Root Pruning is most commonly practised in fruit tree cultivation. It is often resorted to as a means of restoring fertility in plants which have become over rank and sterile in growth. The effect of it, or of transplanting, is to reduce the supply of crude sap to the branches, and consequently to cause a check in their development. In root-pruning all roots that have struck downwards into a cold uncongenial subsoil must be pruned off if they cannot be turned in a lateral direction, and all the lateral ones that have become coarse and fibreless must also be shortened back by means of a clean cut with a sharp knife, while some hard rubbly material may if necessary be put under the tree before it is again planted, all its roots being laid out laterally, radiating as equally as possible from the centre. The operation is best performed early in autumn, and may be safely resorted to in the case of fruit trees of moderate age, and even of old trees if due care be exercised. In transplanting trees all the roots which may have become bruised or broken in the process of lifting should be cut clean away behind the broken part, as they then more readily strike out new roots from the cut parts. In all these cases the cut should be a clean sloping one, and made in an upward and outward direction.

The root-pruning of pot-plants is necessary in the case of many soft-wooded subjects which are grown on year after year—pelargoniums and fuchsias, for example. After the close pruning of the branches to which they are annually subjected, and when the young shoots have shot forth an inch or two in length, they are turned out of their pots and have the old soil shaken away from their roots, the longest of which, to the extent of about half the existing quantity, are then cut clean away, and the plants repotted into small pots. This permits the growing plant to be fed with rich fresh soil, without having been necessarily transferred to pots of unwieldy size by the time the flowering stage is reached.

Ringing.—One of the expedients for inducing a state of fruitfulness in trees, is the ringing of the branches or stem, that is, removing a narrow annular portion of the bark, by which means, it is said, the trees are not only rendered productive, but the quality of the fruit is at the same time improved. The advantage depends on the obstruction given to the descent of the sap. The ring should be cut out in spring, and be of such a width that the bark may remain separated for the season. A tight ligature of twine or wire answers the same end. The advantages of the operation may perhaps be gained by judicious root pruning, and it is not at all adapted for the various stone fruits. Ringi

26. *Training.*—What is called training is the guiding of the branches of a tree or plant in certain positions which they would not naturally assume, the object being partly to secure their full exposure to light, and partly to regulate the flow and distribution of the sap. To secure the former object, the branches must be so fixed as to shade each other as little as possible; and to realize the second, the branches must have given to them an upward or downward direction, as they may require to be encouraged or repressed. Something of the same vegetative vigour which is given to a plant or tree by hard pruning is afforded by training in an upward direction so as to promote the flow of the sap; while the repression effected by summer pruning is supplemented by downward training, which acts as a check. One main object is the pre- Traini

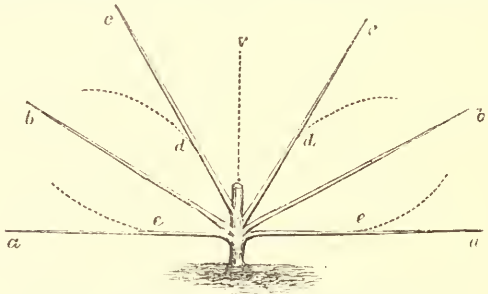

Fig. 77.—Diagram illustrating Branch Distribution.

servation of equilibrium in the growth of the several parts of the tree; and for this various minor details deserve attention. Thus a shoot will grow more vigorously whilst waving in the air than when nailed close to the wall; consequently a weak shoot should be left free, whilst its stronger antagonist should be restrained; and a luxuriant shoot may be retarded for some time by having its tender extremity pinched off to allow a weaker shoot to overtake it.

Mr Robert Thompson, who is to be regarded as an authority, says (*Gardener's Assistant*, 340):—

"A fair exposure to light is one of the principal objects to be borne in mind in training; but the branches may be well regulated as regards exposure to light, without being equally so with respect to the flow of sap. For instance, they may be disposed like the radii of a circle touching the circumference at equal distances (fig. 77, *aa*, *bb* *cc*, *v*). We shall, however, suppose that the central vertical shoot *v* has been cut back nearly to its base in order to furnish from buds there situated the rudiments of other branches. The sap flows with much greater force into the upright or nearly upright branches than it does into those having a horizontal position; therefore branches radiating at equal distances, like those in the figure, would soon become very unequal in point of vigour; *cc* would of course be strong, *aa* comparatively weak, whilst *bb* would maintain a somewhat intermediate condition. If, instead of training the shoots *cc* in a straight direction, we depress them at *dd* and bend them in the growing season as indicated by the curved line towards *bb*, we shall greatly check their over-luxuriance. On the other hand, by elevating the horizontal shoots at *cc*, and training them in the direction of the dotted line towards *bb*, those shoots will be thereby greatly invigorated. In short, by curving the upper branches downwards and the lower ones upwards, the flow of sap is checked in the former and promoted in the latter; and the consequence is that *aa* and *cc* are equal to the medium *bb* and to each other."

By these and other expedients, and by the prudent use of the knife, fruit trees may be readily trained into the forms indicated below, which are amongst the best out of the many which have been devised.

Fig. 78.—Pyramidal Training.

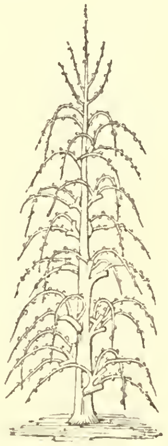

Fig. 79.—Training *en quenouille*.

The training of standard and bush trees in the open ground has been already referred to under the section *Pruning*. When the growth of pyramids is completed, the outline is something like that of fig. 78, and very pretty trees are thus formed. It is better, however, especially if the tendency to bear fruit is rather slack, to adopt what the French call *en quenouille* training (fig 79), which consists in tying or weighting the tips of the branches so as to give them all a downward curve. Pear trees worked on the quince stock, and trained *en quenouille*, are generally very fertile.

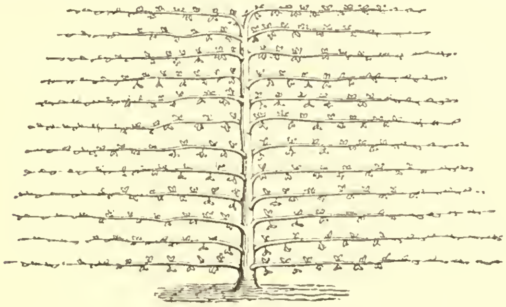

Fig. 80.—Horizontal Training.

Wall trees, it must be evident, are placed in a very unnatural and constrained position, and would in fact soon be reduced to a state of utter confusion, if allowed to grow unrestricted; hence the following modes of training have been adopted.

Horizontal Training (fig. 80) has long been a favourite form in England. There is one principal ascending stem from which the branches depart at right angles, at intervals of about a foot. Horizontal training is best adapted to the apple and the pear; and for the more twiggy growing slender varieties, the forms shown in fig. 81 have been recommended. In these the horizontal branches are placed wider, 18 to 20 inches apart, and the smaller shoots are trained between them, either on both sides, as at *a*, or deflexed from the lower side, as at *b*. The latter is an

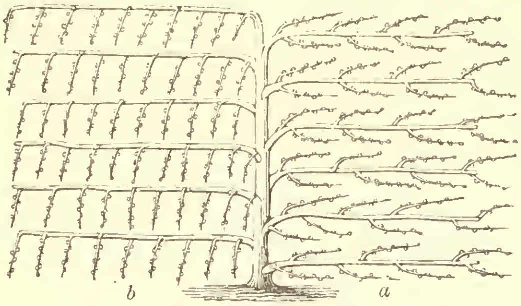

Fig. 81.—Forms of Horizontal Training.

excellent method of reclaiming neglected trees. Every alternate branch should be taken away, and the spurs cut off, after which the young shoots are trained in, and soon produce good fruit.

In *Fan Training* (fig. 82) there is no leading stem, but the branches spring from the base and are arranged somewhat like the spokes of a fan. This mode of training is com-

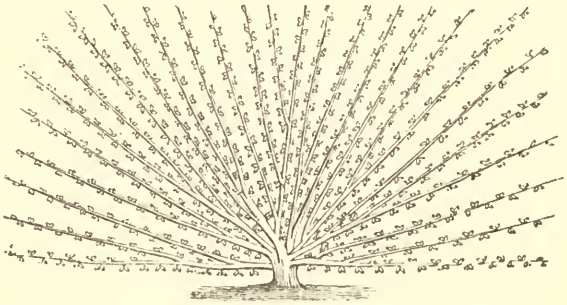

Fig. 82.—Fan Training.

monly adopted for the peach, nectarine, apricot, and Morello cherry, to which it is best adapted. Though sometimes adopted, it is not so well suited as the horizontal form for apples and pears, because, when the branches reach the top of the wall, where they must be cut short, a *tête de saule*, or hedge of young shoots, is inevitable. A modification of the fan shape (fig. 83) is sometimes adopted for

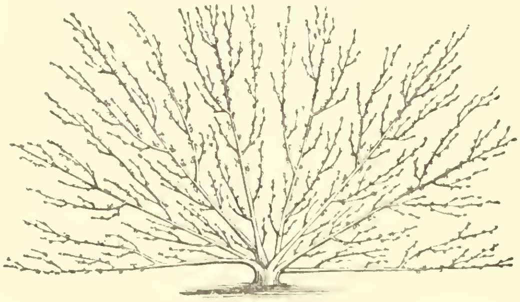

Fig. 83.—Modified Fan Training.

stone fruits, such as the apricot. In this the object is to establish a number of mother branches, and on these to form a series of subordinate members, chiefly composed of bearing wood. The mother branches or limbs should not be numerous, but well-marked, equal in strength, and regularly disposed. The side branches should be pretty abundant, short, and not so vigorous as to rival the leading members.

The *Half-fan* mode of training, which is intermediate between horizontal and fan training, is most nearly allied to the former, but the branches leave the stem at an acute angle, a disposition supposed to favour the more equal distribution of the sap. Sometimes, as in fig. 84, two vertical stems are adopted, but there is no particular advantage in this, and a single-stemmed tree is more manageable. The half-fan form is well adapted for such fruits as the plum and the cherry; and, indeed, for fruits of vigorous habit, it seems to combine the advantages of both the foregoing.

Trees must be fixed to the walls and buildings against which they are trained by means of nails and shreds, or in cases where it is desired to preserve the wall surface intact, by permanent nails or studs driven in in regular order. Sometimes the walls are furnished with galvanized wires, but this has been objected to as causing cankering of the shoots, for which, however, painting is recommended as a remedy, and which is also avoided, it is said, by crossing the tying material between the wire and the wood, and so preventing them from coming in contact. If they are adopted, the wires should be close to the wall to prevent a cold draught between it and the tree. Care should be taken that the ties or fastenings do not eventually cut

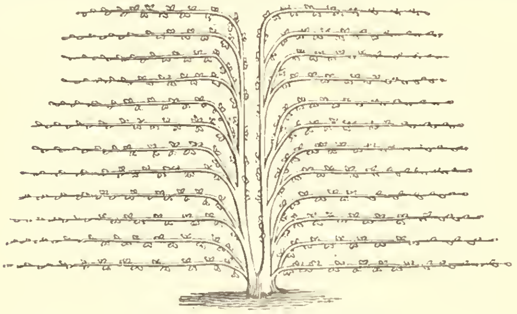

FIG. 84.—Half-Fan Training.

into the bark as the branches swell with increased age. When shreds and nails are used, cast wall nails and "medicated shreds" are the best; the nails should be of small size for the young shoots.

For tying plants to trellises and stakes nothing is better than soft tarred string. Osier ties are sometimes used for espaliers. The training in of summer shoots on wall-trees is often done by means of slender twigs; indeed the prunings of the trees themselves, stripped of their leaves, often serve the purpose very well; the ends are tucked under the adjacent fixed shoots, the young shoots to be fastened in being thus held close to the wall. Crooked shoots should be straightened at the principal or winter training; this is done by pulling the convex side towards the straight line desired by means of the tie or shred, the next above and below being set so as to pull in the opposite direction.

In training greenhouse plants the young branches should be drawn outwards by means of ties fastened to a string or wire under the pot-rim; the centre then fills up, and slender stakes are used as required; but the fewer these are in number the better. Climbers are trained from the bottom around or across trellises, of which the cylindrical or the balloon-shaped, or sometimes the flat oval or circular, are the best forms. The size should be adapted to the habit of the plant, which should cover the whole by the time flowers are produced. Bast fibre and raphia fibre are to be preferred for light subjects of this character, as they can be split to any degree of fineness; but the latter is not durable enough or strong enough for coarse-growing border flowers. Very durable trellises for greenhouse climbers are made of slender round iron rods for standards, having a series of hooks on the inner edge, into which rings of similar metal are dropped; the rings may be graduated so as to form a broad open top, or may be all of the same size, when the trellis will assume the cylindrical form. Fig. 85 shows a pot specimen of clematis trained over a balloon-shaped trellis.

FIG. 85.—Clematis trained on Balloon-shaped Trellis.

The training of bedding plants over the surface of the soil is done by small pegs of birch wood or bracken, by loops of wire, or sometimes by loops of bast having the ends fixed in the soil by the aid of the dibble. The object is to fill up the blank space as quickly and as evenly as possible.

27. *Forcing* is the accelerating, by special treatment, Forc
of the growth of certain plants, which are required to be had in leaf, in flower, or in fruit before their natural season,—as, for instance, the leaves of mint at Eastertide or the leafstalks of sea-kale and rhubarb at Christmas, the flowers of summer in the depth of winter, or some of the choicest fruits perfected so much before their normal period as to complete, with the retarded crops of winter, the circle of the seasons.

In the management of artificial heat for this purpose, a considerable degree of caution is required. The first stages of forcing should, of course, be very gentle, so that the whole growth of the plants may advance in harmony. A very hot atmosphere would unduly force the tops, while the roots remained partially or wholly inactive; and a strong bottom heat, if it did not cause injury by its excess, would probably result in abortive growth.

Any sudden decrease of warmth would be very prejudicial to the progress of vegetation through the successive stages of foliation, inflorescence, and fructification. But it is not necessary that one unvarying range of temperature should be kept up at whatever pains or risk. Indeed, in very severe weather it is found better to drop a little from the maximum temperature by fire heat, and the loss so occasioned may be made good by a little extra heat applied when the weather is more genial. Night temperatures also should always be allowed to drop somewhat, the heat being increased again in the morning. In other words, the artificial temperature should increase by day and decrease by night, should rise in summer and fall in winter, should, in short, imitate as nearly as possible the varying influence of the sun.

For the growth of flowers generally, and for that of all fruits, every ray of light to be obtained in the dull winter season is required, and therefore every possible care should be taken to keep the glass clean. A moist genial atmosphere too is essential, a point requiring unremitting attention on account of the necessity of keeping up strong fires. With moisture as with heat, the cultivator must hold his hand somewhat in very severe or very dull weather; but while heat must not drop so as to chill the progressing vegetation, so neither must the lack of moisture parch the plants so as to check their growth.

There are some few subjects which when forced do not require a light house. Thus amongst flowers the white blossoms of the lilac, so much prized during winter, are produced by forcing the plant in darkness. Rhubarb and sea-kale among esculents both need to be forced in darkness to keep them crisp and tender, and mushrooms also are always grown in dark structures. In fact, a roomy mushroom house is one of the most convenient of all places for forcing the vegetables just referred to. The lilac would be better placed in a dark shed heated to about 60°, in which some dung and leaves could be allowed to lie and ferment, giving off both a genial heat and moisture.

One of the most important preliminaries to successful forcing is the securing to the plants a previous state of rest. The thorough ripening of the preceding season's wood in fruit trees and flowering plants, and of the crown in perennial herbs like strawberries, and the cessation of all active growth before the time they are to start into new growth, are of paramount importance. The ripening process must be brought about by free exposure to light, and by the application of a little extra heat with dryness, if the season should be unfavourable; and both roots and tops must submit to a limitation of their water supply. When the ripening is perfected, the resting process must be aided by keeping the temperature in which they await the forcing process as low as each particular subject can bear.

V. *Flowers.*

wer den. 28. *Flower Garden and Pleasure Grounds.*—Wherever there is a flower garden of considerable magnitude, and in a separate situation, it should be constructed on principles of its own. The great object must be to exhibit to advantage the graceful forms and glorious hues of flowering plants and shrubs. Two varieties of flower gardens have chiefly prevailed in Britain. In one the ground is turf, out of which flower-beds, of varied patterns, are cut; in the other the flower-beds are separated by gravel walks, without the introduction of grass. When the flower garden is to be seen from the windows, or any other elevated point of view, the former is to be preferred; but where the surface is irregular, and the situation more remote, and especially where the beauty of flowers is mainly looked to, the choice should probably fall on the latter.

The situation of the flower garden must be influenced by the nature of the lawns, and of the site of the mansion to which it is attached. Generally speaking, it should not be at any great distance from the house; and in places where there is no distant view of importance, it may be constructed under the windows. On the other hand, when the park is spacious, and the prospects extensive and picturesque, it is perhaps better that the flower garden should be at a little distance from and out of sight of the house, but easy of access in any sort of weather. In most cases, even when it is in the vicinity of the mansion, the flower garden should for security against ground game and other intruders be encircled with some sort of fence. In detached localities the fences may be made sufficiently strong to prevent the intrusion of every species of vagrant; it is not difficult to mask them with shrubs and trees. The style of the mansion should determine that of the flower garden, and also its position. The flower garden attached to an elaborate mansion, should, for the most part, occupy the lawn on the south, the east, or the west front; and the carriage-entrance, where possible, should be on the north front, the park extending nearly or quite up to the front door. This arrangement must, however, sometimes be departed from in consequence of the difficulties of providing a proper approach to the entrance-door, and must also be regulated by the position of the principal rooms, which should if possible command a view of the flower garden.

When the garden is upon a large scale, and especially where a natural inclination in the ground exists, or can be formed artificially, terraces and parapet walls should be introduced, with flights of steps, and embellishments in connexion with them, such as fountains, statuary, sculpture, &c. Grass terraces alone have a mean appearance in such a position. The parapet walls afford excellent accommodation for half-hardy and beautiful flowering plants.

With regard to flower-plots, when the figures are separated by turf, it is necessary that the little lawns or glades should have a certain degree of breadth, as nothing has a worse effect than overcrowding. A multitude of little figures should also be avoided, as they produce the disagreeable effect well named by Gilpin "spottiness." In this sort of flower garden it is desirable that a gravel walk should skirt at least one side of the principal figures, for in the humid climate of Britain the grass would otherwise render them inaccessible with comfort during a great part of the year. In those gardens where turf is wholly or partly excluded, the compartments should be of a larger and more massive character. Narrow borders, bounded by parallel straight lines and concentric curves, should be avoided. The centres of the figures should be filled with tall-growing shrubs, and even with an occasional low evergreen tree, such as a yew or a holly. The walks, arranged in long concave curves, may communicate here and there with one another. A dial, a few seats and arbours, with an urn or two or a vase, may be introduced with good effect.

The flower garden may include several different compartments. Thus, for example, there is the "Rock Garden," which should consist of variously grouped masses of large stones, those which are remarkable for being figured by water-wearing, or containing petrifactions or impressions, or showing something of natural stratification, being generally preferred. In the cavities between the stones, filled with earth, alpine or trailing plants are inserted, and also some of the choicest flowers. In proper situations, a small pool of water may be introduced for the culture of aquatic plants. In a suitable position one of the walks is sometimes arched over with wire-work, and covered with ornamental climbing shrubs, forming a delightful promenade in the glowing days of summer. A separate compartment laid out on some regular plan is often set apart for roses, under the name of the "Rosery." A moist or rather a shady border, or a section of the pleasure ground supplied with bog earth, may be devoted to what is called the "American Garden," which, as it includes the gorgeous rhododendrons and azaleas, forms one of the grandest features of the establishment during the early summer, while if properly selected the plants are effective as a garden of evergreens at all seasons. The number of variegated and various-coloured hardy shrubs is now so great that a most pleasant plot for a "Winter Garden" may be arrayed with plants of this class, with which may be associated hardy subjects which flower during that season or very early spring, as the Christmas rose, and amongst bulbs the crocus and snowdrop. Later on, the spring garden department is a scene of great attraction; and some of the gardens of this character, as those of Cliveden and Belvoir, are among the most fascinating examples of horticultural art.

Lawns. 29. *Lawns.*—In the formation of lawns the ground must be regularly broken up so that it may settle down evenly, any deep excavations that may have to be filled in being very carefully rammed down to prevent subsequent settlement. The ground must also be thoroughly cleared of the roots of all coarse perennial weeds, and be worked to a fine tilth ready for turfing or sowing. The more expeditious method is of course to lay down turf, which should be free from weeds, and is cut usually in strips of 1 foot wide, 3 feet long, and about an inch in thickness. This must be laid very evenly and compactly, and should then be beaten down firmly with the implement called a turf-beater (fig. 86). When there is a large space to cover, it is much the cheaper plan to sow the lawn with grass-seeds, and equally effective, though the sward takes longer to thicken. It is of the utmost importance that a good selection of grasses be made, and that pure seeds should be obtained. The following sorts can be recommended, the quantities given being those for sowing an acre of ground:—

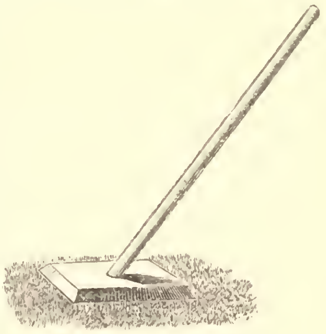

Fig. 86.—Turf-Beater.

Cynosurus cristatus—Crested Dog's-tail	6 lb
Festuca duriuscula—Hard Fescue	3 lb
Festuca ovina—Sheep's Fescue	3 lb
Lolium perenne tenue	18 lb
Poa nemoralis sempervirens—Evergreen Meadow-grass	3 lb
Poa trivialis—Trivial Meadow-grass	3 lb
Trisetum flavescens—Yellow Oat-grass	2 lb
Trifolium repens—Dutch Clover	6 lb

The seeds should be thoroughly mixed, and very evenly sown, after which the surface should be raked over to bury them, and then rolled down while dry so as to finish it off smooth and level. When thus sown, lawns require to be promptly weeded. During the growing season established lawns should be mown at least once a week. They should be occasionally rolled, and towards autumn they require frequent sweepings to remove worm-casts.

Hardy annuals. 30. Hardy Annuals.—Annual plants are those which grow up from seed, flower, ripen seed, and die in the course of one season—one year. They are useful in the mixed garden, for though in some cases they are of short duration, many of them are possessed of much beauty of hue and elegance of form. Annuals may be divided into three classes:—the *hardy*, which are sown at once in the ground they are to occupy; the *half-hardy*, which succeed best when aided at first by a slight hot bed, and then transplanted into the open air; and the *tender*, which are kept in pots, and treated as greenhouse or stove plants, to which departments they properly belong. Some of the more popular annuals, hardy and half-hardy, have been very much varied as regards habit and the colour of the flowers, and purchases may be made in the seed shops of such things as China asters, stocks, Chinese and Indian pinks, larkspurs, phloxes, and others, amongst which some of the most beautiful of the summer flowers may be found.

The hardy annuals may be sown in the open ground during the latter part of March or beginning of April, as the season may determine, for the weather should be dry and open, and the soil in a free-working condition before sowing is attempted. In favourable situations and seasons some of the very hardiest, as Silene pendula, Saponaria, Nemophila, Gilia, &c., may be sown in September or October, and transplanted to the beds or borders for very early spring flowering. Those sown in spring begin to flower about June. The patches, if left to flower where they are sown, should be thinned out while young, to give them space for proper development. It is from having ample room that pricked out transplanted seedlings often make the finest plants. The soil should be rich and light.

The half-hardy series are best sown in pots or pans under glass in mild heat, in order to accelerate germination. Those of them which are in danger of becoming leggy should be speedily removed to a cooler frame and placed near the glass, the young plants being pricked off into fresh soil, in other pots or pans or boxes, as may seem best in each case. All the plants must be hardened off gradually during the month of April, and may generally be planted out some time in May, earlier or later according to the season.

The class of tender annuals, being chiefly grown for greenhouse decoration, should be treated much the same as soft-wooded plants, being sown in spring, and grown on rapidly in brisk heat, near the glass, and finally hardened off to stand in the greenhouse when in flower.

We add a select list of some of the more distinct annuals desirable for general cultivation as decorative plants, and shall then mention a few of the most popular kinds separately:—

Acroclinium roseum: half-hardy, 1 ft., rose-pink or white; everlasting.
Agrostis pulchella: hardy, 6 in.; a most graceful grass for bouquets.
Amberboa moschata atropurpurea (Sweet Sultan): hardy, 1½ ft., purple; musk-scented.
Bartonia aurea: hardy, 2 ft., golden yellow; showy and free.
Brachycome iberidifolia: half-hardy, 1 ft., blue or white with dark disk.
Calendula officinalis Meteor: hardy, 1 ft., orange striped with yellow.
Calliopsis bicolor (tinctoria): hardy, 2 to 3 ft., yellow and chestnut-brown.
Calliopsis Drummondii: hardy, 1 to 2 ft., golden yellow with red disk.
Campanula Loreyi: hardy, 1½ ft., purplish-lilac or white.
Centaurea Cyanus: hardy, 3 ft., blue, purple, pink, or white; showy.
Clarkia pulchella: hardy, 1½ ft., rosy-purple; some varieties very handsome.
Collinsia bicolor: hardy, 1½ ft., white and purple; pretty.
Collinsia verna: hardy, 1 ft., white and azure; sow as soon as ripe.
Convolvulus tricolor atroviolacea: hardy, 1 ft., white, blue, and yellow. This is the Convolvulus minor of gardens.
Erysimum Perofskianum: hardy, 2 ft., deep orange; in erect racemes.
Eschscholtzia californica: hardy, 1½ ft., yellow with saffron eye.
Eschscholtzia crocea flore-pleno: hardy, 1½ ft., orange yellow; double.
Eutoca viscida: hardy, 2 ft., bright blue with white hairy centre.
Gaillardia Drummondii (picta): half-hardy, 1½ ft., crimson, yellow margin.
Gilia achilleæfolia: hardy, 2 ft., deep blue; in large globose heads.
Godetia Lindleyana: hardy, 2 to 3 ft., rose-purple, with crimson spots.
Godetia Whitneyi: hardy, 1 ft., rosy-red, with crimson spots. The variety Lady Albemarle is wholly crimson, and very handsome.
Gypsophila elegans: hardy, 1½ ft., pale rose; branched, very graceful.
Helianthus cucumerifolius: hardy, 3 to 4 ft., golden yellow, black disk; branching, free, and bold without coarseness.
Helichrysum bracteatum: half-hardy, 2 ft.; the incurved crimson, rose, and other forms very handsome.
Hibiscus Trionum (africanus): hardy, 1½ ft., cream colour, black centre.
Iberis umbellata (Candytuft): hardy, 1 ft., white, rose, purple, crimson. Some new dwarf white and flesh-coloured varieties are very handsome.
Kaulfussia amelloides: hardy, 1 ft., blue or rose; the var. kermesina is deep crimson.
Koniga maritima (Sweet Alyssum): hardy, 1 ft., white; fragrant, compact.
Lavatera trimestris: hardy, 3 ft., pale rose showy malvaceous flowers.
Leptosiphon densiflorus: hardy in light soil, 1 ft., purplish or rosy-lilac.
Leptosiphon roseus: hardy in light soil, 6 in., delicate rose; fine in masses.
Linaria bipartita splendida: hardy, 1 ft., deep purple.
Linum grandiflorum: hardy, 1 ft., splendid crimson; var. roseum is pink.
Lupinus luteus: hardy 2 ft., bright yellow, fragrant.
Lupinus mutabilis Cruckshanksii: hardy, 4 ft., blue and yellow; changeable.
Lupinus nanus: hardy, 1 ft., bluish-purple; abundant flowering.
Malcolmia maritima (Virginian Stock): hardy, 6 in., lilac, rose, or white.
Malope trifida: hardy, 3 ft., rich glossy purplish-crimson; showy.
Matthiola græca (Wallflower-lvd. Stock): hardy, 1 ft., various as in Stock.
Mesembryanthemum tricolor: half-hardy, 3 in., pink and crimson, with dark centre.
Mimulus cupreus: half-hardy, 6 in., coppery red, varying considerably.
Mimulus luteus tigrinus: half-hardy, 1 ft., yellow spotted with red; var. duplex has hose-in-hose flowers.
Mirabilis Jalapa: half-hardy, 3 ft., various colours; flowers evening-scented.
Nemesia floribunda: hardy, 1 ft., white and yellow; pretty and compact.
Nemophila insignis: hardy, 6 in., azure blue with white centre.
Nemophila maculata: hardy, 6 in., white with violet spots at the edge
Nigella hispanica: hardy, 1½ ft., pale blue, white, or dark purple.
Œnothera odorata: hardy, 2 to 3 ft., yellow; fragrant.
Omphalodes linifolia (Venus's Navelwort): hardy, 1 ft., white.
Papaver Rhœas flore-pleno: hardy, 2 ft., scarlet and other colours; showy.
Papaver somniferum flore-pleno: hardy, 3 ft., white, lilac, rose, &c.; petals sometimes fringed.
Petunia violacea hybrida: half-hardy, 1½ ft., various colours; sow in heat.
Pharbitis hispida: hardy, 6 ft., various; the many-coloured twining Convolvulus major.
Platystemon californicus: hardy, 1 ft., sulphur yellow; neat and distinct.
Portulaca splendens: half-hardy, 6 in., crimson, rose, yellow, white, &c. single and double; splendid prostrate plants for sunny rockwork.
Pyrethrum Parthenium aureum: half-hardy, 1 ft.; grown for its golden foliage, and much used for bedding.
Reseda odorata (Mignonette): hardy, 1 ft., greenish, but exquisitely fragrant; there are some choice new sorts.
Rhodanthe maculata: half-hardy, 1½ ft., rosy-pink or white; larger flower-heads than the next.
Rhodanthe Manglesii: half-hardy, 1 ft., rosy-pink; a drooping everlasting.
Salpiglossis sinuata: half-hardy, 2 to 3 ft., yellow, purple, crimson, &c.; much varied and beautifully veined.
Sanvitalia procumbens flore-pleno: half-hardy, 6 in., golden yellow; procumbent.
Saponaria calabrica: hardy, 6 to 8 in., bright rose pink or white; continuous blooming, compact-growing.
Schizanthus pinnatus: hardy, 1 to 2 ft., purple-lilac, prettily blotched; curiously lobed flowers.
Schizopetalon Walkeri: hardy, 1 ft., white, sweet-scented at night; curiously fringed petals.
Senecio elegans: half-hardy, 1½ ft., white, rose, or purple; the various double forms are showy.
Silene pendula: hardy, 1 ft., bright rose pink; very showy in masses; var. compacta forms close dense tufts.
Silene Pseudo-Atocion: hardy, 1 ft., rose pink; free-flowering.
Specularia Speculum: hardy, 6 in., reddish-violet; free-flowering.

Sphenogyne speciosa: half-hardy, 1 ft., orange-yellow, with black ring around the disk.

Tagetes signata: half-hardy, 1½ ft., golden yellow; continuous blooming, with elegant foliage. The French and African marigolds, favourites of some, are allied to this.

Tropæolum aduncum (Canary Creeper): half hardy, 10 ft., yellow, fringed; an elegant climber.

Viscaria cœli rosa: hardy, 1½ ft., rosy-purple with pale centre; pretty.

Viscaria oculata cardinalis: hardy, 1½ ft., rosy-crimson; very brilliant.

Waitzia aurea: half-hardy, 1½ ft., golden yellow; a showy everlasting.

Xeranthemum annuum flore-pleno: hardy, 2 ft., lilac-purple; floriferous.

The following annuals are entitled to separate notice:—

China Aster. 31. The China *Aster* (Callistephus chinensis). The groups of asters are very numerous; but some of the best for ornamental gardening are the chrysanthemum-flowered, the pæony-flowered, the crown or cockade, and the globe-quilled, of each of which there are from six to a dozen distinct colours. What are called crown asters have a white centre and dark crimson or purple circumference, and are very beautiful. The colours range from white and blush through pink and rose to crimson, and from lilac through blue to purple, in various shades. These should be sown early in April in pans, in a gentle heat, the young plants being quickly transferred to a cool pit, and there pricked out in rich soil as soon as large enough, and eventually planted out in the garden in May or June, in soil which has been well worked and copiously manured, where they grow from 8 to 18 inches high, and flower in great beauty towards the end of summer. They also make very handsome pot plants for the conservatory.

Stock. 32. The *Stock* (Matthiola annua). These also are much varied both in respect to habit and colour, and of some of the forms as many as two dozen colours are cultivated, some of which are very beautiful. The Ten-week and the large-flowered German are both favourite strains. The fragrance of these flowers renders them universal favourites. They should be treated much the same as asters for autumn-blooming plants, but for early blooming require to be sown about August, and wintered in pots in a cold frame, for which purpose the Intermediate Stock is the best adapted (see *Biennials*, par. 41). They grow from 1 to 2 feet high, according to the variety.

Antirrhinum. 33. The *Snapdragon* (Antirrhinum majus), which grows about 2 feet high, should be sown in February in a warm pit; prick off in pots, and subsequently into boxes, drawing off into a cool frame when established, and planting out in May or June. They are not true annuals, but may be treated as such.

Chinese Pink. 34. The *Chinese* or *Indian Pink* (Dianthus chinensis, and its varieties Heddewigii and laciniatus) and several allied forms, which grow from 6 inches to a foot high, are very richly coloured, and highly varied in marking. Sow in pits in gentle heat, in March, transferring them quickly after germination to a cool pit, that they may not get drawn or leggy; they may be planted out in May. They will also flower later on in favourable seasons, if sown outdoors early in April.

Larkspur. 35. The *Larkspur* affords two distinct types, the Rocket Larkspur (Delphinium Ajacis), which varies from a foot to a foot and a half, and the branching Larkspur (D. Consolida), growing 3 feet high, of each of which there are various colours, double and single. The candelabrum form of the latter is very handsome. Sow in March in the open border where they are to flower.

Phlox Drummondii. 36. The *Phlox Drummondii*, a spreading plant about a foot high, of which there are now many varieties of colour, is one of the most beautiful of all annuals, and very prolific of blossom. Sow in the places where it is to flower, in April, in good firm soil.

Sweet Pea. 37. The *Sweet Pea* (Lathyrus odoratus) is indispensable in every garden, especially Painted Lady (white and rose) and the improved forms called Invincible Scarlet and Invincible Black. Sow in rows or patches in February, and again in March, in good rich soil. The plants grow 3 to 4 feet high, and require stakes to support the stems.

Nasturtium. 38. The *Nasturtium* (Tropæolum majus), in its dwarf form known as Tom Thumb (T. m. nanum), is an excellent bedding or border flower, growing about a foot high, each plant forming a dense patch full of flowers, and blooming on for a considerable period if kept growing. The scarlet, the yellow, and the rose-coloured are very attractive. Sow in April in the beds or borders; and again in May for a succession.

Zinnia. 39. The *Zinnia elegans*, of which both single and double forms are cultivated, grows about 2 feet high, and produces flowers of various colours, the double ones being about the size of asters, and very handsome. The colours include white, yellow, orange, scarlet, crimson, and purple. It is half-hardy, and should be sown and treated much the same as the aster.

Hardy biennials. 40. HARDY BIENNIALS.—Biennials live as undeveloped plants through one winter period. They require to be sown in the summer months, about June or July, in order to get established before winter; they should be pricked out as soon as large enough, and should have ample space so as to become hardy and stocky. They should be planted in good soil, but not of too stimulating a character. Those that are perfectly hardy are best planted where they are to flower in good time during autumn. This transplanting acts as a kind of check, which is rather beneficial than otherwise. Of those that are liable to suffer injury in winter, as the Brompton and Queen Stocks, a portion should be potted and wintered in cold frames ventilated as freely as the weather will permit.

The number of biennials is not large, but a few very desirable garden plants, such as the following, occur amongst them:—

Agrostemma coronaria (Rose Campion): hardy, 1½ ft., bright rose-purple or rose and white.

Beta Cicla variegata: hardy, 2 ft., beautifully coloured leaves and midribs, crimson, golden, &c.

Campanula Medium (Canterbury Bell): hardy, 2 ft., blue, white, rose, &c. The double-flowered varieties of various colours are very handsome.

Campanula Medium calycanthema: hardy, 2 ft., blue or white; hose-in-hose flowered.

Catananche cœrulea: hardy, 2 to 3 ft., blue or white.

Celsia cretica: hardy, 4 to 5 ft., yellow, with two dark spots near centre; in spikes.

Dianthus barbatus (Sweet William): hardy, 1 to 1½ ft., crimson, purple, white, or parti-coloured.

Dianthus chinensis (Indian Pink): half hardy, 1 ft., various; these flower earlier if treated as biennials.

Digitalis purpurea (Foxglove): hardy, 3 to 5 ft., rosy-purple or white; beautifully spotted in the variety called gloxiniæflora.

Echium pomponium: hardy, 4 ft., rosy-pink.

Hedysarum coronarium (French Honeysuckle): hardy, 2 to 3 ft., scarlet or white; fragrant.

Hesperis tristis (Night-scented Rocket): hardy, 3 ft., dull purplish; fragrant at night.

Lunaria biennis (Honesty): hardy, 2 to 3 ft., purple; the silvery dissepiment attractive among everlastings.

Œnothera Lamarckiana (Evening Primrose): hardy, 5 ft., bright yellow; large.

Scabiosa atropurpurea (Sweet Scabious): hardy, 3 ft., dark purple, showy; the variety nana flore-pleno is dwarfer and has double flowers.

Silene compacta: half-hardy, 2 to 3 ft., bright pink; clustered as in S. Armeria.

Verbascum Blattaria: hardy, 3 to 4 ft., yellowish, with purple hairs on the filaments; in tall spikes.

41. The most important of the biennials are the different kinds of *Stocks*. The *Intermediate Stock* (Matthiola annua intermedia) is one of the so-called scarlet stocks, and is very useful, when preserved through the winter in frames, for its dwarfness and early-flowering habit. It is used very extensively for furnishing jardinières, window boxes, flower beds, &c., during the London season, for which purpose it is sown in July and August, while if sown in spring it blooms in autumn, and furnishes a useful successional crop of flowers. Of the East Lothian stock, which is a somewhat larger grower, there are some half dozen colours, those called New Crimson and Mauve Beauty being specially admired; these are sown in July and August for summer blooming, and early in spring for flowering in autumn. Stocks.

42. The *Brompton Stock* (Matthiola incana simplicicaulis) is a robust plant, growing 3 feet high, with a long central flower stem bearing very large flowers, which are crimson, purple, or white. They require rich soil, and should be sown in June or July, being pricked out into nursery beds, and planted in September in the borders where they are to bloom. Two or three plants should be put in one patch, as then any surplusage of single-flowered individuals may be pulled away.

43. The *Queen* or *Twickenham Stock* (Matthiola incana semperflorens) is less vigorous in habit than the Brompton, and is of more spreading habit, the plants growing about 2 feet high, with the lateral branches very much developed. There are the three usual colours, purple, scarlet, and white, the first-named being a special favourite. They require to be sown in June or July, and planted out in September, so as to get well established before winter, and if they have the advantage of good soil they will flower freely in the early part of the ensuing summer. Sometimes the plants acquire almost a woody habit, and live over the second year, but the flowers are not equal to those produced the first blooming season.

44. HARDY PERENNIALS.—This term includes, not only those fibrous-rooted plants of herbaceous habit which spring up from the root year after year, but also those old-fashioned subjects known as florists' flowers, and the hardy bulbs. Some of the most beautiful of hardy flowering plants belong to this class, and their great variety, as well as the long period through which they, one or other of them, yield their flowers, are beginning again to secure them some of the consideration which has long been given mainly to bedding plants. Hardy perennials.

