ossification takes place in the dorsal integument, and this process may go so far as to give rise to bony plates, which may become closely connected with the spines of the subjacent vertebrae (*Brachycephalus*, *Ceratophrys*). In the majority of the *Peromela*, oval, cycloid scales are imbedded in the transverse folds of the integument, and constitute another point of resemblance between the members of this group and the Labyrinthodonts. But the rows of scales are not confined to the ventral surface, and the scales themselves differ in structure from those of the Labyrinthodonts.

In the *Urodela* and *Anura*, the epidermis is periodically exuviated.

*The Alimentary Organs.*—The teeth of the recent *Amphibia* vary a good deal in form. In the *Urodela*, they are usually conical and pointed; frequently more or less curved; sometimes, as in *Anaides*, lancet-shaped. *Siren* has the surfaces of the vomers and palatines covered with parallel series of small *dents en brosse*. In *Ceratophrys*, the bases of the teeth are slightly grooved longitudinally. In *Archegosaurus*, similar grooves are more marked, and give rise to folds of the wall of the tooth. These, extending inwards and ramifying, give rise to the complicated or "labyrinthic" structure exhibited by transverse sections of the teeth of the typical Labyrinthodonts. Very generally, the teeth become ankylosed with the subjacent bones, and are replaced by others developed at their bases. In the Labyrinthodonts, some of the anterior teeth frequently become much larger than the rest. The *Anura* are remarkable for the total absence of teeth in the mandibles, in all but one or two genera, while many have no premaxillary or maxillary teeth. The Toads have no teeth in the upper jaw. *Pipa* is altogether edentulous. *Siren* alone presents plates of horn upon the gingival surfaces of the premaxillæ and of the dentary elements of the mandible.

Teeth may be developed upon the premaxillæ and maxillæ, the palatines, and the dentary and the splenial elements of the mandible; but they do not occur elsewhere,—the so-called sphenoidal teeth of some Salamanders being really borne, as has been seen, on the peculiarly modified palatines.

The buccal cavity is usually spacious, and the widely-separated posterior nares open into the anterior part of it. In the lower *Urodela*, the branchial clefts lie at the sides of the pharynx, and the median aperture of the glottis is situated far back. In the *Urodela*, and some *Anura*, there are no Eustachian passages; but, in most *Anura*, these passages have the form of wide recesses leading out of the pharynx. In *Pipa* and *Dactylethra* alone, the "recesses" are converted into Eustachian "tubes," which open by a common

<sup>1</sup> *Recherches sur les organes sensitifs, qui se trouvent dans l'épiderme du Protée et de l'Azolotl*, by E. Bugnion. Lausanne, 1873.

median aperture; this is relatively wider in *Dactylethra*. Two grooves in the mucous membrane of the roof of the mouth pass from the Eustachian to the posterior nasal apertures, and enclose a lyrate space, in these genera.

The tongue is rudimentary in the lower *Urodela*; but, in the Salamanders, it may be free, fleshy, and even mushroom-shaped. In *Pipa* and *Dactylethra*, no trace of a tongue is to be observed. In *Rana*, as in most *Anura*, the anterior end of the tongue is comparatively small and little elevated above the mucous membrane of the floor of the mouth, but the posterior end is produced into a free fleshy mass, bifurcated at its extremity. It is this free end which is thrown forward in the act of prehension, the tongue turning on its anterior end as on a hinge. *Rhinophrynus* is the only *Anuran* in which the anterior end of the tongue alone is free.

In the males of many *Anura* the mucous membrane of the mouth is produced outwards, on each side, between the mandible and the hyoid, into a sac, which becomes filled with air, and gives rise to a conspicuous projection of the integument of the throat. In some cases these two sacs coalesce into one.

Salivary glands have not been discovered in any *Amphibia*.

Except in the *Peromela*, the gullet is short. It passes into an elongated stomach, the long axis of which coincides with that of the body in the *Urodela* and *Peromela*, but becomes oblique, or transverse, in the *Anura*. The intestine is never very long, and, consequently, its convolutions are few and simple. There is always a marked distinction between the small and the large intestine. The latter opens into a cloaca, which receives the ducts of the urinary and genital apparatus. The stomach and intestine are enclosed in peritoneum, and suspended to the roof of the abdominal cavity by a mesenteric fold. The liver is always provided with a gall-bladder. It is distinctly bilobed in most *Anura*; and, in *Pipa* and *Dactylethra*, the two lobes are completely separate, the gall-bladder being attached to the right lobe. In the *Peromela*, the liver has an exceptional form, being divided into a great number of small lobes, arranged in a longitudinal series so as to overlap one another.

A pancreas is always present; but sometimes, as in *Rana*, it is small, and its glandular substance surrounds the hepatic duct. The spleen, enclosed in the mesentery, is elongated in the *Urodela* and *Peromela*, rounded in the *Anura*.

*The Organs of Circulation.*—The heart is contained within a pericardium, the walls of which generally exhibit numerous scattered pigment cells, and though delicate in the fresh state, are apt to become tough and almost parchmentaceous in spirit specimens. The heart (if we apply that name to the whole apparatus enclosed within the pericardium, except the venæ cavæ), presents a series of five segments, to which, enumerating them from behind forwards, the following terms may be applied:—1, The *sinus venosus*; 2, the *atrium*; 3, the *ventriculus*; 4, the *pylangium* (from *πύλων*, a gateway, and *ἀγγείον*, a vessel); and 5, the *synangium*. *Atrium* here denotes the auricular division of the heart, comprising the right and left auricles. *Pylangium* and *synangium*, together, are the equivalents of that portion of the heart which lies between the ventricle and the anterior wall of the pericardium, and which has been variously named *bulbus*, *cavus*, and *truncus arteriosus*.

These five segments of the heart are so arranged, that the sinus and atrium lie on the dorsal and posterior aspect of the organ, while the others occupy its ventral and anterior region. Viewed sideways, in fact, the heart has the shape

FIG. 15.—The heart of *Siredon mexicanus*. Lateral view of the heart contained within the pericardium, the left wall of the sinus venosus and of the auricles being removed; S, sinus venosus; I.v.c. inferior vena cava; L.s.v.c. left superior vena cava; L.A. left auricle; R.A. right auricle; Spt. septum auriculorum; V, ventricle; T. a. truncus arteriosus; 1, 2, 3, 4, the aortic arches. The arrow traverses the sinu-auricular aperture. The auriculo-ventricular aperture lies to the right of the arch formed by the free edge of the septum.

of a  $\Sigma$ , of which the sinus and atrium occupy the upper, and the other segments the lower half. But it also always presents, more or less, a lateral flexure, between its anterior and posterior points of adherence to the middle line of the pericardium; so that, viewed from above, it approximates the form of an N, of which the right half is represented by the synangium, pylangium, and ventricle, and the left half by the atrium and sinus. The pylangium, in fact, always arises from the right side of the ventricle, while a large part of the atrium and of the sinus very often lies to the left of the ventricle, the auriculo-ventricular aperture of the ventricle looking to the left side and forwards.

There is an interesting difference in the relative position of these segments of the heart in the lower and the higher *Amphibia*. In *Siredon*, for example, the greater part of the sinus lies completely behind the ventricle, and the sinu-auricular aperture is situated on the posterior face of the atrium, on a level with the posterior part of the ventricle; but, in the Frogs, the sinus lies altogether above the ventricle, without sensibly projecting behind it, and the sinu-auricular opening lies in the dorsal face of the atrium, in front of the level of the auriculo-ventricular aperture. In other words, the segments of the heart have a less marked vertical flexure in the lower, than in the higher *Amphibia*, and more nearly approach the condition of the embryonic heart.

In correspondence with this, the superior cavæ traverse the pericardium to enter the sinus near its posterior end in *Siredon*, but about its middle in the Frog.

The *sinus venosus* is a thin walled sac, which is relatively largest in the lower *Amphibia* and smallest in the Frogs. Anteriorly, it usually receives, on each side, one of the two superior venæ cavæ; posteriorly, the single vena cava

FIG. 16.—Ventral view of the same heart contained in the pericardium. R.s.v.c. right superior vena cava. The pylangium laid open to show the two transverse rows of valves, V<sup>1</sup>, V<sup>2</sup>. The commencement of the synangium (Sg.), cut across.

of a  $\Sigma$ , of which the sinus and atrium occupy the upper, and the other segments the lower half. But it also always presents, more or less, a lateral flexure, between its anterior and posterior points of adherence to the middle line of the pericardium; so that, viewed from above, it approximates the form of an N, of which the right half is represented by the synangium, pylangium, and ventricle, and the left half by the atrium and sinus. The pylangium, in fact, always arises from the right side of the ventricle, while a large part of the atrium and of the sinus very often lies to the left of the ventricle, the auriculo-ventricular aperture of the ventricle looking to the left side and forwards.

There is an interesting difference in the relative position of these segments of the heart in the lower and the higher *Amphibia*. In *Siredon*, for example, the greater part of the sinus lies completely behind the ventricle, and the sinu-auricular aperture is situated on the posterior face of the atrium, on a level with the posterior part of the ventricle; but, in the Frogs, the sinus lies altogether above the ventricle, without sensibly projecting behind it, and the sinu-auricular opening lies in the dorsal face of the atrium, in front of the level of the auriculo-ventricular aperture. In other words, the segments of the heart have a less marked vertical flexure in the lower, than in the higher *Amphibia*, and more nearly approach the condition of the embryonic heart.

In correspondence with this, the superior cavæ traverse the pericardium to enter the sinus near its posterior end in *Siredon*, but about its middle in the Frog.

The *sinus venosus* is a thin walled sac, which is relatively largest in the lower *Amphibia* and smallest in the Frogs. Anteriorly, it usually receives, on each side, one of the two superior venæ cavæ; posteriorly, the single vena cava

FIG. 17.—Posterior view of the same heart, removed from the pericardium; P.v. pulmonary vein.

In correspondence with this, the superior cavæ traverse the pericardium to enter the sinus near its posterior end in *Siredon*, but about its middle in the Frog.

The *sinus venosus* is a thin walled sac, which is relatively largest in the lower *Amphibia* and smallest in the Frogs. Anteriorly, it usually receives, on each side, one of the two superior venæ cavæ; posteriorly, the single vena cava

FIG. 18.—The atrium of the same heart laid open and its walls spread out, so as to show the opening of the pulmonary vein, P.v., and the sinu-auricular aperture, S.a.

inferior opens into it. But, in some cases (as in *Menobranchus* and *Pipa*, according to Meyer) the inferior vena cava divides into two branches, each of which coalesces with the superior vena cava of its side before opening into the sinus. The superior cavæ may open into the sinus immediately after they have traversed the pericardium, as in *Menobranchus*; or, they may be short trunks, as in the Frogs; or, as in *Siredon* and the Salamanders, the right cava may be long and the left short.

The sinu-auricular aperture, by which the sinus and the right auricle communicate, is small, relatively to the size of these two cavities, and has an oval form. Its lips may be slightly prolonged towards the cavity of the auricle, but do not give rise to very definite sinu-auricular valves.

The auricular segment of the heart, or atrium, is always more or less bi-lobed, the *truncus arteriosus* being embraced by the two lobes, one of which projects on its right side and the other on the left. The right and left lobes are equal in *Proteus*; both lobes are large and sacculated in *Siren*; in *Menobranchus*, the left lobe seems to be large, in *Epicrion*, the right; but many of these differences are probably accidental. In the Bullfrog (*Rana pipiens*) the two lobes of the atrial segment of the heart completely envelop the *truncus arteriosus*, and become united together by fibrous tissue, which connects their walls on the ventral side of the *truncus*. The atrium is usually divided into two cavities, of which the left is smaller than the right, by a septum, which extends from the left wall of the atrium towards the auriculo-ventricular aperture.

The cavity of the auricular segment thus becomes divided into a smaller, left, auricle, which lies behind and to the left of the septum, and a larger, right, auricle, to the right and in front of the

septum. In the Frogs, the *septum auricularum* is a complete partition, containing muscular fibres, and the septal branches, with their ganglia, of the cardiac nerves of the pneumogastric. It divides the auriculo-ventricular aperture, passing from one auriculo-ventricular valve to the other, and ending between them by a free edge, which might almost be said to lie in the cavity of the ventricle (Fig. 23).

In *Lissotriton punctatus*, and in *Siredon*, the septum, still complete, ends in the cavity of the auricular segment by a free edge, which

Fig. 22.—The left auricle of the bullfrog (*Rana pipiens*) laid open in such a manner as to show the septum with its nerves (n) and ganglia (g), and the manner in which it descends upon the free surfaces of the auriculo-ventricular valves, V<sub>1</sub>, V<sub>2</sub>. P.v. opening of the pulmonary vein; L.s.v.c. left superior vena cava; V. ventricular cavity.

arches over the auriculo-ventricular aperture. In *Menobranchus*, the septum is reduced to little more than a wide-meshed network of branched muscular bands, and, in *Proteus*, the existence of a septum is doubtful.

The auriculo-ventricular aperture is always situated at the left side of the posterior end of the auricular segment, where the latter joins the ventricle. In *Rana esculenta* and *pipiens* it possesses distinct, though short, membranous valves, the free edges of which, directed towards the ventricular cavity, are kept down by fine tendinous filaments.

The common trunk, formed by the union of the two pulmonary veins, runs over the dorsal wall of the *sinus venosus*, passes between the two superior cavæ, and, usually dilating, opens into the cavity of the left auricle, close to the sinu-auricular aperture; and, in fact, separated from it only by the septum, which continues the direction of the right wall of the pulmonary vein.

The ventricular segment always has thick walls and a comparatively small cavity, which lies in the anterior half or base of the ventricle, and takes a direction from left to right, or from the auriculo-ventricular aperture to that of the *truncus arteriosus*. In consequence of the loose and spongy texture of the greater part of the thickness of the ventricular wall, it must be recollected that its apparent cavity by no means represents its capacity.

The *truncus arteriosus* of *Menobranchus* is subcylindrical, in that half which is nearest the ventricle, but, in the other half, has a dilated and ovoid form. The latter, in reality, consists of the origins of the aortic arches, closely united together (*synangium*), while the former subdivision is the gateway between the ventricle and the great vessels, or the *pylangium*. It presents two transverse rows of semilunar valves, three in each row; the lower or posterior row being close to the opening of communication between the pylangium and the ventricle, while the other row is near the anterior end of the pylangium.

In *Siredon* (Figs. 15 and 16) there is the same division into a pylangium proper and a large oval bulb-like *synangium*, formed by the united aortic arches. Three valves in a transverse row are situated at each end of the pylangium. An oblique ridge projects from the dorsal wall of the pylangium, beginning low on the left side, and gradually increasing in size, until it passes into the dorsal valve of the anterior row. There is a small space in front of the anterior row of valves, into which projects the posterior

free end of an oblique, but nearly horizontal septum, which divides the cavity of the synangium. From this thick partition thinner septa radiate to the walls of the synangium, which they thus divide into five longitudinal canals, of which that which lies to the right is twice as large as any of the others. In fact, it also becomes subdivided, further forwards, by a longitudinal septum, and then there are six canals answering to the six aortic arches which spring from the synangium, where it reaches the anterior end of the pericardium. According to Hyrtl's account, the pylangium of *Cryptobranchus* has a very similar structure; but the synangium is completely split into two trunks, each of which contains three canals.

This leads to the structure of the *truncus arteriosus* observed in the Frogs, which consists almost wholly of the pylangium. Three thick semilunar valves are placed at the ventricular

FIG. 23.—The heart of *Rana pipiens*. The ventricle (V), the truncus arteriosus, and the aortic trunks (Ao) are laid open from the ventral side. Spl. free edge of the septum auricularum; v.1, semilunar valves at the ventricular end of the pylangium; v.2, valves at its synangial end; s, the septum of the pylangium; p, the aperture of the pulmonary trunks; Ca, the apertures of the carotid trunks.

end of this region, and three others, also of unequal dimensions, at its synangial end. A longitudinal ridge, with a rounded, free, ventral edge, projects from the dorsal wall of the pylangium. It is thicker anteriorly than posteriorly, and is directed obliquely, so that its anterior end passes into the right anterior valve, while its posterior extremity is close to the left posterior valve. The anterior valves of the pylangium (v<sup>2</sup>) are much larger than the posterior valves; and, of the three anterior valves, that which lies on the dorsal side is the smallest. Immediately beyond it is situated the aperture (p), which leads into the pulmonary trunks. In front of the pulmonary aperture is a wide cavity, whence the two great aortic trunks (Ao, Ao<sup>1</sup>) spring. A tongue-like projection springs from the dorsal wall, and divides the cavity imperfectly. On the ventral side of the base of this tongue are the two openings (Ca) which lead into the carotid trunks. The three trunks—carotid, aortic, and pulmonary—pass out of the pericardium together, so closely united that they appear one. It is only at some distance beyond the pericardium that they separate,—the anterior ending in the *rete mirabile*, which has received the name of the “carotid gland;” the middle becoming the arch of the aorta; the posterior, the pulmo-cutaneous artery.<sup>1</sup>

In the *Peromela* (e.g. *Epicrionum*), the heart presents many singular peculiarities (Fig. 24). In the first place, it is moved back to a distance which is relatively far greater than in any other *Amphibia* and in most lizards. Next, it is extremely elongated, and the *truncus arteriosus* is relatively more prolonged than any other part of the heart. But

the relative proportions of the pylangium and synangium are the reverse of those which obtain in the *Anura*. The two transverse rows of valves which mark the boundaries of the pylangium are situated close to one another, near the origin of the *truncus*, all the rest of which is made up of the synangium. A longitudinal partition, at first, divides the cavity of the synangium into two unequal passages; but, towards its anterior end, it contains four equal canals. Having reached the anterior extremity of the pericardium, the synangium divides, and the two pairs of canals become independent, but closely united, trunks, which run, on each side of the trachea, to about the level of the glottis. Here the two trunks join, and pass into the single arch of the aorta, which turns sharply back beneath the vertebral column. The carotid artery is given off from the junction of the two trunks with the single dorsal aortic arch. Shortly before the two trunks join, that upon the dorsal side gives off the pulmonary artery. A single pulmonary vein opens into the left auricle; and it is worthy of notice, that the auricles and sinus are situated as far forwards on the dorsal aspect of the heart as in the Frogs.

FIG. 24.—Ventral view of the head and trunk of *Epicrionum glutinosum*. Mn, mandible; Hy, hyoid; Br<sup>1</sup>, Br<sup>2</sup>, Br<sup>3</sup>, branchial arches; Gl, glottis; Tr, trachea; L.s.v.c., inferior vena cava; V, ventricle; Au, auricles; R.s.v.c., right and left superior cavæ; T.a., truncus arteriosus; Ao, left aortic arch; P.A., right pulmonary artery. The pericardium (lightly shaded) extends as far as the bifurcation of the synangium.

As regards the number and destination of the great vessels which arise from the synangium, great differences obtain in the different groups of the *Amphibia*.

In the perennibranchiate *Urodela*, each of the three, or four, branchial arches has its appropriate aortic trunk, which springs medially, or immediately, from the synangium. The three anterior aortic trunks supply the gills, but are not wholly distributed to them; so that the trunks which unite to form the dorsal aorta are derived partly from the gills and partly come directly from the ventral aorta. The anterior aortic arch gives off, on its ventral side, a hyomandibular artery to the walls of the oral cavity, which appears to represent the remains of the hyoidean and mandibular aortic arches, while, dorsally, it supplies the internal carotid. The pulmonary artery is given off from the fourth aortic arch, or from the common trunk, which is formed by the union of this with those which precede it.

In *Cryptobranchus*, according to Hyrtl, three trunks are given off on each side from the synangium. The most anterior corresponds with the hyomandibular artery of the perennibranchiate forms. The second belongs to the first branchial arch. It gives off no branch, but unites with the third and largest vessel to form a common trunk, which unites with its fellow beneath the vertebral column, and gives rise to the dorsal aorta. The posterior aortic arch gives off the pulmonary artery (which supplies a branch to the alimentary canal). From the common trunk a maxillary and an internal carotid artery are supplied; while a third branch passes to the ventral side of the atlas, and, turning backwards, passes between the transverse process of the second and succeeding vertebræ as a collateral vertebral artery.

In *Salamandra*, there are four aortic arches. The most anterior of these belongs to the first branchial arch. It gives off a hyomandibular branch, then breaks up into a *rete mirabile*, whence the internal carotid artery is continued, and is connected by a mere *ductus Botalli* with the second arch. The second and third arches give off no branches; but, along with the slender *ductus Botalli* of the fourth arch, coalesce into the trunk which unites with its fellow to form the dorsal aorta. The fourth arch gives off the

<sup>1</sup> The structure of the heart in the *Amphibia* has been recently discussed with great ability, by M. Armand Sabatier in his *Etudes sur le cœur* Montpellier, 1873.

pulmonary artery, and a smaller dorsal cutaneous branch (Hyrtl). The pulmonary artery gives twigs to the stomach.