When the length of the flowering season is considered, it will be obvious that it is impossible to keep up the show of a single border or plot for six months together, since plants, as they are commonly arranged, come dropping into flower one after another; and even where a certain number are in bloom at the same time, they necessarily stand apart, and so the effects of contrast, which can be perceived only among adjacent objects, are lost. To obviate this defect, it has been recommended that ornamental plants should be formed into four or five separate suites of flowering, to be distributed over the garden. Not to mention the more vernal flowers, the first might contain the flora of May; the second that of June; the third that of July; and the fourth that of August and the following months. These compartments should be so intermingled that no particular class may be entirely absent from any one quarter of the garden.

Before commencing to plant, it would be well to construct tables or lists of the plants, specifying their respective times of flowering, colours, and altitudes. To diversify properly and mingle well together the reds, whites, purples, yellows, and blues, with all their intervening shades, requires considerable taste and powers of combination; and ascertained failures may be rectified at the proper time the next season. The one great object aimed at should be to present an agreeable contrast; and, as at particular seasons a monotony of tint prevails, it is useful at such times to be in possession of some strong glaring colours. White, for instance, should be much employed in July, to break the duller blues and purples which then preponderate. Orange, too, is very effective at this season. On the other hand, yellows are superabundant in autumn, and therefore reds and blues should then be sought for. The flower-gardener should have a small nursery, or reserve garden, for the propagation of the finer plants, to be transferred into the borders as often as is required.

As a rule, all the fibrous-rooted herbaceous plants flourish in good soil which has been fairly enriched with manure, that of a loamy character being the most suitable. Many of them also grow satisfactorily in a peaty soil if well worked, especially if they have a cool moist subsoil. Pentstemons and phloxes, amongst others, succeed well in soil of this character, but the surface must be well drained; the former are rather apt to perish in winter in loamy soil, if at all close and heavy. The herbaceous border should be a distinct compartment, and not less than 10 feet in width, backed up by evergreens. Such a border will take in about four lines of plants, the tallest being placed at the back and the others graduated in height down to the front. In the front row patches of the white arabis, the yellow alyssum, and the purple aubrietia, recurring at intervals of 5 or 6 yards on a border of considerable length, carry the eye forwards and give a balanced kind of finish to the whole. The same might be done with dianthuses or the larger narcissi in the second row, with pæonies, columbines, and phloxes in the third, and with delphiniums, aconitums, and some of the taller yellow composites as helianthus and rudbeckia at the back. Spring and autumn flowers, as well as those blooming in summer, should be regularly distributed throughout the border, which will then at no season be devoid of interest in any part. Many of the little alpines may be brought into the front line planted between suitable pieces of stone, or they may be relegated to a particular spot, and placed on an artificial rockery. Most of the hardy bulbs will do well enough in the border, care being taken not to disturb them while leafless and dormant.

Some deep-rooting perennials do not spread much at the surface, and only require refreshing from time to time by top-dressings. Others, as the asters, spread rapidly; those possessing this habit should be taken up every second or third year, and, a nice patch being selected for replanting from the outer portions, the rest may be either thrown aside, or reserved for increase; the portion selected for replanting should be returned to its place, the ground having meanwhile been well broken up. Some plants are apt to decay at the base, frequently from exposure caused by the lifting process going on during their growth; these should be taken up annually in early autumn, the soil refreshed, and the plants returned to their places, care being taken to plant them sufficiently deep.

General list of hardy perennials.

Only a selection of some of the best of the decorative hardy perennials can be noted, before we pass on to those popular subjects of this class which have been directly influenced by the hybridizer and improver. Many more might be added to the subjoined list:—

Acæna.—Neat trailing plants adapted for rockwork, thriving in sandy soil. A. microphylla and A. myriophylla have pretty spiny heads of flowers.

Acantholimon.—Pretty dwarf tufted plants, with needle-shaped leaves, adapted for rockwork. A. glumaceum and A. venustum bear bright pink flowers in July and August. Light sandy loam.

Acanthus.—Bold handsome plants, with stately spikes, 2 to 3 feet high, of flowers with spiny bracts. A. mollis, A. latifolius, and A. longifolius are broad-leaved sorts; A. spinosus and A. spinosissimus have narrower spiny toothed leaves.

Achillea.—Handsome composite plants, the stronger ones of easy culture in common soil. A. Eupatorium and filipendula, 3 to 4 feet, have showy yellow corymbose flowers; A. rosea, 2 feet, rosy-crimson; and A. Ptarmica flore-pleno, 2 feet, double white flowers. Others suitable for front lines or rockwork are A. tomentosa, 9 inches, bright yellow; A. ægyptiaca, 1 foot, silvery leaves and yellow flowers; A. umbellata, 8 inches, silvery leaves and white flowers; and A. Clavennæ, 6 inches, with silvery leaves and pure white flowers.

Aconitum.—Handsome border plants, the tall stems crowned by racemes of showy hooded flowers. A. Camarum, 3 to 4 feet, has deep purple flowers in August; A. sinense, 1½ to 2 feet, has large dark purple flowers in September; A. variegatum, 3 feet, has the flowers white edged with blue; A. autumnale, 3 feet, has pale blue flowers, and A. japonicum, 2½ feet, deep blue flowers, both produced in September and October.

Adenophora.—Bell-shaped flowers. A. stylosa, 2 feet, pale blue, elegant; A. denticulata, 1½ feet, dark blue; and in A. liliifolia, 1½ feet, pale blue, sweet-scented—all blooming during summer. Light soil.

Adonis.—A. vernalis, 1 foot, has large bright yellow stellate flowers in April. Deep light soil.

Ajuga.—Free-growing, dwarf, and showy. A. reptans, 8 inches, has creeping runners, which A. genevensis has not; both bear handsome spikes of blue labiate flowers. Ordinary soil.

Allium.—Hardy bulbs of the garlic family, some species of which are ornamental; the inflorescence is umbellate. In A. azureum, 1 to 2 feet, the flowers are deep-blue; in A. Moly, 1 foot, golden yellow; in A. neapolitanum, 1½ feet, white, very handsome; in A. triquetrum, 8 inches, white with green central stripes; in A. pedemontanum, 9 inches, reddish-violet, very beautiful, the umbels nodding.

Alströmeria.—Beautiful plants with fleshy tuberous roots, which are the better if not often disturbed. A. aurantiaca, 2 to 3 feet, orange streaked with red, in July and August; A. chilensis, 2 to 3 feet, blood-red, streaked with yellow, affording many varieties. Deep sandy loam or peat. Should be planted at least 6 or 8 inches deep.

Alyssum.—Showy rockwork or front row border plants of easy culture in any light soil; the plants should be frequently renewed from cuttings. A. saxatile, with greyish leaves, and deep yellow flowers, produced in April and May, and the dwarfer A. montanum are useful.

Amaryllis.—Noble half-hardy bulbs, for planting near the front wall of a hot-house or greenhouse; the soil must be deep, rich, and well-drained. A. Belladonna, the Belladonna Lily, 3 feet, has large funnel-shaped flowers in September, of a delicate rose colour. The variety A. blanda has paler flowers, almost white.

Anchusa.—Pretty boraginaceous herbs, easily grown. A. italica, 3 to 4 feet, has blue star-like flowers. A. sempervirens, 1½ feet, rich blue, is well suited for rough borders.

Androsace.—Pretty dwarf rock plants, requiring rather careful management and a gritty soil. A. Vitaliana, yellow; A. Wulfeniana, purplish-crimson; A. villosa, white or pale rose; A. lactea, white with yellow eye; A. lanuginosa, delicate rose; and A. Chamæjasme, delicate rose, are some of the best.

Antennaria.—Composite plants, with everlasting flowers. A. margaritacea, 1½ to 2 feet, has white woolly stems and leaves, and white flower-heads.

Anthericum.—Charming border flowers. A. Liliastrum, St Bruno's Lily, 1½ feet, bears pretty white sweet-scented flowers in May; A. Hookeri (Chrysobactron), 2 feet, with long racemes of bright golden yellow flowers, requires cool peaty soil.

Aquilegia.—The Columbine family, consisting of beautiful border flowers in great variety, ranging from 1 to 2 or 3 feet in height. Besides the common purple A. vulgaris with its numerous varieties, double and single, there are of choice sorts A. alpina and A. pyrenaica, blue; A. glandulosa, A. jucunda, and A. cærulea, blue and white; A. leptoceras, blue and yellow; A. canadensis, A. Skinneri, and A. truncata (californica), scarlet and yellow; A. chrysantha, yellow; and A. fragrans, white or flesh-colour, very fragrant. Light rich garden soil.

Arabis.—Dwarf close-growing evergreen cruciferous plants, adapted for rockwork and the front part of the flower border, and of the easiest culture. A. albida forms a conspicuous mass of greyish leaves and white blossoms; A. lucida, which is also white-flowered, bears its bright green leaves in rosettes, and has a variety with prettily gold-margined leaves.

Arenaria.—Evergreen rock plants of easy culture. A. graminifolia and A. laricifolia are tufted, with grassy foliage and white flowers, while A. balearica, a creeping plant, has broad leaves and solitary white flowers.

Armeria.—The Thrift or Sea-Pink, of which the common form A. maritima is sometimes planted as an edging for garden walks; there are three varieties, the common pale pink, the deep rose, and the white, the last two being the most desirable. A. cephalotes, 1½ feet, is a larger plant, with tufts of linear lance-shaped leaves, and abundant globular heads of deep rose flowers, in June and July.

Arum.—Remarkable plants, with tuberous roots, and erect hood-like spathes, enclosing the spike of flowers (spadix). A. crinitum, 1½ feet, has pedate leaves, and fetid dark chocolate hairy spathes; A. Dracunculus, 3 feet, has spotted stems, pedate leaves, and dull purple spathes; A. italicum, with greenish spathes, has the cordate hastate leaves conspicuously veined with white.

Asclepias.—A. tuberosa is a handsome fleshy-rooted plant, very impatient of being disturbed, and preferring good peat soil; it grows 1 to 1½ feet high, and bears corymbs of deep yellow and orange flowers in September. A. incarnata, 2 to 4 feet, produces deep rose sweet-scented flowers towards the end of summer.

Asphodelus.—Handsome liliaceous plants, with fleshy roots, erect stems, and showy flowers, thriving in any good garden soil. A. albus, 4 feet, A. æstivus, 4 feet, and A. ramosus, 4 feet, have all long tapering keeled leaves, and simple or branched spikes of white flowers; A. luteus, 2 feet, has awl-shaped leaves and dense spikes of fragrant yellow flowers; A. capillaris is similar to A. luteus, but more slender and elegant.

Aster.—A very large family of autumn-blooming composites, including some ornamental species, all of the easiest culture. Of these, A. alpinus, 1 foot, and A. Amellus, 1½ feet, with its var. bessarabicus, have broadish blunt leaves, and large starry bluish flowers; A. longifolius formosus, 2 feet, bright rosy lilac; A. elegans, 3 to 5 feet, small pale purple or whitish; A. laxus, 2 feet, purplish-blue; A. pendulus, 2½ feet, white, changing to rose; A. pyrenæus, 2 to 3 feet, lilac-blue; A. turbinellus, 2 to 3 feet, mauve-coloured, are showy border plants; and A. Novæ Angliæ, 5 to 6 feet, rosy-violet; A. cyaneus, 5 feet, blue-lilac; and A. grandiflorus, 3 feet, violet, are especially useful from their late-flowering habit.

Astilbe.—A. japonica, 1 to 1½ feet, better known as Hoteia japonica or Spiræa japonica, thrives in peaty or sandy soil; its glossy tripinnate leaves, and feathery panicles of white flowers early in summer, are very attractive. It proves to be a fine decorative pot-plant, and invaluable for forcing during the spring.

Astragalus.—Showy pea-flowered plants, the smaller species adapted for rockwork; sandy soil. A. dasyglottis, 6 inches, has bluish-purple flowers in August and September; and A. monspessulanus, 8 inches, crimson-purple in July; while A. hypoglottis, 6 inches, produces in summer compact heads of pretty flowers, which are either purple or white. There are many very ornamental kinds.

Aubrietia.—Beautiful dwarf spring-blooming rock plants, forming carpety tufts of flowers of simple cruciferous form. A. deltoidea is of a deep lilac-blue; A. Campbelliæ is more compact and rather darker, approaching to purple; A. grandiflora and græca are rather larger, but of a lighter hue. Light sandy soil.

Bambusa.—The Bamboo family, some of which are hardy, at least in sheltered positions, are elegant arborescent grasses. B. japonica or Metake, 4 to 7 feet, has broadish leaves; B. nigra is about the same height, but more slender; B. aurea, 6 to 10 feet, is slender and graceful; and B. (Arundinaria) falcata sometimes reaches 20 feet in height.

Baptisia.—Stoutish erect-growing, 2 to 3 feet, with smooth foliage and spikes of leguminous flowers. B. australis is purplish-blue, B. alba, white, B. exaltata, deep blue; all flowering in the summer months.

Bellis.—B. perennis flore-pleno, the Double Daisy, consists of dwarf showy 3 to 4 inch plants, flowering freely in spring if grown in rich light soil, and frequently divided and transplanted. The white and pink forms, with the white and red quilled, and the variegated-leaved aucubæfolia, are some of the best.

Bocconia.—Stately poppyworts, 6 to 8 feet. B. cordata has heart-shaped lobed leaves, and large panicles of small flesh-coloured flowers. Sometimes called Macleaya. Deep sandy loam.

Brodiæa.—Pretty bulbous plants. B. grandiflora, 1 foot, has large bluish-purple flowers; B. coccinea, 2 to 3 feet, has tubular campanulate nodding flowers of a rich crimson with green tips. Sandy loam.

Bulbocodium.—Pretty spring-flowering crocus-like bulbs. B. vernum, 4 to 6 inches high, purplish-lilac, blooms in March. Good garden soil.

Buphthalmum.—Robust composite herbs with striking foliage, for the back of herbaceous or shrubbery borders. B. cordifolium, 4 feet, has large cordate leaves, and heads of rich orange flowers in cymose panicles in July. Also called Telekia speciosa.

Calandrinia.—Showy dwarf plants for sunny rockwork, in light sandy soil. C. umbellata, 3 to 4 inches, much branched, with narrow hairy leaves, and corymbs of magenta-crimson flowers in the summer months.

Caltha.—Showy marsh plants, adapted for the margins of lakes, streamlets, or artificial bogs. C. palustris flore-pleno, 1 foot, has double brilliant yellow flowers in May.

Calystegia.—Twining plants with running perennial roots. C. pubescens flore-pleno, 8 to 10 feet, has showy double-pink convolvuloid flowers in July; C. dahurica is a handsome single-flowered summer-blooming kind, with rosy-coloured flowers.

Campanula.—Beautiful, as well as varied in habit and character. They are called bell-flowers. C. pulla, 6 inches, purplish, nodding, on slender erect stalks; C. turbinata, 9 inches, purple, broad-belled; C. carpatica, 1 foot, blue, broad-belled; C. nobilis, 1½ feet, long-belled, whitish or tinted with chocolate; C. persicifolia, 2 feet, a fine border plant, single or double, white or purple, blooming in July; and C. pyramidalis, 6 feet, blue or white, in tall branching spikes, are good and diverse. There are many other fine sorts.

Centaurea.—Bold-habited composites of showy character; common soil. C. babylonica, 5 to 7 feet, has winged stems, silvery leaves, and yellow flower-heads from June to September; C. montana, 3 feet, deep bright blue or white.

Centranthus.—Showy free-flowering plants, for rockwork, banks, or stony soil. C. ruber, 2 feet, branches and blooms freely all summer, and varies with rosy, or crimson, or white flowers. It clothes the chalk cuttings on some English railways with a sheet of colour in the blooming season.

Cheiranthus.—Pretty rock plants, for light stony soils. C. alpinus, 6 inches, grows in dense tufts, and bears sulphur-yellow flowers in May. C. ochroleucus is similar in character.

Chionodoxa.—Charming dwarf hardy bulbous plants of the liliaceous order, blooming in the early spring in company with Scilla sibirica, and of equally easy cultivation. C. Luciliæ, 6 inches, has star-shaped flowers of a brilliant blue with a white centre, and is the finest of the few known species. It blooms about April.

Colchicum.—Showy autumn-blooming bulbs (corms), with crocus-like flowers, all rosy-purple or white. C. speciosum, C. autumnale, single and double, C. byzantinum, and C. variegatum are all worth growing.

Convallaria.—C. majalis, the Lily of the Valley, a well-known sweet-scented favourite spring flower, growing freely in rich garden soil; its spikes, 6 inches high, of pretty white fragrant bells, are produced in May and June; the variety with gold-striped leaves is very ornamental.

Coreopsis.—Effective composite plants, thriving in good garden soil. C. auriculata, 2 to 3 feet, has yellow and brown flowers in July and August; C. grandiflora, 3 to 4 feet, bright yellow, in August; C. tenuifolia, 2 feet, rich golden yellow, in July.

Corydalis.—Interesting and elegant plants, mostly tuberous, growing in good garden soil. C. bracteata, 9 inches, has sulphur-coloured flowers in April, and C. nobilis, 1 foot, rich yellow, in May; C. solida, with purplish, and C. tuberosa, with white flowers, are pretty spring-flowering plants, 4 to 6 inches high.

Cyclamen.—Charming tuberous-rooted plants of dwarf habit, suitable for sheltered rockeries, and growing in light gritty soil. C. europæum, reddish-purple, flowers in summer, and C. hederifolium in autumn.

Cypripedium.—Beautiful terrestrial orchids, requiring to be planted in peat soil, in a cool and rather shady situation. C. spectabile, 1½ to 2 feet, white and rose colour, in June, is a lovely species, as is C. Calceolus, 1 foot, yellow and brown, in May; all are full of interest and beauty.

Delphinium.—The Larkspur family, tall showy plants, with spikes of blue flowers in July. The popular garden varieties are noted under par. 53. Other distinct sorts are D. grandiflorum and D. grandiflorum flore-pleno, 2 to 3 feet, of the richest dazzling blue, flowering on till September; D. chinense, 2 feet, blue, and its double-flowered variety, are good, as is D. Barlowi, 3 feet, a brilliant double blue purple. D. nudicaule, 2 feet, orange-scarlet, very showy, is best treated as a biennial, its brilliant flowers being produced freely in the second year from the seed.

Dianthus.—Chiefly rock plants with handsome and fragrant flowers, the smaller sorts growing in light sandy soil, and the larger border plants in rich garden earth. Of the dwarfer sorts for rock gardens, D. alpinus, D. cæsius, D. deltoides, D. dentosus, D. neglectus, D. petræus, and D. glacialis are good examples; while for borders or larger rockwork D. plumarius, D. superbus, D. Fischeri, D. cruentus, and the clove section of D. Caryophyllus are most desirable.

Dictamnus.—D. Fraxinella is a very characteristic and attractive plant, 2 to 3 feet, with bold pinnate leaves, and tall racemes of irregular-shaped purple or white flowers. It is everywhere glandular, and strongly scented.

Dielytra.—Very elegant plants, of easy growth in good soil. D. spectabilis, 2 to 3 feet, has pæony-like foliage, and gracefully drooping spikes of heart-shaped pink flowers, about May, but it should have a sheltered place, as it suffers from spring frosts and winds; D. formosa and D. eximia, 1 foot, are also pretty rosy-flowered species.

Digitalis.—Stately erect-growing plants, with long racemes of pouch-shaped drooping flowers. The native D. purpurea, or Foxglove, 3 to 5 feet, with its dense racemes of purple flowers, spotted inside, is very showy, but is surpassed by the garden variety called gloxinioides. The yellow-flowered D. lutea and D. grandiflora are less showy. Good garden soil, and frequent renewal from seeds.

Doronicum.—Showy composites of free growth in ordinary soil. D. caucasicum and D. austriacum, 1 to 1½ feet, both yellow-flowered, bloom in spring and early summer.

Draba.—Good rockwork cruciferous plants. D. alpina, D. aizoides, D. ciliaris, D. Aizoon, and D. cuspidata bear yellow flowers in early spring; D. cinerea and D. ciliata have white flowers. Gritty well-drained soil.

Dracocephalum.—Handsome labiate plants, requiring a warm and well-drained soil. D. argunense, 1½ feet, D. austriacum, 1 foot, D. grandiflorum, 1 foot, and D. Ruyschiana, 1½ feet, with its var. japonicum, all produce showy blue flowers during the summer months.

Echinacea.—Stout growing showy composites for late summer and autumn flowering, requiring rich deep soil, and not to be often disturbed. E. angustifolia, 3 to 4 feet, light purplish-rose, and E. intermedia, 3 to 4 feet, reddish-purple, are desirable kinds.

Epimedium.—Pretty plants, growing about a foot high, with elegant foliage, and curious flowers. E. macranthum, white flowers, and E. rubrum, red, are distinctly spurred; E. pinnatum and E. Perralderianum, yellow, less so. They bloom in spring, and prefer a shady situation and a peaty soil.

Erigeron.—Composite plants, variable in character. E. purpureus, 1½ feet, with pink flower-heads, having narrow twisted ray-florets; E. Roylei, 1 foot, dark blue; and E. pulchellus, 1 foot, rich orange, flowering during the summer, are among the best kinds. Good ordinary garden soil.

Erinus.—E. alpinus is a beautiful little alpine for rockwork, 3 to 6 inches, of tufted habit, with small-toothed leaves, and heads of pinkish-purple or, in a variety, white flowers, early in summer. Sandy well-drained soil.

Erodium.—Handsome dwarf tufted plants. E. Manescavi, 1 to 1½ feet, has large purplish-red flowers in summer; E. Reichardi, a minute stemless plant, has small heart-shaped leaves in rosette-like tufts, and white flowers striped with pink, produced successively. Light soil.

Eryngium.—Very remarkable plants of the umbelliferous order, mostly of an attractive character. E. amethystinum, 2 feet, has the upper part of the stem, the bracts, and heads of flowers all of an amethystine blue. Some of more recent introduction have the aspect of the pine-apple, such as E. bromeliæfolium, E. pandanifolium, and E. eburneum. Deep light soil.

Erythronium.—E. dens canis, the Dog's-Tooth Violet, is a pretty dwarf bulbous plant with spotted leaves, and rosy or white flowers produced in spring, and having reflexed petals. Mixed peaty and loamy soil, deep and cool.

Euphorbia.—Plants whose beauty resides in the bracts or floral leaves which surround the inconspicuous flowers. E. aleppica, 2 feet, and E. Characias, 2 to 3 feet, with green bracts, are fine plants for rockwork or sheltered corners.

Ferula.—Gigantic umbelliferous plants, with magnificent foliage, adapted for shrubbery borders or open spots on lawns. They have thick fleshy roots, deeply penetrating, and therefore requiring deep soil, which should be of a light or sandy character. F. communis, F. glauca, and F. tingitana, the last with glossy lozenge-shaped leaflets, grow 8 to 10 feet high; F. Ferulago, with more finely cut leaves, grows 5 to 6 feet high. They flower in early spring, and all have a fine appearance when in bloom, on account of their large showy umbels of yellow flowers.

Funkia.—Pretty liliaceous plants, with simple conspicuously longitudinal-ribbed leaves, the racemose flowers funnel-shaped and deflexed. F. Sieboldiana, 1 foot, has lilac flowers; F. grandiflora, 18 inches, is white and fragrant; F. cœrulea, 18 inches, is violet-blue; F. albo-marginata, 15 inches, has the leaves edged with white, and the flowers lilac. Rich garden soil.

Gaillardia.—Showy composite plants, thriving in good garden soil. G. aristata, 2 feet, has large yellow flower-heads, 2 or 3 inches across, in summer; G. Bæselari and G. Loiselii have the lower part of the ray-florets red, the upper part yellow.

Galanthus.—The Snowdrop. Early spring-flowering amaryllidaceous bulbs, with pretty drooping flowers, snow-white, having the tips of the enclosed petals green. The common sort is G. nivalis, which blossoms on the first break of the winter frosts; G. Imperati and G. plicatus have larger flowers.

Gaura.—G. Lindheimeri, 3 to 5 feet, is much branched, with elegant white and red flowers of the onagraceous type, in long slender ramose spikes during the late summer and autumn months. Light garden soil; not long-lived.

Gentiana.—Beautiful tufted erect-stemmed plants preferring a strong rich loamy soil. G. acaulis, known as the Gentianella, forms a close carpet of shining leaves, and in summer bears large erect tubular deep blue flowers. G. Andrewsii, 1 foot, has, during summer, large deep blue flowers in clusters, the corollas closed at the mouth; G. asclepiadea, 18 inches, purplish-blue, flowers in July.

Geranium.—Showy border flowers, mostly growing to a height of 1½ or 2 feet, having deeply cut leaves, and abundant saucer-shaped blossoms of considerable size. G. ibericum, platypetalum, and Backhousianum are desirable purple-flowered sorts; G. sanguineum, a tufted grower, has the flowers a deep rose colour; and the double-flowered white and blue forms of G. pratense and G. sylvaticum make pretty summer flowers. Good garden soil.

Geum.—Pretty rosaceous plants. The single and double flowered forms of G. chiloense, 2 feet, with brilliant scarlet flowers, and G. montana, 9 inches, yellow, are amongst the best sorts. Good garden soil.

Gynerium.—The Pampas-Grass, a noble species, introduced from Buenos Ayres; it forms huge tussocks, 4 or 5 feet high, above which towards autumn rise the bold dense silvery plumes of the inflorescence. It does best in sheltered nooks.

Gypsophila.—Interesting caryophyllaceous plants, thriving in dryish situations. G. paniculata, 2 feet, from Siberia, forms a dense semi-globular mass of small white flowers from July onwards till autumn, and is very useful for cutting.

Helenium.—Showy composites of free growth in lightish soil. H. autumnale, 4 feet, bears a profusion of yellow-rayed flower-heads in August and September.

Helianthemum.—Dwarf subshrubby plants well suited for rockwork, and called Sun-Roses from their blossoms resembling small wild roses, and their thriving best in sunny spots. Some of the handsomest are H. roseum, mutabile, cupreum, and rhodanthum, with red flowers; H. vulgare flore-pleno, grandiflorum, and stramineum, with yellow flowers; and H. macranthum and papyraceum, with the flowers white.

Helianthus.—The Sunflower genus, of which there are several ornamental kinds. H. multiflorus, 4 feet, and its double-flowered varieties, bear showy golden yellow flower-heads in profusion, and are well adapted for shrubbery borders; H. orgyalis, 8 feet, has drooping willow-like leaves.

Helichrysum.—Composite plants, with the flower-heads of the scarious character known as Everlastings. H. arenarium, 6 to 8 inches, is a pretty species, of dwarf spreading habit, with woolly leaves and corymbs of golden yellow flowers, about July.

Helleborus.—Charming very early blooming dwarf ranunculaceous herbs. H. niger or Christmas Rose, the finest variety of which is called maximus, has white showy saucer-shaped flowers; H. orientalis, 1 foot, rose-coloured; H. atrorubens, 1 foot, purplish-red; and H. colchicus, 1 foot, deep purple. Deep rich loam.

Hepatica.—Charming little tufted plants requiring good loamy soil, and sometimes included with Anemone. H. triloba, 4 inches, has three-lobed leaves, and a profusion of small white, blue, or pink single or double flowers, from February onwards; H. angulosa, from Transylvania, 6 to 8 inches, is a larger plant, with sky-blue flowers.

Hesperis.—H. matronalis, 1 to 2 feet, is the old garden Rocket, of which some double forms with white and purplish blossoms are amongst the choicest of border flowers. They require a rich loamy soil, not too dry, and should be divided and transplanted into fresh soil annually or every second year, in the early autumn season.

Hibiscus.—Showy malvaceous plants. H. Moscheutos, rose coloured, and H. palustris, purple, both North American herbs, 3 to 5 feet high, are suitable for moist borders or for boggy places near the margin of lakes.

Iberis.—The Candytuft, of which several dwarf spreading subshrubby species are amongst the best of rock plants, clothing the surface with tufts of green shoots, and flowering in masses during May and June. The best are I. saxatilis, 6 to 10 inches; I. sempervirens, 12 to 15 inches; and I. Pruitii (variously called coriacea, carnosa, correæfolia), 12 inches.

Lathyrus.—Handsome climbing herbs, increased by seeds or division. L. grandiflorus, 3 feet, has large rose-coloured flowers with purplish-crimson wings, in June; L. latifolius, the Everlasting Pea, 6 feet, has bright rosy flowers in the late summer and autumn; the vars. albus, white, and superbus, deep rose, are distinct. Ordinary garden soil.

Lavatera.—L. thuringiacea, 4 feet, is a fine erect-growing malvaceous plant, producing rosy-pink blossoms freely, about August and September. Good garden soil.

Leucojum.—Snowflake. Pretty early-blooming bulbs, quite hardy. L. vernum, 6 inches, blooms shortly after the snowdrop, and should have a light rich soil and sheltered position; L. pulchellum, 1½ feet, blooms in April and May; and L. æstivum, 2 feet, in May. All have white pendent flowers, tipped with green.

Liatris.—Pretty composites with the flower-heads collected into spikes. L. pumila, 1 foot, L. squarrosa, 2 to 3 feet, L. spicata, 3 to 4 feet, L. pycnostachya, 3 to 4 feet, all have rosy-purplish flowers. Deep, cool, and moist soil.

Linaria.—Toadflax. Pretty scrophulariads, of which L. alpina, 3 to 6 inches, with bluish-violet flowers having a brilliant orange spot, is suitable for rockwork; L. dalmatica, 4 feet, and L. genistæfolia, 3 feet, both yellow flowered, are good border plants.

Linum.—Flax. L. alpinum, 6 inches, large, dark blue; L. narbonense, 1½ feet, large, blue; L. perenne, 1½ feet, cobalt blue; and L. arboreum (flavum), 1 foot, yellow, are all pretty. The last is liable to suffer from damp during winter, and some spare plants should be wintered in a frame.

Lithospermum.—L. prostratum, 3 inches, is a trailing evergreen herb, with narrow hairy leaves, and paniculate brilliant blue flowers in May and June. Well adapted for rockwork or banks of sandy soil.

Lupinus.—Showy erect-growing plants with papilionaceous flowers, thriving in good deep garden soil. L. polyphyllus, 3 feet, forms noble tufts of palmate leaves, and long spikes of bluish-purple or white flowers in June and July; L. arboreus is subshrubby, and has yellow flowers.

Lychnis.—Brilliant erect-growing caryophyllaceous plants, thriving best in beds of peat earth, or of deep sandy loam. L. chalcedonica, 3 feet, has dense heads of bright scarlet flowers, both single and double, in June and July; L. fulgens, 1 foot, vermilion; L. Haageana, 1½ feet, scarlet; and L. grandiflora, 1 foot, coppery-orange, are all large-flowered and showy, but require a little protection in winter.

Malva.—M. moschata, 2 feet, with a profusion of pale pink or white flowers, and musky deeply-cut leaves, though a British plant, is worth introducing to the flower borders when the soil is light and free.

Mertensia.—M. virginica, 1 to 1½ feet, azure-blue, shows flowers in drooping panicles in May and June. It does best in shady peat borders.

Mimulus.—Monkey-flower. Free-blooming, showy scrophulariaceous plants, thriving best in moist situations. M. cardinalis, 2 to 3 feet, has scarlet flowers, with the limb segments reflexed; M. luteus and its many garden forms, 1 to 1½ feet, are variously coloured and often richly spotted; and M. cupreus, 8 to 10 inches, is bright coppery-red. M. moschatus is the Musk-plant, of which the variety Harrisoni is a greatly improved form, with much larger yellow flowers.

Monarda.—Handsome labiate plants, flowering towards autumn, and preferring a cool soil and partially shaded situation. M. didyma, 2 feet, scarlet or white; M. fistulosa, 3 feet, purple; and M. purpurea, 2 feet, deep purple, are good border flowers.

Muscari.—Pretty dwarf spring-flowering bulbs. M. botryoides (Grape Hyacinth), 6 inches, blue or white, is the handsomest; M. moschatum (Musk Hyacinth), 10 inches, has peculiar livid greenish-yellow flowers and a strong musky odour; M. monstrosum (Feather Hyacinth), bears sterile flowers broken up into a feather-like mass. Good garden soil.

Myosotis.—Forget-me-not. Lovely boraginaceous plants. M. dissitiflora, 6 to 8 inches, with large handsome and abundant sky-blue flowers, is the best and earliest, flowering from February onwards; it does well in light cool soils, preferring peaty ones, and should be renewed annually from seeds or cuttings. M. rupicola, 2 to 3 inches, intense blue, is a fine rock plant, preferring shady situations and gritty soil; M. sylvatica, 1 foot, blue, pink, or white, used for spring bedding, should be sown annually in August.

Nardosmia.—N. fragrans, the Winter Heliotrope, though of weedy habit, with ample cordate coltsfoot-like leaves, yields in January and February its abundant spikes, about a foot high, of greyish flowers scented like heliotrope; it should have a corner to itself.

Nepeta.—N. Mussinii, 1 foot, is a compactly spreading greyish-leaved labiate, with lavender-blue flowers, and is sometimes used for bedding or for marginal lines in large compound beds.

Nierembergia.—N. rivularis, 4 inches, from La Plata, has slender creeping rooting stems, bearing stalked ovate leaves, and large funnel-shaped white flowers, with a remarkably long slender tube; especially adapted for rockwork, requiring moist sandy loam.

Œnothera.—The genus of the Evening Primrose, consisting of showy onagrads, all of which grow and blossom freely in rich deep soils. Œ. missouriensis (macrocarpa), 6 to 12 inches, has stout trailing branches, lance-shaped leaves, and large yellow blossoms; Œ. taraxacifolia, 6 to 12 inches, has a stout crown from which the trailing branches spring out, and these bear very large white flowers changing to delicate rose; this perishes in cold soils, and should therefore be raised from seed annually. Of erect habit are Œ. speciosa, 1 to 2 feet, with large white flowers; Œ. fruticosa, 2 to 3 feet, with abundant yellow flowers; and Œ. serotina, 2 feet, also bright yellow.

Omphalodes.—Elegant dwarf borageworts. O. verna, 4 to 6 inches, a creeping shade-loving plant, has bright blue flowers in the very early spring; O. Luciliæ, 6 inches, has much larger lilac-blue flowers, and is an exquisite rock plant for warm sheltered spots. Light sandy soil.

Onosma.—O. taurica, 6 to 8 inches, is a charming boraginaceous plant, from the Caucasus, producing hispid leaves, and cymose heads of drooping tubular yellow flowers. It is of evergreen habit, and requires a warm position on the rockwork, and well-drained sandy soil; or a duplicate should be sheltered during winter in a cold dry frame.

Ourisia.—Handsome scrophulariaceous plants, from Chili, thriving in moist well-drained peaty soil, and in moderate shade. O. coccinea, 1 foot, has erect racemes of pendent crimson flowers.

Papaver.—The Poppy. Very showy plants, often of strong growth, and of easy culture in ordinary garden soil. P. orientale, 3 feet, has crimson-scarlet flowers, 6 inches across, and the variety bracteatum closely resembles it, but has leafy bracts just beneath the blossom. P. alpinum, 6 inches, white with yellow centre; P. nudicaule, 1 foot, yellow, scented, and P. pilosum, 1 to 2 feet, deep orange, are ornamental smaller kinds.

Pentstemon.—The popular garden varieties are noticed under par. 63. Other distinct kinds are P. campanulatus, 1½ feet, pale rose, of bushy habit; P. humilis, 9 inches, bright blue; P. speciosus, cyananthus, and Jaffrayanus, 2 to 3 feet, all bright blue; P. barbatus, 3 to 4 feet, scarlet, in long terminal panicles; P. Murrayanus, 6 feet, with scarlet flowers and connate leaves; and P. Palmeri, 3 to 4 feet, with large wide-tubed rose-coloured flowers.

Phlomis.—Bold and showy labiates, growing in ordinary soil. P. Russelliana (lunariæfolia), 4 feet, yellow, and P. tuberosa, 3 feet, purplish-rose, both with downy hoary leaves, come in well in broad flower borders.

Physostegia.—Tall autumn-blooming labiates, of easy growth in ordinary garden soils. P. imbricata, 5 to 6 feet, has pale purple flowers in closely imbricated spikes.

Polemonium.—Pretty border flowers. P. cœruleum (Jacob's Ladder), 2 feet, has elegant pinnate leaves, and long panicles of blue rotate flowers. The variety called variegatum has very elegantly marked leaves, and is sometimes used as a margin or otherwise in bedding arrangements. Good garden soil.

Polygonatum.—Elegant liliaceous plants, with rhizomatous stems. P. multiflorum (Solomon's Seal), 2 to 3 feet, with arching stems, and drooping white flowers from the leaf axils, is a handsome border plant, doing especially well in partial shade amongst shrubs, and also well adapted for pot culture for early forcing. Good garden soil.

Polygonum.—A large family, varying much in character, often weedy, but of easy culture in ordinary soil. P. vacciniifolium, 6 to 10 inches, is a pretty prostrate subshrubby species, with handsome rose-pink flowers, suitable for rockwork, and prefers boggy soil; P. affine (Brunonis), 1 foot, deep rose, is a showy border plant, flowering in the late summer; P. cuspidatum, 8 to 10 feet, is a grand object for planting where a screen is desired, as it suckers abundantly, and its tall spotted stems and handsome cordate leaves have quite a noble appearance.

Primula.—Beautiful and popular spring flowers, of which many forms are highly esteemed in most gardens. P. vulgaris, 6 inches, affords numerous handsome single and double-flowered varieties, with various-coloured flowers for the spring flower beds and borders (par. 68). Besides this, P. Sieboldii (cortusoides amœna), 1 foot, originally deep rose with white eye, but now including many varieties of colour, such as white, pink, lilac, and purple; P. japonica, 1 to 2 feet, crimson-rose; P. denticulata, 1 foot, bright bluish-lilac, with its allies P. erosa and P. purpurea, all best grown in a cold frame; P. viscosa, 6 inches, purple, and its white variety nivalis, with P. pedemontana and P. spectabilis, 6 inches, both purple; and the charming little Indian P. rosea, 3 to 6 inches, bright cherry rose colour, are but a few of the many beautiful kinds in cultivation.

Pulmonaria.—Handsome dwarf borageworts, requiring good deep garden soil. P. officinalis, 1 foot, has prettily mottled leaves and blue flowers; P. sibirica is similar in character, but has broader leaves more distinctly mottled with white.

Pyrethrum.—Composite plants of various character, but of easy culture P. Parthenium eximium, 2 feet, is a handsome double white form of ornamental character for the mixed border; P. uliginosum, 5 to 6 feet, has fine large white radiate flowers, in October; P. Tchihatchewii, a close-growing dense evergreen creeping species, with long-stalked white flower-heads, is adapted for covering slopes in lieu of turf, and for rockwork.

Ramondia.—R. pyrenaica, 3 to 6 inches, is a pretty dwarf plant, requiring a warm position on the rockwork, and a moist peaty soil more or less gritty; it has rosettes of ovate spreading root-leaves, and large purple yellow-centred rotate flowers, solitary or two to three together, on naked stalks.

Ranunculus.—The florists' ranunculus is noticed in par. 70. R. amplexicaulis, 1 foot, white; R. aconitifolius, 1 to 2 feet, white, with its double variety R. aconitifolius flore-pleno (Fair Maids of France); and R. acris flore-pleno (Bachelor's Buttons), 2 feet, golden yellow, are pretty. Of dwarfer interesting plants there are R. alpestris, 4 inches, white; R. gramineus, 6 to 10 inches, yellow; R. parnassifolius, 6 inches, white; and R. rutæfolius 4 to 6 inches, white with orange centre.

Rudbeckia.—Bold-habited composite plants, well suited for shrubbery borders, and thriving in light loamy soil. The flower-heads have a dark-coloured elevated disk. R. Drummondii, 2 to 3 feet, with the ray-florets reflexed, yellow at the tip and purplish-brown towards the base; R. fulgida, 2 feet, golden yellow with dark chocolate disk, the flower-heads 2 to 3 inches across; and R. speciosa, 2 to 3 feet, orange-yellow with blackish-purple disk, the flower-heads 3 to 4 inches across, are showy plants.

Salvia.—The Sage, a large genus of labiates, often very handsome, but sometimes too tender for English winters. S. Sclarea, 5 to 6 feet, is a very striking plant little more than a biennial, with branched panicles of bluish flowers issuing from rosy-coloured bracts; S. patens, 2 feet, which is intense azure, has tuberous roots, and may be taken up, stored away, and replanted in spring like a dahlia. S. pratensis, 2 feet, blue, a showy native species, is quite hardy; the variety lupinoides has the centre of the lower lip white.

Saxifraga.—A very large genus, comprising plants of varied aspect, many of them handsome though simple in character, and most of them adapted for rockwork, requiring only ordinary good soil. Some of the larger growing species, now often called Megasea, are grand early-flowering border plants with broad leaves and large cymose clusters of rosy-pink flowers, *e.g.*, S. purpurascens, S. cordifolia, and S. crassifolia, with their varieties. Of another group with silvery leaves there are representatives in S. longifolia, S. cæsia, S. Cotyledon, S. pectinata, and S. Rocheliana; of the green mossy group in S. hypnoides, S. ceratophylla, S. muscoides, &c.; and of the London Pride section in S. umbrosa, S. Andrewsii, S. Geum, and S. Bucklandii. S. oppositifolia, 2 to 3 inches, purple or white, is a brilliant plant for rockwork, forming a carpet over the surface of the stones.

Scilla.—Beautiful dwarf bulbous plants, thriving in well-worked sandy loam, or sandy peat. S. bifolia, 3 inches, and S. sibirica, 4 inches, both intense blue, are among the most charming of early spring flowers; S. patula, 6 to 8 inches, and S. campanulata, 1 foot, with star-shaped greyish-blue flowers, freely produced, are fine border plants, as is the later blooming S. peruviana, 6 to 8 inches, dark blue or white.

Sedum.—Pretty succulent plants of easy growth, and mostly suitable for rockwork. They are numerous, varied in the colour of both leaves and foliage, and mostly of compact tufted growth. S. spectabile, 1 to 1½ feet, pink, in great cymose heads, is a fine plant for the borders, and worthy also of pot-culture for greenhouse decoration. Mention may also be made of the common S. acre (Stonecrop), 3 inches, yellow, and its variety with yellow-tipped leaves.

Sempervivum.—House-Leek. Neat-growing succulent plants, forming rosettes of fleshy leaves close to the ground, and rapidly increasing by runner-like offsets; they are well adapted for rockwork, and do best in sandy soil. The flowers are stellate, cymose, on stems rising from the heart of the leafy rosettes. S. arachnoideum, purplish, S. arenarium, yellow, S. globiferum, and S. Laggeri, rose, grow when in flower 3 to 6 inches high; S. calcareum, rose colour, and S. Boutignianum, pale rose, both have glaucous leaves tipped with purple; S. Heuffelii, yellow, with deep chocolate leaves, and S. Wulfeni, sulphur-yellow, are from 8 to 12 inches high.

Silene.—Pretty caryophyllaceous plants, preferring sandy loam, and well adapted for rockwork. S. alpestris, 6 inches, white, and S. quadridentata, 4 inches, white, are beautiful tufted plants for rockwork or the front parts of borders; S. maritima flore-pleno, 6 inches, white, S. Elizabethæ, 4 inches, bright rose, and S. Schafta, 6 inches, purplish-rose, are also good kinds.

Sisyrinchium.—Pretty dwarf iridaceous plants, thriving in peaty soil. S. grandiflorum, 10 inches, deep purple or white, blooms about April, and is a fine plant for pot-culture in cold frames.

Spiræa.—Vigorous growing plants of great beauty, preferring good deep rather moist soil; the flowers small but very abundant, in large corymbose or spicate panicles. S. Aruncus 4 feet, white; S. astilboides, 2 feet, white;

S. Filipendula flore-pleno, 1½ feet, and S. Ulmaria flore-pleno, 3 feet, both white; S. palmata, 2 feet, rosy-crimson; and S. venusta, 3 feet, carmine rose, are some of the best.

Statice.—Pretty plants with broad radical leaves, and a much-branched inflorescence of numerous small flowers. S. latifolia, 2 feet, greyish-blue; S. tatarica, 1 foot, lavender-pink; S. speciosa, 1½ feet, rose colour; and S. eximia, 1½ feet, rosy-lilac—are good border plants. S. bellidifolia, 9 inches, lavender; S. emarginata, 6 inches, purple; S. globulariæfolia, 9 inches, white; and S. nana, 4 inches—are good sorts for the rockery.

Stenactis.—S. speciosa, 1 to 2 feet, is a showy composite, of easy culture in good garden soil; it produces large corymbs of flower-heads, with numerous narrow blue ray-florets surrounding the yellow disk.

Stipa.—S. pennata (Feather Grass), 1½ feet, is a very graceful-habited grass, with stiff slender erect leaves, and long feathery awns to the flowers.

Stokesia.—S. cyanea, 2 feet, is a grand autumn-flowering composite plant, with blue flower-heads, 4 inches across. Sandy loam and warm situation.

Symphytum.—Rather coarse-growing but showy boraginaceous plants, succeeding in ordinary soil. S. caucasicum, 2 feet, with blue flowers changing to red, is one of the finer kinds for early summer blooming.

Thalictrum.—Free-growing but rather weedy ranunculaceous plants, in many cases having elegantly cut foliage. T. aquilegifolium, 2 feet, purplish from the conspicuous stamens, the leaves glaucous, is a good border plant; and T. minus has foliage somewhat resembling that of the Maidenhair fern. Ordinary garden soil.

Triteleia.—Charming spring-flowering bulbs, thriving in any good sandy soil. T. Murrayana, 8 inches, lavender-blue, and T. uniflora, 6 inches, white, are both pretty plants of the easiest culture, either for borders or rockeries.

Tritoma.—Splendid stoutish-growing plants of noble aspect, familiarly known as the Poker plant, from their erect rigid spikes of flame-coloured flowers; sometimes called Kniphofia. T. Uvaria, 3 to 4 feet, bright orange-red, passing to yellow in the lower flowers, is a fine autumnal decorative plant. They should be protected from frosts by a covering of ashes over the crown during winter.

Trollius.—Showy ranunculaceous plants, of free growth, flowering about May and June. T. europaeus, 18 inches, lemon, globular; T. asiaticus, 2 feet, deep yellow; and T. napellifolius, 2 to 2½ feet, golden yellow, are all fine showy kinds. Rich and rather moist soil.

Tulipa.—Splendid dwarfish bulbs, thriving in deep sandy well-enriched garden soil, and increased by offsets. They bloom during the spring and early summer months. T. Gesneriana, the parent of the florists' tulip (par. 71), 12 to 18 inches, crimson and other colours; T. Eichleri, 1 foot, crimson with dark spot; T. Greigi, 1 foot, orange with dark spot edged with yellow, and having dark spotted leaves; T. oculus solis, 1 foot, scarlet with black centre; and T. sylvestris, 12 to 18 inches, bright yellow, are showy kinds.

Verbascum.—Showy border flowers of erect spire-like habit, of the easiest culture. V. Chaixii, 4 to 5 feet, yellow, in large pyramidal panicles; V. phœniceum, 3 feet, rich purple or white; and V. formosum, 6 feet, golden yellow in dense panicles, are desirable species.

Veronica.—The Speedwell family, containing many ornamental members; all the hardy species are of the easiest cultivation in ordinary garden soil. The rotate flowers are in close erect spikes, sometimes branched. V. crassifolia, 2 feet, dark blue; V. incarnata, 1½ feet, flesh-colour; V. corymbosa, 1½ feet, pale blue in corymbosely-arranged racemes; V. gentianoides, 2 feet, grey with blue streaks; and V. virginica, 5 feet, white, are distinct.

Vinca.—Periwinkle. Pretty rock plants, growing freely in ordinary soil. V. herbacea, of creeping habit, with purplish-blue flowers; V. minor, of trailing habit, blue; and V. major, 1 to 2 feet high, also trailing, are suitable for the rock garden. The last two are evergreen, and afford varieties which differ in the colour of their flowers, while some are single and others double.

Viola.—Violet. Charming dwarf plants, mostly evergreen and of tufted habit, requiring well-worked rich sandy soil. V. calcarata, 6 inches, light blue; V. cornuta, 6 to 8 inches, blue; V. lutea, 4 inches, yellow; V. altaica, 6 inches, yellow or violet with yellow eye; V. palmaensis, 6 to 8 inches, lavender-blue; V. pedata, 6 inches, pale blue; and V. odorata, the Sweet Violet, in its many single and double flowered varieties, are all desirable.

Yucca.—Noble subarborescent liliaceous plants, which should be grown in every garden. They do well in light well-drained soils, and have a close family resemblance, the inflorescence being a panicle of white drooping tulip-shaped flowers, and the foliage rosulate, sword-shaped, and spear-pointed. Of the more shrubby-habited sorts Y. gloriosa, recurvifolia, and Treculeana, are good and distinct; and of the dwarfer and more herbaceous sorts Y. filamentosa, flaccida, and angustifolia are distinct and interesting kinds, the first two flowering annually.

The taste for cultivation of the class of plants of which the foregoing list embraces the more prominent members is on the increase, and our gardens will benefit by its extension; but we may hope that the folly of limiting the interest of the flower garden to this class of subjects alone, to the exclusion of the brilliant bedding flowers which have been evolved out of less showy materials by the gardener's skill, as some writers would seem to desire, may never be realized.

We now proceed to notice at greater length the more important plants of this class,—those to which horticulturists have devoted the greatest attention, with the result, in many cases, of largely increasing the varieties of these "florists' flowers."

45. The *Anemone* (Anemone coronaria), often called the Poppy Anemone, is a tuberous-rooted plant, with parsley-like divided leaves, and large showy poppy-like blossoms on stalks of from 6 to 9 inches high; the flowers are of various colours, but the principal are scarlet, crimson, blue, purple, and white. There are also double-flowered varieties, in which the stamens in the centre are replaced by a tuft of narrow petals. It is an old garden favourite, and of the double forms there are named varieties. They grow best in a loamy soil, enriched with well-rotted manure, which should be dug in below the tubers. These may be planted in October, and for succession in January, the autumn planted ones being protected by a covering of leaves or short stable litter. They will flower in May and June, and when the leaves have ripened should be taken up into a dry room till planting time. Anemones are easily raised from the seed, and a bed of the single varieties is a valuable addition to a flower-garden, as it affords, in a warm situation, an abundance of handsome and often brilliant spring flowers, almost as early as the snowdrop or crocus. The genus contains many other lively spring blooming plants, of which A. hortensis and A. fulgens have less divided leaves and splendid rosy-purple or scarlet flowers; they require similar treatment. Another set is represented by A. Pulsatilla, the Pasque-flower, whose violet blossoms have the outer surface hairy; these prefer a calcareous soil. The splendid A. japonica, and its white variety called Honorine Jobert, the latter especially, are amongst the finest of autumn blooming hardy perennials; they grow well in light soil, and reach 2½ to 3 feet in height, blooming continually for several weeks. A group of dwarf species, represented by the native British A. nemorosa and A. apennina, are amongst the most beautiful of spring flowers for planting in woods and shady places.

Antirrhinum.

46. The *Antirrhinum* (Antirrhinum majus) is very easily managed. Sown in heat, and forwarded until the general time for planting out, it becomes a summer annual, and may be so treated (par. 33); but under a slower and more hardy regime it may be sown in boxes in August, and pricked off into other boxes and wintered in a frame, for, though not often destroyed, it sometimes suffers greatly in a severe season. So treated, and planted out in well-prepared beds of good friable garden soil, it will become very showy and effective, and if a good strain of seed has been obtained many very beautiful kinds may generally be selected from the progeny. The named sorts are propagated by cuttings, and wintered in a frame. Some of the double-flowered sorts are interesting. There are forms with white, yellow, rose, crimson, magenta, and variously mottled and striped flowers, some of them of great beauty, but the named sorts are too fugitive to make it desirable to record a list of them.

Auricula.

47. The *Auricula* (Primula Auricula), a native of the Alps, has been an inmate of British gardens for about three hundred years, and is still prized by florists as one of their choicest flowers. The auricula loves a cool soil and shady situation. The florists' varieties are grown in rich composts, for the preparation of which numberless receipts have been given; but many of the old nostrums are now exploded, and a more rational treatment has taken their place. Thus Mr Douglas, the most recent authority, writes (*Hardy Florists' Flowers*):—

> "There is no mystery, as some suppose, about the potting, any more than there is about the potting material. The compost should consist of turfy loam four parts, leaf-mould one part, sharp river or silver sand one part, and a few bits of broken charcoal mixed with it. The pots to be used should be from 3 to 4½ inches in diameter, inside measure; about 1 inch of potsherds should be placed in the bottom of each pot, and over this some fibrous turf, from which the fine particles of earth have been removed. The old soil should be shaken from the roots of the plants to be potted; and before potting cut off, if necessary, a portion of the main root. In potting press the soil rather firmly around the roots."

Auriculas are best grown in a cold frame mounted on legs about 2 feet from the ground, and provided with hinged sashes. A graduated stage formed of wood battens 6 inches broad, with a rise of 2 inches, should be fixed so as to take each one row of pots, with the plants standing at about 15 inches from the glass; the spaces between the shelves should be closed, while the top board of the back and the front should be hinged so as to be let down when desired for ventilation, the sashes, too, being movable for the same purpose, and also to afford facilities for examining and attending to the plants. This frame should face the north, and stand under shelter of a wall or hedge. No protection will be needed except in very severe frosts, when two or three thicknesses of garden mats may be thrown over the glass, and allowed to remain on until the soil is thawed, should it become frozen.

Auriculas may be propagated from seed, which is to be sown as soon as ripe, in July or August, in boxes, kept under cover, and exposed only to the rays of the morning sun. When seed has been saved from the finer sorts, the operation is one of considerable nicety, as it not unfrequently happens that the best seedlings are at first exceedingly weak. They generally flower in the second or third year, a few good sorts being all that can be expected from a large sowing. The established varieties are increased by taking off the offshoots, an operation which is performed at the time of potting in July or the beginning of August.

The original of the auricula is a hardy perennial herb, of dwarf habit, bearing dull yellowish blossoms. This and the commoner forms raised from seed, as well as one or two double forms, are interesting hardy border flowers. The choice florists' varieties are divided into five classes:—the *green-edged*, with the margins of the flowers green; the *grey-edged*, with the green margins powdered with meal so as to appear to be coloured grey; the *white-edged*, with the mealy powder so dense as to cover the green; the *selfs*, which have none of the green variegation of margin seen in the foregoing, but are of some distinct colour, as purple, maroon, &c., but have, like the preceding, a white paste surrounding the eye; and the *alpines*, which resemble the selfs in not having any green marginal variegation, but differ in having a yellow centre more or less dense. The individual flowers of the first three groups of florists' auriculas show four distinct circles:—first the eye or tube, which should have the stamens lying in it, but sometimes has the pin-headed stigma instead, which is a defect; second, the paste or circle of pure white surrounding the eye; third, the body colour, a circle of some dark tint, as maroon or violet, which feathers out more or less towards the edge, but is the more perfect the less it is so feathered, and is quite faulty if it breaks through to the outer circle; fourth, the margin, which is green or grey or white. These circles should be about equal in width and clearly defined, and the nearer they are to this standard the more perfect is the flower. In the group of selfs the conditions are the same, except that there is no margin, and consequently the body colour, which should be uniform in tone, extends to the edge. In the alpines there should be no paste or white surrounding the eye, but this space should be either golden-yellow or creamy-yellow, which makes two subdivisions in this group; and the body colour is more or less distinctly shaded, the edges being of a paler hue. There is besides a group of laced alpines, in which a distinct and regular border of colour surrounds each of the marginal lobes.

The following is a selection of good sorts now obtainable in the respective groups:—

Green-edged.—Leigh's Col. Taylor, Booth's Freedom, Litton's Imperator, Ashton's Prince of Wales, Trail's Prince of Greens, Page's Champion.

Grey-edged.—Headly's George Lightbody, Lancashire's Lancashire Hero, Sykes's Complete, Kay's Alexander Meiklejohn, Walker's George Levick, Headly's C. E. Brown.

White-edged.—Heap's Smiling Beauty, Hepworth's True Briton, Ashworth's Regular, Taylor's Glory, Summerscale's Catherina, Lee's Bright Venus.

Selfs.—Netherwood's Othello, Campbell's Pizarro, Spalding's Blackbird, Pohlman's Garibaldi, Turner's C. J. Perry, Lightbody's Meteor Flag.

Alpines.—Turner's John Leech, Turner's Bessie Ray, Gorton's Diadem, Turner's A. F. Barron, Turner's Jessie, Turner's Susie Matthams.

Carna-ion.

48. The *Carnation* (Dianthus Caryophyllus), a native, as some suppose, of Italy, but occasionally found in an apparently wild state in England, has long been held in high estimation as a garden flower, not only for the beauty but for the delightful fragrance of its blossoms. The varieties are numerous, and are ranged under three groups, called *bizarres, flakes*, and *picotees*. The last, from their distinctness of character, are now generally looked upon as if they were a different plant, whereas they are, in truth, but a seminal development from the carnation itself, their number and variety being entirely owing to the assiduous endeavours of the modern florist to vary and to improve them.

The true carnations, as distinguished from picotees, are those which have the colours arranged in longitudinal stripes or bars of variable width on each petal, the ground colour being white. The *bizarres* are those in which stripes of two distinct colours occur on the white ground, and it is on the purity of the white ground and the clearness and evenness of the striping that the technical merit of each variety rests. There are scarlet bizarres marked with scarlet and maroon, crimson bizarres marked with crimson and purple, and pink and purple bizarres marked with those two colours. The *flakes* are those which have stripes of only one colour on the white ground, and here we have purple flakes striped with purple, scarlet flakes striped with scarlet, and rose flakes striped with rose colour. There are still the *selfs*, or those showing one colour only, as white, yellow, crimson, purple, &c., and these are commonly called *cloves*.

The *picotee* differs from the carnation in having the petals laced instead of striped with a distinct colour; the subgroups bear the designations red-edged, purple-edged, rose-edged, and scarlet-edged, all having white grounds; each group divides into two sections, the heavy-edged and the light-edged respectively. In the heavy-edged sorts the colour appears to be laid on in little touches, passing from the edge inwards, but so closely that they coalesce into one line of colour from $\frac{1}{12}$ to $\frac{1}{16}$ of an inch broad, and more or less feathered on the inner edge, the less feathered the better; while the light-edged sorts display only a fine edge, commonly called a wire edge, of colour on the white ground. To these have to be added yellow picotees, a group of great beauty, but deficient in correctness of marking.

Even the choice varieties of the carnation or picotee may be very successfully grown in most unfavourable localities; but the commoner sorts, such as may be raised freely from seed, on account of their robust constitution, are perhaps to be preferred for the ordinary flower garden; while the single-flowered sorts are by no means to be despised, especially those having decided colours. It is by selecting the best seedlings that new varieties of merit are produced. The established varieties are propagated by layers or by pipings, the former plan being adopted with strong healthy plants in an ordinarily congenial season. The latter is sometimes had recourse to when the plants do not produce young shoots of sufficient length to admit of their being layered; and the cuttings, planted under close glasses in a bed where there is a very slight bottom heat, will generally root. Layering is, however, a more expeditious mode. It is performed at the time the plants are in flower, or as soon after as possible. The rooted layers may be removed and potted or planted out towards the end of September, or early in October, the choice sorts being potted in rather small pots and kept in a cold frame during winter, at which season the great enemy to be guarded against is damp.

The soil for carnations and picotees should be a good turfy loam, free from wireworm, and as fibry as it can be obtained; to four parts of this add one part of rotten manure and one of leaf-mould, with sufficent sharp sand to keep it loose. A moderate addition of old lime rubbish, if attainable, will also be an advantage. This should be laid up in a dry place, and frequently turned over with the fork or spade, so as to be in a free friable condition for use towards the end of February or early in March. As to the size of the blooming pots, Mr Douglas observes:—

"I do not care to use them larger than 10 inches in diameter, inside measure, and three plants may be put into a pot that size; a 9-inch pot may be used for a pair of a strong-growing sort, while weaker growers may be potted two in an 8-inch or even a 7-inch pot. If it is intended to propagate all the layers produced, that must be taken into account, as the plants will not have so good a chance in a small as in a large pot. After potting they should be kept in a well-ventilated frame until established, and set in the open air in an open sunny spot when the weather becomes genial, the flowering stems being tied up carefully as they grow up. At the flowering season they should be put in a thoroughly ventilated glass house, where they can be shaded from bright sunshine, or under the protection of a canvas screen to keep off rain and sun. Where there is any tendency in the flowers to burst the calyx on one side, the other divisions should be slit down a little, and the calyx should have a ligature, not too tight, of thread or matting; this, if done early, will prevent the petals falling aside and destroying the symmetry of the flower."

The groups are so numerous that to name a selection of the best sorts would occupy too much space. Ample information on this head may be obtained from Mr Douglas's book already referred to (*Hardy Florists' Flowers*); and critically descriptive lists of all the varieties then grown, by the highest authority, Mr E. S. Dodwell, will be found in the volumes of the *Florist and Pomologist* for 1876 and 1877.

49. The *Chrysanthemum* (Chrysanthemum sinense) is one of the most popular of autumn flowers. It is a native of China, whence it has long been introduced. The small-flowered pompons, and the grotesque-flowered Japanese sorts are of more recent date, the former having originated from the Chusan daisy, a variety introduced by Mr Fortune in 1846, and the latter having also been introduced by the same traveller about 1862. The plants may be increased by division, in March or April, the divided portions being planted in beds of rich soil, under the shelter of a wall or fence, as a safeguard against cold and stormy weather. The shoots should be thinned out to about four or six from each root, and these should be staked as they grow up. They look extremely well in such a border, if arranged in two or three rows according to their heights, and with a judicious intermixture of colours, the advantage of growing them in this way being that a canvas screen can be put over them, by which means they not only flower in greater perfection, but last for a longer period. They are of the easiest culture, and may be grown readily enough even in town gardens. Chrysan-themum

The chrysanthemum is, however, of very great importance as a greenhouse plant for autumn and winter flowering, and for this purpose, as well as for exhibition culture, it is generally raised from cuttings, or suckers, which are taken off by some growers about October, and planted singly in 3-inch pots, the plants being wintered in cold frames, and shifted into larger-sized pots about March; they are topped when about 6 inches high, and the young shoots thus induced are again topped when 3 or 4 inches long. Others take short cuttings in March, and strike them quickly in a mild hotbed, airing freely as soon as rooted, and shifting and stopping as in the other case. As soon as fine weather sets in in June, the plants, having received one or two previous shifts according to the size which they are required to reach, should be plunged outdoors in a tolerably open spot, and there carefully watered and syringed. About the middle of July they should be shifted into their blooming pots, the pompons requiring less room than the large-flowered and Japanese sorts, and after the end of July it is not advisable to continue the topping—technically "stopping"—of the young shoots, as it may interfere with the blooming. As soon as the flower-buds become visible, the plants are benefited by a watering of weak liquid manure two or three times a week. The pots should still be plunged in a bed of coal ashes or cocoa-nut refuse, till about the end of September, when they should be put under glass as a precaution against injury from autumn frosts, having, however, full ventilation by day. Abundant root watering is necessary until the flowers are developed, when the supply may be slightly diminished, and the atmosphere should be kept dryish by abundant ventilation. The compost used for potting in all the stages after the cuttings, for which any light earth will suffice, should consist of four parts loam to one of rotten dung and one of leaf-mould, giving rather more leaf-mould and less manure for the first potting, and rather more manure for the last; a little coarsely-pounded gritty matter may be added advantageously. For the large-flowered sorts 11-inch pots are large enough to produce very handsome specimens, and 8-inch pots suffice for the pompons, but very useful plants may be had in smaller pots than these. For fine specimen flowers only a single shoot is allowed to grow up, and this goes on unstopped, and finally develops two or three very large flowers; these latter require disbudding, as some sorts give the best flowers from the terminal buds, others from the side buds. The aphis or green fly is a great enemy to the plants, and must be kept under; dusting the hearts of the shoots with tobacco powder is a safe and efficient remedy; but, whatever be the method employed, it should be applied before the blossoms open.

The following are a few of the best varieties in each section:—

Large-flowered.—Abbé Passaglia, Alfred Salter, Beethoven, Beverley, Dr Brock, Emily Dale, Empress of India, George Glenny, Golden Beverley.

Jardin des Plantes, Lady Hardinge, Mrs George Rundle, Mrs Heale, Prince Alfred, Prince of Wales, Princess of Wales, Venus, White Globe. These are all incurved flowers. To them might be added, for their merit as conservatory specimen plants, Chevalier Domage, Crimson Velvet, Julie Lagravère, and Mrs Forsyth.

Japanese.—Elaine, Fair Maid of Guernsey, James Salter, and Wizard, early sorts; Dr Masters, Fulton, Grandiflora, Hero of Magdala, Meg Merrilees, Purpureum album, Red Dragon, and The Daimio, later sorts.

Anemone-flowered.—Acquisition, Empress, Fleur de Marie, Gluck, King of Anemones, Lady Margaret, Louis Bonamy, Miss Margaret, Miss Pethers, Prince of Anemones, Princess Louise, Sunflower.

Pompons.—Adonis, Andromeda, Brilliant, General Canrobert, Mdlle. Martha, Modèle, St Michael, Salamon. To these may be added of Anemone-flowered pompons—Antonius, Astrea, Calliope, Cedo Nulli (four colours), Firefly, Jean Hachette, Madame Montels, Marie Stuart, Miss Nightingale, Mr Astie, Perle, Rose Marguerite, Virginale.

Within the last few years a new type of dwarf-growing early-blooming varieties has sprung up, and these are now increasing in number. They come into flower in August and September, and are extremely useful for filling up exhausted beds in the flower garden as well as for cutting. They are cultivated exactly as the others. The following are useful sorts of this group:—Adrastus, Chromatella, Delphine Caboche, Frédéric Pelé, Madame Alphonse Dufoy, Madame Piconl, Precocité, and Scarlet Gem.

ocus. 50. The *Crocus* sets our gardens aglow with its bright colours almost as soon as winter has departed. These crocuses of the flower garden are mostly seminal varieties of C. vernus and C. aureus, the former yielding the purple and striped, and the latter the yellow varieties. The headquarters of the genus is in eastern Europe and Asia Minor, but C. vernus is found wild in some parts of England. It has been much improved by Dutch florists, and large quantities are annually imported from Holland. The crocus succeeds in any fairly good garden soil, and is usually planted near the edges of beds or borders in the flower garden, or in broadish patches at intervals along the mixed borders. The roots or corms should be planted 3 inches below the surface, and as they become crowded they should be taken up and replanted with a refreshment of the soil, at least every five or six years. Crocuses have also a pleasing effect when dotted about on the lawns and grassy banks of the pleasure ground. Some of the best of the varieties are :—

Purple: David Rizzio, Sir J. Franklin. *Shaded light blue*: Lilaceus superbus. *Blue tipped with white*: Ne plus ultra. *Striped*: Albion, La Majestueuse, Sir Walter Scott, Cloth of Silver. *White*: Caroline Chisholm. *Yellow*: Large Dutch, Cloth of Gold.

The species of Crocus are not very readily obtainable, but those who make a speciality of hardy bulbs ought certainly to search them out and grow them. They require the same culture as the more familiar garden varieties; but, as some of them are apt to suffer from excess of moisture, it is advisable to plant them in prepared soil in a raised pit, where they are brought nearer to the eye, and where they can be sheltered when necessary by glazed sashes,—which, however, should not be kept closed except when the plants are at rest. The autumn-blooming kinds include many plants of very great beauty.

Of the spring-flowering species, there are C. aureus, Susianus, stellaris, sulphureus, chrysanthus, mesiacus, Olivieri, and vitellinus, having yellow flowers of various shades; C. vernus, etruscus, Imperati, minimus, suaveolens, and veluchensis, with blue or lilac flowers; C. albiflorus, Fleischerianus, versicolor, strictus, and biflorus, with white or whitish flowers. Of the autumn-blooming species, there are C. speciosus, Clusianus, medius, Orphanidis, longiflorus (odorus), Pallasii, Thomasii, Salzmannianus, nudiflorus, autumnalis, serotinus, Sieberi, Cartwrightianus, and byzantinus, with lilac or purple flowers; C. Boryanus, vallicola, hadriaticus, cancellatus, and Cambessedianus, with white or whitish flowers; and C. Scharojani with flowers of a rich saffron yellow.

Crown Imperial. 51. The *Crown Imperial* (Fritillaria imperialis) grows up to a height of about 3 feet, the lower part of the stoutish stem being furnished with leaves, while near the top is developed a coronal of large pendent flowers surmounted by a tuft of bright green leaves like those of the lower part of the stem, only smaller. The flowers are bell-shaped, yellow or red, and in some of the forms double. The plant grows freely in good garden soil, preferring a deep well-drained loam, and is all the better for a top-dressing of manure as it approaches the flowering stage. Strong clumps of five or six roots of one kind have a very fine effect. It is a very suitable subject for the back row in mixed flower borders, or for recesses in the front part of shrubbery borders. It flowers in April or early in May. There are a few named varieties, but the most generally grown are the single and double yellow, and the single and double red, the single red having also two variegated varieties, with the leaves striped respectively with white and yellow.

Dahlia. 52. The florists' *Dahlia* (Dahlia variabilis) yields two groups or varieties, which are known as show and fancy dahlias,—the former consisting of all self-coloured flowers and those light-ground ones which are edged, tipped, or laced with a dark colour; the latter, all flowers with the colour in stripes like a carnation, and all dark-ground flowers tipped with white. Besides these there are bedding dahlias, which are dwarf-growing sorts with decided colours, much used in flower-gardens where large effects are required to be produced; and pompon dahlias, which are very symmetrical small-flowered sorts, better adapted for cutting than the more bulky flowers of the show varieties. The single-flowered D. coccinea, a most brilliant and highly effective ornamental plant, with some other allied kinds, has recently attracted much attention, and can be commended as an admirable half-hardy border flower, and well adapted for cutting to fill large vases. It is rather more delicate than the forms of D. variabilis, and the tuberous roots are very apt to be lost during winter, but it is readily raised from seeds, and if sown early flowers the same season. The varieties of the florists' dahlia selected for the flower garden should be those only which are of effective colours, whether selfs or others, and such as throw out their flower heads or long stalks clear of the foliage. The same remark applies to the pompons.

New varieties are procured from seed, which should be sown in pots or pans towards the end of March, and placed in a hotbed or propagating pit, the young plants being pricked off into pots or boxes, and gradually hardened off for planting out in June; they will flower the same season if the summer is a genial one. The older varieties are propagated by dividing the large tuberous roots, in doing which care must be taken to leave an eye to each portion of tuber, otherwise it will not grow. Rare varieties are sometimes grafted on the roots of others (see fig. 57, p. 237). The best and most general mode of propagation is by cuttings, to obtain which, the old tubers are placed in heat in February, and as the young shoots, which rise freely from them, attain the height of 3 inches, they are taken off with a heel, and planted singly in small pots filled with fine sandy soil, and plunged in a moderate heat. They root speedily, and are then transferred to larger pots in light rich soil, and their growth encouraged until the planting-out season arrives, which is about the middle of June.

Dahlias succeed best in an open situation, and in rich deep loam, but there is scarcely any garden soil in which they will not thrive, if it is manured. For the production of fine show flowers the ground must be deeply trenched, and well manured annually. The branches as well as the blossoms require a considerable but judicious amount of thinning; they also need shading in some cases, and individual protection from rain and wind. They may stand singly like common border flowers, but have the most imposing appearance when seen in masses arranged according to their height. Florists usually devote a plot of ground to them, and plant them in lines 5 to 10 feet apart. This is done about the beginning of June, sheltering them if necessary from late frosts by inverted pots or in some other convenient way. Old roots often throw up a multitude of stems, which render thinning necessary. As the plants increase in height, they are furnished with strong stakes, to secure them from high winds. Dahlias flower on till they are interrupted by frost in autumn. The roots are then taken up, dried, and stored in a cellar, or some other place where they may be secure from fros and moisture. See article DAHLIA, vol. vi. p. 762.

53. The *Delphinium*, or Bee-Larkspur, is so called from the resemblance of the petals in the original species, D. elatum, to the hairy body of a bee. Delphinium. The original had comparatively small flowers, but by hybridizing they have been very much increased in size, and improved in quality, and now constitute one of the brightest ornaments of the mixed border, or the shrubbery group, often throwing up secondary blooming stems, especially if the first are removed in good time, instead of being allowed to form seeds. The colour varies from reddish-blue to pale blue or grey, but the prevailing one is dark blue. Delphiniums need a good rich soil, that of a loamy character being the best. They must be replanted at least every second year, and the soil either renewed or well manured and thoroughly broken up. Replanting may be done equally well early in autumn or when growth recommences in spring. The commoner single varieties, such as the brilliant D. formosum, may be reproduced with but slight variation from seed, but the double ones must be propagated by division. Unless sown as soon as ripe the seed is apt to take long to vegetate. If novelties are required, the flowers can be cross-fertilized. For mere propagation the best method is division; for this purpose the stems should be cut down early, say in July, the offsets potted each into a small pot of light soil, and wintered in a frame. The plants should be well exposed to the sun, but sheltered from strong winds, and promptly and carefully staked. In a mixed border they should be planted in one of the back rows; but their spire-like inflorescence is very effective when they are planted several together in a group or bed in the front part of the shrubbery border. They vary in height from 3 to 6 feet. The following are some of the best modern varieties :—

Single-flowered.—Amabilis, Celestial, Gloire de St Mande, Madame Chaté, Madame Henri Jacotot, Mrs Gerard Leigh.

Double-flowered.—Barlowi, Clair Courant, grandiflorum plenum, Keteleeri, Manteau de Minerva, Roi Léopold.

54. The *Gladiolus*, described separately in vol. x. p. 732, has become one of our most popular flowers, and is a striking ornament of our gardens during the late summer months. Gladiolus. The modern race of flowers has sprung from G. gandavensis, but others (see separate article) are grown to a smaller extent, and come in at an earlier season. G. cardinalis, cruentus, and floribundus belong to this latter series, and are pretty subjects for the mixed borders, while for beds G. brenchleyensis, one of the early hybrids, is still one of the most brilliant and effective, the flowers being of a glowing scarlet. The choicer kinds afford a variety of colours, including white, yellow, blush, rose, salmon, cerise, scarlet, crimson, and rosy-purple, many of them being prettily striped or blotched. Being tall (3 to 4 feet), and spare of leaves, they are most effective when planted in beds

furnished below with some bushy foliage plants, between which their spikes of brilliant flowers may appear; or they may be planted in the mixed border, where clumps of half a dozen roots of one kind have a much finer appearance than when they are dotted about singly.

A deep sandy loam is the best soil for the gladiolus, and this should be trenched up in October and enriched with well-decomposed manure, consisting partly of cow dung, the manure being disposed altogether below the bulbs, a layer at the bottom of the upper trench, say 9 inches from the surface, and another layer at double that depth. The bulbs (technically, corms) should be planted in succession at intervals of two or three weeks through the months of March, April, and May. They should be planted about 3 inches deep, a little pure soil or sand being laid over each before the earth is closed in about them, an arrangement which may be advantageously followed with bulbous plants generally. In hot summer weather they should have a good mulching of half-rotten manure, and, as soon as the flower spikes are produced, liquid manure may occasionally be given them with advantage.

The gladiolus is easily raised from seeds, which should be sown in March, in pots of rich soil placed in heat, the pots being kept near the glass after they begin to grow, and the plants being gradually hardened to permit their being placed out-of-doors in a sheltered spot for the summer. In October they will have ripened off, and must be taken out of the soil, and stored in paper bags in a dry room secure from frost. They will have made little bulbs from the size of a hazel nut downwards, according to their vigour. In the spring they should be planted like the old bulbs, and the larger ones will flower during the season, while the smaller ones must be again harvested and planted out as before.

The following are good varieties of their respective colours, but new varieties are continually appearing, which have at least the merit of constitutional vigour:—

Crimson, Scarlet, Red, &c.—Horace Vernet, John Waterer, Lord Bridport, Victory, Virgil, Lord Napier, Hesperia, Magnificent, Astrea, Lycoris, Addison, Meyerbeer.

Rose, Salmon, &c.—Figaro, Mons. Legouve, Sappho, Madame Furtado, Oberon, Grandeur, Ulysse, Milton, Ninon de l'Enclos, Sir Joseph Paxton.

Purple.—Antiope, Eugène Scribe, Robert Fortune, Lacépède, Thomas Methven, Madame Vilmorin, La Favorite, Mozart.

White ground.—Accins, Mrs Reynolds Hole, Reine Blanche, Canova, Hogarth, Osci, Didon, Norma, Sylphide, Madame Adèle Souchet, Berthe Rabourdin.

Yellow.—Citrinus, Nestor, Yellow King, Ophir, Crœsus, Pactolo.

Hollyhock. 55. The *Hollyhock* (Althæa rosea), having been already treated of in this volume (page 102), it only remains to add that, though it is a perennial, it is not to be had in perfection unless a supply of young plants is raised annually. The early part of August may be considered as the season for the blooming of the hollyhock.

The following are a few good sorts for a beginner:—Acme, Black Gem, Constance, Conquest, Edward Speed, Eleanor, Emperor, Fire King, Golden Drop, Incomparable, Jessie Dean, Joshua Clarke, Marvellous, Mr Chater, Octavia, Ruby Queen, Scarlet Gem, Tyrian Prince.

Hyacinth. 56. The *Hyacinth* (Hyacinthus orientalis), noticed under the heading HYACINTH (*q.v.*), one of the most beautiful and fragrant of the spring flowers, is a native of the Levant, where it occurs abundantly, in form not unlike our common harebell. It has long been a favourite in the East; but it has been brought to its present artificial perfection in Holland, chiefly since the beginning of the last century, and the bulbs are annually imported from Haarlem and its vicinity in very large numbers.

The hyacinth delights in a rich light sandy soil. The Dutch incorporate freely with their naturally light soil a compost consisting of one-third coarse sea or river sand, one-third rotten cow dung without litter, and one-third leaf-mould. The soil thus renovated retains its qualities for six or seven years, but hyacinths are not planted upon the same place for two years successively, intermediary crops of narcissus, crocus, or tulips being taken. A good compost for hyacinths is sandy loam, decayed leaf-mould, rotten cow dung, and sharp sand in equal parts, the whole being collected and laid up in a heap and turned over occasionally. Well drained beds made up of this soil, and refreshed with a portion of new compost annually, would grow the hyacinth to perfection. The best time to plant the bulbs is towards the end of October; they should be arranged in rows, 8 inches asunder, there being four rows in each bed. The bulbs should be sunk about 3 or 4 inches deep, with a small quantity of clean sand placed below and around each of them. The beds should be covered with decayed tan-bark, or half-rotten dung litter, and in severe weather may be covered with mats supported on hoops, which may be continued at night when the plants have grown up, but they should have full exposure to daylight. As the flower-stems appear, they are tied to little rods to preserve them from accident. If the bulbs are at all prized, the stems should be broken off as soon as the flowering is over, so as not to exhaust the bulbs; the leaves, however, must be allowed to grow on till matured, but as soon as they assume a yellow colour, the bulbs may be taken up, the leaves cut off near their base, and the bulbs laid out in a dry airy shady place to ripen, after which they are cleaned of loose earth and skin, ready for storing. It is the practice in Holland, about a month after the bloom, or when the tips of the leaves assume a withered appearance, to take up the bulbs, and to lay them sideways on the ground, covering them with an inch or two of earth. About three weeks later they are again taken up and cleaned. In the store-room the roots should be kept dry, well-aired, and apart from each other.