It is clear that the posterior trunk of *Cryptobranchus* represents the second, third, and fourth aortic arches of *Salamandra*; and that the first aortic arch of *Salamandra* answers to the first and second trunks which spring from the syngangium of *Cryptobranchus*.

In the *Anura* there are apparently only two aortic arches; but, as has already been observed, each of them is divided into three canals. The anterior canal ends in a *rete mirabile*, whence the internal carotid artery proceeds, and it gives off the hyomandibular or lingual artery. It therefore answers to the first arch of the Salamanders. The second or middle canal is the largest, and passes into a trunk which runs along the sides of the gullet; and curving backwards, unites with that of the opposite side in the dorsal aorta. The third canal ends in a trunk which divides into the pulmonary and the great cutaneous arteries, which latter is distributed to the dorsal integument. It answers to the third and fourth arches in the Salamanders.

FIG. 25.—The heart, great arterial trunks, and the adjacent principal nerves of *Rana esculenta*, drawn to scale. The positions of the auditory capsule (*Au.*), Eustachian tube (*Eu.*), and hyoidian cornu (*Hy.*), are indicated diagrammatically. *L.*, root of the left lung; *S.V.*, sinus venosus; *vt.*, ventricle; *Au.*, auricle; *Tr. A.*, truncus arteriosus; *C.G.*, carotid gland; *lg.*, lingual artery; *Cr.*, carotid artery; *Oph.*, ophthalmic artery. 2. Left arch of the aorta, passing through the muscular diaphragm to the aorta (*Ao.*) beneath; *tr. iii.*, the transverse process of the third vertebra; *br.*, the brachial artery. 3. Pulmonary artery; *ct.*, its cutaneous, *p.*, its pulmonary division. Nerves:—*V1*, *V2*, *V3*, first, second, and third divisions of the trigeminal; *VIIa*, *VIIp*, anterior and posterior divisions of the portio dura; *IX.*, the glossopharyngeal; *X1*, the cutaneous branch of the vagus; *X2*, the visceral trunk, giving off *X3*, the cardiac, *X4*, the pulmonary, and *X5*, the gastric branches; *X4*, the laryngeal branch. *Sp.I.*, the first spinal (hypoglossal) nerve; *Sp.II.*, the cut trunk of the second spinal nerve.

In the *Peromela* (*Epicrion*) the two aortic trunks which spring from the *truncus arteriosus* would seem to correspond with the second and third of the frog, the first having become absorbed into the second. This is a point which can be cleared up satisfactorily only by the study of development; but it is obvious that the heart and its arches have undergone greater changes in this group than in any of the others.

With respect to the venous system, it is worthy of notice that the blood returning from the hinder part of the body and the posterior extremities is, in part, carried to the kidneys, and in part poured into a vein which runs in the anterior wall of the abdominal cavity,—the *anterior abdominal vein*. Of the branches in which this vein terminates anteriorly, one communicates with the portal vein, and one is distributed to the liver directly. In the *Anura*, venous radicles in the integument covering the back of the head and shoulders, unite to form a great cutaneous vein, which passes backwards, perforates the external oblique muscle, and then turning abruptly forwards, ends in the subclavian vein. This vein carries away a large part of the blood of the cutaneous artery, which accompanies it in a great part of its course.

The *lymphatic system* has been most carefully studied in the frog, where it consists of (1.) widely-distributed lymphatic capillaries, and sinuses which ensheath the blood-vessels; (2.) subcutaneous lymph sacs; (3.) a large subvertebral *cisterna*, enclosed between the diverging lamellæ of the mesentery, and placed in communication with the peritoneal cavity by minute openings or stomata; (4.) four lymph hearts, two situated close to the transverse process of the third vertebra and two at the sides of the coccygeal style. These

hearts pump the lymph into the adjacent veins. As the two pairs of lymph hearts have been discovered in *Triton* and *Salamandra* as well as in *Rana*, it is probable that they are present in the *Urodela* generally. No *Amphibia* possess lymphatic glands.

The *Thymus gland* in the *Urodela* lies behind the angle of the mandible (*Triton*, *Salamandra*), or close to the dorsal ends of the branchial arches (*Proteus*, *Menobranchus*, *Siredon*, *Amphiuma*, *Menopoma*). In the *Peromela* it has the same position as in the abbranchiate *Urodela*. In the tadpole the thymus occupies a place similar to that which it possesses in the branchiate *Urodela*. In the adult frog it is to be found just behind the suspensorium. The *Thyroid gland*, usually double, but single (according to Leydig) in *Proteus*, always lies in the immediate vicinity of the lingual vessels.<sup>1</sup>

*The Respiratory Organs.*—The glottis in the *Amphibia* is situated in the middle line of the floor of the pharynx. In the perennibranchiate *Urodela*, it is a very small longitudinal slit leading into a narrow passage, which widens into a chamber into which the elongated pulmonary sacs open. The *Urodela* and the *Peromela* present mere cartilaginous rudiments of a larynx; but, in the *Anura*, this structure attains a great development, and becomes the instrument of the powerful voice with which many of these animals are provided. The larynx is lodged in the angle between the two thyro-hyals, with which it is closely connected. The chief part of the larynx is an annular cricoid cartilage, with which two arytaenoid cartilages are articulated. Membranous folds, or freely projecting cartilaginous processes of the arytaenoid cartilages (*Pipa*), play the part of vocal ligaments. In *Pipa* the larynx is extensively ossified. In *Proteus*, the lungs are long tubes, dilated at their posterior blind ends, and fixed to the dorsal walls of the abdominal cavity by folds of the peritoneum. In *Triton* they are somewhat wider sacs, but, in both, the inner surfaces of the pulmonary sacs are smooth. In *Siren* and *Salamandra*, the walls of the sacs become cellular, and in *Amphiuma*, *Menopoma*, *Cryptobranchus*, and the *Anura*, the cellulation acquires a considerable development.

In *Amphiuma*, *Menopoma*, *Cryptobranchus*, and in the *Peromela*, there is a distinct trachea, which is of great length in the *Peromela*. In *Pipa* and *Dactylethra* there is no trachea, but each lung is connected with the laryngeal cavity by a bronchus.

*The Renal Organs.*—The kidney is a more or less elongated organ—longer in the *Urodela* and *Peromela*, shorter in the *Anura*—which lies on each side of the vertebral column, its posterior end being close to, or even extending back on the dorsal side of, the cloaca.

In the female the efferent ducts of each kidney unite into a longer or shorter common trunk, which appears always to open into the cloaca by an aperture distinct from that of the oviduct, though the contrary statement is very generally received.<sup>2</sup> In *Rana esculenta*, there can be no doubt as to the distinctness of the minute urinary apertures from the large and conspicuous oviducal openings, close to which they are situated. Hyrtl says of *Cryptobranchus*—"Ureter . . . super latera cloacæ descendens in collum allantoidis exoneratur" (*op. cit.*, p. 84).

In the male *Amphibia*, on the other hand, there is a longer or shorter duct common to both the renal and the genital products, which opens into the cloaca. In the *Urodela*, the duct is continued forwards along the outer side of the kidney to the anterior end of the ab-

<sup>1</sup> See Leydig, *Anatomisch-histologische Untersuchungen über Fische und Reptilien*, 1853.

<sup>2</sup> See, for example, Stannius, *Handbuch der Amphibien*, pp. 250, 251. On the other side, comp. Milne-Edwards, *Leçons*, t. vii. p. 336

dominal cavity, and clearly represents the Wolffian duct of the embryo. Both the urinary tubuli and the *vasa efferentia* of the testis open into this duct. In *Cryptobranchus* the kidney is divided by a constriction into two portions—a slender, anterior, and a much thicker and longer, posterior, division. From the latter the efferent urinary canals proceed, and, curving outwards and backwards, join the posterior part of the Wolffian duct. The former is traversed by the *vasa efferentia* of the testes, which pass from its outer edge to the anterior portion of the Wolffian duct, so that it resembles an epididymis.<sup>1</sup>

In *Proteus*, according to Leydig, the anterior end of the Wolffian duct is infundibuliform and open; the *vasa efferentia* of the testes open into the anterior moiety of the duct, the renal ducts, into its posterior moiety. The numerous arcuated renal ducts of the Salamanders and Tritons unite together, and open into the Wolffian duct near its cloacal end. The Wolffian duct persists in *Bombinator igneus* and *Discoglossus pictus*<sup>2</sup>; but, in most *Anura*, it becomes obliterated for the greater part of its extent, and the same canals serve to convey both the urinary and the spermatic fluids to the persistent cloacal end of the Wolffian duct, which ordinarily receives the name of ureter. The urinary bladder is always large, and is often bifurcated anteriorly.

*The Nervous System.*—The amphibian brain is remarkable for the rudimentary condition of the cerebellum, which has the form of a mere band arching over the anterior part of the fourth ventricle. The mesencephalon is divided above, more or less distinctly, into two optic lobes. The cerebral hemispheres are always relatively large, subcylindrical in the *Urodela*, but wider behind than in front in the *Anura*, and they are generally closely united together by their inner faces.

FIG. 26.—Diagram of the chief cranial nerves of *Rana esculenta*. II, optic; IV, pathetic; V<sup>1</sup>, orbito-nasal; V<sup>2</sup>, superior maxillary; V<sup>3</sup>, inferior maxillary; VIIa, VIIb, anterior and posterior divisions of the portio dura; IX, the glossopharyngeal; X, the pneumogastric; X<sup>1</sup>, its dorsal branch. Sp. I, The first spinal nerve (hypoglossal). Ol, olfactory nerve; Tg, tongue; Hy, cornu of the hyoid; Hd, Hædlerian gland.

Ten pairs of cranial nerves are always found—viz., 1, The olfactory; 2, optic; 3, oculomotor; 4, pathetic; 5, trigeminal; 6, abducens; 7, portio dura; 8, auditory; 9, glossopharyngeal; 10, pneumogastric. The hypoglossal is always an extra-cranial nerve.

1. The *olfactory* is usually a rounded cord, not dilated at its anterior end. Fischer has observed it to arise by two roots in *Pipa*.

2. The *optic* nerves are attached, as usual, to the floor of the thalamencephalon. Fischer<sup>3</sup> found no chiasma in *Siredon* or *Menobranchus*. Dr Humphrey found none in

*Cryptobranchus*; but sections of the brain are needful before the actual absence of the chiasma can be considered to be satisfactorily proved.

3. The *oculomotor* nerve remains distinct from the trigeminal in most *Amphibia*, but its branch to the superior *rectus* muscle appears to coalesce with the orbito-nasal division of the fifth in *Salamandra terrestris* (Fischer).