Few plants are better adapted than the hyacinth for pot culture as greenhouse decorative plants; and by the aid of forcing they may be had in bloom as early as Christmas. They flower fairly well in 5-inch pots, the stronger bulbs in 6-inch pots. To bloom at Christmas, they should be potted early in September, in a compost resembling that already recommended for the open-air beds; and, to keep up a succession of bloom, others should be potted at intervals of a few weeks till the middle or end of November. The bulbs should be planted about level with the soil, and if a little sand is put immediately around them so much the better. The pots should be set in an open place on a dry hard bed of ashes, and be covered over to a depth of 6 or 8 inches with the same material; and when the roots are well developed, which will take from six to eight weeks, they may be removed to a frame, and gradually exposed to light, and then placed in a forcing pit in a heat of from 60° to 70°. When the flowers are fairly open, they may be removed to the greenhouse or conservatory.

The hyacinth may be very successfully grown in glasses for ornament in dwelling houses. The glasses are filled to the neck with rain water, a few lumps of charcoal being dropped into them. The bulbs are placed in the hollow provided for them, so that their base just touches the water. This may be done in September or October. They are then set in a dark cupboard for a few weeks till roots are freely produced, and then gradually exposed to light.

There are both single and double-flowered varieties, but the single are generally preferred, as the bells are arranged more closely, so that they form a better spike than the doubles. A few good sorts are named below:—

Reds.—Of singles—Cavaignac, Lina, Macaulay, Norma, Sultan's Favourite, Von Schiller, Vuurbaak, Josephine, Fabiola, Robert Steiger, Madame Hodgson, Emmeline. Of doubles—Lord Wellington, Waterloo, Milton.

Blues.—Of singles—Argus, Charles Dickens, Grand Lilas, Haydn, Lord Palmerston, Orondates, Baron von Tuyll, Bleu Morant, Leonidas, General Havelock, Feruck Khan, Von Humboldt; the last three very dark. Of doubles—Laurens Koster, Van Speyk, Bloksberg.

Whites.—Of singles—Grand Vainqueur, Mont Blanc, Queen of the Netherlands, Grand Vedette, Madame Van der Hoop, La Franchise, La Grandesse, Elfrida (blush), Grandeur à Merveille (blush), alba maxima, Mirandoline, Queen Victoria. Of doubles—La Tour d'Auvergne, Prince of Waterloo, Jenny Lind.

Yellows.—Of singles—Ida, Bird of Paradise, Duc de Malakoff (striped with red). Of doubles—Jaune Suprême, Ophir d'Or, Crœsus.

To these may be added the early-flowering single white Roman hyacinth, a small-growing pure white variety, remarkable for its fragrance, and well adapted for forcing, as it can be had in bloom if required by November. For windows it grows well in the small glasses commonly used for crocuses; and for decorative purposes should be planted about five bulbs in a 5-inch pot, or in pans holding a dozen each. If grown for cut flowers it can be planted thickly in boxes of any convenient size.

57. The *Iris* family includes a large number of kinds of various habit and character, all of them being plants of exceeding beauty, and remarkable for their brilliant colours, and for having the three outer segments of their flowers reflexed. There are two well-distinguished groups called the bulbous and the rhizomatous. The hardier bulbous irises, including the Spanish iris (I. Xiphium), and the English iris (I. xiphioides), require to be planted in thoroughly drained beds in very light open soil, moderately enriched, and should have a rather sheltered position. Both these present a long series of beautiful varieties of the most diverse colours, flowering in June and July, the smaller Spanish iris being the earlier of the two. There are many other smaller species of bulbous iris. Being liable to perish from excess of moisture, they should have a well-drained bed of good but porous soil made up for them, in some sunny spot, and in winter should be protected by a 6-inch covering of half-decayed leaves or fresh cocoa-fibre refuse. To this set belong I. persica, reticulata, filifolia, Histrio, juncea, and others. Iris.

The herbaceous perennial irises, known commonly as the flag irises, are for the most part of the easiest culture; they grow in any good free garden soil, the smaller and more delicate species only needing the aid of turfy ingredients, either peaty or loamy, to keep it light and open in texture. The earliest to bloom are the forms of Iris pumila, which blossom during March, April, and May, and are quite dwarf in habit. I. susiana and I. iberica, with singularly mottled flowers, also dwarf in habit, bloom in April and May; and during the latter month and the following one most of the larger species, such as I. germanica, florentina, pallida, variegata, amœna, flavescens, sambucina, neglecta, ruthenica, &c., produce their gorgeous flowers. Of many of the foregoing there are, besides the typical form, a considerable number of named garden varieties.

The beautiful Japanese Iris Kæmpferi is of comparatively modern introduction, and though of a distinct type is equally beautiful with the better known species. In their outer segments they are rather spreading than deflexed, forming an almost circular flower, which becomes quite so in some of the very remarkable duplex varieties, in which six of these broad segments are produced instead of three. Of this too there are numberless varieties cultivated under names. They require a sandy peat soil, on a cool moist subsoil.

Lily. 58. The *Lily* (Lilium) is a very popular family of hardy bulbous flowers, and one which takes a high position in public estimation. The species are very handsome, and some of them have long been grown. They are so numerous and varied that no general cultural instructions will be alike suitable to all. Some species, as L. Martagon, candidum, chalcedonicum, Szovitzianum, and others, will grow in almost any good garden soil, and succeed admirably in loam of a rather heavy character. L. chalcedonicum has an especial dislike to peat, which on the other hand suits the tiger lily (L. tigrinum) well, and is indispensable for the beautiful American L. superbum and canadense. The choice and more delicate species, such as the grand L. auratum, speciosum, and Krameri, which have come to us in recent times from Japan, the Californian L. Humboldtii, pardalinum, &c., and the splendid hybrid L. Parkmanni, are more particular as to soil, and require a deep bed of mixed turfy loam and peat, with plenty of sharp grit, and a cool moist bottom. The margin of rhododendron beds, where there are sheltered recesses amongst the plants, suit many of the more delicate species well, partial shade and shelter of some kind being essential. The bulbs should be planted about 6 inches below the surface, which should at once be mulched over with half-decayed leaves or cocoa-fibre to keep out frost.

Dr Wallace, who has paid much attention to the culture of these plants, remarks, in his *Notes on Lilies*, that—

"Lilies require, so far as their roots are concerned, a cool bottom, abundant moisture, and for most kinds a free drainage." He also recommends to "plant deeply, say 6 to 8 inches, so that the roots may easily get into a moist subsoil, and be sheltered from the scorching drying influence of the sun's rays, to plant early in the autumn, so that the roots may be at work all the winter, and to plant in a cool shady border, not exhausted by the roots of trees, where the roots may always obtain moisture, and yet not be saturated."

The noble L. auratum, with its large white flowers, having a yellow band and numerous red or purple spots, is a magnificent plant when grown to perfection; and so are the varieties called rubro-vittatum and cruentum, which have the central band crimson instead of yellow. Of L. speciosum, also Japanese, the true typical form and the red-spotted and white varieties are grand plants for late summer blooming in the conservatory. The tiger lily, L. tigrinum, and its varieties Fortunei, splendidum, and flore-pleno, are amongst the best species for the flower garden, L. Thunbergianum and its many varieties being also good border flowers. The pretty L. Leichtlinii and colchicum, with drooping yellow flowers, and the scarlet drooping-flowered L. tenuifolium make up, with those already mentioned, a series of the finest hardy flowers of the summer garden. The Indian L. giganteum is perfectly distinct in character, having broad heart-shaped leaves, and a noble stem 10 feet high, bearing a dozen or more large deflexed, funnel-shaped, white, purple-stained flowers; and the Chinese L. cordifolium is similar in character, but dwarfer in habit.

For pot culture, the soil should consist of three parts turfy loam to one of leaf-mould and thoroughly rotted manure, adding enough pure grit to keep the mass porous. If leaf-mould is not at hand, turfy peat may be substituted for it. The plants should be potted in October. The pots should be plunged in a cold frame and protected from frost, and about May may be removed to a sheltered and moderately shady place out-doors to remain till they flower, when they may be removed to the greenhouse. This treatment suits the gorgeous L. auratum, the splendid varieties of L. speciosum, and also the chaste-flowering trumpet-tubed L. longiflorum and its varieties.

Lobelia. 59. The *Lobelia* is familiar in gardens under two very different forms, that of the dwarf-tufted plants used for summer bedding, and that of the tall showy perennials. Of the former the best type is L. Erinus, growing from 4 to 6 inches high, with many slender stems, bearing through a long period a profusion of small but bright blue two-lipped flowers. That which is called speciosa offers the best strain of the dwarf lobelias, but the actual varieties are being constantly superseded by new sorts. A good variety will reproduce itself sufficiently true from seed for ordinary flower borders, but for formal bedding arrangements it is necessary to secure exact uniformity by propagating from cuttings.

The herbaceous lobelias, of which L. fulgens may be taken as the type, may be called hardy except in so far as they suffer from damp in winter; they throw up a series of short rosette-like suckers round the base of the old flowering stem, and these sometimes, despite all the care taken of them, rot off during winter. The roots should either be taken up in autumn, and planted closely side by side in boxes of dry coal ashes, these being set for the time they are dormant either in a cold frame or in any airy place in the greenhouse; or they may be left in the ground, in which case a brick or two should be put beside the plants, some coal ashes being first placed round them, and slates to protect the plants being laid over the bricks, one end resting on the earth beyond. About February they should be placed in a warm pit, and after a few days shaken out and the suckers parted, and potted singly into small pots of light rich earth. After being kept in the forcing pit until well established, they should be moved to a more airy greenhouse pit, and eventually to a cold frame preparatory to planting out. They should have a loamy soil, well enriched with manure; they require copious waterings when they start into free growth. These tall-growing lobelias make good pot plants, for which purpose the suckers should be parted and the strong ones only potted singly in autumn; they should be placed in a warm pit to induce them to root freely, transferred when well established to an airy greenhouse shelf, and shifted on frequently during spring till they occupy pots a foot in diameter. The soil should be a very rich loam, top-dressing being given when they are coming into flower, and a very free supply of water is essential. They may be raised from seeds, which, being very fine, require to be sown carefully; but they do not flower usually till the second year except they are sown very early in heat. A few good sorts are—Carminata, Distinction, Excellent, Peach-blossom, Ruby, and Victoria Regina.

60. The *Narcissus* is a garden flower of great beauty and considerable variety of form. The species are all bulbous plants of low stature, and are with few exceptions perfectly hardy. There are five well-marked sections. Narcissus.

The Hoop-petticoat Narcissi, sometimes separated as the genus *Corbularia*, are not more than from 3 to 6 inches in height, and possess grassy foliage and yellow or white flowers. These have the coronet in the centre of the flower very large in proportion to the other parts, and much expanded, like the old hooped petticoats. The common hoop-petticoat, N. Bulbocodium, has comparatively large bright yellow flowers; N. tenuifolius is smaller and somewhat paler; N. citrinus is paler and larger; while N. monophyllus is white. The small bulbs should be taken up in autumn and replanted in January or February, according to the state of the season. They bloom about March or April. The soil should be free and open, so that water may pass off readily.

A second group is that of the Pseudo-Narcissi, constituting the genus *Ajax* of some botanists, of which the daffodil, N. Pseudo-Narcissus, is the type. In this the corona is also very large and prominent, but is more elongated and trumpet-shaped. Of this group the most striking species perhaps is N. bicolor, which has the perianth almost white, and the coronet deep yellow; it yields two fine varieties, Horsfieldii and Empress. N. cernuus (moschatus) and N. cernuus plenus are double and single forms of a cream-coloured species of great beauty; and besides these there are N. lobularis, nobilis, obvallaris, Telamonius, maximus, and others, amongst the most stately of the species, besides N. minor and minimus, which are miniature repetitions of the daffodil. All these grow well in good garden soil, and blossom from March onwards, coming in very early in genial seasons.

Another group, the Mock Narcissi, with coronets of medium size, includes the fine varieties of N. incomparabilis, one of which is known as butter-and-eggs, N. poculiformis (montanus), N. odorus and odorus minor (Queen Ann's jonquil), N. juncifolius, and others. The hardier forms of this set thrive in the open border, but the smaller sorts, like Queen Ann's jonquil, are better taken up in autumn, and replanted in February; they bloom freely about April or May.

The Polyanthus Narcissi form another well-marked group, whose peculiarity of producing many flowers on the stem is indicated by the name. In these the corona is small and shallow as compared with the perianth. Some of the hardier forms, as N. Tazetta itself, the type of the group, succeed in the open borders in light well-drained soil, but the bulbs should be deeply planted, not less than 6 or 8 inches below the surface, to escape risk of injury from frost. Many varieties of this form of narcissus are grown. They admit of being forced into early bloom, like the hyacinth and tulip. They vary with a white creamy or yellow perianth, and a yellow, lemon, primrose, or white cup or coronet; and, being richly fragrant, they are general favourites amongst spring flowers. The jonquils, noticed above, as well as the double white narcissus, are also grown in pots for early flowering; and the polyanthus narcissi are sometimes used for bedding out in the spring garden. The following varieties are good:—Bazelman major, Gloriosa, Sir Isaac Newton, white with yellow cup; Grand Monarque and White Pearl, white with pale yellow cup; Paper White, pure white, early; Bathurst, Perle d'Amour, and Sulphurine, yellow with yellow or orange cup; and Grand Primo, a very fine yellow. These are planted or potted about October, and treated in the same way as the hyacinth.

There remains another little group, the Pheasant's-eye Narcissi (N. poeticus), in which the perianth is large, spreading, and conspicuous, and the coronet or cup very small and shallow. These pheasant's-eye narcissi, of which there are several species or well-marked varieties, as N. radiiflorus, poetarum, recurvus, &c., blossom in succession during April and May, and all do well in the open borders as permanent hardy bulbs. N. biflorus, the primrose peerless, a two-flowered whitish yellow-cupped species, is equally hardy and easy of culture; N. gracilis is yellow-flowered and blooms later, as does the yellow-flowered N. Jonquilla, better known as the jonquil, of which there are single and double flowered varieties, the latter species being a great favourite.

61. The *Pæony* is a remarkably showy plant, of which two very distinct types occur in gardens:—one the stout-growing herbaceous Pæony.

perennials, with fleshy tuberiform roots and annual stems, which have sprung mainly from Pæonia albiflora and P. officinalis; the other called the tree pæony, stiff growing plants with half-woody permanent stems, which have sprung from the Chinese P. Moutan.

The herbaceous pæonies usually grow from 2 to 3 feet in height, and have large much-divided leaves, and ample flowers of varied and attractive colours, and of a globular form in the double varieties which are those most prized in gardens. They blossom about the months of May and June as well as later in the summer, and as ornaments for large beds in pleasure grounds, and for the front parts of shrubberies, few flowers equal them in gorgeous effect. A good loamy soil—rather light than heavy—suits them best, and a moderate supply of manure is beneficial. They are impatient of frequent transplantings or repeated divisions for purposes of propagation, but when necessary they may be multiplied by this means, care being taken that a sound bud is attached to each portion of the tuberous roots.

The older varieties of P. albiflora include candida, festa, fragrans, Humei, Pottsii, Reevesii, rubescens, vestalis, Whitleyi, &c.; those of P. officinalis embrace albicans, anemoniflora, Baxteri, blanda, rosea, Sabini, &c. The garden varieties of modern times are, however, still more beautiful, the flowers being in many instances delicately tinted with more than one colour, such as buff with bronzy centre, carmine with yellowish centre, rose with orange centre, white tinted with rose, &c. We name a selection of a few of the light and dark coloured sorts, the former including tinted whites and yellows, and the latter crimsons, roses, pinks, &c.:—

Light-coloured Varieties:—Aurora, Boule de Neige, candida plena, carnea plena, Chamois, Cleopatra, delicata, festiva maxima, Impératrice Charlotte, Leonie, Madame Calot, Madame Vilmorin, magnifica, Marie Lemoine, Virginie.

Dark-coloured Varieties:—Ambroise Verschaffelt, atrosanguinea, Bossuet, Dr Bretonneau, Gloire de Douai, Jeanne d'Arc, Madame Furtado, Modeste-Guérin, Mons. de Villeneuve, Oberlin, Prince Troubetskoi, purpurea superba, Reine des Roses, Souvenir de l'Exposition Universelle, Surpasse Pottsii, Victoire d'Alma.

The Siberian P. tenuifolia, with finely-cut leaves, and crimson flowers, is a graceful border plant, and its double-flowered variety is perhaps the most elegant of its race.

The Moutans or Tree Pæonies are remarkable for their sub-shrubby habit, forming vigorous plants sometimes attaining a height of 6 to 8 feet, and producing in April or May magnificent flowers which vary in colour from white to lilac, purple, and rose. These are produced on the young shoots, which naturally bud forth early in the spring, and are in consequence liable, unless protected, to be cut off by spring frosts. They require to be thoroughly ripened in summer, and therefore a hot season and a dryish situation are desirable for their well-being; and they require perfect rest during winter. Small plants with a single stem, if well matured so as to ensure their blossoming, make very attractive plants when forced. They are increased by grafting in autumn on the roots of the herbaceous pæonies.

Of the older varieties the most conspicuous is papaverifolia, while the following are of more recent acquisition:—Atrosanguinea, globosa, lilacina, picta, Reevesiana, salmonea, and versicolor. Other garden varieties are—Gloria Belgarum, alba grandiflora, Emperor of China, lactea, ocellata, purpurea, atropurpurea, Rollissoni, violacea purpurea, violacea plena, unicolor purpurea, Beauty of Canton, Blanche de Noisette, Comte de Flandre, Elizabeth d'Italie, Hendersoni, Impératrice, Joséphine, Leopoldii, Madame Stuart Low, Mandarin, Professeur Morren, Robert Fortune, Triomphe de Gand, and Souvenir de Gand.

Pansy.

62. *The Pansy.*—This popular flower, also called heartsease, has sprung from the native British Viola tricolor, which has probably been crossed with some of the allied species of this large and varied genus. The modern varieties of the pansy consist in the main of three types:—the show varieties; the fancy varieties, obtained a few years ago from Belgium, and now very much improved; and the bedding varieties, which are free-blooming sorts marked rather by effectiveness of colour in the mass than by quality in the individual flower. The latter are extremely useful in spring flower gardening.

The pansy flourishes in well enriched garden soil, in an open but cool situation, a loamy soil being preferable. Cow dung is the best manure. The established sorts are increased by cuttings, whilst seeds are sown to procure novelties. The cuttings, which should consist by preference of the smaller growths from the centre of the plant, may be planted early in September, in sandy soil, under a hand light or in boxes under glass, and as soon as rooted should be removed to a fresh bed of fine sandy soil. The seeds may be sown in August or September. The bed may be prepared early in September, to be in readiness for planting, by being well manured with cow dung and trenched up to a depth of 2 feet. The plants should be planted in rows at about a foot apart. In spring they should be mulched with half-rotten manure, and the shoots as they lengthen should be pegged down into this enriched surface to induce the formation of new roots. If the blooms show signs of exhaustion by the inconstancy of their colour or marking, all the flowers should be picked off, and this top-dressing and pegging down process performed in a thorough manner, watering in dry weather, and keeping as cool as possible. Successional beds may be put in about February, the young plants being struck later, and wintered in cold frames. The fancy pansies require similar treatment, but are generally of a more vigorous constitution.

When grown in pots in a cold frame, about half a dozen shoots filling out a 6-inch pot, pansies are very handsome decorative objects. The cuttings should be struck early in August, and the plants shifted into their blooming pots by the middle of October; a rich open loamy compost is necessary to success, and they must be kept free of aphides. Both the potted plants and those grown in the open beds are benefited by the use of liquid manure.

The bedding pansies possess a dwarf compact free-branched habit of growth, which results in the production of a constant succession of flowers. They are a hardy race, flowering freely from the early spring onwards. These, with the varieties of Viola lutea and Viola cornuta, have latterly acquired great prominence from their utility in furnishing early flowers for the spring garden, and novelties are being rapidly produced.

63. *The Pentstemon.*—Many species of Pentstemon have been introduced to our gardens, and rank amongst the finest of all the herbaceous perennials. The pentstemon of the florist has, however, sprung from P. Hartwegii, a suffruticose species, which has been more or less hybridized with P. gentianoides, P. Cobæa, and possibly some others. The plants are not absolutely hardy, but endure English winters unharmed in favoured situations. They are freely multiplied by cuttings, selected from the young side shoots, planted early in September, and kept in a close cold frame or under a hand light till rooted. They should then be potted singly in small pots, and wintered in a cold frame, the pots being plunged in ashes or cocoa-nut refuse, in order to keep the soil from drying too rapidly, and to prevent the frost from injuring the young roots. To obtain strong plants, they should be shifted into 5-inch pots early in March, and kept growing in well-ventilated frames until May. They flower freely in July and August and onwards till cut down by frosts. Smaller plants may be had by leaving the cuttings in the cutting pot during the winter, and introducing them to the propagating pit in February or March, when their young shoots can be taken off, struck, potted, and grown on in frames till about May. Seedlings, if raised in heat in February or early in March, and pricked out and forwarded under glass till May, will flower the same year, but probably not so early as those raised from cuttings. Pentstemon.

The following are good kinds, and varied in colour and character, but new ones appear every season, and sometimes show a marked advance on the older sorts:—Andrew Hunter, Apollon, Countess of Eglinton, Bon Villageois, Col. Long, The Bride, Dr St Paul, John F. Kinghorn, John M'Pherson, Lady Coutts Lindsay, Molière, Mrs A. Sturry, W. P. Laird, Le Khédive, Black Knight, Stanstead Rival, Souvenir de St Paul, Georges Sand.

64. The *Phlox*, with its modern improvements, constitutes one of the finest of hardy herbaceous plants. There are two types—the pyramidalis or early-flowering sorts, which appear to grow best in the northern districts, and the decussata or late-flowering sorts, which are taller and are those most frequently grown in English gardens. Phlox.

The early-flowering phloxes are increased by division of the root or by cuttings which may be obtained about the middle or end of March, and strike readily under a hand glass. They should be grown in beds, and will make good blooming plants for the following year. The older or blooming plants should be grown in beds of deep rich loamy soil, mulched with half-rotten dung as they come on towards flowering. They should have abundance of water in dry weather. It is not advisable to allow more than five stems to grow up to flower. The varieties of this section flower a month or six weeks earlier than those of the decussata group, and are at the height of their bloom in July.

A few good sorts are—Duchess of Athole, Lady Napier, Miss Robertson, Perfection, Waverley, Stella, Alexandra, Iona, Marquis, James Mitchell, Elvina, James Neilson, Miss Hunter, Bayard, Purple Emperor, Mauve Queen.

The late-flowering phloxes may be raised either from cuttings or by division. From cuttings in early spring vigorous young plants may be obtained which flower well the following season. By division of the older plants into separate rooted portions, plants are obtained which flower well the same year. The latter require a deeply trenched soil, thoroughly manured, and should be well watered in dry weather; indeed, as they grow up to bloom, manure water may be given judiciously with advantage.

A good selection of these are—A. F. Barron, Liervalli, Lothair, Roi des Roses, Lucien Tisserand, Madame la Comtesse de Turenne, Madame Domage, Menottii, Mons. H. Low, Coccinea, Mrs Laing, Rêve d'Or, Marie Saisson, Madame Thibaut, Madame Rœmpler, Gloire de Neuilly, J. K. Lord, La Candeur, Mons. Malet, Chanzy, Queen of Whites.

65. The *Pink* of the garden has resulted from the cultivation and improvement of Dianthus plumarius. The pink is a great favourite with florists, those varieties being preferred which have the margin of the petals entire, and which are well marked in the centre with bright crimson or dark purple. Its grassy but glaucous foliage is much like that of the carnation, but the whole plant is smaller, and the greater portion of the colouring of the flowers forms a blotch near the base of the petal, instead of being laid on in stripes as in the carnation, or confined to the outer edge as in the picotee. Pink.

Pinks require a free loamy soil deeply trenched, and well enriched with cow dung. They are readily increased by pipings (fig. 60, *d*), taken off during the flowering period, and planted in light soil under a hand light, or in the open ground in a shady situation; they may be planted an inch apart in rows 2 or 3 inches asunder, and should be pressed firmly into the soil. When rooted, which will be about August, they should be planted 4 inches apart in a nursery bed, where they may remain till the latter part of September or the early part of October. The chief attention required during winter is to press them down firmly should they become lifted by frosts, and in spring the ground should be frequently stirred and kept free from weeds. As the flowering stems grow up they should be supported by sticks, and when the buds appear they should be assisted to burst regularly by tying a soft ligature round them. The pink is also raised from seeds, not only to obtain new varieties, but to keep up a race of vigorous growing sorts. The seeds may be sown in March or April, in pots in a warm frame, and the young plants may be pricked off into boxes and sheltered in a cold frame. They should be planted out in the early part of the summer in nursery beds, in which, if they have space, they may remain to flower, or the alternate ones may be transplanted to a blooming bed in September or the early part of October; in either case they will bloom the following summer. These will grow in any good garden soil, but the richer it is the better.

There is also a number of varieties which are useful for forcing during the early spring months. These are propagated from early pipings, and grown in nursery beds, being taken up in October, and potted in a rich loamy compost, and wintered in a cold pit till required for the forcing house. The varieties named Anne Boleyn, Lady Blanch, Lord Lyons, Mrs Pettifer, and Coccinea are good useful forcing sorts.

Of choice florists' varieties the number is not very large. The following would form a good selection:—Turner's Boiard, Dr Masters, Dr Maclean, Shirley Hibberd, Lord Kirkaldy, Godfrey, and Bertram; Maclean's Annie, Beauty, John Ball, and New Criterion; Marris's Excelsior and Vesta; Kirtland's Rev. G. Jeans; Bragg's Nonpareil and Goliath; and Hooper's Beauty of Bath.

P-
nthus. 66. The *Polyanthus* is one of the oldest of the florists' flowers, and is no doubt an umbellate form of the primrose, Primula vulgaris. For some time it has been held in low repute, but is now coming into greater favour, and novelties are being slowly produced. The florists' polyanthus has a golden margin, and is known as the gold laced polyanthus, the properties being very distinctly laid down and rigidly adhered to. The chief of these are—a clear unshaded blackish or reddish ground colour, an even margin or lacing of yellow extending round each segment and cutting through its centre down to the ground colour, and a yellow band surrounding the tube of exactly the same hue as the yellow of the lacing. The plants are quite hardy, and grow best in strong loamy soil, tolerably well enriched with dung and leaf-mould; they should be planted about October. Plants for exhibition present a much better appearance if kept during winter in a cold well-aired frame. Of these, Cheshire Favourite, Earl of Lincoln, and Criterion, with black grounds, and Exile, Lancer, and Sunrise, with red grounds, are amongst the best.

For the flower borders what are called fancy polyanthuses are adopted. These are best raised annually from seed, the young crop each year blooming in succession. The seed should be sown as soon as ripe, the young plants being allowed to stand through the winter in the seed bed. In April or May they are planted out in a bed of rich garden soil, and they will bloom abundantly the following spring. A few of the better thrum-eyed sorts should be allowed to ripen seed; the rest may be thrown away.

Pon-
til 67. The *Potentilla*, as a specialty, is a flower of modern times. The double-flowered varieties are especially remarkable for their ornamental qualities. A soil of a good loamy staple, enriched with rotten dung, will grow the potentilla to perfection. They may be increased, though not very freely, by parting them into as many pieces as there are crowns, the side growths being those which can usually be thus separated. This may be done in autumn or spring, and the plants will generally bloom the following season. The plants like an open situation, and are well suited for filling a small or moderate-sized bed, as the foliage is of a neat and pleasing character when the plants are not in bloom.

The following are good named sorts:—Chromatella, Le Vésuve, Louis Van Houtte, Meteor, Pluton, Vulcan, Le Dante, Mars, Nigra, Caméléon, Fénelon, Etna.

Primrose. 68. The *Double Primrose* is closely allied to the polyanthus. There are some very handsome varieties grown, as the crimson, white, yellow, purple, blue, and others. These all succeed under the treatment given to the choicer kinds of polyanthus (par. 66).

Py-
thrum. 69. The *Pyrethrum* is quite a modern garden flower, extremely useful as blooming in the early summer months, and remarkable for its neat habit and the great variety of character and colour which it presents. The type forms are the P. roseum and P. carneum of botanists, hardy perennials, with finely cut leaves, and large flower-heads, having in the one case a ray of deep rose-coloured and in the other of flesh-coloured ligulate florets surrounding the centre or disk. They bloom during the months of May and June, as well as later on, and are always most welcome ornaments for the flower borders, and useful for cutting for decorative purposes.

The pyrethrum grows best in soil of a loamy texture; this should be well manured and deeply trenched up before planting, and should be mulched in the spring by a surface dressing of half-decayed manure. The plants may be increased by division, the side shoots being taken off early in autumn with a portion of roots attached. They may be placed either in separate beds or in the mixed flower border as may be required. In beds they can be supplemented as the season passes on by the intermixture of later-blooming subjects, such as gladioli. Slugs are often destructive to the young shoots. Seeds should be sown in spring in a cold frame, and the young plants should be put out into beds when large enough, and should flower the following May.

The following will make a useful selection of sorts:—Aurora, Bonamy, Boule de Neige, Brilliant, carminatum plenum, Charles Baltet, delicatum, Émile Lemoine, floribundum plenum, Gloire d'Italie, Hermann Stenger, Iveryanum, La Vestale, Le Dante, Madame Billiard, Minerva, Ne plus ultra, Prince of Wales, Solfaterre, Titiens.

70 The *Ranunculus* (R. asiaticus), a native of the Levant, is one of the older florists' flowers, which has sported into numberless varieties, but was formerly held in much greater esteem than it is at the present time. According to the canons of the florists, the flowers, to be perfect, should be of the form of two-thirds of a ball, the outline forming a perfect circle, with the centre close, the petals smooth-edged, the colour dense, and the marking uniform. Ranunculus.

The ranunculus requires a strong and moist soil, with a fourth of rotten dung. The soil should be from 18 inches to 2 feet deep, and at about 5 inches below the surface there should be placed a stratum 6 or 8 inches thick of two-year-old rotten cow dung, mixed with earth, the earth above this stratum, where the roots are to be placed, being perfectly free from fresh dung. The tubers are planted in rows 5 or 6 inches apart, and 3 or 4 inches separate in the rows, the turban sorts in October, the more choice varieties in February. They should be so close that the foliage may cover the surface of the bed. The autumn-planted roots must be sheltered from frost by old tan or sifted coal ashes. The plants when in flower should be covered with an awning; when the leaves wither, the roots are to be taken up, dried, and stored. The ranunculus is readily propagated from seed obtained from semi-double sorts, which are often of themselves very beautiful flowers. It is generally sown in boxes in autumn or spring. The young plants thus raised flower often in the second, and always in the third year.

The turban varieties, which are very showy for the borders, are of a few positive colours, as scarlet, yellow, brown, carmine, and white. The florists' varieties have been bred from the Persian type, which is more delicate.

The following sorts may be taken as the foundation of a collection:—Apollo, Eliza, Marquis of Hertford, Helena, Interestor, Sincerity, Garibaldi, Enchanter, Flaminius, Coronation, Strephon, Melanchthon.

71. The *Tulip* (Tulipa Gesneriana) is a native of the East, whence it was introduced into Europe about the middle of the 16th century. About the year 1635 its culture was very engrossing; and, indeed, the rage for possessing rare sorts had become so great in Holland as to give rise to a strange species of gambling, known to the collectors of literary and scientific anecdotes by the name of Tulipo-mania. At present, though not to be met with in every garden, the finer tulips have yet some ardent cultivators, while certain varieties, as the early Duc Van Thol and its allies, and the double tulips of the Tournesol type, are much used for general garden decoration, and for forcing. The latter, however, spring from other species of the genus. Tulip.

The florists' varieties of tulips, which have sprung from Tulipa Gesneriana, are arranged in separate classes named bizarres, byblœmens, and roses, according to their colour and marking. Tulips are readily raised from seeds, and the seedlings when they first flower are of one colour,—that is, they are self-coloured. Judged by the florists' rules, they are either good or bad in form, and pure or stained (white or yellow) at the base; the badly formed and stained flowers are thrown away, while the good and pure are grown on, these being known as "breeder" tulips. The breeder bulbs and their offsets may grow on for years producing only self-coloured flowers, but after a time, which is varied and indefinite, some of the progeny "break," that is, produce flowers with the variegation which is so much prized. The flower is then said to be "rectified"; it is a *bizarre* when it has a yellow ground marked with purple or red, a *byblœmen* when it has a white ground marked with violet or purple, or a *rose* when it has a white ground marked with rose colour. One of the most important of the properties of a fine florists' tulip is that the cup should form, when expanded, from half to a third of a hollow ball, the divisions of the perianth being six in number, broad at the ends, and smooth at the edges, so that the divisions may scarcely show an indenture. Another is that the ground colour should be clear and distinct, whether white or yellow. The least stain at the base of the flower, technically called the "bottom," would render a tulip comparatively valueless. What are called feathered flowers are those which have an even close feathering, forming an unbroken edging of colour all round, flamed flowers being those which have a beam or bold mark down the centre, not reaching to the bottom of the cup. Some flowers are both feathered and flamed, and in all cases the colour must be uniformly distributed.

Tulips are usually grown in beds, which should be made up, to the depth of about 2 feet, with a rich compost of about four parts loam to one of leaf-mould and one of thoroughly decomposed manure, which should have been well mixed some time before required for use. The bottom of the bed must be thoroughly drained, and so arranged that the water may not only soak down to the bottom, but find egress there. New soil is not required every year, but it should be deeply turned up and laid in ridges, and every third year it should be renewed to about a foot in depth, and the new soil well mixed with the old. The bed should be in an open but sheltered position, and should be got ready in September or early in October, the bulbs being planted in October or early in November, 6 inches apart, and 3 or 4 inches deep. The bed should be 4 feet wide—sufficient to take seven rows of bulbs, a little river sand being placed about each. An awning should be placed over the bed when the buds show colour, in order to lengthen the duration of the flowers, and removed when the flowers fade. After the flowers have fallen, the seed-vessels are broken off close by the stem, to prevent the plant from exhausting itself in perfecting seed, and to direct its energies to the forming of the new bulb, and when the leaves and stalks turn brown the bulbs are taken up and laid out for a few days in a cool airy place, when they should be stored in drawers till planting time, being occasionally examined in case any of them decay.

Tulips are readily propagated by offsets, which are taken off from the parent bulbs, and nursed in separate beds till they be full grown. New varieties are raised from seed, and are from five to seven years old before they flower.

The following are a good selection of show tulips:—

Bizarres.—Feathered: Demosthenes, Sir Joseph Paxton, Garibaldi, Commander, Sulphur, George Hayward. *Flamed*: Excelsior, Dr Hardy, Surpass Polyphemus, Masterpiece, Ajax, William Lea.

Byblœmens.—Feathered: William Bentley, Friar Tuck, David Jackson, Dessie, Mrs Cooper, Talisman. *Flamed*: Duchess of Sutherland, Nimbus, Talisman, Bacchus, Adonis, Carbuncle.

Roses.—Feathered: Charmer, Industry, Nanny Gibson, Lady Wilton, Mrs Lea, Madame St Arnaud. *Flamed*: Annie Macgregor, Lady Sefton, Mrs Barlow, Sarah Headly, Adair, Triomphe Royale.

For decorative purposes, as forcing and spring bedding, the following are some of the best sorts grown:—

Singles.—Canary Bird, Couleur Cardinal, Couronne Pourpre, Duc Van Thol, Duchesse de Parma, Keizerskroon, Proserpine, Roi Pépin, Bride of Haarlem, Pottebakker, White Pottebakker, Thomas Moore, Vermillon Brillant, Yellow Prince.

Doubles.—Couronne des Roses, Duke of York, Gloria Solis, Imperator Rubrorum, Mariage de ma Fille, Overwinnar, Rex Rubrorum, Tournesol, Yellow Tournesol, La Candeur.

Hardy trees and shrubs. 72. HARDY TREES AND SHRUBS.—Much of the beauty of the pleasure garden depends upon the proper selection and disposition of ornamental trees and shrubs. It is to be regretted that this department of the garden is often greatly neglected, and the many ornamental subjects introduced during the last half century are too frequently overlooked by planters and garden artistes. We can only afford space here for lists of some of the better and more useful and ornamental trees and shrubs, old and new, supplemented by a brief notice of the rhododendron and its congeners, and of the rose.

The following list, which is not exhaustive, furnishes material from which a selection may be made to suit various soils and situations. The shrubs marked * are climbers.

Hardy Deciduous Trees.

Acer—Maple.
Æsculus—Horse-Chestnut.
Ailantus—Tree of Heaven.
Alnus—Alder.
Amygdalus—Almond.
Betula—Birch.
Carpinus—Hornbeam.
Carya—Hickory.
Castanea—Chestnut.
Catalpa.
Celtis—Nettle Tree.
Cerasus—Cherry.
Cercis—Judas Tree.
Cotoneaster.
Cratægus—Thorn.
Diospyrus.
Fagus—Beech.
Fraxinus—Ash.
Ginkgo—Maidenhair Tree.
Gleditschia—Honey Locust.
Gymnocladus—Kentucky Coffee Tree.
Juglans—Walnut.
Kölreuteria.
Laburnum.
Larix—Larch.
Liriodendron—Tulip.
Magnolia.
Morus—Mulberry.
Negundo—Box-Elder.
Ostrya—Hop Hornbeam.
Paulownia.
Planera.
Platanus—Plane.
Populus—Poplar.
Ptelea—Hop Tree.
Pyrus—Pear, &c.
Quercus—Oak.
Rhus—Sumach.
Robinia—Locust Tree.
Salix—Willow.
Sophora.
Taxodium—Deciduous Cypress.
Tilia—Lime.
Ulmus—Elm.
Virgilia.
Xanthoceras.

Hardy Evergreen Trees.

Abies—Silver Fir.
Araucaria—Chili Pine.
Arbutus—Strawberry Tree.
Biota—Arbor Vitæ.
Buxus—Box.
Cedrus—Cedar.
Cephalotaxus.
Cryptomeria—Japan Cedar.
Cupressus—Cypress.
Ilex—Holly.
Juniperus—Juniper.
Laurus—Bay Laurel.
Libocedrus.
Magnolia.
Picea—Spruce Fir.
Pinus—Pine.
Quercus—Oak.
Retinospora.
Sciadopitys—Umbrella Pine.
Sequoia (Wellingtonia).
Taxus—Yew.
Thuiopsis.
Thuya—Arbor Vitæ.
Tsuga.

Hardy Deciduous Shrubs.

Abelia.
Acer—Maple.
Æsculus—Horse-Chestnut.
Amelanchier.
Ampelopsis.*
Amygdalopsis.
Aralia.
Aristolochia.*
Berberis—Berberry.
Bignonia*—Trumpet Flower.
Calophaca.
Calycanthus—Carolina Allspice.
Caragana.
Cerasus—Cherry.
Chimonanthus.
Clematis.*
Colutea—Bladder Senna.
Cornus—Dogwood.
Cotoneaster.
Cratægus—Thorn.
Cydonia—Japan Quince.
Cytisus—Broom, &c.
Daphne.
Deutzia.
Edwardsia.
Elæagnus.
Euonymus—Spindle Tree.
Forsythia.*
Fremontia.
Genista.
Halesia—Snowdrop Tree.
Hamamelis—Wych Hazel.
Hibiscus—Althæa frutex, &c.
Hippophae—Sea Buckthorn.
Hypericum—St John's Wort.
Jasminum*—Jasmine.
Kerria.
Laurus—Laurel.
Ligustrum—Privet.
Lonicera*—Honeysuckle
Lycium.*
Magnolia.
Menispermum*—Moonseed.
Periploca.*
Philadelphus—Mock Orange.
Rhus—Wig Tree, &c.
Ribes—Flowering Currant.
Robinia—Rose Acacia, &c.
Rosa—Rose.
Rubus*—Bramble.
Spartium—Spanish Broom.
Spiræa.
Staphylæa—Bladder-Nut.
Symphoricarpus—Snowberry.
Syringa—Lilac.
Tamarix—Tamarisk.
Viburnum—Guelders Rose, &c.
Vitis—Vine.
Weigela.

Hardy Evergreen Shrubs.

Akebia.*
Arbutus.
Aucuba—Japan Laurel.
Azara.
Bambusa—Bamboo.
Berberidopsis.*
Berberis—Berberry.
Buddleia.
Bupleurum.
Buxus—Box.
Ceanothus.
Cerasus—Cherry-Laurel, &c.
Cistus—Sun-Rose.
Cotoneaster.
Cratægus—Thorn.
Daphne.
Desfontainea.
Erica—Heath.
Escallonia.
Euonymus.
Fabiana.
Fatsia (Aralia).
Garrya.
Griselinia.
Hedera*—Ivy.
Hypericum—St John's Wort.
Ilex—Holly.
Jasminum*—Jasmine.
Kadsura.*
Lardizabala.*
Laurus—Sweet Bay.
Ligustrum—Privet.
Lonicera*—Honeysuckle.
Magnolia.
Osmanthus.
Pernettya.
Phillyrea.
Photinia.
Retinospora.*
Rhamnus—Alaternus.
Rhododendron—Rose-Bay.
Rosa*—Rose.
Ruscus.
Skimmia.
Smilax.*
Stauntonia.*
Ulex—Furze.
Viburnum—Laurustinus.
Vinca—Periwinkle.
Yucca—Adam's Needle.

73. *The Rhododendron.*—In places where the soil is suitable, the rhododendron, on account of its flowering qualities, is fast taking the place of the laurel in the mixed shrubbery. This plant, with its associates the azalea, kalmia, andromeda, and the like, requires, generally speaking, a peaty soil, and a cool, rather moist situation; but, though a peaty soil is preferable, especially for the choice kinds, it is not essential. When, however, the soil is loamy, it must have incorporated with it a liberal portion of leaf-mould and decayed manure, cow dung being preferable, and, if at all heavy, some clean road grit. The plants do not thrive in soil which contains calcareous matter. Rhododendron.

These subjects, in view of the source of most of the originals, are commonly called American plants; and a separate plot (called the American garden) is often set apart for them. For such a plot the catawbiense type of rhododendron is preferable, being hardier, producing better foliage, and comprising many of the finest flowering sorts. Such varieties as Sir Thomas Sebright, Old Port, Mrs Heneage, Michael Waterer, H. W. Sargent, Alexander Dancer, Brayanum, Scipio, Everestianum, Minnie, Mrs John Clutton, J. Marshall Brooks, Sigismund Rucker, Mrs Milner, and fastuosum flore-pleno, may be counted on as sterling sorts, which will always give satisfaction. The varieties of *Azalea*, though deciduous in habit, are desirable on account of their brilliant and effective colours, and with them may be associated such subjects as Andromeda, Cassandra, Leucothoe, Dabeocia, Daphne Cneorum, the hardy Heaths, Gaultheria, Kalmia, Ledum, Pernettya, Rhodora, Vaccinium, and Zenobia.

74. *The Rose.*—The rose is so universal a favourite that some portion of the garden must necessarily be devoted to it, if the situation be at all favourable. Roses will not, however, thrive in the vicinity of large towns, since they require a pure air, and do not endure a smoky atmosphere. The best soil for them is a deep rich strong loam free from stagnant moisture. Very light sandy or gravelly soils, or soils which are clayey and badly drained, are not suitable, and both must be greatly improved if rose-growing on them is attempted. Light soils would be improved by a dressing of strong loam in conjunction with cow dung or nightsoil; the latter, provided it is properly prepared and not too fresh, is indeed the very best manure for roses in all but soils which are naturally very rich. Heavy soils are improved by adding burned earth or gritty refuse, with stable manure and leaf-mould or cocoa-fibre refuse; and damp soils must necessarily be Rose.

drained. Roses require a constant annual supply of manure, and, if this is given as a mulching in autumn, it serves to protect their roots through the winter. They also require liberal supplies of water during the growing season, and especially to be kept clear of aphides and other insect pests, which may be done by dusting them with snuff while moist, and washing it off with the syringe next day, or by syringing with dilute tobacco water or some of the many insecticides now provided to facilitate this rather troublesome task.

Some growers prefer roses grown on their own roots, some on the Manetti, and others on the brier stock. There is this to be said in favour of their own roots that, if the tops are killed down by accident or by severe weather, the roots will usually throw up new shoots true to their kind, which cannot be looked for if they are worked, though it is sometimes recommended to plant deep in order that the rose itself may learn to do without its foster parent the stock. Too often, however, in the case of persons unfamiliar with roses, the choice rose dies, and the stock usurps its place.

An open situation, not shaded, but sheltered from strong winds, is what the rose prefers. October and November are the best months for planting the hardy kinds. The tender varieties are better laid in in a sheltered place, and the planting deferred till March or April. In regard to pruning, roses vary considerably, some requiring close cutting and others only thinning out; some again may be safely pruned in autumn, and others are better left till spring. Instructions on this point as to the several groups of varieties will be found in most rose catalogues.

Where dwarf beds of roses are required, a good plan is to peg down to within about 6 inches from the ground the strong one year old shoots from the root. In due time blooming shoots break out from nearly every eye, and masses of flowers are secured, while strong young shoots are thrown up from the centre, the plant being on its own roots. Before winter sets in the old shoots which have thus flowered and exhausted themselves are cut away, and three or four or more of the strongest and best ripened young shoots are reserved for pegging down the following season, which should be done about February. In the meantime, after the pruning has been effected, plenty of good manure should have been dug in about the roots. Thus treated, the plants never fail to produce plenty of strong wood for pegging down each succeeding season.

ding lts. 75. BEDDING PLANTS.—This term is chiefly applied to those summer-flowering plants, such as pelargoniums, petunias, dwarf lobelias, verbenas, &c., which are employed in masses for filling the beds of a geometrical parterre. Of late years, however, more attention has been bestowed on arrangements of brilliant flowering plants with those of fine foliage, and the massing also of hardy early-blooming plants in parterre fashion has been very greatly extended. Bedding plants thrive best in maiden soil, and therefore the beds should be occasionally wholly or partly renovated with fresh earth. A light loam, liberally manured with thoroughly rotten dung from an old hotbed or thoroughly decomposed cow droppings and leaf-mould, forms the best kind of compost, but in the case of free-growing plants, like pelargoniums, over-richness must be avoided.

76. *Spring Bedding.*—For this description of bedding, hardy plants only must be used; but even then the choice is tolerably extensive. For example, there are the Alyssums, of which A. saxatile and A. gemonense are in cultivation; Antennaria tomentosa; Arabis albida; Aubrietias, of which the best sorts are A. Campbelliæ and A. grandiflora; the double Bellis perennis or Daisy; the Wallflowers, including Cheiranthus Cheiri (the Common Wallflower), C. alpina, and C. Marshallii; Hepaticas, the principal of which are the varieties of H. triloba, and the blue H. angulosa; Iberis or Candytuft; Lithospermum fruticosum; Myosotis or Forget-me-not, including M. alpestris, M. dissitiflora, M. azorica, and M. sylvestris; Phloxes, like P. subulata, with its varieties setacea, Nelsoni, nivalis; the single-flowered varieties of the Primrose, Primula vulgaris; Pyrethrum Parthenium aureum, called Golden Feather; Sempervivum calcareum; the pink-flowered Silene pendula; self-coloured varieties of the Pansy, V. tricolor, and of V. lutea and V. cornuta, as well as some recent hybrids. Besides these there are the various spring-flowering bulbs, such as the varieties of Hyacinthus, Tulipa, Narcissus, Fritillaria, Muscari or Grape Hyacinth, Crocus, Scilla, and Galanthus or Snowdrop.

77. *Summer Bedding.*—There is great variety amongst the plants which are used for bedding out in the garden during the summer months, but we can note only some of the most important of them. Amongst them are the Ageratums, the old tall-growing sorts of which have been superseded by dwarfer varieties, as Imperial Dwarf and Swanley Blue; Alternantheras, the principal of which are A. amœna, amœna spectabilis, magnifica, paronychioides major aurea, and amabilis; Alyssum maritimum variegatum; some of the named varieties of Antirrhinum majus, especially the dwarf varieties; Arundo Donax variegata; Begonias; Calceolarias; Cannas; Centaurea ragusina; Clematises, of which the hybrids of the Jackmanni type are best; Dahlia variabilis, and the single-flowered forms of D. coccinea; Echeverias, of which E. secunda and E. metallica are much employed; Gazanias; Heliotropium peruvianum; Iresine; the Lantanas; Lobelias; Mesembryanthemum cordifolium variegatum; Pelargoniums, of which the various classes of zonal or bedding varieties are unapproachable for effect and general utility; Petunias; Phloxes; Polemonium cœruleum variegatum; Pyrethrum Parthenium aureum, especially useful as an edging to define the outline of beds upon grass; Tropæolums, especially some of the varieties of T. Lobbianum; and Verbenas, the offspring of Tweedieana, chamædrifolia, and others. Few bulbs come into the summer flower gardens, but amongst those which should always be well represented are the Gladiolus, the Lilium, and the Tigridia.

78. *Subtropical Bedding.*—A few years ago the late Mr John Gibson, then superintendent of Battersea Park, introduced the style of planting known as subtropical gardening, from the use that is made of subtropical plants. In the climate of London and the south and west of England this new feature proved very successful, but less so in the north of England and in Scotland, except in very favoured localities. These subtropical materials may be used either in masses of one kind, or in groups arranged for contrast, or as the centres of groups of less imposing or of dwarfer-flowering subjects; or they may be planted as single specimens in appropriate open spaces, in recesses, or as distant striking objects terminating a vista. Some of the finest of these plants of bold and striking habit are found in the Aralia or Fatsia, the Wigandia, the Montagnæa, the Uhdea, and the Ferdinanda; Aralia japonica and papyrifera are very fine, and so are Wigandia caracasana and Vigieri, Montagnæa heracleifolia (also known as Polymnia grandis), Uhdea bipinnatifida, and Ferdinanda eminens. Many palms, some tree ferns, and the noble Musas, especially Musa Ensete, do fairly well in sheltered situations. The Cannas afford great variety of size, form, and colour. The different forms of Ricinus, which are of the bolder type of subjects, the more elegant Arundo Donax and its variegated variety, and the very graceful Arundo conspicua may also be named. Arundinaria falcata and other Bamboos, if grown in large pots or tubs and plunged in shady sheltered places during summer, give a striking tropical effect; and in warm situations some of these may be introduced as permanent plants. Of lesser subjects Centaurea ragusina and gymnocarpa, Erythrinas, Funkias, Gunnera scabra, and some of the Solanums, as S. marginatum and robustum, are all useful and effective; and many others might be added.

79. *Carpet Bedding* or *Mosaiculture* consists in covering the surface of a bed, or a series of beds forming a design, with close low-growing plants, in which certain figures are brought out by means of plants of a different habit or having different-coloured leaves. Sometimes, in addition to the carpet or ground colour, individual plants of larger size and handsome appearance are dotted symmetrically over the beds, an arrangement which is very telling. Some of the best plants for carpeting the surface of the beds are—Antennaria tomentosa, white; Sedum corsicum and glaucum, grey; and Sedum Lydium, Mentha Pulegium gibraltaricum, and Herniaria glabra, green. The Alternantheras, Amaranthuses, Iresines, and Coleuses furnish high and warm colours; while Pyrethrum Parthenium aureum yields greenish yellow; Mesembryanthemum cordifolium variegatum, creamy yellow; Centaureas and others, white; and the succulent Echeverias and Sempervivums, glaucous rosettes, which last add much to the general effect.

80. GREENHOUSE PLANTS.—These are plants requiring the shelter Green-of a glass house, provided with a moderate degree of heat, of which house 35° Fahr. may be taken as the minimum. The house should be plants. opened for ventilation in all mild weather in winter, and daily throughout the rest of the year.

The following is a select list of miscellaneous decorative plants in addition to special subjects which will be noticed separately:—

Abutilon Boule de Neige has pure white drooping bell-shaped flowers.

Acacias are remarkably profuse-flowering plants with yellow flowers. A. armata and A. Drummondii are flowering bushes; A. lophantha has ample fern-like leaves; A. Riceana has pale yellow flowers in early spring, and is well suited for training up rafters or pillars.

Adenandra fragrans produces highly fragrant pink star-shaped flowers in May and June.

Agapanthus is very ornamental and easily grown, A. umbellatus having a large umbel of pale blue flowers, and A. umbellatus albiflorus white flowers.

Aphelexis embraces various species of close-growing plants, half procumbent in habit, producing handsome purplish-crimson and rosy-pink everlasting flowers freely on the points of the shoots in May and June.

Aralias have large palmate leaves.

Araucaria excelsa has regularly spreading branches resembling gigantic ostrich feathers.

Begonias. The new tuberous-rooted hybrids are very showy, and continue to flower all through the summer and autumn.

Boronias are a fine group of hard-wooded shrubs, having chiefly pink flowers, which bloom profusely from the mature wood; the best examples of the family are B. pinnata, Drummondii, and serrulata.

Chorozemas are quick-growing slender-habited plants, with highly-coloured red and yellow pea-shaped flowers, produced in racemes from the axils of the leaves; C. varium, cordatum, and spectabile are fine and distinct.

Cordylines are stately plants, of which the principal are C. indivisa, with a noble crown of glaucous leaves marked by orange ribs, and C. australis with narrower leaves.

Cytisus racemosus is one of the best subjects for early spring blooming, of dense bushy habit, and bearing yellow flowers; C. Everestianus has flowers of a deep orange.

Daphne indica is unsurpassed for its perfume.

The Dasylirions have stout woody stems and large heads of narrow leaves.
Epacris is a winter-flowering genus, easily grown and free-blooming, the principal sorts being E. hyacinthiflora candidissima, hyacinthiflora carminata, miniata, and the pure white onosmaeflora flore-pleno nivalis.
Grevilleas are shrubs of slender habit, some having handsome flowers, while G. robusta and others almost rival the ferns in the elegance of their leaves.
Hydrangea Hortensia produces immense heads of bloom of a delicate pink, which continue long in flower, and may be changed to blue by the admixture of iron filings with the soil.
Imantophyllum miniatum is a grand plant, the umbels of pale flame-red flowers being produced at various seasons.
Kalosanthes consists of splendid flowering plants, which, however, rarely bloom well two years in succession.
Lachenalia pendula, luteola, and tricolor are exceedingly pretty dwarf bulbs, useful about April and May.
Lapageria rosea is one of the very finest greenhouse climbers in existence, and bears waxy bell-shaped red flowers, mottled with white; L. rosea alba is still more beautiful, a clear waxy white.
Lilium auratum, speciosum, and Krameri are fine, L. auratum being one of the noblest flowering plants in existence.
Mandevilla suaveolens, a strong-growing climber, bears beautiful, fragrant, trumpet-shaped white blossoms in August and September.
The Neriums are tall strong-growing subjects, with flowers of great beauty, produced in cymes from the points of the mature shoots.
The Passifloras produce their showy singularly-formed flowers most profusely, and are very suitable for decorating the roof of a conservatory.
Pimeleas are free-growing, compact-habited plants, producing flower-heads from the points of the shoots; P. spectabilis rosea has flower-heads, white flushed with rose, almost as large as those of a guelder-rose; P. Hendersoni has deep pink, P. hispida white, and P. elegans straw-coloured flowers.
Pleroma elegans is a free-flowering melastomaceous shrub, producing in succession its lovely saucer-shaped flowers of the most intense purple hue, from June to September.
Plumbago capensis is another abundant bloomer, and one of the very best of greenhouse climbers, with large bunches of delicate grey-blue flowers.
The Rhododendron furnishes a large contingent, of which the most suitable are Countess of Haddington, Dalhousie, Edgworthii, Gibsoni, Thompsoni, javanicum, with jasminiflorum and its beautiful varieties, Princess Royal, Princess Alexandra, Princess of Wales, and Duchess of Edinburgh.
Statices include some very highly ornamental plants, especially S. brassicæfolia, profusa, and imbricata.
Tacsonias are magnificent climbers; indeed, T. Van Volxemii is one of the very finest of the climbing plants which flower in autumn.
Trachelospermum jasminoides, better known as Rhynchospermum, very fragrant, and moderately vigorous, is suitable for a pillar, and produces white flowers in May and June.
Tropæolums are charming pot climbers, of which may be mentioned T. azureum, brachyceras, speciosum, tricolorum, and Jarrattii.
Vallota is a very choice evergreen bulb, V. purpurea producing highly-coloured scarlet flowers, in umbels, in August and September.

Agave. 81. *Agave.*—Bold-habited succulent plants, some of the larger of which are well adapted for conservatory decoration and prominent situations on terraces, &c. The American Aloe, Agave americana, with its varieties variegata and mediopicta, all require to be kept moderately dry and safe from frost during the winter, and grow well in strong loam, sand, and rotten manure. Among others of the larger varieties are A. potatorum and miradorensis, and of the smaller ones, A. filifera, applanata, Verschaffeltii, and schidigera. Still smaller dense-growing sorts are A. Richardii, horrida, Victoriæ Reginæ, and Bessereriana.

Aloe. 82. *Aloe.*—Succulent plants, extremely variable in character. They all thrive best in a sandy loam, well drained, and not over watered. The old Partridge-breast Aloe, A. variegata, is well adapted for a window; A. ferox, supralævis, and arborescens are tall plants; A. saponaria, mitræformis, albocincta, and lineata are smaller; A. serra, variegata, humilis, and serrulata are dwarf. The Fan Aloe, A. plicatilis, produces its flowers in winter. A group of dwarf showy-flowered aloes, often separated under the name of Gasteria, flower in early spring. The following are of a spiral habit of growth—G. spiralis, obliqua, undata, and carinata; while, of those of distichous growth, G. nigricans, lingua, verrucosa, and intermedia may be recommended. Besides these there are the Apieras and the Haworthias, all formerly known as aloes, which are very dwarf.

Azalea. 83. *Azalea.*—The beautiful varieties now in cultivation have been bred from a few originals, natives of the hilly regions of India and China. They are perhaps unequalled as indoor decorative plants. The Chinese species, A. vittata, will commence to open its blooms in September, and other sorts keep up a succession for several months, for some of the varieties may be forced into bloom during the winter, and others flower through the spring up to May and June. They are usually increased by grafting the half-ripened shoots on the stronger-growing kinds, the shoots of the stock and the grafts being in a similarly half-ripened condition, and the plants being placed in a moist heat of 65°. Large plants of inferior kinds, if healthy, may be grafted all over with the choicer sorts, so as to obtain a large specimen in a short time. They require a rich and fibrous peat soil, with a mixture of sand to prevent it getting water-logged. The best time to pot azaleas is three or four weeks after the blooming is over. The soil should be made quite solid to prevent its retaining too much water. To produce handsome plants, they must while young be stopped as required. Specimens that have got leggy may be cut back just before growth commences. The lowest temperature for them during the winter is about 35°, and during their season of growth from 55° to 65° at night, and 75° by day, the atmosphere being at the same time well charged with moisture. They are liable to the attacks of thrips and red spider, which do great mischief if not promptly destroyed.

84. *Calceolaria.*—Originally introduced under various specific forms from Chili and Peru, the calceolaria of the present day has been developed into a highly decorative plant, in which the herbaceous habit has preponderated. The plants are now very generally raised annually from seed, which is sown about the end of July in a mixture of loam, leaf-mould, and sand, and, being very small, must only be slightly covered. When the plants are large enough to handle they are pricked out an inch or two apart into 3-inch or 5-inch pots; when a little more advanced they are potted singly. They should be wintered in a greenhouse with a night temperature of about 40°, occupying a shelf near the light. By the end of February they should be moved into 8-inch or 10-inch pots, using a compost of three parts good turfy loam, one part leaf-mould, and one part thoroughly rotten manure, with a fair addition of sand. They need plenty of light and air, but must not be subjected to draughts. When the pots get well filled with roots, they must be liberally supplied with manure water. In the early stages of growth the plants are subject to the attacks of the green fly, for which they must be fumigated. Named varieties are not now grown, as a good strain of seed will yield satisfactory flowers. Calceolaria.

The shrubby calceolarias used for bedding are increased from cuttings, planted in autumn in cold frames, where they can be wintered, by the use of mats and a good layer of litter placed over the glass and round the sides as a protection from frost.

85. *Camellia.*—This favourite plant, a native of Japan, is deservedly popular, on account of its glossy foliage and magnificent flowers. It is usually propagated by cuttings, to furnish stocks on which the choicer kinds are grafted. It will succeed either in peat or loam or a mixture of both, but in any case an addition of turfy fibre and of sand is also necessary. The plants should have abundance of water, especially in the growing season, and should be potted as they complete their growth and are about to set their flowers; they do not, however, require repotting so often as most plants. Fire heat need only be employed when the object is to obtain flowers in the autumn and winter months. To produce them at this season it becomes necessary to start the plants into growth correspondingly early. When grown in cold houses, they do not generally flower until about February or March, at which stage the plants enjoy a temperature of 45° or 50°. When fire heat is applied to assist the opening of the flowers, it should not much exceed 55°, and whilst the plants are subjected to this heat the atmosphere must on no account be allowed to become dry, or the buds will probably drop. When making their growth they need an abundant supply of water at the roots, as well as copious syringings twice a day, but as terminal buds become visible they should be kept drier. Liquid manure is of great assistance to plants that have flowered very heavily, while they are making their growth, and the addition of a little soot imparts a dark-green colour to the leaves. If grown in an open-roofed light house, shade will be required during very bright weather whilst the young shoots are being developed, but if grown in a lean-to house facing the north, shade will not be required. It is sometimes necessary to move the plants out of the house after they have set their flowers, to keep them from coming on too rapidly. In this case they should have placed over them a light framework and movable screen. Camellia.

The scale is the most troublesome insect which attacks the camellia. To remove the white scale, the plants should be washed with a sponge and solution of soft soap as soon as their growth is completed, and again before the buds begin to swell. The brown scale may be got rid of by repeated washings with one of the many insecticides, such as Fowler's, but it should be applied at a temperature of 90°. See CAMELLIA, vol. iv. p. 737.

Some of the best varieties are—Alba plena (old double white), Bealii, Bonomiana, candidissima, Chandler's Elegans, Contessa Lavinia Maggi, Countess of Ellesmere, Donckelaari, eximia, fimbriata, Henri Favre, imbricata, imbricata alba, Jubilee, Madame Ambroise Verschaffelt, Mathotiana, Mathotiana alba, Princess Mary, reticulata flore-pleno, Saccoi nova, and Valtavaredo.

86. *Cinerarias* can be raised freely from seeds, and though there are named varieties in existence, a good strain of seed will yield flowers almost as fine. They must be kept, especially while young, free from aphides, to which they are more than ordinarily subject. For spring flowering the seeds may be sown in April or May in well-drained pots or pans, in soil of three parts loam to two parts leaf-mould, with one-sixth sand; cover the seed thinly with fine soil, and press the surface firm. When the seedlings are large enough to handle, prick them out in pans or pots of similar soil, and when more advanced pot them singly in 4-inch pots, using soil a trifle less sandy. They should be grown in shallow frames facing the north, and, if so situated that the sun shines upon the plants in the middle of the day, they must be slightly shaded; give plenty of air, and never allow them to get dry. When well established with roots, shift them into 6-inch pots, which should be liberally supplied with manure water as they get filled with roots. In winter they should be removed to a pit or house, where a little heat can be supplied whenever there is a risk of their getting frozen. They should stand on a moist bottom, but must not be subjected to cold draughts. When the flowering stems appear, give manure water at every alternate watering. Seeds sown in March, and grown on in this way, Cineraria.

will be in bloom by Christmas if kept in a temperature of from 40° to 45° at night, with a little more warmth in the day; and those sown in April and May will succeed them during the early spring months, the latter set of plants being subjected to a temperature of 38° or 40° during the night.

rea. 87. *Correa.*—This genus of Australian plants is extremely useful for winter flowering. The best of them is C. cardinalis, which affords a succession of tube-shaped crimson flowers during the whole of the winter. They are increased by cuttings, and grown in rough peaty soil, with a slight addition of loam and sand. After the plants have done flowering, they should all get a little artificial warmth, plenty of moisture, and a slight shade, while they are making their growth, during which period the tips of the young shoots should be nipped out when 6 or 8 inches long. When the growth is complete, a half-shady place outdoors during August and September will be suitable, with protection from parching winds and hot sunshine.

cla n. 88. *Cyclamen.*—Of late years this flower has been so much improved that no plant of moderate size can be made to contribute more floral display in winter. It is raised from seeds in various shades of colour, from the purest white to a deep purple. The seeds should be sown in October or November, in well-drained seed-pans, in an equal mixture of fine loam and leaf-mould with an addition of sand, the seeds slightly covered, and the pans placed near the light in a temperature of 50°. When the seedlings appear, they must be pricked out into 5-inch pots, six or eight in each, and wintered in a similar temperature and situation. In spring they must be potted singly in 3-inch pots, and thinly shaded during bright weather. When they have filled their pots with roots they should be repotted, using similar soil, into 4-inch pots, in which they are to flower. In potting, the corms or tuberous roots should not be more than half covered with the soil. A low house or pit is the best place in which to grow them, shading them if requisite, giving plenty of air, watering regularly, and syringing overhead in the afternoon to keep down thrips and red spider. The temperature should range from 45° to 50°, with plenty of air. They should flower in February and March. After blooming they should be placed in a pit where they can be shaded as required, and as they show signs of going to rest they should receive less water, but should not be allowed to get quite dry. In autumn they may be shifted into pots a size larger, and they will come into flower earlier than in the first year. It is not advisable to keep them after the third season. Some growers recommend after flowering to turn the plants out of their pots into a bed of prepared peat or leaf-soil in some half-shady spot, where they can be sprinkled overhead every afternoon during dry sunny weather, so as to encourage plenty of healthy foliage. In this case they should be lifted early in the autumn.

n. 89. *Erica.*—The species of heaths cultivated in English greenhouses are mostly South African, or have sprung from South African originals. They are of dense twiggy growth, with needle-shaped leaves, and beautiful wax-like flowers, which in some or other of the kinds are produced almost throughout the year. During the winter and early months E. caffra, gracilis, vernalis, hiemalis, melanthera, persoluta, rubens, Willmorei, Sindryana, and others produce their blossoms; later on bloom E. florida, affinis, Cavendishiana, exquisita, ventricosa and its many varieties, and the charming aristata; next come E. Savileana, Irbyana, Austiniana, Jacksoni, retorta major, and others, which last on till September, a few continuing till the end of the year. Heaths are propagated under bell-glasses by cuttings, which should be taken as soon in the spring as the wood is sufficiently firm, and planted in silver sand, the lower leaves having been removed; they should be kept in a temperature of 60°, and the glasses must be wiped occasionally to prevent the plants from damping off. When rooted they should be gradually inured to the air by the occasional removal of the glasses. In the spring following they should be potted singly into thumb pots, and kept close and moist until they take to the new soil. Heaths require peat soil, which for hard-wooded slow-growing kinds should be of a close hard texture, while for soft-wooded slow-growing sorts a mixture of two-thirds of hard peat with one of a softer nature, and for the soft-wooded quick-growing varieties equal quantities of hard and soft peat should be used, with silver sand according to the composition of the peat. The pots must always be well drained, and the plants must never be allowed to become pot-bound. The best season for potting is in March and April, or in September when the summer heats are over. The new soil must be made as firm as the old ball, so as to retain the water. A low span-roofed house, admitting abundance of light, is most suitable for these plants; and they require air in abundance, especially during the season of active growth. They have so great a dislike to fire heat that any degree of cold short of actual frost is preferable to it. When they have grown into specimen plants they should be set out of doors, from the latter part of July till the beginning of September, in order to enable them to resist the attacks of mildew. Water should never be given before the soil has got sufficiently dry to need it, nor should the plants be syringed overhead summer or winter. Especially is this the case with the hard-wooded kinds. See HEATH, vol. xi. p. 589.

Some of the best of the earlier flowering heaths are—E. affinis, aristata, Bergiana, Candolleana, Cavendishiana, Devoniana, florida, hiemalis, Lindleyana, Massoni major, mutabilis, propendens, Sindryana, tortiliflora, ventricosa and its varieties, Victoria, and Willmorei. The later ones are well represented by E. Austiniana, ampullacea and its varieties, Aitoniana Turnbullii, ferruginea superba, gemmifera elegans, Hartnelli, Irbyana, jasminiflora alba, Marnockiana, obbata, Parmentieriana rosea, Paxtoni, Savileana major, Spenceriana, Shannoni, tricolor and its varieties, and vestita and its varieties.

90. *Fuchsia.*—This well-known decorative soft-wooded plant comes from the temperate parts of South America, but has been improved by selection and hybridization. Fuchsias strike readily from cuttings, the most usual method being to place old plants in warmth about February, and as soon as they have pushed shoots a couple of inches or so in length, to take them off and put them in small pots, in a temperature of 60°; they will root in two or three weeks, when they should be moved singly into 3-inch pots; and they must be again shifted into 8-inch or 9-inch pots as soon as those they already occupy are moderately filled with roots. The leading shoot, as well as the side branches, should be topped two or three times during the spring, and a single stick placed to the main stem so as to keep it upright. They should be syringed in the afternoons, to promote growth and to keep down aphides and red spider. By the end of June or July such plants will be disposed to flower. A good compost for fuchsias consists of four parts good fibrous loam to two parts well-rotted manure and leaf-mould, with a fair sprinkling of sand. When larger plants are required the cuttings should be struck about the end of July or beginning of August, and kept gently growing through the autumn and winter in 6-inch pots on a shelf near the glass, with a night temperature of 50°. At the end of February they should be shifted into 10-inch or 12-inch pots, and by the end of April they will be in a condition to move to 16-inch or 18-inch pots, and the temperature should be raised to 55°. The shape of the plants should be regulated by timely pinching of the shoots, the pyramidal and standard forms being the most elegant. The old plants may be kept during winter in any dryish place free from frost; prune them back in spring, and repot in fresh soil. The varieties are constantly changing through the introduction of novelties. See FUCHSIA, vol. ix. p. 806. Fuchsia.

91. *Heliotropium.*—The Peruvian Heliotrope, Heliotropium peruvianum, is a great favourite with cultivators, on account of the delicious fragance of its blossoms, which has obtained for it the popular name of "cherry pie." The plants are easily increased by cuttings, which are struck in July and August, or from young shoots obtained in heat in early spring; when rooted they should be potted singly into small pots, using as a compost fibry loam, sandy peat, and well-decomposed stable manure from an old hotbed. The plants soon require to be shifted into a pot a size larger. To secure early-flowering plants, cuttings should be struck in August, potted off before winter sets in, and kept in a warm greenhouse. In the spring larger pots should be given, and the plants shortened back to make them bushy. They require frequent shiftings during the summer, to induce them to bloom freely. There are many varieties, differing in habit and in the colour of their flowers. Heliotropium.

The heliotrope makes an elegant standard. The plants must in this case be allowed to send up a central shoot, and all the side growths must be pinched off until the necessary height is reached, when the shoot must be stopped and lateral growths will be produced to form the head. During winter they should be kept somewhat dry, and in spring the ball should be reduced and the plants repotted, the shoots being slightly pruned, so as to maintain a symmetrical head. When they are planted out against the walls and pillars of the greenhouse or conservatory an abundance of highly-perfumed blossoms will be supplied all the year round. See HELIOTROPE, vol. xi. p. 633.

92. *Mesembryanthemum.*—These are interesting Cape plants, some of them of a very showy character, and others remarkable as curiosities. They belong to the class of succulents, and with the exception of the curious sorts, all grow and strike freely in a mixture of loam and leaf-mould with a dash of sand. The flowering kinds should be kept only two or three years. Cuttings should be put in about May, and well exposed. They will stand a few degrees of frost, but should be kept from growing in winter. Mesembryanthemum.

The best flowering sorts, most of which are adapted for window-boxes, are—M. barbatum, blandum, candens, conspicuum, curviflorum, falcatum, formosum, glaucum, polyanthum, reflexum, retroflexum, roseum, and spectabile. These can be used for sunny summer beds very well, as those that require it can be pegged down. Of the curious varieties, some of the choicest are M. agninum, albinum, caninum, felinum, murinum, tigrinum, vulpinum, dolabriforme, densum, fissum, linguaeforme, minimum, obconellum, and octophyllum. These are all dwarf growers, and require more sand and some brick rubbish in the soil; they should also have less water.

93. *Pelargonium.*—The various races of pelargoniums have sprung from the intermixture of some of the species obtained from the Cape. The older show-flowered varieties have been gradually acquired through a long series of years. The fancy varieties, as well as the French spotted varieties and the market type, have been evolved from them. The zonal race, on the other hand, has been perfected within the last quarter of a century. In all the sections the varieties are of a highly ornamental character, but for general culti- Pelargonium.

vation the market type is preferable for indoor purposes, while the zonals are effective either in the greenhouse or flower garden. Some of the Cape species are still in cultivation,—the leaves of many of them being beautifully subdivided, almost fern-like in character, and some of them deliciously scented. A few of these are well adapted for bedding out.

Some of the most striking of this set are—P. Blandfordianum, echinatum, graveolens, melananthum, and Schottii; while the following have finely-scented leaves:—P. capitatum, citriodorum, crispum, and odoratissimum. To these may be added, from amongst the earlier hybrids, those named Lady Plymouth, Fair Helen, ignescens, Moore's Victory, Pretty Polly, quercifolium and its varieties, Shrubland Pet, and the various sports from Unique.

The best soil for pelargoniums is a mellow fibrous loam with good stable manure in about the proportion of one-fifth; when used it should not be sifted, but pulled to pieces by the hand, and as much sand should be added as will allow the water to pass freely through it. The large-flowered and fancy kinds cannot bear so much water as most soft-wooded plants, and the latter should have a rather lighter soil.

All the pelargoniums are readily increased by cuttings made from the shoots when the plants are headed down after flowering, or in the spring, when they will root freely in a temperature of 50°. They must not be kept too close, and must be very moderately watered. When rooted they may be moved into well-drained 3-inch pots, and should have the points pinched out in order to induce them to push out several shoots near the base. These shoots are, when long enough, to be trained in a horizontal direction; and when they have made three joints they should have the points again pinched out. These early-struck plants will be ready for shifting into 6-inch pots by the autumn, and should still be trained outwards. The show varieties after flowering should be set out of doors in a sunny spot to ripen their wood, and should only get water enough to keep them from flagging. In the course of two or three weeks they will be ready to cut back within two joints of where these were last stopped, when they should be placed in a frame or pit, and kept close and dry until they have broken. When they have pushed an inch or so, turn them out of their pots, shake off the old soil, trim the straggling roots, and repot them firmly in smaller pots if practicable; keep them near the light, and as the shoots grow continue to train them outwardly. They require to be kept in a light house, and to be set well up to the glass; the night temperature should range about 45°; and air should be given on all mild days, but no cold currents allowed, nor more water than is necessary to keep the soil from getting parched. The young shoots should be topped about the end of October, and when they have grown an inch or two beyond this, they may be shifted into 7-inch pots for flowering. The shoots must be kept tied out so as to be fully exposed to the light. If required to flower early they should not be stopped again; if not until June they may be stopped in February.

The zonal varieties, which are almost continuous bloomers, are of much value as decorative subjects; they seldom require much pruning after the first stopping. For winter flowering, young plants should be grown on during the summer, and not allowed to flower. When blossoms are required, they should be placed close up to the glass in a light house with a temperature of 60°, only just as much water being given as will keep them growing. For bedding purposes the zonal varieties are best struck towards the middle of August in the open air, taken up and potted or planted in boxes as soon as struck, and preserved in frames or in the greenhouse during winter.

The fancy varieties root best early in spring from the half-ripened shoots; but they are slow growers, rather delicate in constitution, and very impatient of excess of water at the root.

Petunia. 94. *Petunia.*—The varieties of petunia, especially the double forms, make admirable specimens for pot culture. These and the other named varieties are propagated by cuttings taken from stock plants kept through the winter on a dry warm shelf, and moved into a brisk moist heat in early spring; the young shoots are planted in pans or pots filled with sandy soil, and, aided by a brisk bottom heat, strike root in a few days. They are then potted singly into thumb-pots, and when once established are gradually hardened off, and afterwards repotted as required. The shoots should be topped to make bushy plants, and their tops may be utilized as cuttings. The single varieties are raised from seeds sown in light sandy soil in heat, in the early spring, and very slightly covered. The plants need to be pricked out or potted off as soon as large enough to handle. Good strains of seeds supply plants suitable for bedding; but, as they do not reproduce themselves exactly, any sorts particularly required must be propagated, like the double ones, from cuttings.

Primula. 95. *Primula.*—One of the most popular of winter and early spring decorative plants is the Chinese Primrose, Primula sinensis, of which some superb strains have during the last few years been obtained. For ordinary purposes young plants are raised annually from seeds, sown about the beginning of March, and again for succession in April, and if needed in May. The seed should be sown in well-drained pans, in a compost of three parts light loam, one part well-rotted leaf-mould, and one part clean gritty sand, as it does not germinate freely if the soil contains stagnant moisture. The surface should be pressed smooth and gently watered before sowing, and the seeds should be only just covered with some very fine compost, half soil half sand, and over that a thin layer of chopped sphagnum to keep it damp, and obviate the necessity of watering. When the seeds germinate, remove the moss, and place them in a well-lighted position near the glass, shading them from the sun with thin white paper, and giving water moderately as required. When they are large enough to handle, prick them out in pans or shallow boxes, and, as soon as they have made leaves an inch long, pot them singly in 3-inch pots, using in the soil a little rotten dung. They should then be placed in a light frame near the glass in an open situation, facing the north. When their pots are filled with roots they should be moved into 6-inch or 7-inch pots. The soil should now consist of three parts good loam broken with the hand, one part rotten dung and leaf-mould, and as much sand as will keep the whole open. They should be potted firmly, and kept in frames close up to the glass till September, excess in watering being carefully avoided. In the autumn they should be transferred to a light house and placed near the glass, the atmosphere being kept dry by the occasional use of fire heat. The night temperature should be kept about 45°. When the flowering stems are growing up, manure water once or twice a week will be beneficial. The semi-double varieties are increased from seeds, but the fully double ones and any particular sort can only be increased by cuttings made by dividing the crowns with a portion of stem attached, the plants being first well dried, almost to shrivelling; the cuttings should be placed in small pots in sandy soil, put in a moderate dryish heat, and only just watered enough to prevent flagging. When they are well rooted, they may be potted like the others. In winter they require an intermediate temperature of 45° or 50° at night, and a little higher in the day, with air when the weather is suitable.