4. The *pathetic* nerve remains distinct in *Siredon* and *Cryptobranchus*, and in the *Anura*; but in *Salamandra terrestris*, Fischer found that the superior oblique muscle was supplied by a branch from the orbito-nasal, with which, therefore, the pathetic had probably coalesced.

5. The *trigeminal* gives rise, as usual, to a Gasserian ganglion; and this ganglion remains distinct from that of the seventh nerve in all the *Urodela*, though united with it by a commissural band, which appears to answer to the *nervus petrosus superficialis minor* of the higher *Vertebrata*. In the *Anura*, on the contrary, the two ganglia are closely approximated (*Pelobates*, *Bombinator*)<sup>4</sup>, or confounded together (*Rana*, *Hyla*, *Bufo*) in the adult, though they are distinct in the tadpole. The orbito-nasal, or first division of the trigeminal, is always separated from the second and third divisions by the ascending process of the suspensorium, when this structure is present. It supplies the tentacles of the *Peromela*. In the tadpole, and in some *Urodela*, a cutaneous branch to the dorsum of the head is given off from the fifth.

6. The *abducens* is distinct from the trigeminal in *Salamandra* and *Bufo*, but coalesces with the Gasserian ganglion in *Rana*, *Pipa*, and most *Anura*.

7 and 8. The *portio dura* and *portio mollis* arise by a common trunk, from which the *portio dura* soon separates, and either forms a distinct ganglion, as in the *Urodela* and *Peromela*, or fuses with the trigeminal.

9. The ganglion of the *glossopharyngeal* nerve appears to coalesce with that of the vagus, and the roots of the two nerves pass out of the same foramen in all the *Amphibia* except *Siren*, where, according to Fischer (*op. cit.*, p. 147), the nerve leaves the skull by a distinct aperture, close in front of that for the pneumogastric, and forms a ganglion of its own.

10. The *vagus* or *pneumogastric*, in the perennibranchiate *Amphibia*, supplies the second and third branchia, and the *cucullaris* muscle; gives off cutaneous, laryngeal, cardiac, pulmonic, and gastric branches, and sometimes as many as three cutaneous branches, one of which runs along the junction of the dorsal and ventral muscles to the hinder part of the body. These lateral nerves of the pneumogastric exist also in *Menopoma*, *Amphiuma*, and *Triton*, and in tadpoles; but appear to be absent in *Salamandra terrestris* and in the adult *Anura* (Fischer, *l.c.*) These, however, possess a cutaneous branch of the vagus, which accompanies the cutaneous branch of the pulmo-cutaneous artery, and is distributed more or less widely to the dorsal integument of the head and trunk.

Fischer considers that a fine nerve, arising lower down than the vagus, and distributed to the abductors of the head in *Pipa*, is to be regarded as an *accessorius*. But, seeing that, in the *Amphibia* generally, the motor nerves of the larynx, and, where a *cucullaris* exists, the nerves of that muscle also, are supplied from the pneumogastric, the question of the presence or absence of an *accessorius* seems to reduce itself to this: Does the pneumogastric receive nerve fibres arising from the sides of the *medulla oblongata* and spinal cord between the roots of the spinal nerves? And, as it certainly does not, the *accessorius*, as it exists in the higher *Vertebrata*, must be admitted to be absent in *Amphibia*.

In most *Amphibia*, the first cervical nerve has the dis-

<sup>1</sup> Schmidt, Goddard, and Van der Hoeven, *Aanteekningen over de Anatomie van den Cryptobranchus japonicus*.

<sup>2</sup> According to Von Wittich. "Beiträge zur morphologischen und histologischen Entwicklung der Harn und Geschlechtswerkzeuge der nächsten Amphibien," *Zeitschrift für Wissenschaftliche Zoologie*, bd. iv.

<sup>3</sup> *Anatomische Abhandlungen*, p. 123, *et seq.*

<sup>4</sup> According to Stannius, *Handbuch*, p. 150.

tribution of the hypoglossal; in *Menobranchus*, however, the corresponding nervous supply is furnished by the second and third cervical nerves,—the first spinal nerve, in this genus, perforating the sides of the body of the atlas, and being distributed to a muscle which passes from this vertebra to the occiput (Fischer, *l.c.*, p. 158). In *Pipa* the hypoglossal is furnished by the second cervical nerve; in *Salamandra*, by the first and second. There is no trace of any suboccipital nerve in the *Amphibia*; and as, in the absence of this nerve, the first spinal would appear to answer to the second cervical of the higher *Vertebrata*, the fact that it takes the place of the hypoglossal becomes very perplexing.

In the *Anura* (*Rana*) the sympathetic is represented by a double chain of ganglia, situated at the sides of the aorta, and receiving branches from the anterior divisions of the spinal nerves. It appears to be continued in the skull by commissural cords which pass forwards on the inner side of the auditory capsule, and connect the ganglion of the vagus with that of the trigeminal.

*The Organs of the Higher Senses.*—The nasal sacs are elongated in *Proteus*, *Menobranchus*, and *Siren*, and not covered by nasal bones or alinasal cartilages. In the other *Amphibia* they are broader, and enclosed by cranial cartilages and ossifications. The olfactory mucous membrane is variously folded; and, in *Rana*, some of these folds are supported by ingrowths of the anterior cartilaginous wall of the nasal chamber.

In *Proteus* the eye is completely hidden by the continuation of the unaltered integument over it, and the organ of vision is almost as much obscured in the *Peromela*. In the other pennibranchiate *Urodela*, and in *Pipa*, the integument covering the eye forms a transparent cornea, but there are no eyelids. The abranchiate *Urodela* have an upper and a lower lid; and, in the higher *Anura*, the lower lid becomes transparent, and is usually regarded as a *membrana nictitans*, as it is provided with a peculiar motor apparatus. In the *Anura*, the eye possesses not only the ordinary four *recti* muscles and the two *obliqui*, but there is a *retractor bulbi*. The Frogs and probably other *Anura*, possess a Harderian gland; but no lachrymal gland has been observed. The sclerotic may be chondrified, but it is not ossified. There is no pecten.

With regard to the organ of hearing, the membranous labyrinth is enclosed between the pro-otic bone, in front, and the representatives of the opisthotic and epiotic (usually confounded with the exoccipital), behind. The *fenestra ovalis* always occupies a space in the line of junction of the pro-otic with the posterior ossification, whether it be occupied by a broad unossified space, as in *Menopoma*, or the two bones be ankylosed together, as in *Siren*, *Triton*, and old Frogs. The stapes is more or less ossified, and its outer face is frequently provided with a styliform appendage, in the *Urodela*. In the *Urodela* (which have no tympanic cavity), a ligament passes from the stapes to the suspensorium, and there is no *columella auris*. The like absence of *columella auris* and of a tympanum obtains in several *Anura*. Dugès states that the *columella* is wanting in *Bombinator* and *Pelobates*<sup>1</sup> (*Recherches*, p. 41), and the absence of the *columella auris*, as of the tympanum and Eustachian tubes, has since been noticed in *Telmatobius*, *Phrynisus*, *Atelopis varius*, and *Brachycephalus ephippium* (Stannius, *op. cit.*, p. 61). In the higher *Anura*, there is a complete tympanum, with Eustachian tubes, and a *columella auris*, which extends from the stapes to the *membrana tympani*. The tympanic membrane is either quite similar to the rest

of the integument or markedly different from it. In some genera (*e.g.* *Rana*), the tympanic membrane is set in a frame of cartilage. In *Pipa* and *Dactylethra*, the Eustachian tubes, as already remarked, have a common opening, and the *columella* is very peculiar. Recent investigations make it probable that the *Amphibia* possess a rudimentary cochlea.<sup>2</sup> Whether the opening, which in the Frogs has been described as a *fenestra rotunda*, is really of that nature, is doubtful.

*The Reproductive Organs.*—The ovaria and testes are attached to the dorsal wall of the abdominal cavity, in the immediate vicinity of the kidneys, by the mesoarial and mesorchial folds of the peritoneum, which invest them.

The ovaria, when fully developed, become hollow, and in the *Anura* their internal cavities may be divided by septa.

The oviducts are long, usually more or less convoluted, tubes, which open posteriorly into the cloaca; while, anteriorly, their funnel-shaped apertures lie in the anterior part of the abdomen, sometimes, as in the Frogs, as far forward as the root of the lung. Their walls are glandular, and secrete a viscid substance which invests the ova in their passage down the oviduct.

In the male *Urodela*, the persistent Wolffian duct, already mentioned, occupies the position of the oviduct in the female, and the *vasa efferentia*, after traversing the kidney, open into it. This duct persists in *Bombinator igneus* and *Discoglossus pictus*; but in the male *Anura*, in general, the greater part of it is obliterated, only so much remaining as plays the part of ureter and *vas deferens*. In the *Urodela* accessory glands open into the cloaca, and in *Triton* there is a rudimentary copulatory papilla. Some female *Urodela* are provided with *receptacula seminis*. In the terrestrial Salamanders and in the anurous *Rhinoderma Gayi* the young are developed within the dilated uterine terminations of the oviducts. In *Pipa* the eggs are deposited on the back of the female, and the integument grows up round each, and encloses it in a cell, in which it undergoes its development. In some tree-frogs (*Nototrema* and *Opisthodelphys*) the eggs are received into a sort of marsupial pouch formed by an up-growth of the margins of the dorsal integument, which, when complete, has a small posterior aperture. On the other hand, it is the male *Alytes obstetricans* which twists the strings of eggs laid by the female round his hind-legs, and, thus cross-gartered, retires into seclusion until the young are ready to be hatched, when he resorts to the water in which the tadpoles are to perform their further metamorphoses.

*Development of the Amphibia.*—The yolk of the ovum undergoes complete division, in which respect the *Amphibia* agree with the *Pharyngobranchii*, *Marsipobranchii*, and *Mammalia*, and differ from other *Vertebrata*; though it must be remembered that the process of yolk division in the *Ganoidei* and *Dipnoi* is not yet known.

Except in some viviparous species, the embryo, when hatched, is pisciform and apodal; and three pairs of external gills, which become more or less branched, are developed from the first, second, and third branchial arches. In the larval *Triton* a very singular elongated appendage makes its appearance on each side of the head, in front of the branchiæ;<sup>3</sup> and in the tadpole two eminences of the ventral integument, with glandular terminal faces, are developed—one on each side of the middle line, behind the mouth. The larvæ of *Dactylethra* have two long tentacles attached near the angle of the mouth. An opercular fold of the integument grows back from each hyoidean arch, and the two are connected by a free fold of the subgular integument. The limbs make their appearance as buds from the sides of the body, the anterior pair appearing first. The anterior limbs attain a considerable size before the posterior pair are developed in *Triton*; but, in the Frogs, the posterior limbs grow much faster than the anterior, which long remain inconspicuous and hidden.

In the *Urodela* larvæ, teeth are very early developed in the pre-maxillary, maxillary, vomerine, palatine, splenial, and dentary

<sup>1</sup> *Pelobates*, however, has an extremely minute, ossified, *columella auris*.

<sup>2</sup> See Hasse, *Die vergleichende Anatomie des hautigen Gehörorgans*, Leipzig, 1873.

<sup>3</sup> The larval *Siredon* has no such hyoidean (?) appendage.

regions; and, indeed, in *Triton* and *Siredon*, the teeth precede the corresponding bones, which arise by the ossification of the mucous membrane about the bases of the teeth; and there are no labial cartilages, and no horny labial papillæ, or beak-like armature of the jaw. The abdomen is slender, in accordance with the brevity of the intestine, and the little animal is altogether carnivorous.

In the *Anura*, on the other hand, teeth are not developed until a later stage. A pair of cartilages appear in the roof of the mouth in front of the ends of the trabeculæ ("rostraux supérieurs," Dugès; "upper labials," Parker), and another pair opposite them ("rostraux inférieurs," Dugès; "lower labials," Parker); and the epithelium of the mucous membrane covering them becomes converted into an upper and a lower brown horny toothed plate, having some resemblance to the beaks of a Chelonian. The curtain-like lips, which surround the oral aperture, are also beset with horny papillæ, which call to mind the corneous teeth of the Marsipobranchii. The abdomen is swollen and almost globular, and lodges a long and spirally-coiled intestine. The animal is herbivorous, though it does not despise animal food, even in the shape of the weaker members of its own family.

The space allotted to this article does not allow the details of the development of the *Amphibia* to be even sketched; but attention may be directed to one or two of the more important points.

The skull presents some singular differences in the course of its development in the *Urodela* (*Triton*, *Siredon*) and the *Anura* (*Rana*, *Alytes*) respectively. In the former, the mandibular and trabecular arches become connected only at their dorsal ends, by the pedicle of the mandibular arch; the pterygoid arch is developed late; and the mandibular arch appears to give rise to no orbital process. In the latter, the mandibular and trabecular arches not only unite at their dorsal ends by the pedicle, but, at a very early period, the mandibular arch is united with the antorbital process of the trabecula; and the pterygoid grows *pari passu* with the subsequent divergence of the mandibular and the trabecular arches. A large orbital process is developed from the mandibular arch.

In the *Urodela*, the hyoidean and branchial apparatus consists, at first, of elongated cartilaginous hyoidean cornua, united with a median chondrification, which represents the basi-hyal and basi-branchial pieces, to which last two cerato-branchials are attached. The first cerato-branchial is continued dorsally into the first epibranchial, while the second cerato-branchial supports the other three epibranchials. As the development of the *Triton* proceeds, the hyoidean arch becomes connected with the suspensorium, and with the stapes, by ligament. The second basi-branchial ossifies, detaches itself from the first, and lies as a forked bone in front of the larynx; and only the two cerato-branchials, with the first epibranchial, remain—the rest of the branchial apparatus disappearing.

In the *Anura*, the hyoidean arches are, at an early period, very thick, and relatively short, and are articulated with the suspensoria. A relatively broad and short cartilage represents the basi-hyal and basi-branchial, and at the sides of this are two very broad cartilages, which correspond with the two cerato-branchials, inasmuch as their dorsal edges bear the four epibranchial cartilages. As the tadpole grows older, the hyo-branchial apparatus becomes more like that of the Urodele larva, the hyoid arch elongating into a slender rod, and the two cerato-branchials becoming distinct. The basi-branchial region of the median cartilage, which unites the cerato-branchials ventrally, becomes forked, and the processes which form the fork ossify and become the thyro-hyals, which therefore would seem to correspond with the *os ypsilonoides* of the *Urodela*. Finally, the extreme dorsal end of the hyoidean arch detaches itself from the suspensorium, and enters into close union with the periotic capsule, from the outer wall of which the *columella auris* is developed.<sup>1</sup>

*The Distribution of the Amphibia.*—Darwin has pointed out (*Origin of Species*, p. 350) that *Amphibia* are met with on no islands but New Zealand, New Caledonia, the Andaman Islands, and perhaps the Solomon Islands and the Seychelles. "This general absence of frogs, toads, and newts in so many true oceanic islands cannot be accounted for by their physical conditions; indeed, it seems that these are peculiarly fitted for those animals, for frogs have been introduced into Madeira, the Azores, and Mauritius, and have multiplied so as to become a nuisance. But as these animals and their spawn are immediately killed (with the exception, so far as is known, of one Indian species) by sea-water, there would be great difficulty in their transportal across the sea, and therefore we can see why they do not exist in strictly oceanic islands."

Leaving the oceanic islands aside, the distribution of the *Am-*

*phibia* is world-wide, but the different groups are very remarkably localised.

The *Urodela*, for example, are limited not only to the arctogeal province, but to the temperate parts of that province; and, in curious correspondence with the Ganoid fishes, their headquarters are in North America. *Stiren*, *Menobranchus*, *Amphiuma*, *Menopoma*, *Dicamptodon*, *Heredia*, *Anaides*, *Desmognathus*, *Batrachoseps*, *Hemidactylus*, and *Plethodon* are exclusively North American; and the majority of species of *Amblystoma* and *Spelerpes* appertain to that region,—*Amblystoma* being represented in North Asia, and *Spelerpes* in the circum-Mediterranean area. *Triton* alone is spread over the whole temperate arctogeal area. *Salamandra*, *Pleurodeles*, *Bradybathe*, *Chioglossa*, and *Salamandrina* are confined to Europe and North Africa. The singular *Salamandra atra* is limited to the Swiss and Austrian Alps, *Proteus* to Carniola and Carinthia. Four genera—*Ellipsoglossa*, *Isodactylum*, *Omychodactylus*, and *Ramodon*—are confined to North Asia; and *Cryptobranchus*, if it be a distinct genus, is limited to Japan.

If the distribution of the *Urodela* calls to mind that of the Ganoid fishes, that of the *Peromela* is rather comparable to the distribution of the Tapirs. Of the four genera, *Siphonops* and *Rhinatrema* are exclusively inhabitants of the hotter part of the Austro-Columbian province—as are the great number of the species of *Cæcilia*; but the remaining species of that genus are East Indian, and *Epicrionum* is confined to Java and Ceylon.

In strong contrast with the foregoing, the *Anura*<sup>2</sup> are of world-wide distribution, being abundantly represented in all the great provinces. A great preponderance of the genera and species, however, are Austro-Columbian, the *Anura* having their headquarters in South America, as markedly as the *Urodela* have theirs in the northern division of that continent. North America, in fact, is poor in *Anura*, having only three peculiar genera, viz., *Saxiphopus*, *Acris*, and *Pseudacris*; while the rest of northern Arctogæa has five, viz., *Pelodytes*, *Discoglossus*, *Alytes*, *Pelobates*, and *Bombinator*.

The genus *Rana* itself, however, is characteristically arctogeal, having only a single species in the Mexican border-land of Austro-Columbia, and none in Australia. *Rana esculenta* extends from France to China and Japan, and from North Europe to Tunis. *Rana temporaria* covers even a larger area, as it occurs in the British Islands and in North America, as well as in North Asia and Japan.

The Austro-Columbian region not only presents the greatest number of species, but among them are some of the most singular forms, such as *Pseudis*, *Ceratophrys*, *Brachycephalus*, *Rhinoderma*, *Engystoma*, *Otilophus*, *Notolema*, *Opisthodelphys*, *Rhinophrymus*, and *Pipa*; in which respect the South American *Anura* run parallel with the birds of the same region. And, as is seen in other cases, the nearest allies of many of these singular forms are to be found in Ultra-Saharal (Æthiopic) Africa, e.g., *Hemisis* (*Brachycephalus*), *Breviceps* (*Engystoma*), *Dactylethra* (*Pipa*). It is remarkable that *Pseudophryne*, which is closely allied with the Æthiopic *Hemisis* and the Austro-Columbian *Brachycephalus*; and *Chelydobatrachus*, which is similarly related to the Æthiopic *Breviceps* and the Austro-Columbian *Engystoma*, are Australian.

The Australian region is remarkable for the absence of the genera *Rana* and *Bufo*, which occur everywhere else; and for the occurrence of *Cystignathus*, which is an Austro-Columbian, North American, and Æthiopic form, but does not occur in India. If it were not for its tree-frogs, Australia would be poorer in *Anura* than Europe is.

These *Anura*, modified for arboreal life, or "tree-frogs," are represented in all the distributional provinces—the genus *Hyla* having its chief seat in Austro-Columbia, and extending thence over North America, Europe, North Africa, Western and Eastern Asia, and Australia, but not into India or Ultra-Saharal Africa, in which other forms of the same group are met with.

The British Islands possess the following species of *Amphibia*:—*Rana temporaria*, *Bufo vulgaris*, *B. calamita*, *Triton cristatus*, *T. Bibronii*, *Lissotriton punctatus*, *L. palmipes*.

*Geological Distribution.*—No fossil *Peromela* are known. *Anura* occur in the Miocene deposits of France and Germany. The best preserved forms belong to the genera *Palæobatrachus* and *Latonia*, and occur in the schists of Oeningen along with their tadpoles. They possess maxillary teeth, and present no important differences from existing *Anura*, except that, in *Palæobatrachus*, the sacral vertebra has coalesced with the two preceding vertebræ, while, in existing forms, only one of the pre-sacral vertebræ is known to become confluent with the sacral. *Urodela* also occur in the same Miocene deposits. Of these the famous *Andrias Scheuchzeri* is very closely allied to *Menopoma* and *Cryptobranchus*, while other forms appear to be generically identical with *Triton* and *Salamandra*. The singular genus *Orthophysis* presents a good deal of resemblance to *Proteus*, but appears to have possessed no limbs.

The older Cainozoic and the upper and middle Mesozoic formations have yielded no *Amphibia*. A doubtful form, *Irhinosaurus*,

<sup>2</sup> See Dr Güntler's valuable *Catalogue of the Batrachia salientia*.