96. *Richardia.*—This plant, R. æthiopica, called also Calla æthiopica and the Nile Lily, is a fine subject for greenhouse decoration during the spring months. It is a stately tuberous-rooted perennial, with broad arrow-shaped leaves, and large white flower-spathes, that last long in beauty. The plants should be carefully divided about March, and planted out during May in well-enriched shallow trenches. Being semi-aquatics, they cannot be kept too moist all through the summer months. Plants kept in pots are generally neglected in this way, and hence are rarely seen in really first-class condition. The richardias are hardy if their crowns are kept under water; but a very little frost disfigures the foliage, and therefore they should be placed in the pits or the greenhouse towards the end of October. They may be had in flower during the winter, but in that case they must have a little warmth to give them a start. Richardia.

97. *Salvia.*—Some of the Salvias or Sages are among the best and most showy among soft-wooded winter-flowering plants, the blossoms being of a bright-glowing scarlet. The three most useful species are S. splendens, S. Heeri, and S. gesneræflora, the first commencing to flower early in the autumn and lasting till Christmas, while the others follow immediately in succession, and continue in full beauty till April. Young plants should be propagated annually about February, and after nursing through the spring should be grown outdoors in a fully exposed situation, where they can be plunged in some non-conducting material, such as half-decomposed leaves. The young shoots should be stopped to secure bushy plants, but not later than the middle of August. The most suitable compost for them is a mixture of mellow fibry loam enriched with a little mild thoroughly decomposed manure, made sufficiently porous by the addition of sand or grit. In spring, and during the blooming period, the temperature should be intermediate between that of a stove and greenhouse. There are other very ornamental species of easy growth, increased by cuttings in spring, and succeeding well in ordinary rich loamy soil. Of these S. angustifolia bears spikes of fine bright-blue flowers in May or June; S. chamædryoides, a dwarfish subject, has deep-blue flowers in August; S. fulgens produces scarlet flowers in August; and S. involucrata produces fine red flowers during the autumn. S. patens is a lovely blue free-blooming sort, flowering in August, the colour being unique. Salvia.

98. STOVE PLANTS.—For the successful culture of stove plants two houses at least, wherein different temperatures can be maintained, should be devoted to their growth. The temperature during winter should range at night from about 55° in the cooler to 65° in the warmer house, and from 65° to 75° by day, allowing a few degrees further rise by sun heat. In summer the temperature may range 10° higher by artificial heat, night and day, and will often by sun heat run up to 90° or even 95°, beyond which it should be kept down by ventilation. During the growing period the atmosphere must be kept moist by damping the walls and pathways, and by syringing the plants, according to their needs; when growth is completed less moisture will be necessary. Watering, which, except during the resting period, should generally be copious, is best done in the forenoon; while syringing should be done early in the afternoon to admit of the foliage drying moderately before night. When the pots become filled with roots, waterings of weak liquid manure Stove plants.

help very much towards a successful blooming. In ventilating, cold draughts must be avoided.

The following are select miscellaneous stove plants:—

Acalypha tricolor (Wilkesiana).
Æschynanthus Boschianus, Lobbianus, and splendens.
Allamanda Chelsoni, Schottii, grandiflora, Hendersoni, and nobilis.
Alocasia Jenningsii, Lowii, Veitchii, macrorrhiza variegata, and metallica.
Anthurium crystallinum, regale, Warocqueanum, Veitchii, magnificum, Scherzerianum, and Andréanum.
Aphelandra nitens and Roezlii.
Aralia elegantissima, filicifolia, and Veitchii.
Ardisia crenulata and Oliveri.
Aristolochia Duchartrei and floribunda.
Bertolonia superbissima and Van Houttei.
Bignonia Chamberlaynii and venusta.
Bougainvillea glabra and spectabilis.
Centropogon Lucyanus.
Cissus discolor.
Clerodendrum fallax, Balfourianum, and splendens.
Combretum purpureum.
Croton angustifolius, trilobus Disraeli, Andréanus, gloriosus, majesticus, undulatus, Weismanni, spiralis, and Williamsii.
Cyanophyllum magnificum.
Dieffenbachia Bausei, Leopoldii, Carderi, and splendens.
Dipladenia Brearleyana, regina, and amabilis.
Ficus elastica (India-rubber Plant).
Franciscea eximia, calycina, magnifica, and confertiflora.
Gardenia Stanleyana, citriodora, and florida.
Gesnera Cooperii, Donckelaari, and superba.
Hibiscus rosa sinensis miniatus semiplenus, and its varieties—refulgens, zebrinus, puniceus, Collerii, fulgidus, schizopetalus, and Cooperii.
Hoya imperialis, carnosa, campanulata, and bella.
Ipomœa Horsfalliæ and Learii.
Ixora coccinnea, Colei, javanica, splendens, regina, and Williamsii.
Luculia gratissima.
Maranta fasciata, albo-lineata, roseolineata, Makoyana, regalis, roseopicta, Veitchii, zebrina, and Massangeana.
Medinilla magnifica and amabilis.
Nelumbium speciosum.
Nepenthes (Pitcher-Plant) Veitchii, sanguinea, lævis, Stewartii, Williamsii, Hookeri, and Rafflesiana.
Nymphæa Devoniana, dentata, and cœrulea.
Pandanus graminifolius, elegantissimus, Vandermeerschii, and Veitchii.
Passiflora Raddiana (kermesina), Decaisneana, Buonapartea, Hahnii, edulis, and princeps racemosa.
Pavetta borbonica.
Pentas carnea rosea.
Plumbago rosea.
Rogiera cordata and gratissima.
Rondeletia speciosa major.
Stephanotis floribunda.
Sphærogyne latifolia.
Thyrsacanthus rutilans.
Tillandsia musaica, tessellata, Lindeniana, and Zahnii.
Tornelia fragrans (Monstera deliciosa).
Victoria regia.
Vinca rosea, rosea oculata, and rosea alba.

99. *Achimenes* have scaly tubers, which are kept dry and in a state of rest in a temperature of 55° during the winter months, and started into growth about March, a second batch being started in April. They should be placed 6 inches asunder in pans filled to within 1½ inches of the rim with leaf-mould or cocoa-refuse, made rather sandy, and slightly covered with the soil. The pans should be set in a warm pit or frame, and the soil kept slightly moistened, and when the young shoots are a couple of inches long they may be placed six or eight in a 6-inch pot, in a soil of three parts fibrous loam and two parts leaf-mould, mixed with a little sand. The temperature should be from 65° to 70°, and they should be well exposed to light. When 6 inches long, pinch out the points to induce them to branch, and give more water, syringing overhead to keep red spider in check. As soon as the flower buds appear, give weak manure water two or three times a week. They should all through their growth have sufficient air to keep them from getting drawn, and when the flowers begin to open should be gradually inured to bear the temperature of the conservatory. When they show signs of going to rest, less water may be given; and after the tops have died down, the tubers may be stored in dry sand in a temperature of about 55°. Achimenes have also a fine effect grown in wire baskets from the roof of the plant house.

The following are good kinds:—Ambroise Verschaffelt, belmontensis, Firefly, longiflora alba, longiflora major, Mauve Queen, Parsonsii, Rose Queen, Stella, and Williamsii.

100. *Amaryllis.* This genus, also called Hippeastrum, consists of splendid bulbous plants, of easy culture and free-blooming habit. Like other bulbs they are increased by offsets, which should be carefully removed when the plants are at rest, and should be allowed to attain a fair size before removal. These young bulbs should be potted singly in February or March, in mellow loamy soil with a moderate quantity of sand, about two-thirds of the bulb being kept above the level of the soil, which should be made quite solid. They should be removed to a temperature of 60° by night and 70° by day, very carefully watered until the roots have begun to grow freely, after which the soil should be kept moderately moist. As they advance the temperature should be raised to 70° at night, and to 80° or higher with sun heat by day. They do not need shading, but should have plenty of air, and be syringed daily in the afternoon. When growing they require a good supply of water. After the decay of the flowers they should be returned to a brisk moist temperature of from 70° to 80° by day during summer to perfect their leaves, and then be ripened off in autumn. Through the winter they should have less water, but must not be kept entirely dry. The minimum temperature should now be about 55°, to be increased 10° or 15° in spring. As the bulbs get large they will occasionally need shifting into larger pots.

A few of the best sorts are—Ackermanni pulcherrima, aulica, conspicua, Duchess of Connaught, Hercules, Leopoldii, Meteor, Mrs Baker, Mrs Morgan, Oriflamme, pardina, pyrrochroa, Queen Victoria, striata superba, Thalia, Unique, Virgil, and vittata. New varieties are being constantly raised.

101. *Begonias* are represented by numerous species, herbaceous and subshrubby. There are several free-flowering hybrids, such as B. weltoniensis, Saundersii, fuchsioides, prestoniensis, ascotiensis, &c.; there is the group of ornamental-leaved kinds represented by B. Rex; and there is the tuberous-rooted free-blooming brilliant race, developed recently, mainly from B. boliviensis and B. Veitchii. Begonia.

Cuttings from flowering begonias root freely in sandy soil, placed in heat at any season when moderately firm, and as soon as rooted should be potted singly into 3-inch pots, in sandy loam mixed with leaf-mould and sand. They should be stopped to keep them bushy, placed in a light situation, and thinly shaded in the middle of very bright days. In a few weeks they will require another shift. They should not be overpotted, but instead assisted by manure water. The pots should be placed in a light pit near the roof glass. The summer-flowering kinds will soon commence blooming, but the autumn and winter-flowering sorts should be kept growing on in a temperature of from 55° to 60° by night, with a few degrees more in the day. The tuberous-rooted sorts require to be kept at rest in winter, in a medium temperature, almost but not quite dry. In February they should be potted in a compost of sandy loam and leaf-mould, and placed in a temperate pit until May or June, when they may be moved to the greenhouse for flowering. If they afterwards get at all pot-bound, weak manure should be applied. After blooming the supply of water must be again slackened, and in winter the plants should be stored in a dry place, secure from frost; they are increased by late summer and autumn cuttings, after being partially cut down.

102. *Bouvardia.*—These plants are best increased by cuttings taken off in April, and placed in a brisk heat in a propagating frame with a close atmosphere. When rooted they should be potted singly into 3-inch pots in fibrous peat and loam, mixed with one-fourth leaf-mould, and a good sprinkling of sand, and kept in a temperature of 70° by night and 80° during the day; shade when required; syringe overhead in the afternoon, and close the house with sunheat. The plants should be topped to ensure a bushy habit, and as they grow must be shifted into 6-inch or 7-inch pots. After midsummer they should be moved to a cool pit, where they may remain till the middle of September, receiving plenty of air and space. They should then be removed to a house, and a portion of the plants should be put at once in a temperature of about 70° at night, with a few degrees higher in the day time, to bring them into flower. Others must be moved into heat to supply flowers in succession through the winter and spring. Some of the best kinds are B. elegans, Hogarth, jasminiflora, Maiden's Blush, and Vreelandii. Bouvardia.

103. *Cactus.*—This old-fashioned name includes many modern genera of handsome or interesting succulents, the principal of which are briefly mentioned below. *Cereus* is well represented by C. speciosissimus, a quadrangular-stemmed spiny plant, requiring stove heat, and a loamy soil freely mixed with hard drainage material; it must not be overpotted. *Echinocactus* is a genus of dwarf fleshy spiny plants, which are slow growers, and must have plenty of sun heat; they require sandy loam, with a mixture of sand and bricks finely broken, and must be potted firmly, and kept dry in winter. *Echinopsis* is a group of dwarfish plants resembling the Echinocacti, which bear flowers about a foot long, varying from white to deep rose. *Epiphyllum* is a group of handsome plants easily increased from cuttings, but from their drooping habit they are better adapted for grafting on the *Pereskia*, so as to form small standards. The Pereskia stocks are struck during the winter or spring from cuttings placed in heat, and should be grown in sandy loam, the pots being well drained; these must be kept to a single stem, and when a foot or 18 inches high, and of a firm woody texture, should be grafted with small pieces of the Epiphyllum. They may be grown for a considerable time in 6-inch or 7-inch pots, but must have free drainage. After grafting they should be grown on in heat and in plenty of light through the summer, but by the autumn should have less warmth and moisture. A winter temperature of 50° will be sufficient, but in January a portion may be started in a temperature of 60°, in which they will soon show flower. This treatment being continued they will last for many years, and go on increasing in size. There are a number of varieties of E. truncatum, differing chiefly in the amount and shade of rose colour or crimson in the flowers. *Mammillaria* consists of very interesting dwarf globular or cylindrical plants, remarkable for the beautiful colour of their numerous spines, and the irregular arrangement of the mammillæ into which their surface is broken up. They grow freely in a cool greenhouse, and require moderate watering in summer, with occasional syringing overhead. The spines are in some species white, in others yellow, or red, or brown, or almost black. *Opuntia* is the prickly pear of southern Europe, or Indian fig of South America; the species are scarcely ornamental plants, but are interesting on account of their variable development. The cochineal insect is reared on some of the larger-growing sorts. O. vulgaris and Rafinesquiana are hardy in the south of England. *Phyllocactus* is one of the most ornamental genera of cacti, and is of easy culture, requiring dry stove treatment. Cuttings strike readily in spring before growth has commenced; they should be potted in 3-inch or 4-inch pots, well-drained, in loamy soil made very porous by the admixture of finely-broken crocks and Cactus.

sand, and placed in a temperature of 60°; when these pots are filled with roots they are to be shifted into larger ones, but overpotting must be avoided. During the summer they need considerable heat, all the light possible, and plenty of air. In winter a temperature of 45° or 50° will be sufficient, and they must be kept tolerably dry at the root. By the spring they may have larger pots if required, and should be kept in a hot and fairly moistened atmosphere; and by the end of June, when they have made new growth, they may be turned out under a south wall in the full sun, water being given only as required. In autumn they are to be returned to a cool house, and wintered in a dry stove. The turning of them outdoors to ripen their growth is the surest way to obtain flowers, but they do not take on a free blooming habit until they have attained some age. Amongst the best sorts are P. Ackermanni, Jenkinsoni, crenatus, and speciosus.

Caladium. 104. *Caladium.*—These beautiful arads are increased by division of the young growths made in the spring. They should be potted in small pots in fibrous sandy peat, well drained, and kept in a temperature of 65° by night; afterwards they should be changed into larger ones, using lumpy soil. The summer temperature may range about 68° or 70° by night, with an increase of 10° by day. The plants will go to rest towards autumn, and when the leaves have all died away the soil may be allowed to become nearly dry, and the pots may be set on a shelf, in a temperature of about 55°, till February.

Coleus. 105. *Coleus.*—These are very ornamental plants, the colour of their leaves being exceedingly varied, and often very brilliant. They are of the easiest culture. The cuttings of young shoots should be propagated every year, about March, being planted in thumb pots, in sandy loam, and placed in a close temperature of 70°. After taking root they should be shifted into 6-inch pots, using ordinary light loamy compost, containing abundance of leaf-mould and sand, and keeping them near the light. They may be passed on into larger pots as often as required, but 8-inch pots will be large enough for general purposes, as they can be fed with liquid manure. The young spring-struck plants like a warm growing atmosphere, but by midsummer they will bear more air and stand in a greenhouse or conservatory. They should be wintered in a temperature of 60° to 65°. The stopping of the young shoots must be regulated by the consideration whether bushy or pyramidal plants are desired.

Dracæna. 106. *Dracæna.*—These are extremely useful as decorative stove plants, and are easy to grow. They may be increased by cuttings planted in sandy soil in a temperature of from 65° to 70° by night, the spring being the best time for propagation. The old stems laid flat in a propagating frame will push young shoots, which may be taken off with a heel when 2 or 3 inches long, and planted in sandy peat in 3-inch pots; the tops can also be taken off and struck. The established plants do best in fibry peat made porous by sand. In summer they should have a day temperature of 75°, and in winter one of 65°. Shift as required, using coarser soil as the pots become larger. By the end of the summer the small cuttings will have made nice plants, and in the spring following they can be kept growing by the use of manure water twice a week. Those intended for the conservatory should be gradually inured to more air by midsummer, but kept out of cold draughts. When the plants get too large they can be headed down and the tops made cuttings. D. terminalis, with its bronzy leaves and rosy variegation, still ranks amongst the best sorts, but there are also many novel varieties of great merit and beauty. D. Goldieana is a grandly variegated species from tropical Africa, and requires more heat.

Eucharis. 107. *Eucharis.*—This is the most chastely beautiful of all decorative plants, having white flowers, of a very distinct character. It is a bulbous plant, and is propagated by removing the offsets, which may be done in spring, potting them singly in 6-inch pots. It requires good loamy soil, with sand enough to keep the compost open, and should have a good supply of water and a temperature of 65° to 70° during the night, with a rise of 8° or 10° in the day. During summer, growth is to be encouraged by repotting, but the plants should afterwards be slightly rested by removal to a night temperature of about 60°, water being withheld for a time, though they must not go too long dry, the plant being an evergreen. By the turn of the year they may again have more heat and more water, and this will probably induce them to flower. After this is over they may be shifted and grown again as before; and, as they get large, they can either be divided to form new plants or allowed to develop into nobler specimens. With a stock of the smaller plants to start them in succession, they may be had in flower all the year round.

Gloxinia. 108. *Gloxinia.*—The gloxinia, a charming decorative plant, may be grown much in the same way as the achimenes. A good strain of seed will produce many superb and charmingly coloured varieties, and if sown early in spring, in a temperature of 65° at night, they may be shifted on into 6-inch pots, and in these may be flowered during the summer. The bulbs are kept at rest through the winter in a dry sand, in a temperature of 50°, and to yield a succession should be started at intervals, say at the end of February and the beginning of April. To prolong the blooming season, use weak manure water when the flower-buds show themselves.

109. *Poinsettia.*—The Poinsettia pulcherrima, with its brilliant scarlet bracts, stands unrivalled amongst decorative plants. The white-bracted sort, P. p. alba, is not so effective, but the double-flowered P. p. plenissima, in which the cymose inflorescence is branched, is as brilliant as the type, and keeps long in flower. They are increased by cuttings in spring, which when taken off with a heel strike freely in a brisk heat. They require good turfy loam, with an addition of one-sixth of leaf-mould and a little sand, and should be kept in a heat of from 65° to 70° at night, with a rise of 10° by day. To prevent their growing lanky, they should be kept with their heads almost touching the glass; and as the pots get filled with roots they must be shifted into others, 8 inches or 10 inches in diameter. About August they may be inured to a heat of 50° at night, and should be brought to bear air night and day whilst the weather is warm, or they may be placed out of doors for a month under a south wall in the full sun. This treatment matures and prepares them for flowering. In autumn they must be removed to a house where the temperature is 50° at night, and by the end of September some of them may be put in the stove, where they will come into flower, the remainder being placed under heat later for succession. When in bloom they may be kept at about 55° by night, and so placed will last longer than if kept in a higher temperature. Poinsettia.

Tydæa. 110. *Tydæa.*—These handsome plants, which have sprung from the beautiful Achimenes picta, require similar treatment to achimenes, except that, being winter bloomers, they must be started into growth at a different season, namely, the later spring months, as April and May. The summer-blooming sorts, which should be started earliest, should, as they come into flower, be removed to the conservatory. The autumn and winter flowering sorts, being at first grown slowly in a gentle heat, must as they show flower have a nice growing temperature of 70° or 75° afforded them with abundance of light; manure water may be given once a week. The tubers should be stored away dry in winter, like those of achimenes.

Orchids. 111. ORCHIDS.—For the successful cultivation of a mixed collection of tropical orchids, it is necessary that two or three houses, in which different temperatures can be maintained, should be provided. The greater number of them are epiphytes or air plants, and heat and moisture afford all or nearly all the nourishment they require. The plants themselves are the better for being associated with such objects as ferns and palms, and the appearance of the houses is greatly improved by their being thus grouped.

The East Indian orchid house takes in those species which are found in the warm parts of the eastern hemisphere, as well as those from the hottest parts of the western, and its temperature should range from about 75° to 85° during the summer or growing season, and from 65° to 70° during winter. The Mexican or Brazilian orchid house accommodates the plants from the warm parts of South America, and its temperature should range from about 65° to 75° during summer, and from 60° to 65° in winter. A structure called the cool orchid house is set apart for the accommodation of the many lovely mountain species from South America and India, such as odontoglossums, masdevallias, &c., and in this the more uniform the temperature can be kept the better, that in summer varying between 60° and 70°, and in winter from 45° to 60°. A genial moist atmosphere must be kept up in the hottest houses during the growing season, with a free circulation of air admitted very cautiously by well-guarded ventilators. In winter, when the plants are at rest, little water will be necessary; but in the case of those plants which have no fleshy pseudobulbs to fall back upon for sustenance, they must not be suffered to become so dry as to cause the leaves to shrivel. In the Mexican house the plants will generally be able to withstand greater drought occasionally, being greatly assisted by their thick pseudobulbs. In the cool or odontoglossum house a considerable degree of moisture must be maintained at all times, for in these the plants keep growing more or less continuously.

For potting or basketing purposes, or for plants requiring block-culture, the only materials admissible are light fibrous peat and living sphagnum moss, which supply free drainage for the copious supply of water required. The water should, however, be so used as not to run down into the sheathing bases of the leaves. While in flower, orchids may with advantage be removed to a drier and cooler situation, and may be utilized in the drawing-room or boudoir.

From amongst the great wealth of tropical orchids, now in cultivation, the following is a very limited selection of some of the most useful:—

Ada.—Epiphytal: A. aurantiaca.
Aerides.—Epiphytal: A. affine, crassifolium, crispum, Fieldingii, Lobbii, nobile, odoratum, and suavissimum.
Angræcum.—Epiphytal: A. sesquipedale.
Anguloa.—Terrestrial: A. Clowesii and Ruckeri.
Barkeria.—Cool epiphytal: B. elegans, Skinneri, and spectabilis.
Bollea.—Epiphytal: B. Backhousiana, cœlestis, Lalindei, and Patinii.
Calanthe.—Terrestrial: C. Masuca, Veitchii, and vestita.
Cattleya.—Epiphytal: C. amethystoglossa, bulbosa, Dowiana, exoniensis, gigas, labiata, lobata, Mossiæ, quadricolor, Skinneri, superba, and Trianæ.
Cœlogyne.—Epiphytal: C. barbata, cristata, Gardneriana, Lowii, pandurata, and speciosa.
Cymbidium.—Terrestrial: C. eburneum, Lowianum, and Mastersii.
Cypripedium.—Terrestrial: C. Argus, barbatum superbum, caudatum, con-

color, Dayanum, Harrisianum, insigne Maulei, lævigatum, Lowii, niveum, Schlimmi, Stonei, and superbiens.

Dendrobium.—Epiphytal: D. aggregatum majus, Ainsworthii, barbatulum, Bensoniæ, chrysotis, chrysotoxum, crassinode, crystallinum, Devonianum, Falconeri, fimbriatum oculatum, formosum giganteum, lituiflorum, nobile, Paxtoni, pulchellum, suavissimum, and Wardianum.

Dendrochilum.—Epiphytal: D. filiforme and glumaceum.

Disa.—Cool terrestrial: D. grandiflora and Barrellii.

Epidendrum.—Epiphytal: E. dichromum, Frederici Guilielmi, ibaguense, macrochilum, nemorale majus, and vitellinum majus.

Lælia.—Epiphytal: L. anceps, autumnalis, cinnabarina, elegans, harpophylla, majalis, Perrinii, purpurata, and superbiens.

Limatodes.—Terrestrial: L. rosea.

Lycaste.—Cool epiphytal: L. Skinneri, with its many variations.

Masdevallia.—Cool epiphytal: M. Davisii, Harryana, ignea, Lindeni, tovarensis, and Veitchiana.

Mesospinidium.—Cool epiphytal: M. sanguineum and vulcanicum.

Miltonia.—Epiphytal: M. spectabilis, with its fine variety Moreliana.

Odontoglossum.—Cool epiphytal: O. Alexandræ (crispum), Andersonianum, citrosmum, cirrhosum, grande, Hallii, Insleayi, membranaceum, Pescatorei, Phalænopsis, Roezlii, triumphans, vexillarium.

Oncidium.—Epiphytal: O. ampliatum majus, Barkeri, crispum, cucullatum, curtum, macranthum, Marshallianum, ornithorrhynchum, roseum, Papilio majus, sarcodes, and varicosum Rogersii.

Pescatoria.—Epiphytal: P. Dayana, lamellosa, Roezlii, and Wallisii

Phajus.—Terrestrial: P. grandifolius and Wallichii.

Phalænopsis.—Epiphytal: P. amabilis, grandiflora, and Schilleriana.

Pleione (Indian Crocus).—Epiphytal: P. Hookeriana, humilis, lagenaria, maculata, præcox, Reichenbachiana, and Wallichiana.

Renanthera.—Epiphytal: R. coccinea and Lowii.

Saccolabium.—Epiphytal: S. ampullaceum, Blumei majus, curvifolium, guttatum, miniatum, and retusum.

Sobralia.—Terrestrial: S. macrantha splendens.

Sophronitis.—Epiphytal: S. grandiflora.

Stanhopea.—Epiphytal: S. grandiflora, insignis, oculata, and tigrina.

Thunia.—Terrestrial: T. alba and Bensoniæ.

Trichopilia.—Epiphytal: T. crispa, marginata, suavis, and tortilis.

Vanda.—Epiphytal: V. Cathcartii, cœrulea, cœrulescens, suavis, and tricolor.

Zygopetalum.—Epiphytal: Z. Gautieri, Mackayi, maxillare, and rostratum.

Palms. 112. PALMS, while quite young, form charming ornaments for the drawing-room and the dinner table. When more fully developed, and long before their full growth is attained, they are among the best ornamental foliaged conservatory plants. For the most part they are stove plants (75° to 80°), but after the growth is matured, many of them thrive for some time in the temperature of a dwelling house. They are of very easy cultivation, but require plenty of water and thorough drainage. The soil should consist of equal parts of loam, peat, and vegetable mould, with abundance of sand, and they thrive best in comparatively small pots. See PALMS.

The following is a selection of useful species:—

Acanthophœnix.—Pinnate: A. crinita and Herbstii.

Acanthorrhiza.—Fan-leaved: A. stauracantha and Warscewiczii.

Areca. Pinnate: A. alba, aurea, lutescens, and rubra.

Astrocaryum.—Pinnate: A. acaule, Murumuru, and rostratum.

Attalea.—Pinnate: A. funifera, nucifera, and speciosa.

Bactris.—Pinnate: B. baculifera, integrifolia, and simplicifrons.

Brahea.—Fan-leaved: B. filamentosa (a Californian species, having the edges of the leaf-segments developed into long threadlike pendent filaments) and B. Roezlii.

Calamus.—Pinnate, and exceedingly handsome as young plants, but afterwards assuming the habit of climbers: C. adspersus, asperrimus, ciliaris, Flagellum, Impératrice Marie, Jenkinsianus, melanochætes, palembanicus, plumosus, and viminalis.

Caryota.—Pinnate: C. Cumingii is the dwarfest of the species, bipinnate, the leaves from 3 to 6 feet long; C. urens.

Ceroxylon.—Pinnate: C. andicola is a majestic species.

Chamædorea.—Pinnate, and well suited for indoor decoration during the winter months: C. Arenbergiana, desmoncoides, elegans, Ernesti-Augusti, glaucifolia, graminifolia, microphylla, and Warscewiczii.

Chamærops.—Fan-leaved, comparatively dwarf, and admirably adapted for decoration: C. excelsa, Fortunei, humilis, and Martiana.

Cocos.—Pinnate: Shade-loving plants, some of which are most charming, especially C. Bonneti, elegantissima, plumosa, and Weddelliana.

Cyphokentia.—Pinnate: C. gracilis and macrocarpa (Kentia Lindeni).

Euterpe.—Pinnate: E. edulis

Geonoma.—Pinnate: Small-growing and nearly all very handsome while young, especially G. congesta, elegans, gracilis, macrostachys, Martiana, Porteana, pumila, and Schottiana

Hyophorbe.—Pinnate: H. amaricaulis, indica, and Verschaffeltii.

Jubæa.—Pinnate: the Chilian J. spectabilis is highly decorative, and may be grown in the open during summer.

Kentia.—Pinnate: K. Baueri, Belmoreana, Fosteriana, sapida, and Wendlandiana are ornamental greenhouse palms.

Latania. Fan-leaved: L. aurea, Commersoni, and rubra.

Licuala.—Fan-leaved: L. acutifida, elegans, and peltata.

Livistonia.—Fan-leaved, and of robust constitution: L. altissima, australis, Hoogendorpii, olivæformis, and sinensis (Latania borbonica).

Malortiea.—Pinnate, dwarf elegant palms, well adapted for table decoration: M. gracilis and simplex.

Martinezia.—Pinnate, with singular erose leaflets: M. erosa, granatensis, and Lindeniana.

Oncosperma.—Pinnate: O. Van Houtteanum, a splendid plant for exhibition purposes.

Oreodoxa.—Pinnate, and while young beautiful as table plants, standing long in a room without injury: O. oleracea and regia.

Phœnicophorium.—Entire-leaved, magnificent ornaments in the stove: P. sechellarum, known also as Stevensonia grandifolia.

Phœnix.—The Date Palm of commerce, P. dactylifera, although common, is extremely ornamental, and so hardy that it may be used in almost any situation during the summer months; other fine sorts are P. reclinata, rupicola, sylvestris, and tenuis.

Pritchardia.—Fan-leaved: P. aurea, grandis, macrocarpa, Martiana, and pacifica.

Ptychosperma.—Pinnate, and of robust constitution: P. Alexandræ, Cunninghamii (Seaforthia elegans), and rupicola.

Rhapis.—Fan-leaved, slender-stemmed, and of hardy constitution: R. flabelliformis and humilis.

Sabal.—Fan-leaved, noble plants reaching gigantic proportions: S. Blackburniana and umbraculifera.

Thrinax.—Fan-leaved, with slender petioles, and leaves much divided; peculiarly light and elegant for table or other decoration: T. arborea, barbadensis, elegans, graminifolia, multiflora, parviflora, and radiata.

Trithrinax.—Fan-leaved: T. mauritiæformis.

Verschaffeltia.—Entire-leaved, in the way of Phœnicophorium, and requiring strong moist heat: V. melanochætes and splendida (Regelia majestica) are remarkable for their long needle-like black spines.

Welfia.—Pinnate: W. regia.

113. FERNS.—These popular plants are usually increased by means of their spores, the "dust" produced on the back of their fronds. Ferns. The spores should be sown in well-drained pots or seed pans on the surface of a mixture of fibrous sifted peat and small broken crocks or sandstone; this soil should be firmly pressed and well-watered, and the spores scattered over it, and at once covered with propagating glasses or pieces of sheet glass, to prevent water or dry air getting to the surface. The pots should be placed in pans full of water, which they will absorb as required. A shady place is desirable, with temperature of 50° to 55° by night and 65° to 70° by day, or they may be set on a shelf in an ordinary propagating pit. The spores may be sown as soon as ripe, and when the young plants can be handled, or rather can be lifted with the end of a pointed flat stick, they should be pricked out into well-drained pots or pans filled with similar soil, and should be kept moist and shady. As they become large enough, pot them singly in 3-inch pots, and when the pots are fairly filled with roots shift on into larger ones.

The best time for a general repotting of ferns is in spring, just before growth commences. Those with creeping rhizomes can be propagated by dividing these into well-rooted portions, and, if a number of crowns is formed, they can be divided at that season. In most cases this can be performed with little risk, but the gleichenias, for example, must only be cut into large portions, as small divisions of the rhizomes are almost certain to die; in such cases, however, the points of the rhizomes can be led over and layered into small pots, several in succession, and allowed to remain unsevered from the parent plant until they become well-rooted. In potting the well-established plants, and all those of considerable size, the soil should be used in a rough turfy state, not sifted but broken, and one-sixth of broken crocks or charcoal and as much sand as will insure free percolation should be mixed with it.

The stove ferns require a day temperature of 65° to 75°, but do not thrive in an excessively high or close dry atmosphere. They require only such shade as will shut out the direct rays of the sun, and, though abundant moisture must be supplied, the atmosphere should not be loaded with it. The water used should always be at or near the temperature of the house in which the plants are growing. Some ferns, as the different kinds of Gymnogramma and Cheilanthes, prefer a drier atmosphere than others, and the former do not well bear a lower winter temperature than about 60° by night. Most other stove ferns, if dormant, will bear a temperature as low as 55° by night and 60° by day from November to February. About the end of the latter month the whole collection should be turned out of the pots, and redrained or repotted into larger pots as required. This should take place before growth has commenced. Towards the end of March the night temperature may be raised to 60°, and the day temperature to 70° or 75°, the plants being shaded in bright weather. Such ferns as Gymnogrammas, which have their surface covered with golden or silver powder, and certain species of scaly-surfaced Cheilanthes and Nothochlæna, as they cannot bear to have their fronds wetted, should never be syringed; but most other ferns may have a moderate sprinkling occasionally (not necessarily daily), and as the season advances, sufficient air and light must be admitted to solidify the tissues.

Space will only permit that we should append a list of choice ferns, which, however, might be much extended. We shall arrange them under the heads of stove, greenhouse, and hardy.

Select Stove Ferns.

Acrophorus affinis, chærophyllus, and immersus (Leucostegia).

Acrostichum aureum.

Adiantum æmulum, cardiochlæna, caudatum, concinnum, cristatum, cuneatum, curvatum, farleyense, gracillimum, Henslovianum, lunulatum, macrophyllum, mundulum, peruvianum, polyphyllum, princeps, pulverulentum, Seemanni, subcordatum, tenerum, trapeziforme, Veitchianum, villosum, and Williamsii.

Alsophila armata, aspera, glauca, philippensis, pruinata, pycnocarpa, radens, and Tænitis.

Aglaomorpha Meyenianum.

Anemia adiantifolia, cheilanthoides, collina, and mandioccana.

Anemidictyon Phyllitidis, and its several forms—fraxinifolium, laciniatum, longifolium, and tessellatum.

Aspidium trifoliatum.

Asplenium alatum, caudatum, cicutarium, erectum, Fabianum, ferulaceum, formosum, heterocarpum, horridum, laserpitiifolium, longissimum, myriophyllum, neo-caledonicum, planicaule, rachirhizon, rhizophorum, schizodon, serra, Veitchianum (Belangeri), and viviparum.

Blechnum brasiliense, gracile, Lanceola, longifolium, occidentale, and orientale.

Campyloneurum lucidum, repens, nitidum, and decurrens.

Ceratopteris thalictroides, an aquatic sub-annual species with proliferous sterile fronds.

Cheilanthes Borsigiana, cuneata, elegans, farinosa, frigida, pulveracea, radiata, spectabilis, and viscosa.

Cibotium Barometz, Chamissoi, glaucum, Menziesii, pruinosum, regale, and Schiedei.
Cionidium Moorei.
Cyathea arborea, canaliculata, excelsa, insignis (Cibotium princeps), and serra.
Davallia aculeata, bullata, dissecta, divaricata (polyantha), elata, elegans, fijiensis, Mooreana, ornata, pentaphylla, solida, and tenuifolia.
Dennstædtia cicutaria.
Deparia prolifera.
Dicksonia chrysotricha.
Dictyoxiphium panamense.
Didymochlæna lunulata.
Diplazium alternifolium, celtidifolium, grandifolium, Shepherdii, striatum, sylvaticum, and zeylanicum.
Doryopteris collina, nobilis, palmata, and sagittæfolia.
Drynaria coronans, diversifolia, morbillosa, and quercifolia.
Elaphoglossum cuspidatum, L'Herminieri, scolopendrifolium, squamosum, and numerous other species.
Gleichenia dichotoma, furcata, pectinata, and pubescens.
Goniophlebium appendiculatum, colpodes, lachnopus, Lepidopteris, loriceum, squamatum, subauriculatum, and verrucosum.
Goniopteris asplenioides, crenata, Ghiesbreghtii, refracta, and reptans.
Gymnogramma chrysophylla and its variety Parsonsii; flexuosa, L'Herminieri, Pearcei, peruviana and its variety argyrophylla; pulchella, sulphurea, tartarea, trifoliata, and Wettenhalliana.
Hemitelia grandifolia, horrida, Karsteniana, and speciosa.
Humata alpina, heterophylla, and pedata.
Hymenodium crinitum.
Hymenophyllum, any of the species.
Hymenostachys elegans.
Hypolepis repens.
Lastrea augescens, deltoidea, patens, recedens, and strigosa (crinita).
Lindsæa cultrata, guianensis, and trapeziformis.
Litobrochia aurita, denticulata, macroptera, podophylla, and tripartita.
Lomaria attenuata, fraxinifolia, L'Herminieri, and onocleoides.
Lygodictyon Forsteri.
Lygodium flexuosum, venustum, and volubile.
Microlepia hirta cristata.
Nephrodium articulatum, cyatheoides, Hookerii, pteroides, truncatum, unitum, and venustum.
Nephrolepis davallioides and its variety furcans; Duffii, ensifolia, exaltata, pectinata, pluma, tuberosa, and undulata.
Niphobolus costatus, Gardneri, and pertusus.
Nothochlæna flavens, nivea, rufa, sinuata, and trichomanoides.
Oleandra articulata, neriiformis, and nodosa.
Olfersia cervina.
Onychium auratum.
Osmunda palustris (evergreen).
Phlebodium areolatum, aureum, pulvinatum, and sporadocarpum.
Platycerium alcicorne and its variety majus; biforme, grande, Hillii, Stemmaria, Wallichii, and Willinckii.
Pleocnemia Leuzeana.
Pleopeltis albo-squamata, incurvata, leiorhiza, longissima, and Phymatodes.
Polybotrya caudata and osmundacea.
Polypodium Dianæ, Paradiseæ, pectinatum, and Schkuhrii.
Polystichum coniifolium, denticulatum, lentum, ordinatum, triangulum, and viviparum.
Pteris argyrea, aspericaulis, longifolia, quadriaurita, semipinnata, tricolor, serrulata and its many varieties.
Sadleria cyatheoides.
Sagenia cicutaria, macrophylla, Pica, and repanda.
Schizæa dichotoma and elegans.
Stenosemia aurita.
Thamnopteris australasica and Nidus.
Thyrsopteris elegans.
Trichomanes, any of the species.

Select Greenhouse Ferns.