<sup>1</sup> See the Memoirs of Dugès and Parker, already cited, for the details of these metamorphoses. The account given by Mr Parker of the modifications of the dorsal extremity of the hyoidean arch, however, does not accord with the results of the present writer's later investigations. No coalescence of the hyoidean with the mandibular arch takes place; and the "supra-hyo-mandibular" has nothing to do with the *columella auris*.

occurs in the Lias of Simbirsk. In the earliest Mesozoic deposits—the Trias,—and in the later Palaeozoic—the Permian and the Carboniferous formations, *Amphibia* occur, sometimes in great abundance. In the Trias, they have been found in greatest numbers in Germany, while the Carboniferous formations have furnished the largest supply in the British Islands, Germany, and North America. It is interesting to observe that the last-named region has recently yielded elongated apodal forms, allied to the *Ophiderpeton* of the Kilkenny coal measures.

*Ætiology of the Amphibia.*—In taking a general survey of the relations of the different great divisions of the *Amphibia*, the most striking fact is their singular distinctness and isolation from one another. None of the *Peromela* present the slightest indication of an approximation towards the *Anura* or the *Urodela*.

It may be suggested that the incompleteness of the jugal arch in *Breviceps*, *Pipa*, and *Dactylethra*; the absence or rudimentary condition of the palatine bones in *Breviceps*, *Bombinator*, and *Alytes*; the rudimentary condition of the tympanum, and the absence, or reduction to a rudiment, of the *columella auris*, in so many forms; the presence of rudimentary ribs attached to some of the anterior vertebræ of *Bombinator* and *Alytes*; the presence of mandibular teeth in *Hemiphractus* and *Grypsiscus*; and the peculiar spermatozoa of *Bombinator*, are so many indications of an approach towards the type of structure observed in the higher *Urodela*.

But, without underestimating the force of these considerations, it must be admitted that they count for very little, when we take into consideration the fixity of the number of the vertebræ, and of the characters of the pelvis and of the limbs, in the *Anura*.

It is to be regretted that nothing is known of the development of any of the *Peromela*; of any of the *Urodela*, except *Salamandra*, *Triton*, and *Siredon* (*Amblystoma*); and of more than a few of the *Anura*. Among the lower forms of this division, the development of *Alytes* and *Pelobates* has been studied thoroughly by Vogt<sup>1</sup> and Van Bameke;<sup>2</sup> and the more advanced conditions of the tadpole of *Dactylethra* are known. So far as these observations go, however, they tend to show that the larvæ of all the *Anura* possess the horny beak, which distinguishes them from those of the *Urodela*.

If we assume, as the fundamental similarities between the different divisions of the *Amphibia* lead us to do, that they have resulted from the modification of some one primitive form, the problem, at present seemingly insoluble, presents itself, whether these differences in structure and habit of the larvæ of the *Urodela* and *Anura* indicate that the caudate ancestor of the *Anura* was already different from the ancestor of the *Urodela*, or whether they result from modifications which have taken place in the larvæ of the *Anura*, since that group came into existence.

In view of this problem, *Siren* possesses a particular interest. Its horny jaw-sheaths might be compared to those of the Anuran tadpole, and it might be regarded as showing the way by which the Anuran became differentiated from the caudate original stock. But the horny sheaths in *Siren* rest directly upon the premaxillæ and the dentaries, and not on labial cartilages; and as to its habits of life, *Siren* appears to be eminently carnivorous (Duméril et Bibron, *Erpétologie Générale*, i. 196). As has been already stated, no fossil remains of *Peromela* are known, but *Urodela* and *Anura* occur in some abundance, and, in certain cases, in an excellent state of preservation, as far back as the middle of the Tertiary epoch. Now, these fossils show that the Anurous and Urodelous types of organisation were, at that time, thoroughly differentiated from one another. *Puleobatrachus*, with its three vertebræ ankylosed into a sacrum, is, in fact, a singularly modified frog; while among the *Urodela*, the *Salamandridæ*, the *Menopomida*, and very possibly the *Proteida*, are severally represented. The young of the Miocene *Anura* were tadpoles so similar in form to those of the existing frogs and toads, that there is no reason to doubt their resembling them in other respects.

There can be little question, then, that the Anurous and the Urodelous types must have been represented before the Tertiary epoch; but here their history breaks off, no amphibian belonging to any living groups having been discovered in Mesozoic or older strata, as far as the Lias.

From the Trias to the Carboniferous formations, inclusively, the fresh-water deposits abound in *Amphibia*. But all these, so far as we have any positive knowledge, are referable to the Labyrinthodont type. No Labyrinthodont presents the slightest approximation towards the *Anura*; but elongated and apodal, as well as salamandroid forms occur; and in their cranial structure, no less than in the presence of scale-like dermal ossifications, they approach the *Peromela*. In regard to their possible relations with the *Urodela*, it is interesting to observe that in some Labyrinthodonts, at any

rate,<sup>3</sup> the manus has the five digits, one of which, at least, is lost in all the *Urodela*, and the pelvis appears to have had a distinct and completely ossified pubic element, which has also disappeared in all existing *Amphibia* (Miall, *Report*, l.c.)

The Labyrinthodonts present a few characters—such as the paired supra-occipital ossifications and the complications of the folds of their teeth—by which they approach the Ganoid fishes more than any other *Vertebrata*; and it is worthy of notice that the lowest Labyrinthodonts, such as *Archegosaurus*, present no approximation to the cranial characters of the lower *Urodela*, and show no evidence of the largely-developed branchial apparatus which is so characteristic of the latter.

Thus, if upon such slender evidence as exists, it is justifiable to speculate at all concerning the “phylogeny” of the *Amphibia*, the most probable conclusion appears to be that the *Labyrinthodonta*, the *Urodela*, and the *Anura* diverged from one another at a very early period of geological history; while, possibly, the *Peromela* are the last remnants of the peromelous modification of the Labyrinthodont type.

With respect to the origin of the amphibian stock itself, the following considerations appear to be of fundamental importance:—  
1. The early stages of development of the *Amphibia* do not resemble those of any known Ganoid, Telostean, or Elasmobranch fish, and are similar to the corresponding stages of the *Marsipobranchii*.  
2. The skull of the lowest *Urodela* has, in some respects, advanced but little beyond the Marsipobranch stage. In the higher *Urodela* there are numerous points of resemblance with the Ganoids. The skull of the tadpole, on the other hand, has much in common with that of *Chimæra* (as Müller has pointed out), and with that of the *Dipnoi*, while the chondrocranium of the adult frog has many singular affinities with that of the *Elasmobranchii*, and particularly of the Rays.  
3. The only *Vertebrata*, besides the *Amphibia*, which have transitory external gills are the *Elasmobranchii*, the *Dipnoi*, and perhaps some Ganoids.  
4. The only fishes in which the cerebellum is rudimentary are the *Marsipobranchii* and *Ganoidæ*.  
5. The only fishes in which the amphibian and embryonic connection between the male reproductive organs and the renal efferent ducts is observed are the Ganoids.  
6. The only fishes which have a “pylangium,” with valves disposed as in the *Amphibia*, are the Ganoids, Elasmobranchs, and *Dipnoi*.  
7. The only fishes which possess morphological (*Polypterus*) or functional (*Dipnoi*) lungs are the Ganoids and *Dipnoi*.  
The conclusions suggested by these facts appear to be that the *Amphibia* took their origin from some primordial form common to them, the *Elasmobranchii*, the *Ganoidæ*, and the *Dipnoi*; and that the main distinction by which their earliest forms were marked off from those of the other groups, was the development of that pentadactyle type of limb, which is common to all the higher *Vertebrata*. And seeing that the Elasmobranch, Ganoid, and Dipnous types were fully differentiated from one another in the Devonian epoch, it is reasonable to believe that the existence of the *Amphibia*, as a group, dates back at least as far as that remote period of the earth's history.

#### TAXONOMIC SYNOPSIS OF THE AMPHIBIA.

##### I. THE URODELA.

###### A. Branchiæ persistent throughout life. (*Perennibranchiata*.)

1. *Trachystomata*.—Skull elongated; premaxillæ and dentary piece of the mandible provided with horny plates; premaxillæ not ankylosed; no nasal bones, but ossifications between the ascending processes of the premaxillæ; maxillæ rudimentary or absent; palatines small, oval, and beset with “*dents en brosse*”; pterygoid absent; four persistent branchial arches; pelvic arch and limbs absent.

*Siren*.

2. *Proteida*.—Skull elongated; premaxillæ and dentaries dentigerous; maxillæ rudimentary or absent; premaxillæ not ankylosed; no nasal bones; palatines bearing a single row of teeth, and coalescent with the pterygoids; three persistent branchial arches; both the pectoral and the pelvic arches and limbs developed.

*Proteus, Menobranchius*.

###### B. Branchiæ caducous; gill-clefts persistent. (*Derotremata*.)

3. *Amphiumida*.—Skull elongated; premaxillæ and dentaries dentigerous; maxillæ large; premaxillæ ankylosed; large nasal bones; palatines absent; pterygoid present, elongated; a basihyal cartilage; four persistent branchial arches; both the pectoral and the pelvic limbs developed, though very small.

*Amphiuma*.

<sup>1</sup> Vogt, *Untersuchungen über die Entwicklungsgeschichte der Geburtshelferkörte* (*Alytes obstetricans*), 1842.

<sup>2</sup> Van Bameke, “Recherches sur le développement du Pelobate brun,” *Mém. de l'Acad. de Belgique*, 1863.

<sup>3</sup> “Description of the Vertebrate Remains from the Jarrow Colliery,” by Prof. Huxley, F.R.S., *Transactions of the Royal Irish Academy*, vol. xxiv. 1867, pl. xix. fig. 2.

4. *Menopomida*.—Skull broad; premaxillæ and dentaries dentigerous; maxillæ large; premaxillæ not ankylosed; large nasal bones; palatines absent; pterygoid present and very broad; a basihyal cartilage; persistent branchial arches may be reduced to the first and second; the cerato-hyal and epibranchial are confluent in the first, distinct in the second branchial arch; both pectoral and pelvic limbs well developed.

*Menopoma, Cryptobranchus.*

- C. Branchiæ caduuous, and gill-clefts closed in the adult condition. (*Myxodera*.)

5. *Salamandrida*.—Skull broad; premaxillæ and dentaries dentigerous; maxillæ large; premaxillæ separate or ankylosed; nasal bones present, and usually large; palatines present in the young state, and situated as in the *Trachystomata* and *Proteidea*, but changing their relations in the adult; pterygoids present; the first and second branchial arches persistent,—the first two-jointed, the second a single piece.