Acrophorus hispidus (Davallia Novæ-Zelandiæ).
Adiantum affine, assimile, cuneatum, decorum, excisum and its variety multifidum; formosum, glaucophyllum, hispidulum, reniforme, and sulphureum.
Alsophila australis, capensis, excelsa, and Leichardtiana.
Asplenium appendiculatum, bulbiferum, Colensoi, compressum, dimorphum, Dregeanum, flabellifolium, flaccidum, Hemionitis (palmatum), lucidum, monanthemum, obtusatum, polyodon, and præmorsum.
Balantium Culcita.
Blechnum australe and serrulatum.
Ceterach aureum.
Cheilanthes alabamensis, argentea, capensis, fragrans, hirta Ellisiana, micromera, microphylla, pteroides, and tenuifolia.
Cyathea Burkei, Cunninghamii, dealbata, Dregei, medullaris, and Smithii.
Cyrtomium caryotideum, falcatum, and Fortunei.
Davallia canariensis and pyxidata.
Dennstædtia davallioides Youngii.
Dicksonia antarctica, Berteroana, Sellowiana, squarrosa, and Youngii.
Doodia aspera and its varieties multifida and corymbifera; blechnoides, caudata and its variety confluens; and media.
Gleichenia circinata and its variety glauca; Cunninghamii, dicarpa, flabellata, hecistophylla, rupestris, semivestita, and Speluncæ.
Humata Tyermanni.
Hymenophyllum æruginosum, crispatum, cruentum, demissum, dilatatum, flabellatum, flexuosum, fuciforme, polyanthos, pulcherrimum, and scabrum.
Hypolepis Bergiana, distans, Millefolium, and tenuifolia.
Lastrea aristata variegata, decomposita, decurrens, elongata, erythrosora, glabella, hispida, laserpitiifolia, Sieboldii, and varia.
Litobrochia comans, macilenta, and vespertilionis.
Llavea cordifolia.
Lomaria australis, blechnoides, capensis, ciliata, discolor and its variety bipinnatifida; dura, fluviatilis, Fraseri, gibba and its variety Bellii; Gilliesii, lanceolata, magellanica, nuda, obtusata, Patersoni, and procera.
Loxsoma Cunninghamii.
Microlepia cristata, platyphylla, scabra, and strigosa.
Niphobolus heteractis, Lingua, and rupestris.
Nothochlæna canariensis, Eckloniana, lævis, lanuginosa, and Marantæ.
Platyloma atropurpureum, bellum, Brownii, Calomelanos, cordatum, falcatum, flexuosum, and rotundifolium.
Pleopeltis Billardieri and pustulata.
Polystichum capense, falcinellum, frondosum, lepidocaulon, proliferum, tripteron, venustum, and vestitum.
Pteris arguta, crenata, cretica albo-lineata, hastata, Kingiana, longifolia, semipinnata, serrulata and its many garden sports (angustata, Applebyana, corymbifera, cristata, cristata variegata, Goeziana, polydactyla, semifastigiata, Leyi, and fimbriata), tremula, and umbrosa.
Todea barbara (africana), Fraseri, hymenophylloides (pellucida), and superba.
Trichomanes elongatum, reniforme, and venosum.
Woodsia mollis.
Woodwardia orientalis, and radicans with its variety cristata.

Select Hardy Ferns.

Adiantum Capillus Veneris and the varieties incisum, magnificum, and cornubiense; and pedatum.
Allosorus crispus.
Asplenium Adiantum nigrum and the variety grandiceps; alternans, angustifolium, ebeneum, fontanum; lanceolatum and the variety microdon; marinum and the varieties ramosum, trapeziforme, subbipinnatum, and crenatum; Trichomanes and the varieties incisum, Moulei, ramosum, multifidum, and cristatum.
Athyrium Filix fœmina and the varieties corymbiferum, crispum, Frizelliæ, Applebyanum, grandiceps, plumosum, Victoriæ, apiculatum, acrocladon, apuæforme, coronatum, Elworthii, gracillimum, Grantiæ, marinum, multiceps, multifidum, polyclados, polydactylon, thyssanotum, &c.; and Goringianum pictum.
Blechnum Spicant and the varieties imbricatum, multifurcatum, ramosum.
Camptosorus rhizophyllus.
Ceterach officinarum.
Cyrtomium falcatum.
Cystopteris bulbifera, fragilis and the varieties angustata and Dickieana; montana, and sudetica.
Dennstædtia punctilobula (Dicksonia pilosiuscula).
Dictyogramma japonica.
Diplazium lanceum and thelypteroides.
Gleichenia alpina.
Hymenophyllum tunbridgense and unilaterale.
Lastrea æmula (fœniseeii), atrata, cristata; dilatata and its varieties Chanteriæ, dumetorum, lepidota; erythrosora; Filix mas and the varieties Bollandiæ, cristata, cristata angustata, grandiceps, paleacea, Pinderi; Goldieana, marginalis; montana and the varieties crispa, cristata, Nowelliana; noveboracensis, remota, rigida, spinulosa and Thelypteris.
Lomaria alpina and chilensis.
Lygodium palmatum.
Nothochlæna Marantæ and vestita.
Onoclea sensibilis.
Onychium lucidum (japonicum).
Osmunda cinnamomea, spectabilis, gracilis, Claytoniana (interrupta), regalis and its variety cristata.
Polypodium alpestre and its variety flexile; Dryopteris, Krameri, Phegopteris, Robertianum (calcareum), vulgare and its varieties cambricum, cristatum, omnilacerum, pulcherrimum, semilacerum, and cornubiense.
Polystichum acrostichoides; aculeatum and its varieties lobatum, multifidum, acrocladon, &c.; angulare and its varieties cristatum, grandiceps, Holeanæ, parvissimum, Pateyi, polydactylum, proliferum, proliferum Wollastoni, rotundatum, grandidens, imbricatum, plumosum, Kitsoniæ, pterophorum, tripinnatum, &c.; falcinellum, Lonchitis, and setosum.
Pteris aquilina, cretica albo-lineata, and scaberula.
Scolopendrium vulgare and its varieties acrocladon, Claphamii, columnare, Coolingii, crispum, crispum fertile, crispum minus, crispum latum, cristatum, laceratum, marginatum, multifidum, Stansfieldii, and many others.
Struthiopteris germanica, japonica, and pennsylvanica.
Trichomanes radicans.
Woodsia alpina, ilvensis, obtusa, and polystichoides Veitchii.
Woodwardia areolata, japonica, and virginica.

See FERNS, vol. ix. pp. 100-107.

VI. *Fruits.*

114. *Fruit Tree Borders.*—No pains should be spared, in the preparation of fruit tree borders, to secure their thorough drainage. The soil is sometimes placed upon a pavement flooring supported by stone or brick piers, with a cavity below of 18 inches or 2 feet deep, into which air is admitted by small vertical eyes, placed along the edges of the walk, and covered with open iron gratings. This arrangement is expensive, and the same advantages can generally be secured by placing over the sloping bottom a good layer of coarse rubbly material, communicating with a drain in front to carry off the water, while earthenware drain tubes may be laid beneath the rubble from 8 to 10 feet apart, so as to form air drains, and provided with openings both at the side of the walk and also near the base of the wall. Over this rubbly matter, rough turfy soil, grass-side downwards, should be laid, and on this the good prepared soil in which the trees are to be planted. Such an elaborate system of drainage is necessary only in the case of adhesive clayey subsoils.

The borders should consist of three parts rich turfy calcareous loam, the top spit of a pasture, and one part light gritty earth, such as road-grit, with a small portion (one-sixth) of fine lime and brick rubbish. They should not be less than 12 feet in breadth, and may vary up to 15 or 18 feet, with a fall from the wall of about 1 inch in 3 feet. The border itself should be raised a foot or more above the general level. The bottom of the border as well as that of the drain must be kept lower than the general level of the subsoil, else the soakage will gather in all the little depressions of its surface. Fruit-tree borders should not be at all cropped with culinary vegetables, or very slightly so, as the process of digging destroys the roots of the trees, and drives them from near the surface, where they ought to be.

Shallow planting, whether of wall trees or standards, is generally to be preferred, a covering of a few inches of soil being sufficient for the roots, but a surface of at least equal size to the surface of the hole should be covered with dung or litter so as to restrain evaporation and preserve moisture. In the case of wall trees, a space of 5 or 6 inches is usually left between the stem at the insertion of the roots and the wall, to allow for increase of girth. Young standard trees should be tied to stakes so as to prevent their roots being ruptured by the wind-waving of the stems.

In the selection and distribution of fruit trees regard must of course be had to local situation and climate. The best walls having a south or south-east aspect are devoted to the peach, apricot, and fig. Cherries and the generality of plums succeed very well either on an east or a west aspect. In Scotland the mulberry requires the protection of a wall, and several of the finer apples and pears do not arrive at perfection without this help, and a tolerably good aspect. The wall-trees intended to be permanent are called dwarfs, from their branches springing from near the ground. Between these, trees with tall stems, called riders, are planted as temporary occupants of the upper part of the wall. The riders should have been trained in the nursery into good-sized trees, in order that when planted out they may come into bearing as speedily as possible.

Standard Fruit Trees should not be planted, if it can be avoided, in the borders of the kitchen garden, but in the outer slips, where they either may be allowed to attain their full size, or may be kept dwarfed. Each sort of fruit should be planted by itself, for the sake of orderly arrangement, and in order to facilitate protection when necessary by a covering of nets. Their produce is often superior in flavour to that of the same kind of fruit grown on walls.

.lmond. 115. The *Almond*, Amygdalus communis, is very ornamental in respect to its flowers in the early spring months, but of little value for its fruit. There are two varieties, one producing large flowers and sweet-kernelled fruits, and the other small flowers and bitter kernels. Every good garden should contain a tree or two, especially of the sweet almond, for their ornamental aspect in spring. The almond requires a warm light soil, well drained, and a sheltered position and warm aspect. It is propagated by budding on the seedling almond, or for heavier soils on the plum stock. See ALMOND, vol. i. p. 594.

.pple. 116. The *Apple*, Pyrus Malus, is amongst the most useful of all our hardy fruits, and succeeds in localities too cold for either the pear or the plum, while from its flowering later in the spring it is less liable to be cut off by frosts.

It may be propagated by seeds to obtain stocks for grafting, and also for the production of new varieties. The established sorts are usually increased by grafting, the method called whip-grafting being preferred. The stocks should be at least as thick as the finger; and should be headed back to where the graft is to be fixed in January, unless the weather is frosty, but in any case before vegetation becomes active. The scions should be cut about the same time, and laid in firmly in a trench, in contact with the moist soil, until required.

The apple-tree will thrive in any good well-drained soil, the best being a good mellow calcareous loam, while the less iron there is in the subsoil the better. The addition of marl to soils that are not naturally calcareous very much improves them. The trees are liable to canker in undrained soils or those of a hot sandy nature. Where the soil is not naturally rich enough, it should be well manured, but not to the extent of encouraging over-luxuriance. It is better to apply manure in the form of a compost than to use it in a fresh state or unmixed.

To form an orchard, standard trees should be planted at from 25 to 40 feet between the rows, according to the fertility of the soil and other considerations. The trees should be selected with clean, straight, self-supporting stems, and the head should be shapely and symmetrical, with the main branches well balanced. In order to obtain such a stem, all the leaves on the first shoot from the graft or bud should be encouraged to grow, and in the second season the terminal bud should be allowed to develop a further leading shoot, while the lateral shoots should be allowed to grow, but so that they do not compete with the leader, on which the growth of leaves should be encouraged in order that they may give additional strength to the stem below them. The side shoots should be removed gradually, so that the diminution of foliage in this direction may not exceed the increase made by the new branches and shoots of the upper portion. Dwarf pyramids, which occupy less space than open dwarfs, if not allowed to grow tall, may be planted at from 10 to 12 feet apart. Dwarf bush trees may be planted from 10 to 15 feet apart, according to the variety and the soil. Dwarf bushes on the Paradise stock are both ornamental and useful in small gardens, the trees being always conveniently under control. These bush trees, which must be on the proper stock—the French Paradise—may be planted at first 6 feet apart, with the same distance between the rows, the space being afterwards increased, if desired, to 12 feet apart, by removing every alternate row.

"Cordons" are trees trained to a single shoot, the laterals of which are kept spurred. They are usually trained horizontally, at about $1\frac{1}{2}$ feet from the ground, and may consist of one stem or of two, the stems in the latter case being trained in opposite directions. In cold districts the finer sorts of apples may be grown against walls as upright or oblique cordons. From these cordon trees very fine fruit may often be obtained. The apple may also be grown as an espalier tree, a form which does not require much lateral space. The ordinary trained trees for espaliers and walls should be planted 20 feet apart.

The fruit of the apple is produced on spurs which form on the branchlets of two years old and upwards, and continue fertile for a series of years. The principal pruning should be performed in summer, the young shoots if crowded being thinned out, and the superabundant laterals shortened by breaking them half through. The general winter pruning of the trees may take place any time from the beginning of November to the beginning of March, in open weather. The trees are rather subject to the attacks of the American blight (*Eriosoma mali*), which may be removed by scrubbing with a hard brush, by painting the affected spots with any bland oil, or by washing them with dilute paraffin and soft soap.

The following are a few of the most approved varieties of the apple tree, arranged in the order of their ripening, with the months in which they are in use:—

Dessert Apples.

White Juncating	July.	Ribston Pippin	Nov.-Mar.
Early Red Margaret	Aug.	Golden Pippin	Nov. Apr.
Irish Peach	Aug.	Golden Reinette	Nov.-Apr.
Devonshire Quarrenden	Aug., Sept.	Northern Spy	Nov.-Apr.
Duchess of Oldenburg	Aug., Sept.	Rosemary Russet	Nov.-Apr.
Oslin	Aug., Sept.	Ashmead's Kernel	Nov.-May.
Red Astrachan	Sept.	Aromatic Russet	Dec.-Feb.
Kerry Pippin	Sept., Oct.	White Winter Calville (grown under glass)	Dec.-Mar.
Peasgood's Nonesuch	Sept., Oct.		
King of the Pippins	Oct.-Jan.	Braddick's Nonpareil	Dec.-Apr.
Cox's Orange Pippin	Oct.-Feb.	Court-pendû Plat	Dec.-Apr.
Court of Wick	Oct.-Mar.	Wyken Pippin	Dec.-Apr.
Blenheim Pippin	Nov.-Feb.	Cornish Gilliflower	Dec.-May.
Sam Young	Nov.-Feb.	Golden Harvey	Dec.-May.
Sykehouse Russet	Nov.-Feb.	Scarlet Nonpareil	Jan.-Mar.
Fearn's Pippin	Nov.-Mar.	Cockle's Pippin	Jan.-May.
Herefordshire Pearmain	Nov.-Mar.	Lamb Abbey Pearmain	Jan.-May.
Mannington's Pearmain	Nov.-Mar.	Old Nonpareil	Jan.-May.
Margil	Nov.-Mar.	Sturmer Pippin	Feb.-June.

Kitchen Apples.

Keswick Codlin	Aug., Sept.	Gloria Mundi	Nov.-Jan.
Lord Suffield	Aug., Sept.	Blenheim Pippin	Nov.-Feb.
Manks Codlin	Aug.-Oct.	Tower of Glammis	Nov.-Feb.
Ecklinville Seedling	Aug.-Nov.	Warner's King	Nov.-Mar.
Stirling Castle	Aug.-Nov.	Alfriston	Nov.-Apr.
Stone's	Aug.-Nov.	London Pippin	Nov.-Apr.
Emperor Alexander	Sept.-Dec.	Northern Greening	Nov.-Apr.
Waltham Abbey Seedling	Sept.-Jan.	Reinette de Canada	Nov.-Apr.
Cellini	Oct., Nov.	Bess Pool	Nov.-May.
Gravenstein	Oct.-Dec.	Royal Russet	Nov.-June.
Hawthornden	Oct.-Dec.	Gooseberry	Nov.-July.
Baumann's Red Winter Reinette	Oct.-Jan.	Winter Greening	Nov.-July.
		Rhode Island Greening	Dec.-Apr.
Mère de Ménage	Oct.-Jan.	Rymer	Dec.-Apr.
Beauty of Kent	Oct.-Feb.	Lane's Prince Albert	Jan.-June.
Yorkshire Greening	Oct.-Feb.	Norfolk Beaufin	Jan.-June.

See APPLE, vol. ii. p. 211.

117. The *Apricot*, Prunus Armeniaca or Armeniaca vulgaris, is Aprico propagated by budding on the mussel or common plum stock. The tree succeeds in good well-drained loamy soil, rather light than heavy. It is usually grown as a wall tree, the east and west aspects being preferred to the south, which induces mealiness in the fruit, though in Scotland the best aspects are necessary. The most usual and best mode of training is the fan method in the modified form represented in par. 26, under fig. 83. The fruit is produced on shoots of the preceding year, and on small close spurs formed on the two-year-old wood. The trees should be planted about 20 feet apart. The summer pruning should commence early in June, at which period all the irregular fore-right and useless shoots are to be pinched off; and, shortly afterwards, those which remain are to be fastened to the wall. At the winter pruning all branches not duly furnished with spurs and fruit buds are to be

removed. The young bearing shoots are moderately pruned at the points, care being, however, taken to leave a terminal shoot or leader to each branch. The most common error in the pruning of apricots is laying in the bearing shoots too thickly; the branches naturally diverge in fan training, and when they extend so as to be about 15 inches apart, a fresh branch should be laid in, to be again subdivided as required. The blossoms of the apricot open early in spring, but are more hardy than those of the peach; the same means of protection when necessary may be employed for both. If the fruit sets too numerously, it is thinned out in June and in the beginning of July, the later thinnings being used for tarts. In the south of England, where the soil is suitable, the hardier sorts of apricot, as the Breda and Brussels bear well as standard trees in favourable seasons. In such cases the trees may be planted from 20 to 25 feet apart.

Forcing.—The ripening of the fruit of the apricot may be accelerated by culture under glass, the trees being either planted out like peaches, or grown in pots on the orchard-house system. They must be very gently excited, since they naturally bloom when the spring temperature is comparatively low. At first a maximum of 40° only must be permitted; after two or three weeks it may be raised to 45°, and later on to 50° and 55°, and thus continued till the trees are in flower, air being freely admitted, and the minimum or night temperature ranging from 40° to 45°. After the fruit is set the temperature should be gradually raised, being kept higher in clear weather than in dull. When the fruit has stoned, the temperature may be raised to 60° or 65° by day and 60° by night; and for ripening off it may be allowed to reach 70° or 80° by sun heat.

The Moorpark is undoubtedly the best apricot in cultivation, and should be planted for all general purposes; the Peach is a very similar variety, not quite identical; and the Hemskerk is also similar, but hardier. The Large Early, which ripens in the end of July and beginning of August, and the Kaisha, a sweet-kernelled variety, which ripens in the middle of August, are also to be recommended. For standard trees in favourable localities the Breda and Brussels may be added. See APRICOT, vol. ii. p. 214.

Cherry. 118. The *Cherry*, Cerasus avium and C. vulgaris, is increased by budding on the wild gean, obtained by sowing the stones of the small black or red wild cherries. To secure very dwarf trees, the Cerasus Mahaleb has been used for the May Duke, Kentish, Morello, and analogous sorts, but it is not adapted for strong-growing varieties like the Bigarreaus. The stocks are budded, or, more rarely, grafted, at the usual seasons. The cherry prefers a free, loamy soil, with a well-drained subsoil. Stiff soils and dry gravelly subsoils are both unsuitable, though the trees require a large amount of moisture, particularly the large-leaved sorts, such as the Bigarreaus. For standard trees, the Bigarreau section should be planted 30 feet apart, or more in rich soil, and the May Duke, Morello, and similar varieties 20 or 25 feet apart; while, as trained trees against walls and espaliers, from 20 to 24 feet should be allowed for the former, and from 15 to 20 feet for the latter.

In forming the stems of a standard tree, the temporary side-shoots should not be allowed to attain too great a length, and should not be more than two years old when they are cut close to the stem. The first three shoots retained to form the head should be shortened to about 15 inches, and two shoots from each encouraged, one at the end, and the other 3 or 4 inches lower down. When these have become established, very little pruning will be required, and that chiefly to keep the principal branches as nearly equal in strength as possible for the first few years.

Espalier trees should have the branches about a foot apart, starting from the stem with an upward curve, and then being trained horizontally. In summer pruning the shoots on the upper branches must be shortened at least a week before those on the lower ones. After a year or two clusters of fruit buds will be developed on spurs along the branches, and those spurs will continue productive for an indefinite period.

For wall trees any form of training may be adopted; but as the fruit is always finest on young spurs, fan-training is probably the most advantageous. A succession of young shoots should be laid in every year. The Morello, which is of twiggy growth, and bears on the young wood, must be trained in the fan form, and care should be taken to avoid the very common error of crowding its branches.

Forcing.—The cherry will not endure a high temperature nor a close atmosphere. A heat of 45° at night will be sufficient at starting, this being gradually increased during the first few weeks to 55°, but lowered again when the blossom buds are about to open. After stoning the temperature may be again gradually raised to 60°, and may go up to 70° by day, or 75° by sun heat, and 60° at night. The best forcing cherries are the May Duke and the Royal Duke, the Duke cherries being of more compact growth than the Bigarreau tribe, and generally setting better; nevertheless a few of the larger kinds, such as Bigarreau Napoléon, Black Tartarian, and St Margaret's, should be forced for variety. The trees may be either planted out in tolerably rich soil, or grown in large pots of good turfy friable calcareous loam mixed with rotten dung. If the plants are small, they may be put into 12-inch pots in the first instance, and after a year shifted into 15-inch pots early in autumn, and plunged in some loose or even very slightly fermenting material. The soil of the pots should be protected from snow-showers and cold rains. Occasionally trees have been taken up in autumn with balls, potted, and forced in the following spring; but those which have been established a year in the pots are to be preferred. Such only as are well furnished with blossom-buds should be selected. The trees should be removed to the forcing house in the beginning of December, if fruit be required very early in the season. During the first and second weeks it may be kept nearly close; but, as vegetation advances, air becomes absolutely necessary during the day, and even at night when the weather will permit. If forcing is commenced about the middle or third week of December, the fruit ought to be ripe by about the end of March. After the fruit is gathered, the trees should be duly supplied with water at the root, and the foliage kept well syringed till the wood is mature.

The following are some of the best varieties now in cultivation. B. signifies that they belong to the Bigarreau, D. to the May Duke, and M. to the Morello section; K. indicates that they are specially adapted for culinary purposes; and b., m., and e. show that they are in use at beginning, middle, and end respectively of the month stated:—

Belle d'Orleans, B.	b. m. June.	Archduke, D.	m. July.
Early Purple Gean, B.	m. June.	Royal Duke, D.	m. July.
Early Red Bigarreau, B.	m.e. June.	Joc-o-sot, B.	m. July.
Early Jaboulay, B.	e. June.	Büttner's Yellow, B.	m. July.
Early Lyons, B.	e. June.	Büttner's Black Heart, B.	m. July.
Early Rivers, B.	e. June.	Bigarreau, B.	m. July.
Black Tartarian, B.,	e. June. b. July.	Mammoth, B.	m. e. July.
Bigarreau Noir de Schmidt, B.,	July.	Reine Hortense, D.	m. e. July.
Frogmore Early, B.	b. July.	Kentish, M., K.	m. e. July.
Elton, B.	b. July.	Morello, M., K.	July–Oct.
Black Eagle, B.	b. July.	Bigarreau Napoléon, B.	e. July.
Governor Wood, B.	b. July.	Duchesse de Pallnau, D.	e. July.
May Duke, D. (on walls)	e. June. b. July.	St Margaret's, B.	e. July, b. Aug.
		Florence B.	m. e. Aug.
		Büttner's October, D. K.	October.

See CHERRY, vol. v. p. 586.

Cranberry. 119. *The Cranberry.*—The American cranberry, Oxycoccus macrocarpus, grows freely in beds of peat soil or bog earth formed for their reception in any damp situation. Beds are often prepared around the edges of a pond by depositing a layer of rubble or stones at the bottom, and over these a good thickness of peat or bog earth mixed with sand, extending about 6 inches below and about 4 inches above the usual level of the water surface. On this bed the cranberry plants should be put in at 2 feet apart, in autumn or spring; spreading in all directions, they will soon cover the whole surface with a dense mat of trailing shoots.

The common cranberry, Oxycoccus palustris, a native of Britain, bears fruit which is inferior to that of the American cranberry in size and quality. The plants may be treated in the same manner, and in some places are very successfully cultivated. See CRANBERRY, vol. vi. p. 545.

Currants. 120. The *Currants* are among the most useful of small fruits. The red and the white currant are included as varieties under Ribes rubrum, the white being a pale-fruited variety of the red. The black currant is the produce of Ribes nigrum. Of both types there are several greatly improved varieties.

Red and white currants are readily propagated by cuttings. They succeed in any well-enriched garden soil, but thrive best in warm moist situations, where they enjoy an abundance of air; occasionally they are trained perpendicularly against low walls or fences. As bushes they are best planted in compartments by themselves, at about 5 or 6 feet apart each way, and should be on clean single stems some 8 or 10 inches long. They are sometimes trained as standards on single stems, 3 or 4 feet high, in which form the fruit is more accessible. The winter pruning consists in shortening the young bearing wood on the sides of the branches so as to form spurs of an inch or two in length. The leading shoots are left about 6 inches long. Some cultivators reduce the young shoots to about half their length as soon as the fruit begins to colour, which is found to increase the size and improve the flavour of the berries.

The black currant thrives best in a moist deep soil and shady situation. Its culture is much the same as that of the other currants, but the young shoots are not spurred, all the pruning necessary being to keep the branches thinned out so as to stand clear of each other, and to promote the formation of young wood. If the fruit is intended for preserving, it should not be gathered while wet, nor, if it can be avoided, immediately after a wet period.

Aphides often cluster in vast numbers at the extremities of the summer shoots, especially of red and white currants, and should be destroyed by cutting off and burning the parts infested, or by applying some of the many insecticides.

The following are the best sorts of currants for general purposes:—

Red.—Red Dutch, Knight's Large Red, Houghton Seedling or Orangefield (late), Gondouin or Raby Castle (late), Lace-leaved or Large Sweet Red, Champagne (flesh-coloured).
White.—White Dutch, Wilmot's Large White.
Black.—Black Naples, Black Grape or Ogden's, Lee's Prolific.
See CURRANTS, vol. vi. p. 715.

g. 121. The *Fig*, Ficus Carica, lives to a great age, and along the southern coast of England bears fruit abundantly as a standard; but in Scotland and in many parts of England a south wall is indispensable for its successful cultivation out of doors.

Fig trees are propagated by cuttings, which should be put into pots, and placed in a gentle hotbed. They may be obtained more speedily from layers, which should consist of two or three years old shoots, and these, when rooted, will form plants ready to bear fruit the first or second year after planting. The best soil for a fig border is a friable loam, not too rich, but well drained; a chalky subsoil is congenial to the tree, and, to correct the tendency to over-luxuriance of growth, the roots should be confined within spaces surrounded by a wall enclosing an area of about a square yard. The sandy soil of Argenteuil, near Paris, suits the fig remarkably well; but the best trees are those which grow in old quarries, where their roots are free from stagnant water, and where they are sheltered from cold, while exposed to a very hot sun, which ripens the fruit perfectly. The fig succeeds well planted in a paved court against a building with a south aspect.

The fig tree naturally produces two sets of shoots and two crops of fruit in the season. The first shoots generally show young figs in July and August, but these in the climate of England very seldom ripen, and should therefore be rubbed off. The late or midsummer shoots likewise put forth fruit-buds, which, however, do not develop themselves till the following spring; and these form the only crop of figs on which the British gardener can depend.

The fig tree grown as a standard should get very little pruning, the effect of cutting being to stimulate the buds to push shoots too vigorous for bearing. When grown against a wall, it has been recommended that a single stem should be trained to the height of a foot. Above this a shoot should be trained to the right, and another to the left; from these principals two other subdivisions should be encouraged, and trained 15 inches apart; and along these branches, at distances of about 8 inches, shoots for bearing, as nearly as possible of equal vigour, should be encouraged. The bearing shoots produced along the leading branches should be trained in at full length, and in autumn every alternate one should be cut back to one eye. In the following summer the trained shoots should bear and ripen fruit, and then be cut back in autumn to one eye, while shoots from the bases of those cut back the previous autumn should be trained for succession. In this way every leading branch will be furnished alternately with bearing and successional shoots.

When protection is necessary, as it may be in severe winters, though it is too often provided in excess, spruce branches have been found to answer the purpose exceedingly well, owing to the fact that their leaves drop off gradually when the weather becomes milder in spring, and when the trees require less protection and more light and air. The principal part requiring protection is the main stem, which is more tender than the young wood.

Forcing.—The fig requires more heat than the vine to bring it into leaf. It may be subjected to a temperature of 50° at night, and from 60° to 65° in the day, and this should afterwards be increased to 60° and 65° by night, and 70° to 75° by day, or even higher by sun heat, giving plenty of air at the same time. In this temperature the evaporation from the leaves is very great, and this must be replaced and the wants of the swelling fruit supplied by daily watering, by syringing the foliage, and by moistening the floor, this atmospheric moisture being also necessary to keep down the red spider. When the crop begins to ripen, a moderately dry atmosphere should be maintained, with abundant ventilation when the weather permits.

The fig tree is easily cultivated in pots, and by introducing the plants into heat in succession the fruiting season may be considerably extended. The plants should be potted in turfy loam mixed with charcoal and old mortar rubbish, and in summer top-dressings of rotten manure, with manure water two or three times a week, will be beneficial. While the fruit is swelling, the pots should be plunged in a bed of fermenting leaves.

The following are a few of the best figs; those marked F. are good forcing sorts, and those marked W. suitable for walls:—

Agen: brownish-green, turbinate.
Angélique (Madeleine), F., W.: yellow, turbinate.
Brown Ischia, F.: chestnut-coloured, roundish-turbinate.
Brown Turkey (Lee's Perpetual), F., W.: purplish-brown, turbinate
Brunswick, W.: brownish-green, pyriform.
Col di Signora Blanca, F.: greenish-yellow, pyriform.
Col di Signora Nero: dark chocolate, pyriform.
Datte: pale dingy brown, pyriform.
Early Violet, F.: brownish-purple, roundish.
Grizzly Bourjassotte: chocolate, round.
Grosse Monstreuse de Lipari: pale chestnut, turbinate.
Lucrezia: dull white, roundish.
Negro Largo, F.: black, long pyriform.
Royal Vineyard: purple, long pyriform.
White Ischia, F.: greenish-yellow, roundish-obovate.
White Marseilles, F., W.: pale green, roundish-obovate.

See FIG, vol. ix. p. 153.

se- 122. The *Gooseberry* has a double parentage, Ribes Grossularia
y. being the parent of the rough or hairy-fruited sorts, and R. Uva-crispa that of the smooth-fruited ones. It prefers a loose rich soil, which readily imbibes, but does not retain, much moisture. The plant is propagated by cuttings, and should be transplanted early in autumn, the trees, like those of the currant, being ranged in lines or grouped in compartments. The trees should be formed with single stems a foot high; and the suckers, if any spring up from the roots, should be carefully removed. Formerly it was the practice in Scotland to spur all the annual wood; but now the black currant system of pruning is more generally and advantageously followed. The ground on which the bushes stand should be forked over once a year, but only slightly, so as not to disturb the roots, and manure should be applied either as a top-dressing or in a liquid form. The caterpillars which attack the plant may be destroyed by dusting the leaves with powdered white hellebore, which seems to be the only certain remedy, as even hand-picking fails in some seasons when the caterpillars are very abundant, and the trees are numerous.

The gooseberry, like the currant, may be trained on walls or espaliers, to accelerate the ripening or increase the size of the fruit. The following is a good limited selection of sorts:—

Hairy Reds.—Red Champagne, Red Warrington, Keens' Seedling, Rough Red, Lord Derby, Henson's Seedling, Crown Bob, Companion.
Hairy Yellows.—Yellow Champagne, Early Sulphur (very early), Catharina, Fanny, Broom Girl.
Hairy Greens.—Early Green Hairy, Glenton Green, Thunder.
Hairy Whites.—White Champagne, Bright Venus, White Lion, Transparent, Snowdrop, Fascination, Antagonist.
Downy Whites.—Whitesmith, Cheshire Lass, Maid of the Mill, Early White.
Smooth Reds.—London (very large), Plough Boy, Small Red Globe, Turkey Red.
Smooth Yellows.—Smiling Beauty, Leveller, Gipsy Queen, Leader, Ringer.
Smooth Greens.—Pitmaston Green-gage, Telegraph, Heart of Oak, Green Overall, Shiner, General Markham.
Smooth Whites.—White Honey, White Fig, Careless, Freedom.

See GOOSEBERRY, vol. x. p. 779.

123. The *Medlar*, Mespilus germanica, is a deciduous tree, native Medlar.
of the middle and south of Europe, and found in hedges and woods in England. Its fruit is hard, acid, and unfit for eating till it loses its green colour and becomes "bletted," in which state it acquires an agreeably acid and somewhat astringent flavour.

The medlar is propagated by budding or grafting upon the whitethorn, which is most suitable if the soil is dry and sandy, or on the quince if the soil is moist. It produces the best fruit in rich, loamy, somewhat moist ground. The tree may be grown as a standard, and chiefly requires pruning to prevent the branches from crossing and rubbing each other. The fruit should be gathered in November, on a dry day, and laid out upon shelves in the fruit room. It becomes bletted and fit for use in the course of two or three weeks.

124. The *Melon*, Cucumis Melo, is an annual tropical plant of Melon.
climbing or trailing habit, extensively cultivated in Persia and some parts of India. The plant requires artificial heat to grow it to perfection, the rock and cantaloup varieties succeeding with a bottom heat of 70° and an atmospheric temperature of 75°, rising with sun heat to 80°, and the Persian varieties requiring a bottom heat of 75°, gradually increasing to 80°, and an atmospheric temperature ranging from 75° to 80° when the fruit is swelling, as much sun heat as the plants can bear being allowed at all times. The melon grows best in rich turfy loam, somewhat heavy, with which a little well-rotted dung, especially that of pigeons or fowls, should be used, in the proportion of one-fifth mixed in the compost of loam. Melons are grown on hotbeds of fermenting manure, when the soil should be about a foot in thickness, or in pits heated either by hot water or fermenting matter, or in houses heated by hot water, in which case the soil bed should be 15 or 18 inches thick. The fermenting materials should be well prepared, and, since the heat has to be kept up by linings, it is a good plan to introduce one or two layers of faggots in building up the bed. A mixture of dung and leaves gives a more subdued but more durable heat.

For all ordinary purposes February is early enough for sowing the first crop, as well-flavoured fruits can scarcely be looked for before May. The seeds may be sown singly in 3-inch pots in a mixture of leaf-mould with a little loam, the pots being plunged in a bottom heat of 75° to 80°, and as near the glass as possible, in order that the young plants may not be drawn up. The hill or ridge of soil should be about a foot in thickness, the rest of the surface being afterwards made up nearly to the same level. If the fruiting bed is not ready when the roots have nearly filled the pots, they must be shifted into 4-inch pots, for on no account must they be allowed to get starved or pot-bound. Two or three plants are usually planted in a mound or ridge of soil placed in the centre of each light, and the rest of the surface is covered over to a similar depth as soon as the roots have made their way through the mound.

The mode of pruning and training is similar whether the plants are grown on a trellis or on the surface of a bed, with this difference that in the former case the main stem has to be carried up to a sufficient height to reach the trellis before it is stopped. When the plants are trained on the surface of the beds the tops should be pinched off as soon as the second rough leaf is fairly formed, the stopping being effected either long enough before planting to allow the buds to break, or not until the plants have taken fresh root after planting. One branch will thus be developed from the axil of each of the two leaves, and they should be trained one towards the front and the other towards the back of the frame, before reaching which the points should be pinched off and lateral fruit-bearing shoots will then be produced.

The melon being one of those plants which produce distinct male and female flowers (diœcious), it is necessary to its fertility that both should be produced, and that the pollen of the male flower should, either naturally by insect agency, or artificially by the cultivator's manipulation, be conveyed to the stigma of the female flower; this setting of the fruit is often done by stripping a male flower of its corolla, and inverting it in the centre of the fruit-bearing flower. After the fruit has set and has grown to the size of an egg, it should be preserved from contact with the soil by placing it on a piece of tile or slate; or if grown on a trellis by a little swinging wooden shelf, just large enough to hold it. In either case the material used should be tilted a little to one side, so as to permit water to drain away. Before the process of ripening commences, the roots should have a sufficient supply of moisture, so that none may be required from that time until the fruit is cut.

When the melon is grown in a house there should be a good depth of drainage over the tank or other source of bottom heat, and on this should be placed turfs, grass side downwards, below the soil, which should not be less than 15 and need not be more than 18 inches in thickness. The compost should be made moderately firm, and only half the bed should be made up at first, the rest being added as the roots require it. The melon may also be grown in large pots, supplied with artificial manure or manure water. The stems may be trained up the trellis in the usual way, or the rafters of a pine stove may be utilized for the purpose. If the trellis is constructed in panels about the width of the lights, it can be taken down and conveniently stowed away when not in use.

The presence of too much moisture either in the atmosphere or in the soil is apt to cause the plants to damp off at the neck, but the evil, if it appears, may be checked by applying a little fresh-slaked lime round the stem of the plant.

The varieties of melon are continually receiving additions which are more or less permanent. A great deal depends on getting the varieties true to name, as they are very liable to get cross-fertilized by insect agency. Some of the best are—

Scarlet-fleshed.—Scarlet Gem, and Read's Scarlet-fleshed.
White-fleshed.—Colston Basset Seedling, and Queen Emma.
Green-fleshed.—Victory of Bath, Eastnor Castle, and Egyptian.

Mulberry.

125. The *Mulberry*, Morus nigra, is a deciduous tree, with monœcious flowers, and oblong compound fruits, having a rich aromatic flavour and a fine subacid juice. The fruit is in request for the dessert during the months of August and September. It is a native of Persia, and succeeds well as a standard in the warmer parts of England, especially in sheltered situations, but in the north of England and the less favoured parts of Scotland it requires the assistance of a wall. The standard trees require no other pruning or training than an occasional thinning out of the branches, and are generally planted on grassy lawns, to prevent the fruit being damaged when it falls.

The tree succeeds best in a rich, deep, and somewhat moist loam, but grows well in any good garden ground. It is usually propagated either by cuttings or layers, which latter, if made from the older branches of the tree, come sooner into bearing. Cuttings planted in the spring should consist of well-ripened shoots of the preceding year, with a joint of two-year-old wood at their base, or if planted in autumn should have the shoots well matured, and furnished with a heel of two-year-old wood. The branches and even stout limbs are sometimes employed as cuttings instead of the younger shoots, especially when the object is to obtain a bearing tree quickly. The branch should be planted deeply in autumn in good soil, and if necessary supported in an upright position by a stake. The most common mode of propagation, however, is by layering the young branches. The mulberry may be grown in pots, and gently forwarded in an orchard house, and under these conditions the fruit acquires a richness of flavour and a melting character which is unknown in the fruit ripened outdoors. If cultivated in this way it requires abundance of water while the fruit is swelling, and also frequent dressings of artificial fertilizers or doses of liquid manure.

Nectarine.

126. The *Nectarine* is merely a smooth-skinned variety of the peach, and will be included under that head (see par. 129).

Nut.

127. The *Nut*, Corylus Avellana, or hazel-nut, one of our indigenous shrubs, is the parent of the Filberts, Cob Nuts, and other improved varieties which are met with under cultivation. These succeed best in a rich dry loam, deeply worked, and should receive from time to time a slight manuring. They are generally planted in the slip, but thrive best in an open quarter by themselves. The different varieties are propagated by layers, or more generally by suckers; or, if required, they may be grafted. The Cosford is a favourite kind, being a thin-shelled nut, and having a kernel of high flavour. If either this or the filbert be grafted on small stocks of the Spanish nut, which grows fast, and does not send out suckers, dwarfish prolific trees may be obtained; and, by pruning the roots in autumn, the trees may be kept quite neat and bushy.

The county of Kent has long been celebrated for the culture of nuts for the London market. The young plants are almost always suckers from old bushes, and are planted from 10 to 12 feet apart, being subsequently kept from crowding or shading each other by pruning. They are suffered to grow without restraint for about three years, and then, being cut down to within 12 or 18 inches of the ground, they will push out from near the top five or six shoots, which at the winter pruning in their second year are shortened one-third. A hoop of sufficient diameter is then placed within the branches, and the shoots are fastened to it at about equal distances. In the spring of the fourth year all the laterals are cut back nearly to the principal stems, and from these cut-back laterals short shoots proceed, on which fruit may be expected in the following year. Those which have borne fruit are afterwards removed by the knife. The leading shoots are always shortened about two-thirds. Every bearing twig is deprived of its top, and all suckers are carefully rooted out.