[The latest writer on the classification of the *Urodela*, Professor Strauch ("Revision der Salamandrinengattungen," *Mém. de l'Acad. Imp. des Sciences de St Petersburg*, se. vii. tome xvi.), divides the *Salamandrida* into two tribes,—*Mecodontia* and *Lechriodonta*; the first comprising all those species, the vomero-palatine teeth of which are disposed along the inner edges of two backwardly diverging processes of the bones, and therefore form two longitudinal series divergent posteriorly; and the second, those which have the teeth disposed along the posterior edges of the vomero-palatine bones, which are sometimes truncated posteriorly, sometimes produced into a longer or shorter median process, and on which, therefore, the teeth are either directed transversely, or form two oblique series, more or less rapidly converging backwards.]

a. *Mecodontia*—

*Salamandra, Pleurodeles, Bradybates, Triton, Chioglossa, Salamandrina.*

b. *Lechriodonta*—

*Ellipsoglossa, Isodactylum, Onychodactylus, Amblystoma, Ranodon, Dicamptodon, Plethodon, Desmognathus, Anaxides, Hemidactylum, Ileredia, Spelerpes, Batrachoseps.*

II. THE ANURA.

[For the classification of the *Anura*, consult Dr Günther's valuable *Catalogue of the Batrachia salientia*; Mr Cope's papers in the *Natural History Review*, 1865, and in the *Journal of the Academy of Natural Science of Philadelphia*, N.S., vol. vi.; and Mr Mivart's essay "On the Classification of the Anurous Batrachians," in the *Proceedings of the Zoological Society*, 1869. Far more minute investigation of the structure of the *Anura* than has yet been carried out seems to be requisite before their classification can be placed upon more than a provisional footing. The phases through which the Frog passes in the course of its development, show that those *Anura* which are devoid of a tympanic cavity are of a more embryonic character than those which possess one. The arboreal habit is so evidently adaptive, that it can hardly be regarded as a safe basis for classification. Even *Rana temporaria*, at a year old, will climb up the vertical side of a glass vessel, flattening out the ends of its toes, and applying its belly against the surface of the glass, like a Tree-frog.]

- A. The tympanic cavity, with its Eustachian passage of communication with the mouth, may be present or absent. When present, the oral apertures of the Eustachian tubes are separate, and the pterygoid bones do not furnish a floor to them.

- a. No teeth in the premaxillæ or maxillæ; tongue free, either in front or behind, but usually behind.

c. No tympanic cavity. Eustachian recesses sometimes present.

*Rhinophrynus* (1), *Phrymuseus, Pseudophryne, Brachycephalus* (2), *Hemisis* (3), *Microhyla*.

- β. A tympanic cavity and Eustachian tubes.

*Hylaplesia, Kalophrynus, Bufo, Ottilophus, Peltaphryne, Pseudobufo, Schismaderma, Xenorhina* (4), *Engystoma* (4), *Diplopelma* (4), *Cacopus* (*Systema*) (4), *Glyphoglossus* (4), *Callula* (4), *Brachymerus* (4), *Adenomera* (4), *Pachybatrachus* (?), *Breviceps, Chelydobatrachus, Hypopachus, Rhinoderma, Atelopus, Coeca, Paludicola.*

- δ. Teeth in the premaxillæ and maxillæ; the tongue may be fixed by its whole circumference, but is usually free behind.

a. No tympanic cavity; Eustachian recesses sometimes present.

*Bombinator* (1), *Pelobates, Didacus, Alsodes, Telmatobius, Cacopus, Liopelma.*

- β. A tympanic cavity and Eustachian tubes.

*Plectromantis, Alytes* (1), *Scaphiopus, Hyperolius, Helioporus, Nattereria, Phyllomedusa, Pelodryas, Chirodryas, Hyla, Hylælla, Otolygon, Pseudacris, Pœtia, Litoria, Tripurion, Opisthodelphys, Trachycephalus, Nototrema, Ixalus, Megalaculus, Hylarana, Leptomantis, Hylambates, Platymantis, Cornufer, Hemimantis, Rhacophorus, Chiromantis, Polypedates, Theloderma, Roppia, Acris, Leiyla, Elodia, Epirhexis, Phyllobates, Hylodes, Crossodactylus, Strabomantis, Calostethus, Rana, Odontophrynus, Dicroglossus, Oxyglossus, Phrynobatrachus, Hoplobatrachus, Phrynosglossus, Clinotarsus, Pseudis, Pithecopis, Mizophyes, Pygæcephalus, Ceratophrys* (2), *Zachænus, Platyplectrum, Neobatrachus, Cyclorhamphus, Limnodynastes, Crinia, Eusophelus, Pleurodema, Leiuperus, Hylorhina, Limnochelis, Cystignathus, Hemiphractus* (3), *Chiroleptes, Calyptrocephalus, Cryptotis* (4), *Asterophrys* (4), *Xenophrys* (4), *Megalophrys* (4), *Nannophrys* (4), *Pelodytes, Leptobranchium, Dicroglossus* (1), *Zaphrissa* (1), *Latonia* (1), *Paleobatrachus, Arthroleptis, Grypsius* (3).

(1) Opisthocælian vertebræ; rudimentary ribs attached to the anterior vertebræ. (2) Dorsal dermal ossifications, (3) Mandibular teeth. (4) Opisthocælian vertebræ.

- B. The Eustachian tubes of the well-developed tympanic cavity have a common median aperture in the roof of the mouth, and the pterygoid bones extend beneath and form a floor to them. The tongue is wanting. The lungs are attached to bronchial tubes; and the vertebræ are opisthocæulous.

- a. No teeth.

*Pipa.*

- b. Teeth in the premaxillæ and maxillæ.

*Dactylethra.*

III. THE PEROMELA.

- a. With a tentaculiferous fossa on the fore part of the face.

*Cæcilia, Siphonops* (1), *Epicrionum.*

- b. With no tentaculiferous fossa.

*Rhinatrema.*

(1) *Siphonops annulatus* has no scales.

IV. THE LABYRINTHODONTA.

*Amphibamus, Anthracosaurus,\* Apateon, Archeosaurus,† Baphates,\* Batrachiderpeton, Bothriceps,† Brachydoctes, Brachyops,\* Capitosaurus,\* Chalcosaurus,\* Cocytinus, Colosteus,† Dasyceps,\* Dendroterpeton,\* Dictyocephalus, Dolichosoma, Erpetocephalus,\* Eupelon,\* Eurythorax,\* Goniolyptus,\* Hylterpeton, Hylonomus, Ichthyterpeton,\* Ichthyocampsa, Keraterpeton,\* Labyrinthodon,\* Lepidosaurus, Lepterpeton,\* Leptophractus, Lozonma,\* Mastodonsaurus,\* Melosaurus,\* Metopias,\* Micropholis,\* Molyophis,† Osteocephalus (?)† Ophiderpeton,† Osteophorus,\* Pachygonia,\* Pariostegus, Pholidterpeton,\* Phlegæthontior,† Pteroplax, Pityonius,† Raniceps,† Rhinosaurus, Sauropleura,\* Trematosaurus,† Tuditanus,† Urocordylus,† Xestorrhytias,\* Zygosauros.\**

[A satisfactory grouping of these genera has not yet been effected; and it is possible that some of the forms here enumerated may not be true Labyrinthodonts. To those about the truly Labyrinthodont character of which there seems no doubt a \* or a † is attached—the † denoting the serpentine genera. *Batrachiderpeton, Pariostegus*, and *Pteroplax* are remarkable for the incompleteness of the jugal arch, and some other characters by which they appear to represent the *Proteidea*. The true position of *Hylterpeton* and *Hylonomus* is still doubtful.]

(T. H. H.)

(1) Tongue free in front. (2) Dorsal dermal ossifications. (3) Tongue retractile. (4) No plescoracoids.

AMPHICTYONY, in *Greek Antiquity*, was an association of several tribes for the purpose of protecting some temple common to them all, and for maintaining worship within it. The members were called ἀμφικτιόνες or ἀμφικτιῶνες, a word which means "the dwellers around." The second form of the word Benfey supposes to have arisen from a digammated ἀμφικτιῶνες. Out of the name the Athenians, according to their habit, easily discovered the founder of the Delphic Amphictyony, with which they were connected; and hence in later times, by an inverse process, the name was derived from Amphictyon, one of the fabulous kings of Attica.

Similar religious confederations existed in Greece at a very early period, and there is reason to believe that at their stated assemblies they discussed questions of international law and matters affecting their political union as well as religious subjects. Gradually, however, the political influence of the Amphictyonies died away. As states of great power stood on an equality with insignificant tribes in the number of votes, they naturally prevented the settlement of important political matters in such an assembly. Accordingly, during the flourishing period of Greek history the Amphictyonies almost disappear. They are not mentioned in Thucydides and Xenophon. But they appear again in vigour in the time of Philip, and become engines by which political parties, under pretence of religious zeal for the interests of the gods, wreak their vengeance on their rivals and antagonists.

This is especially true of the Amphictyony of Delphi, the most important of all these associations. Though we know better about this confederation than about any other, yet many particulars are hidden in obscurity, and considerable doubts gather around others of which we know something. The Amphictyony existed in very early times, and Æschines states that it arose when the temple at Delphi was first built. It is more likely, however, that it was originally connected with Thermopylæ and the temple of Demeter Amphictyonis which was there. The Amphictyony consisted of a union of twelve tribes, each of which had a right to two votes. These tribes were for the most part Thessalian or bordering on Thessaly; and it is probable that the others, as the Dorians and Ionians, gained admission in consequence of colonies that came to them from Thessaly.

There are nine lists of the tribes that constituted the Delphic Amphictyony in the classical writers and in inscriptions. Of these only one is complete; and the rest differ from each other in some particulars. The one that is complete was found on a Delphic stone containing a decree of the Amphictyonic council in regard to money due to the Delphic treasury. On this stone are given the votes of each tribe, and the final decision of the council in harmony with the majority of votes for one of the opinions held. The list is as follows:—The Delphians, two votes; Thessalians, two votes; Phocians, two votes; Dorians from Metropolis, one vote; the Dorians from Peloponnesus, one vote; the Athenians, one vote; the Eubœans, one vote; the Bœotians, two votes; the Achæan Phthiots, two votes; the Malians, one vote; the Ceteans, one vote; the Dolopians, one vote; the Perrhæbians, one vote; the Magnetes, two votes; the Ænians, two votes; the Locri Hypocnemidii, one vote; the Locri Hesperii, one vote. The exact date of the decree recorded on the Delphic stone is matter of dispute, but the most probable conjecture places it about the year 130 B.C. We have therefore clear testimony as to the constitution of the Amphictyonic council at this date; and, starting from this, we can form some idea of the changes which took place in the members of the council. It is generally believed that no change took place in the tribes forming the league till the time of the second sacred

war, 345 B.C. Of these tribes Æschines gives us a list, with the omission of one. They are the Thessalians, Bœotians, Dorians, Ionians, Perrhæbians, Magnetes, Locri, Ceteans, Phthiots, Malians, Phocians; and there can be little doubt that it is the Dolopians who have been by some mistake omitted. The confusions in some of the other lists have arisen probably from the ignorance of transcribers, who did not know that the Ænians and Ceteans lived close to each other, and were often comprehended under the same name, and who made two tribes of the Achæan Phthiots, Achæans and Phthiots. Æschines says that all these tribes had equal right of voting; but the inscription on the Delphic stone shows that the two votes of one tribe might be divided among two different portions of it. At the conclusion of the Phocian war the Phocians were excluded, and the Macedonians received their votes; and the vote of the Lacedæmonians was given to the other Doric tribes of Peloponnesus. The Delphians also obtained votes, either at this time or after the third sacred war, 338 B.C., by some of the smaller tribes that had two votes being restricted to one. In the same way, and also by the exclusion of the Locri Ozolæ, the Ætolians secured a place in the council in 338 B.C., and gradually took possession of a great number of votes. The Phocians were restored to their place in 279 B.C., on account of their gallant resistance to the Gauls. Finally, the Ætolians and Macedonians were excluded from the council, and the constitution of the council as given in the Delphic stone was formed. The last change mentioned in classical writers is detailed by Pausanias, but the passage is evidently corrupt. Augustus wished to give votes to Nicopolis, and for this purpose so altered the constitution of the council as to make the votes thirty in number.

The objects of the league are distinctly expressed in the oath which the Amphictyons had to take, and which is preserved in Æschines's oration "De Falsa Legatione." This oath bound the Amphictyons not to destroy any of the Amphictyonic towns, not to turn away its running waters either in time of war or in time of peace; and if any one should attempt to rob the temple of Delphi (the common centre of the confederacy), to employ their hands, feet, tongue, and their whole power to bring him to punishment. The humanising influence which this and other enactments of the confederacy were intended to exercise, is perceptible in the part relating to war. The framer of the law evidently regarded war only as an unavoidable means of settling disputes between two states; but it was to be carried on only for the purpose of bringing the dispute to a decision, and not for destruction and devastation. Another enactment probably was that the inhabitants of a conquered city should not be sold as slaves. But the chief care of the Amphictyons appears to have been to watch over the temple, to punish those who were guilty of a crime against it, and to reward those who did anything to increase its splendour and glory.

There is difficulty in determining how often the Amphictyons met. But the most likely inference from the somewhat indefinite statements of ancient writers is, that they went twice every year both to Delphi and Thermopylæ, in spring and in autumn. There is also some difficulty in determining the relative positions of the two sets of officials named in connection with the Amphictyony, the Hieromnemones and the Pylagoroi or Pylagorai. But there can scarcely be a doubt that the Hieromnemon was the principal official. There were as many Hieromnemones as there were votes; and the Hieromnemones were alone entitled to vote. The assembly proper consisted therefore only of the Hieromnemones. It is most likely that the Hieromnemones were elected annually by lot. In the case of the smaller states it is probable that the right to elect

went round by turns, while the more important states sent their representatives every year. There might be several Pylagoroi from each state. Æschines mentions that there were on one occasion three from Athens. They were elected by vote. Their function seems to have been to advise with the Hieromnemon, to address the assembly when anything relating to their own state was discussed, and to bring all their influence to bear on the assembly on behalf of their own state. The office of Hieromnemon remained in high honour till a late period. When the Dionysiac theatre in Athens was excavated in 1862, a chair of honour was found with the inscription *ἱερομνήμωνος*, and as it is certain that dramatic exhibitions took place in this theatre in the time of the Antonines, the office of Hieromnemon must have existed at that period.

The meetings, however, were attended not only by the deputies, but by thousands of others who flocked to Delphi or Thermopylæ for religious and mercantile purposes, or only for the sake of amusement. This occasioned popular meetings (*ἐκκλησίαι*) distinct from those of the regular deputies. But we cannot suppose that all the Greeks indiscriminately were allowed to take part in those popular assemblies, which must have consisted of visitors from the states which were members of the Amphictyony.

Wise and humane as were the objects of the Amphictyons, yet wherever they actively interfered in the affairs of Greece during the historical period, we find that they were more powerful for evil than for good; and the holy wars which were carried on by them in the defence of the Delphic temple and the honour of its god, contributed not a little to the demoralisation of the Greeks.

The very first time that the Amphictyons interfered in the affairs of Greece we find them acting in direct opposition to the spirit of their institution. We allude to the Crissæan or first sacred war, which broke out in 594, and lasted till 585 B.C. The inhabitants of Crissa (or Cirrha), on the Corinthian Gulf, were charged with extortion and violence towards the strangers who landed at their port, or passed through their territory on their way to Delphi. For this the Amphictyons declared war against Crissa, and it was vigorously carried on by the Thessalians and Cleisthenes, the tyrant of Sicyon. They even pretended to have the sanction of Apollo to dedicate the Crissæans and their territory to the god, to enslave them, and make their land a waste for ever. The war is said to have been terminated by a stratagem of Solon, who poisoned the waters of the river Pleistos, from which the town was supplied. When the town was taken, the vow of the Amphictyons was literally carried into effect: Crissa was razed to the ground, its harbour choked up, and its fertile plain changed into a wilderness. Such was the terrible vengeance taken by a body of confederates, whose original object was to prevent those very things which they now perpetrated to uphold the honour of the deity presiding over them. The second sacred war, which likewise lasted for ten years, from 355 to 346 B.C., was carried on with unparalleled exasperation for all that period, and nearly all the Greeks took part in it. The Thebans had set their hearts upon conquering Phocis, but screened their designs behind a charge preferred against the Locrians, alleging that they had robbed the temple of Delphi, because they had taken into cultivation a tract of land belonging to the Delphic temple. The Amphictyonic council, before which the charge was brought, condemned the Phocians to pay a heavy fine, and to destroy the crops of the sacred fields. No sooner was this verdict pronounced than the Thebans, Thessalians, Locrians, and Ceteans took up arms to execute it. The Phocians were joined by Athens and Sparta, and took possession of the temple of Delphi and its treasures, which they were obliged to employ in defraying

the expenses of the war. The war was carried on with unexampled cruelty, for even the surrender of the dead for burial was refused, and all Phocian captives were put to death. This war also afforded Philip of Macedonia an opportunity to interfere in the affairs of Greece. Being invited by the Thessalians to co-operate with them against the Phocians, Philip and his Macedonians acted as the champions of the god, and defeated the Phocians in a bloody battle near Magnesia. Three thousand captive Phocians were put to death. The latter, however, remained undaunted until at length they were compelled by treachery to surrender. The Amphictyons now excluded them for ever from the league, their arms and horses were to be delivered up, their towns to be destroyed, and the people were henceforth to live in small villages, and to pay annually to the god sixty talents (about £15,000) until the temple should be completely indemnified. Macedonian and Theban troops carried the judgment into execution; twenty-two towns disappeared from the face of the earth, and the otherwise fertile country remained for many years a wilderness. A third sacred war was decreed against the town of Amphissa, because its inhabitants had taken into cultivation the plain of Crissa; but in reality the war was brought about by the venal creatures who endeavoured to promote the ambitious schemes of Philip of Macedon, who was bent upon making himself master of Greece. This war broke out in 338 B.C., and its unfortunate consequences led to the catastrophe which deprived Greece of her independence in the battle of Charonea. Such is a brief outline of the history of the Delphic Amphictyony, which not only itself violated its first principles, but is not known to have ever raised its voice to condemn the wanton destruction of other Amphictyonic towns, such as Plataeæ and Thebes.

There were many other confederations of a similar kind, some of which, however, do not bear the name of Amphictyonies in the authorities from which we derive our information regarding them. The following were among the most noted:—

1. The *Amphictyony of Calauria*, an island near Treezen, consisted of the seven states of Hermione, Epidaurus, Ægina, Athens, Prasiæ, Nauplia, and the Minyan Orchomenos. These states took part in the sacrifices which were offered up in the temple of Poseidon, situated on the island. Sparta and Argos displaced Nauplia and Prasiæ when these lost their independence. It is difficult to see what object could unite states so widely apart. Some suppose that the tribes forming the league were originally Ionian; others, that they all were interested in the defence of seaports against inland states.

2. *Amphictyony of Onchestos*, in the territory of Haliartus in Bœotia, was likewise connected with the temple of Poseidon. As at all other Amphictyonies, the meetings of the members were celebrated with various religious rites, solemnities, and public games. We do not know the nations that constituted this league.

3. *Amphictyony of Amarynthos*, in Eubœa, connected with the temple of Artemis. We know that the two towns of Eretria and Chalcis were members of it, and that there existed an ancient treaty by which these two cities pledged themselves not to use against each other any missiles thrown from afar.

4. *Amphictyony of Delos*, connected with the temple of Apollo, was a league formed among the inhabitants of the Cyclades and the Ionians in the neighbourhood. Its institution was ascribed to Theseus. The solemnities connected with its meetings gradually fell into disuse, until they were revived and increased in 426 B.C., when the island of Delos was purified by the Athenians. The Athenians, after this time, regularly sent an annual embassy to Delos, and

they also retained for themselves the superintendence of the temple and the administration of its treasures.

AMPHION, in *Greek Mythology*, the son of Zeus by Antiope, and the husband of Niobe, was a musician of such wonderful power, that at the sounds of his lyre the stones began to move, and formed themselves into walls around Thebes, after his conquest of that city. He was killed by Apollo for assaulting his temple; or, as some report, he destroyed himself in despair at the slaughter of his children by that god. The famous Farnese bull, discovered in 1546, represents Amphion punishing Dirce for her treatment of his mother. There are four other mythical personages of this name.

AMPHIOXUS, a species of fish, differing widely from all other known animals. See LANCELET.

AMPHIPOLIS, a city of Macedonia, situated on the east bank of the river Strymon, about three miles from the sea. It was originally a Thracian town, known as the *Ἐννέα ὁδοί* (Nine Roads), and was colonised by the Athenians in 437 B.C., two previous attempts (497 and 465 B.C.) having been unsuccessful. In 424 B.C. it surrendered to the Lacedæmonians without resistance, and the Athenians never afterwards recovered possession of it. For his failure to prevent this disaster Thucydides was banished from Athens. The site of Amphipolis is occupied by the modern *Jeni Keui*.