The nut being a monœcious plant, it is necessary in the winter or spring pruning to take care that a sufficiency of the male flowers—those produced in pendulous catkins—are preserved. The female flowers, which produce the fruit, are not visible till spring, and appear in the form of plump buds, producing from their apex several deep crimson threads, which are the styles to which the pollen from the catkins should be applied.

The best kinds of nuts for garden cultivation are Lambert's Filbert, the Red and the White Filberts, the Cosford, the Norwich Prolific, and Pearson's Prolific.

128. The *Orange*, Citrus Aurantium, has been usually cultivated in England for the beauty of the plant and the fragrance of its blossoms, rather than for the purpose of affording a supply of edible fruit. The latter can, however, be easily grown in a hot-house, some of the fruits thus grown, especially those of the pretty little Tangierine variety, being superior in quality to the imported fruit. The best form of orange house is the span-roofed, with glass on both sides, the height and other conditions being similar to those recommended for stove plants. The trees may be planted out, a row on each side a central path, in a house of moderate width. The borders must be carefully made, with a drainage bottom of from 9 to 12 inches of broken bricks or rubbly stones, and a drain leading to the exterior. Rough turf with the grassy side downwards should be laid over the drainage material, and then 18 inches of good turfy loam mixed with gritty sand or fine burnt ballast, to keep it permeable to water. The trees, if intended to be permanent, should be placed 10 to 12 feet apart. Bottom heat (about 80°) is beneficial; but it is questionable if its advantages beneath a bed of soil are not more than counterbalanced by the risk of over-dryness, and the inconvenience of getting access to the heating pipes in case of repairs becoming necessary. It will generally be found more convenient to grow the plants in pots or tubs, and then bottom heat can be secured by placing them on or over a series of hot-water pipes kept near to or above the ground level. The pots or tubs should be thoroughly well drained. The temperature may be kept at about 50° or 55° in winter, under which treatment the trees will come into bloom in February; the heat must then be increased to 60° or 65° in the day time, and later on to 80° or 85°. Throughout the growing season the trees should be liberally watered, and thoroughly washed every day with the garden engine, care being taken not to injure the young leaves; this will materially assist in keeping down insects. The fruit may be expected to ripen from about the middle of October to January, and if the sorts are good will be of excellent quality. When the trees are at rest the soil must not be kept too wet, since this will produce a sickly condition, through the loss of the small feeding roots. The trees require little pruning or training. When a branch appears to be robbing the rest, or growing ahead of them, it should be shortened back or tied down.

When grown for the production of flowers, which are always in great request, the plants must be treated in a similar manner to that already described, but may do without bottom heat.

The favourite sorts of oranges are the Tangierine, a delicious small-fruited early variety; the Mandarin, which is larger than Tangierine; the St Michael's, which is the most commonly grown; the Maltese Blood, which is a very distinct sort with red flesh; and the Plata or silver orange.

129. The *Peach*, Amygdalus Persica, or Persica vulgaris, is one of the most delicious of exotic garden fruits. There are two principal races, the *Peach* proper, which has fruits covered with a downy skin, and the *Nectarine*, which has fruits covered with a smooth skin. The peach and the nectarine would therefore appear to be distinct kinds of fruit, and indeed have an appreciable difference of flavour; but as both peaches and nectarines have been known to grow on the same branch, and individuals half-peach half-nectarine have been produced, they must be regarded as merely varieties of one kind of fruit. Their treatment, moreover, is the same in every respect.

To perpetuate and multiply the choicer varieties, peaches and nectarines are budded upon plum or almond stocks. For dry situations almond stocks are preferable, but they are not long-lived, while for damp or clayey loams it is better to use plums. Double-working is sometimes beneficial ; thus an almond budded on a plum stock may be rebudded with a tender peach, greatly to the advantage of the latter. The peach border should be composed of turfy mellow loam, such as is suitable for the vine and the fig ; this should be used in as rough a state as possible, or not broken small and fine. The bottom should slope towards the outer edge, where a drain should be cut, with an outlet, and on this sloping bottom should be laid a thickness of from 9 inches to 12 inches of rough materials, such as broken bricks or mortar rubbish, over which should be placed a layer of rough turf with the grassy side downwards, and then the good loamy soil to form the border, which need not be of greater depth than 18 inches, for the peach tree is most productive when the roots are kept near the surface. The borders should not be cropped heavily with culinary vegetables, as deep trenching is very injurious. Sickly and unfruitful trees may often be revived by bringing up their roots within 5 or 6 inches of the surface. The experience of the last few seasons has, however, been so disastrous that it has been questioned whether it may not be better, in cold soils and bleak situations, to abandon outdoor peach culture, and to cover the walls with a casing of glass, so that the trees may be under shelter during the uncongenial spring weather.

The fruit of the peach is produced on the ripened shoots of the preceding year. If these be too luxuriant, they yield nothing but leaves ; and if too weak, they are incapable of developing flower buds. To furnish young shoots in sufficient abundance, and of requisite strength, is the great object of peach training and pruning. Trees of slender-growing, twiggy habit naturally fall most readily into the fan form of training, and accordingly this has generally been adopted in the culture of peaches and nectarines. The old fan form is very nearly that of fig. 82 (p. 245). The young tree is, in many cases, procured when it has been trained for two or three years in the nursery ; but it is generally better to commence with a maiden plant, that is, a plant of the first year after it has been budded. It is then in ordinary practice headed down to five or six buds, and in the following summer from two to four shoots, according to the vigour of the plant, are trained in, the laterals from which, if any, are thinned out and nailed to the wall. If there are four branches, the two central ones are shortened back at the subsequent winter pruning so as to produce others, the two lower ones being laid in nearly at full length. In the following season additional shoots are sent forth ; and the process is repeated till eight or ten principal limbs or mother branches are obtained, forming, as it were, the frame-work of the future tree. The branches may be depressed or elevated, so as to check or encourage them, as occasion may arise ; and it is highly advantageous to keep them thin, without their becoming in any part deficient of young shoots. Sometimes a more rapid mode of formation is now adopted, the main shoots being from the first laid in nearly at full length, instead of being shortened. The pruning for fruit consists in shortening back the laterals which had been nailed in at the disbudding, or summer pruning, their length depending on their individual vigour and the luxuriance of the tree. In well-developed shoots the buds are generally double, or rather triple, a wood bud growing between two fruit buds ; the shoot must be cut back to one of these, or else to a wood bud alone, so that a young shoot may be produced to draw up the sap beyond the fruit, which is generally desirable to secure its proper swelling. The point of this leading shoot is subsequently pinched off, that it may not draw away too much of the sap. If the fruit sets too abundantly, it must be thinned, first when as large as peas, reducing the clusters, and then when as large as nuts to distribute the crop equally ; the extent of the thinning must depend on the vigour of the tree, but one or two fruits ultimately left to each square foot of wall is a full average crop. The final thinning should take place after stoning.

The best-placed healthy young shoot produced from the wood buds at the base of the bearing branch is to be carefully preserved and in due time nailed to the wall. In the following winter this will take the place of the branch which has just borne, and is to be cut out. If there be no young shoot below, and the bearing branch is short, the shoot at the point of the latter may sometimes be preserved as a fruit bearer, though if the bearing branch be long it is better to cut it back for young wood. It is the neglect of this which constitutes the principal fault in carrying out the English fan system, as it is usually practised. Several times during summer the trees ought to be regularly examined, and the young shoots respectively topped or thinned out ; those that remain are to be nailed to the wall, or braced in with pieces of slender twigs, and the trees ought occasionally to be washed with the garden engine.

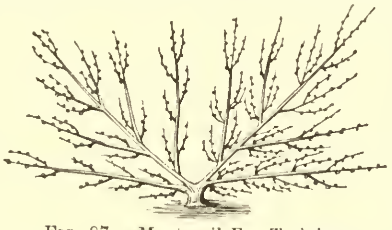

Fig. 87.—Montreuil Fan Training.

The Montreuil form of training is represented by fig. 87. The principal feature is the suppression of the direct channel of the sap, and the substitution of four or more commonly two mother branches, so laid to the wall that the central angle contains about 90°. The other branches are all treated as subordinate members. This form is open to the objection that, if the under branch should die, the upper one cannot be brought down into its place.

The form à la Dumoutier (fig. 88), so called from its inventor, is merely a refinement on the Montreuil method. The formation of

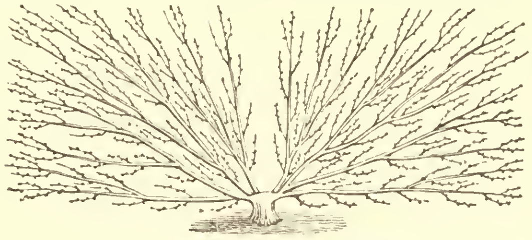

Fig. 88.—Dumoutier's Fan Training.

the tree commences with the inferior limbs and proceeds towards the centre, the branches being lowered from time to time as the tree acquires strength. What is most worthy of notice in this method is the management of the subordinates in the pruning for fruit. When a shoot promises blossom, it is generally at some distance from the point of insertion into the old wood, and the intermediate space is covered with wood buds. All the latter, therefore, which are between the old wood *a* and the blossom *c* in fig. 89, except the lowest *b*, are carefully removed by *ebourgeonnement*. This never fails to produce a shoot *d*, the growth of which is favoured by destroying the useless spray *e* above the blossoms, and pinching off the points of those which are necessary to perfect the fruit. A replacing shoot is thus obtained, to which the whole is invariably shortened at the end of the year.

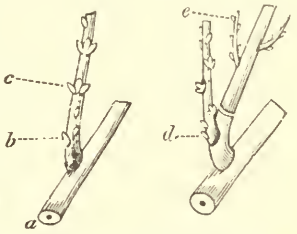

Fig. 89.—Pruning à la Dumoutier.

Mr Seymour's form (fig. 90) approaches more nearly to the French method than any other practised in England, but the direct channel of the sap is not suppressed. It will be seen that the bearing shoots are all on the upper side of the mother branches, and that these bearing shoots are wholly reproduced once a year. The one side of the annexed figure represents the tree after the winter pruning, the other (left hand) side before it has undergone that operation. On the latter side the young shoots will be seen to be in pairs, and at the winter pruning the lower one, or that which has borne fruit, is cut out, and the other is brought down into its place, and shortened to about 8 or 9 inches, care being taken to cut at a wood bud. At

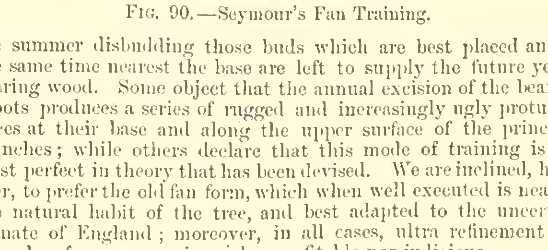

Fig. 90.—Seymour's Fan Training.

the summer disbudding those buds which are best placed and at the same time nearest the base are left to supply the future year's bearing wood. Some object that the annual excision of the bearing shoots produces a series of rugged and increasingly ugly protuberances at their base and along the upper surface of the principal branches; while others declare that this mode of training is the most perfect in theory that has been devised. We are inclined, however, to prefer the old fan form, which when well executed is nearest the natural habit of the tree, and best adapted to the uncertain climate of England ; moreover, in all cases, ultra refinement for the sake of appearance is neither profitable nor judicious.

For cold and late situations, the late Thomas Andrew Knight recommended the encouragement of spurs on the young wood, as such spurs, when close to the wall, generate the best organized and most vigorous blossoms, and generally insure a crop of fruit. They may be produced, by taking care, during the summer pruning or disbudding, to preserve a number of the little shoots emitted by the yearly wood, only pinching off the minute succulent points. On the spurs thus formed blossom buds will be developed early in the following season. This practice is well adapted to cold situations.

Peach trees require protection, especially at the period of blossoming, particularly in the north of England and in Scotland. Canvas or bunting screens are most effectual. By applying these early in the season, great benefit may be derived from retarding the blossom till the frosty nights of spring have passed. Wooden and glass copings are also very useful in warding off frosts.

Forcing.—The pruning and training of the trees in the peach house do not differ materially from the methods practised out of doors. It may also be stated here that when occasion arises peach trees well furnished with buds may be transplanted and forced immediately without risking the crop of fruit, a matter of some importance when, as sometimes happens, a tree may accidentally fail. In the forcing of peaches fire heat is commonly applied about December or January; but it may, where there is a demand, begin a month sooner. At first the house should be merely kept closed at about 45°, but the heat should gradually increase to 55° by the time the trees are in flower, and to 60° when the fruit is set, after which the house should be kept moist by sprinkling the walls and paths, or by placing water troughs on the return pipes, and the temperature should range from 65° by day to 70° or more with sun heat. After the fruit has set, the foliage should be refreshed and cleansed by the daily use of the syringe or garden engine. When the fruit has stoned, that is, as soon as the kernels have been formed, the temperature should be raised to about 60° as a minimum, and to 70°, with 75° by sun heat, as a maximum. Water must now be copiously supplied to the border, and air admitted in abundance. After the end of April little fire heat is required. When the fruit begins to ripen, syringing must be discontinued till the crop is gathered, after which the syringe must be again occasionally used. If the leaves should happen to shade the fruit, not only during the ripening process, but at any time after the stoning period, they should be gently turned aside, for, in order that the fruit may acquire good colour and flavour, it should be freely exposed to light and air when ripening; it will bear the direct rays of the sun, even if they should rise to 100°. The trees often suffer from mildew, which is best prevented by keeping the borders of the peach house clear and sufficiently moist, and the house well ventilated.

The following are some of the best peaches and nectarines, arranged in the order of the times of their ripening:—

Peaches.

Early Beatrice	e. July.	Premier	e. Aug. / b. Sept.
Early Louisa	e. July.		
Frogmore Golden	e. July.	Royal George	e. Aug. / b. Sept.
Hale's Early	b. Aug.		
Rivers's Early York	b.m. Aug.	Bellegarde	b.m. Sept.
A Bec	m. Aug.	Belle Bauce	m. Sept.
Washington Rathripe	m. Aug.	Dymond	m. Sept.
Early Silver	m.e. Aug.	Late Admirable	m.e. Sept.
Crawford's Early	e. Aug. / b. Sept.	Desse Tardive	e. Sept. / b. Oct.
Grosse Mignonne	e. Aug. / b. Sept.	Walburton Admirable	e. Sept. / b. Oct.
Noblesse	e. Aug. / b. Sept.	Salway	e. Oct. / b. Nov.

Nectarines.

Lord Napier	b. Aug.	Violette Hâtive	e. Aug. / b. Sept.
Rivers's White	m. Aug.		
Murrey	e. Aug.	Welbeck Seedling	e. Aug. / b. Sept.
Balgowan	e. Aug. / b. Sept.	Victoria (under glass)	Sept.
Elruge	e. Aug. / b. Sept.	Pine apple	b. Sept.
		Stanwick Elruge	b. Sept.
Pitmaston Orange	e. Aug. / b. Sept.	Albert Victor	m.e. Sept.
		Stanwick (under glass)	m.e. Sept.

Pear. 130. The *Pear* has originated in part from the wild species, Pyrus communis, and in part from other species of the genus, including P. sinensis from China, P. Achras from Southern Russia, P. Sinai from Syria, and P. salicifolia from the Caucasus. It may be readily raised by sowing the pips of ordinary cultivated or of wilding kinds, these forming what are known as free or pear stocks, on which the choicer varieties are grafted for increase. For new varieties the flowers should be fertilized with a view to combine, in the seedlings which result from the union, the desirable qualities of the parents. The dwarf and pyramid trees, more usually planted in gardens, are obtained by grafting on the quince stock, the Portugal quince being the best; but this stock, from its surface-rooting habit, is most suitable for thin shallow soils, or for those of a cold damp nature. Some of the finer pears do not unite readily with the quince, and in this case double working is resorted to; that is to say, a vigorous-growing pear is first grafted on the quince, and then the choicer pear is grafted on the pear introduced as its foster parent.

In selecting young pear trees for walls or espaliers, some persons prefer plants one year old from the graft, but trees two or three years trained are equally good. The trees should be planted immediately before or after the fall of the leaf. The wall trees require to be planted from 25 to 30 feet apart when on free stocks, and from 15 to 20 feet when dwarfed. Where the trees are trained *en pyramide*, or *en quenouille* (see figs. 78, 79), they may stand 8 or 10 feet apart, but standards in orchards should be allowed at least 30 feet, and dwarf bush trees half that distance.

In the formation of the trees the same plan may be adopted as has already been described as suitable for the apple (par. 116). For the pear orchard a warm situation is very desirable, with a soil deep, substantial, and thoroughly drained. Any good free loam is suitable, but a calcareous loam is the best. The late Mr Rivers recommends that pear trees worked on the quince should have the stock covered up to its junction with the graft. This is effected by raising up a small mound of rich compost around it, a contrivance which induces the graft to emit roots into the surface soil, and also keeps the stock from becoming hard or bark-bound. The fruit of the pear is produced on spurs, which appear on shoots more than one year old. The mode most commonly adopted of training wall pear-trees is the horizontal (see figs. 80, 81). For the slender twiggy sorts the fan form is to be preferred, while for strong growers like Gansel's Bergamot, the half-fan or the horizontal is more suitable. In the latter form old trees are apt to acquire an undue projection from the wall, and become scraggy, to avoid which a portion of the old spurs should be cut out annually.

The summer pruning of established wall or espalier-rail trees consists chiefly in the timely displacing or rubbing off of the superfluous shoots, so that the winter pruning, in horizontal training, is little more than adjusting the leading shoots and thinning out the spurs, which should be kept close to the wall, and allowed to retain but two or at most three buds. In fan-training, the subordinate branches must be regulated, the spurs thinned out, and the young laterals finally established in their places. When horizontal trees have fallen into disorder, the branches may be cut back to within 9 inches of the vertical stem and branch, and trained in afresh, or they may be grafted with other sorts, if a variety of kinds is wanted.

Summer and autumn pears should be gathered before they are fully ripe, otherwise they will not in general keep more than a few days. The Jargonelle, as Forsyth rightly advises, should be allowed to remain on the tree, and be pulled daily as wanted, the fruit from standard trees thus succeeding the produce of the wall trees. In reference to the Crassane, Mr G. Lindley recommends gathering the crop at three different times, the first a fortnight or more before it is ripe, the second a week or ten days after that, and the third when fully ripe. The first gathering will come into eating latest, and thus the season of the fruit may be considerably prolonged. It is evident that the same method may be followed with other sorts which continue only a short time in a mature state.

The varieties of pears are very numerous, while comparatively few sorts are required in any ordinary garden. The following is a small selection of good sorts which do well in the climate of Britain, and they are arranged according to the months when they are commonly in use,—a period which, however, varies considerably in different seasons:—

Dessert Pears.

Doyenné d'Été	July.	Maréchal de Cour	Oct., Nov.
Beurré de l'Assomption	Aug.	Pitmaston Duchesse d'Angoulême	Oct., Nov.
Jargonelle	Aug.		
Souvenir du Congrès	Aug., Sept.	Althorp Crassane	Oct.-Dec.
Williams's Bon Chrétien	Aug., Sept.	Thompson's	Nov.
Beurré d'Amanlis	Sept.	Huyshe's Prince Consort	Nov., Dec.
Madame Treyve	Sept.	Passe Colmar	Nov., Dec.
Beurré Superfin	Sept., Oct.	Winter Nelis	Nov.-Feb.
Fondante d'Automne	Sept., Oct.	Chaumontel	Nov.-Mar.
Baronne de Mello	Oct.	Beurré d'Arenberg	Dec., Jan.
Comte de Lamy	Oct.	Glou Morceau	Dec., Jan.
Louise Bonne of Jersey	Oct.	Huyshe's Victoria	Dec., Jan.
Seckel	Oct.	Monarch	Dec., Jan.
Belle Julie	Oct., Nov.	Zéphirin Grégoire	Dec., Jan.
Beurré Bosc	Oct., Nov.	Beurré de Jonghe	Dec.-Feb.
Doyenné du Comice	Oct., Nov.	Joséphine de Malines	Jan., Feb
Duchesse d'Angoulême	Oct., Nov.	Easter Beurré	Jan.-Apr
Gansel's Bergamot	Oct., Nov.	Nec plus Meuris	Jan.-Apr.
Marie Louise	Oct., Nov.	Nouvelle Fulvie	Feb., Mar.

Kitchen Pears.

Besi d'Héry	Oct.-Jan.	Bellissime d'Hiver	Nov.-Apr.
Black Worcester	Nov.-Feb.	Catillac	Dec.-Apr.
Flemish Bon Chrétien	Nov.-Mar.	Winter Franc Réal	Jan.-Mar.
Verulam	Nov.-Mar.	Uvedale's Saint Germain	Jan.-Apr.

131. The *Pine-apple*, Bromelia Ananas, or Ananassa sativa, requires for its cultivation a tropical climate similar to that of the West Indies—a mean temperature of 70° at the coldest and of 83° at the warmest season, with a range of about 10° between the night and day temperature. It also requires a supply of heat, averaging about 90°, to the soil in which the roots are placed, and hence it is grown in a hot-house, where it can be supplied with bottom heat, by being plunged in a bed of fermenting material, such as tanner's bark or decaying leaves, or by hot water applied either in pipes passing through hollow chambers, or shallow hot-water tanks placed beneath the plunging beds. The heat arising from violent fermentation is, however, greater than the tender roots can bear, and if great watchfulness be not employed, the labour of many months may be wasted in a single day. Bottom heat should not exceed 95°, and may be brought down when active growth is not required to about 75°. Pine-apple

It must be regulated in its application by the amount of light and of warmth in the air. During the season when the plants are at rest it should be comparatively low; during their season of active growth it should be considerable; and during their ripening season it should be highest of all.

The top spit of an old loamy pasture, including the turf, and mixed with about one-third the bulk of good well-rotted dung, forms a suitable compost for the pine-apple. The soil used at Meudon, where these fruits have been very successfully grown, is a sandy peat or leaf-mould obtained from a high-lying spot, where hard-wooded trees, chiefly beech, have long been growing. The late Mr Fleming, when at Trentham, used a mixture of three parts turfy maiden loam to one part of peat, these ingredients being mixed together and laid under a wooden platform on which sheep were fed (which was so constructed that the dung and urine of the sheep fell through), and left there long enough to become well enriched. Other noted cultivators have recommended turfy loam and sheep or deer dung in the proportion of six of loam to three of the manure, one of leaf-mould being added. The compost should be prepared a considerable time beforehand, and frequently turned over and aerated; when used, it should be roughly broken with the spade, but not screened. Some cultivators, who do not otherwise enrich the soil, use half-inch bones and soot at the time of potting in the proportion of an 8-inch potful of each to a barrowful of fibrous surface soil. The plants when growing freely are benefited by the use of liquid manure of an ammoniacal character.

The pine-apple is sometimes propagated by planting the crowns which grow on the fruit, but more commonly from the suckers which appear at the base of the stem, these being a less time in arriving at a fruiting state. When removed from the fruit or stem, the crowns or suckers are trimmed and laid aside till the scar has dried, after which they are potted. This usually takes place during August or September, as the offsets should be allowed to obtain considerable size before they are removed, for the reason that large suckers grow with more vigour and come sooner into fruit than those of smaller size. They should be placed in 6-inch or 8-inch pots, the soil being somewhat lighter then than that used afterwards. They may be slightly shaded for a short period, and in about eight or twelve days may receive a little water. The old routine of pine-apple culture embraced a period of three years, but this has been reduced by modern growers to about eighteen months. The more rapid method was first brought into notice by Abercrombie. Its chief features are the employment of more mature suckers at the outset, and the acceleration of the growth of the plants afterwards by the application of a hotter and moister atmosphere than formerly, so as to obtain the growth of two summers in one.

The roots should be preserved in a fresh healthy state during winter, so as not to require being cut away, as was formerly done; and this may be secured by giving very moderate and judicious waterings, and by keeping the bottom heat well under control. About the beginning of March, or earlier, the forwardest young plants from suckers are selected from the stock of succession plants, and the earth and roots examined; they are then put into larger pots in good soil, and plunged in a bed having a genial bottom heat of about 85°. They require to be shaded for a few days, and after they begin to root should receive moderate waterings. As soon as the roots thicken in the balls of soil, which will be about the beginning of August, they are to be transferred into 10-inch or 12-inch pots, in which they will mature their fruit. At each successive shift the ball of earth and roots is to be preserved entire. From March onwards the temperature is gradually increased as follows:—In March, 60° to 70° by night, 70° to 80° by day; April 70° to 75° by night, 80° to 85° by day; May 75° to 80° by night, 90° to 95° by day; June 80° to 85° by night, 95° to 100° by day. After the beginning of August the heat is allowed to decline gradually until it arrives at the winter temperature of 60°. While fire heat is used, the nocturnal temperature should not exceed 80°, and sufficient moisture must be supplied. To prevent the plants from being drawn, they should be allowed ample space—2 feet from plant to plant is not too much—and be placed as near the glass as possible. In August and September abundance of air and more copious supplies of water are given. To prevent the roots from damping off in winter, water must be cautiously applied, and the pits should be heated by means of fire heat rather than by fermenting materials. Some gardeners apply this biennial mode of cultivation only to the varieties of the Queen type, but our best cultivators for the most part adopt it in its main features for all varieties, and the fruit produced is finer than that grown upon the triennial course. Those, however, who wish to cultivate such large and coarse sorts as the Providence may possibly find it necessary to take a longer period for fruiting them.

The period at which pine-apple plants first show their fruit stems is the most critical in their whole culture. The plant must be of a certain age, or at least of a certain magnitude, before it will start freely or to good purpose. In the second year a Queen pine is capable of producing a perfect fruit; and in the third year the large varieties arrive at puberty. The solid part of the stem is then observed to have increased in bulk, and to have ascended considerably above the soil. The start is generally required to be made at a particular period, but the fruit stalks do not appear until the pot is filled with roots. It is therefore necessary that the roots shall have nearly occupied all the new soil by the time the development of the fruit is required, and care should be taken that in winter the tender fibres should suffer neither from drought nor from excessive moisture or heat. After the plants show fruit they are never shifted; but the surface soil may be replaced by some fresh and rich compost. Water is supplied from time to time, but should never be colder than the average temperature of the house. Whilst the fruit is swelling, care must be taken to carry on the growth of the plant with equability and moderation. As the fruit approaches maturity, water is gradually withheld, lest the flavour should be impaired. Pine-apples should be cut a short time before they obtain complete maturity; they do not keep sound long after being cut, and consequently, if they have to be kept over for a short period the plant, pot and all, should be moved to a dryish moderately cool room.

The Hamiltonian system of pine growing was at one time more frequently adopted than now. Instead of the suckers being detached from their parent stems before fruiting, the base of the old stem was bared of leaves and earthed up with rich compost, into which it rooted freely, each sucker thus producing a ripe fruit in from eight to twelve months from the time it was started. When this fruit was cut, the process was repeated till a third succession of fruit and a fourth were obtained, after which the sucker which bore the last fruit was cut off with 6 or 8 inches of the main stem, and potted so as to furnish another similar progeny of suckers.

The Queen, as a quick-fruiting sort, and the larger Smooth-leaved Cayenne, are the chief favourites among cultivators. It may, however, be useful to give the names of a few of the best varieties:—

Spineless-leaved Pine-apple.

Smooth-leaved Cayenne, fruit large, cylindrical: good in win

Spiny-leaved Pine-apples.

Black Jamaica: fruit oval, 4 to 5 lb; one of the best for winter use.
Charlotte Rothschild: fruit cylindrical, 7 to 11 lb; good in winter.
Enville: fruit pyramidal, 6 to 7 lb.
Lady Beatrice Lambton: fruit pyramidal, 11 lb; good in winter; very juicy.
Lord Carington: fruit cylindrical, 5 to 7 lb; good in winter.
Prince Albert: fruit pyramidal, 6 to 8 lb; best in summer and autumn.
Queen: fruit cylindrical, 4 to 8 lb; the best sort for general purposes.
Thoresby Queen: fruit roundish-ovate, 6 to 8 lb.

132. The *Plum*, Prunus domestica, is considered a native of Plum.
England, but many of the best cultivated varieties have been introduced from France. The fruit is not only prized for dessert, but also for culinary purposes.

Plums are propagated chiefly by budding on stocks of the Mussel, Brussels, St Julien, and Pear plums. The damson, wine sour, and other varieties, planted as standards, are generally increased by suckers. For planting against walls, trees which have been trained for two years in the nursery are preferred by some, but maiden trees can be very successfully introduced, and by a course of liberal treatment, with less hard pruning, may be more speedily got to a fruiting state. Any good well-drained loamy soil is suitable for plums, that of medium quality as to lightness being decidedly preferable. Walls with an east or west aspect are generally allowed to them, the distance between the trees being from 20 to 30 feet. The horizontal mode of training is adopted by many, but the fan or half-fan forms are also very commonly followed, and where there is sufficient height probably the fan system is the best. The shoots ought to be laid in nearly or quite at full length. The fruit is produced on small spurs on branches at least two years old, and the same spurs continue fruitful for several years. Standard plum trees should be planted 25 feet apart each way, and dwarfs 15 or 20 feet. Such trees require only to have a portion of their wood thinned out occasionally when they are young. The hardy kinds grown in this way are very productive.

In favourable seasons the crops require thinning, to relieve the branches from the excessive weight. The unripe fruit, if fully grown and beginning to change colour, is quite fit for cooking. For dessert purposes the fruit should be allowed to remain on the tree as long as it will hang, and should be gathered by the stalk without disturbing the bloom. Such kinds as Coe's Golden Drop and Ickworth Impératrice, if gathered dry, wrapped in tissue paper, and laid in a dry cool fruit-room, may be kept for months fit for use.

The following is a selection of good reliable varieties of plums, with their times of ripening:—

Dessert Plums.

Early Green Gage	e. July.	Woolston Black	b. Sept.
Royal Hâtive	e. July. b. Aug.	Jefferson	b.m. Sept.
Rivers's Early Apricot	b. Aug.	Kirke's	b.m. Sept.
Denniston's Superb	m. Aug.	Hulings's Superb	m. Sept.
Oullins Golden	m. Aug.	Reine Claude du Comte Hathem	m. Sept.
Green Gage	m.e. Aug.	Coe's Golden Drop	e. Sept.
M'Laughlin's	e. Aug.	Reine Claude de Bavay	e. Sept. b. Oct.
Washington	Sept.	Ickworth Impératrice	b. Oct.

Prince of Wales	e. Aug. / b. Sept.	Sandall's	e. Sept.
		Belle de Septembre	b.m. Oct.

Quince. 133. The *Quince*, Cydonia vulgaris, is but little cultivated in Great Britain, two or three trees planted in the slip or orchard being in general found to be sufficient for a supply of the fruit; in Scotland it seldom approaches maturity, unless favoured by a wall. The fruit has a powerful odour, but in the raw state is austere and astringent; it, however, makes an agreeable marmalade, and is often used to give flavour and poignancy to stewed or baked apples.

The quince prefers a rich light and somewhat moist soil. The tree is generally propagated by cuttings or layers, the former making the best plants, but being longer in growing. It is much used as a dwarfing stock for certain kinds of pears, and for this purpose the young plants when bedded out in the quarters should be shortened back to about 18 or 20 inches. Those required to form standard fruit-bearing trees should be trained up to a single stem till a height of 5 or 6 feet is attained.

There are three principal varieties of the quince, the Portugal, the apple-shaped, and the pear-shaped. The Portugal is a taller and more vigorous grower than the others, and has larger and finer fruit; the apple-shaped, which has roundish fruit, is more productive, and ripens under less favourable conditions than either of the others; while the pear-shaped has roundish-pyriform fruit, which ripens later than that of the apple-shaped variety.

Raspberry. 134. The *Raspberry*, Rubus Idæus, which is found wild in Great Britain and in woods throughout Europe and Asiatic Russia, is propagated from suckers, which may be taken off the parent stools in October, and planted in rows 5 or 6 feet apart, and at 3 feet asunder in the rows. It is the habit of the plant to throw up from the root every year a number of shoots or canes, which bear fruit the subsequent year, and then decay. In dressing the plants, which is done immediately after the crop is gathered, all these exhausted stems are cut away, and of the young canes only three or four of the strongest are left, which are shortened about a third. The stems, being too weak to stand by themselves, are sometimes connected together by the points in the form of arches, or a stake is driven in midway between the plants, and half the canes are bent one way and half the other both being tied to the stake. Sometimes they are tied upright to stakes fixed to each stool. The best support is, however, obtained by fastening the points of the shoots to a slight horizontal rail or bar, placed a foot and a half on the south side of the rows, by which means the bearing shoots are deflected from the perpendicular to the sunny side of the row, and are not shaded by the annual wood. When this mode of training is adopted, the plan of planting 1 foot apart in the row and leaving one or two canes only to each shoot is preferable. The ground between the rows should never be disturbed by digging; but an abundant supply of good manure should be given annually in autumn as a dressing, which should be forked in regularly to a depth of 4 or 5 inches. All surplus suckers should be got away early in the summer before they have robbed the roots,—five or six, to be reduced to the four best, being reserved to each root. Fresh plantations of raspberries should be made every six or seven years. The double-bearing varieties, which continue to fruit during autumn, require light soils and warm situations. These should be cut close down in February, as it is the strong young shoots of the current year which bear the late autumnal crops. The other varieties may be made to bear in autumn by cutting the stems half-way down at an early period in spring; but, as with all other fruits, the flavour of the raspberry is best when it is allowed to ripen at its natural season.

The following are some of the finer sorts now in cultivation:—

Baumforth's Seedling—a large summer-bearing red.
Carter's Prolific—a large summer-bearing red.
Fastolf or Filby—a large summer-bearing red.
M'Laren's Prolific—a large double-bearing red.
Northumberland Fillbasket—a large summer red.
October Red—a fine autumn-bearing red.
October Yellow—a fine autumn-bearing yellow.
Prince of Wales—a large summer-bearing red.
Red Antwerp—a large summer-bearing red.
Rogers's Victoria—a large autumn-bearing red.
Round Antwerp—a large summer-bearing red.
Sweet Yellow Antwerp—a large summer-bearing yellow.

Service. 135. The *Service*, Pyrus Sorbus or P. domestica, is a European tree which has been regarded as a native of England on the evidence of a single tree, which has probably been planted, now existing in the forest of Wyre. Though not much cultivated, its fruit is esteemed by some persons, and therefore two or three trees may very well be provided with a place in the orchard, or in a sheltered corner of the lawn. The tree is seldom productive till it has arrived at a goodly size and age. The fruit has a peculiar acid flavour, and, like the medlar, is fit for use only when thoroughly mellowed by being kept till it has become bletted. There is a pear-shaped variety, pyriformis, and also an apple-shaped variety, maliformis, both of which may be propagated by layers, and still better by grafting on seedling plants of their own kind. The fruit is sometimes brought to market in winter.

136. The *Strawberry* of the garden has been obtained by the crossing of several species of Fragaria, the larger-fruited sorts from F. grandiflora, chilensis, and virginiana, and the smaller alpines from F. vesca. The alpine varieties should be raised from seeds; while the other sorts are continued true to their kinds by runners. If new varieties are desired, these are obtained by judicious crossing and seeding. Stra- berr

The seeds of the alpines should be saved from the finest fruit ripened early in the summer. They should at once be sown, either in a sheltered border outdoors or in pots. The soil should be rich and light, and the seeds very slightly covered by sifting over them some leaf-mould or old decomposed cow dung. When the plants appear and have made five or six leaves, they should be transplanted to where they are to remain for bearing. The seeds sown in pots may be helped on by gentle heat, and when the plants are large enough should be pricked out in fine rich soil, and in June transferred to the open ground for bearing; they will produce a partial crop in the autumn, and a full one in the following season. The same treatment may be applied to the choicer seedlings of the larger-fruited sorts from which new varieties are expected.

The runners of established sorts should be allowed to root in the soil adjoining the plants, which should, therefore, be kept light and fine, and as soon as a few leaves are produced on each the secondary runners should be stopped. When the plants have become well-rooted, they should at once be planted out. They do best in a rather strong loam, and should be kept tolerably moist. The scarlet section prefers a rich sandy loam. The ground should be trenched 2 or 3 feet deep, and supplied with plenty of manure, a good proportion of which should lie just below the roots, 10 or 12 inches from the surface. The plants may be put in on an average about 2 feet apart. Mr Myatt, a well-known strawberry-grower for market, plants in rows 18 inches apart, and the same distance from plant to plant in the rows, but leaves a space of 30 inches for an alley separating groups of three rows, and after the first year the middle row is cleared away. Some of the best growers allow 2½ feet between the rows, with the plants 2 feet from each other.

A mulching of strawy manure put between the rows in spring serves to keep the ground moist and the fruit clean, as well as to afford nourishment to the plants. Unless required, the runners are cut off early, in order to promote the swelling of the fruit. The plants should be watered during dry weather after the fruit is set, and occasionally till it begins to colour. As soon as the fruit season is over, the runners are again removed, and the ground hoed and raked. The plantation should be renewed every second or third year, or less frequently if kept free of runners, if the old leaves are cut away after the fruit has been gathered, and if a good top-dressing of rotten dung or leaf-mould is applied. A top-dressing of loam is beneficial if applied before the plants begin to grow in spring, but after that period they should not be disturbed during the summer either at root or at top. If the plants produce a large number of flower-scapes, each should, if fine large fruit is desired, have them reduced to about four of the strongest. The lowest blossoms on the scape will be found to produce the largest, earliest, and best fruits. The fruit should not be gathered till it is quite ripe, and then, if possible, it should be quite dry, but not heated by the sun. Those intended for preserving are best taken without the stalk and the calyx.

Forcing.—The runners propagated for forcing are layered into 3-inch pots, filled with rich soil, and held firm by a peg or stone. If kept duly watered, they will soon form independent plants. The earlier they are secured the better. When firmly rooted they are removed and transferred into well-drained 6-inch pots, of strong well-enriched loam, the soil being rammed very firmly into the pots, which are to be set in an open airy place. In severe frosts they should be covered with dry litter or bracken, but do not necessarily require to be placed under glass. They are moved into the forcing houses as required. The main points to be kept in view in forcing strawberries are, first, to have strong stocky plants, the leaves of which have grown sturdily from being well exposed to light, and secondly, to grow them on slowly till fruit is set. When they are first introduced into heat, the temperature should not exceed 45° or 50° by fire heat, and air must be freely admitted; should the leaves appear to grow up thin and delicate, less fire heat and more air must be given, but an average temperature of 55° by day may be allowed, and continued while the plants are in flower. When the fruit is set the heat may be gradually increased, till at the ripening period it stands at 65°, and occasionally at 75° by sun-heat. While the fruit is swelling the plants should never be allowed to get dry, but when it begins to colour no more water should be given than is absolutely requisite to keep the leaves from flagging. The plants should be removed from the house as soon as the crop is gathered. The forced plants properly hardened make first-rate outdoor plantations, and if put out early in summer, in good ground, will often produce a useful autumnal crop.

The varieties are very numerous. The following are some of the best and most distinct of those now in cultivation, those marked * being specially suitable for forcing:—

Amateur—a brisk-flavoured variety.
British Queen *—one of the best-flavoured sorts; requires good cultivation.
Dr Hogg—a hardier form of British Queen.
Elton—late, and valuable for preserving.
Enchantress—a fine-flavoured late variety.
Filbert Pine *—an excellent high-flavoured sort.
Frogmore Late Pine—a good late sort.
James Veitch *— a large solid showy variety.
Keens' Seedling *—a fine old sort, of great merit for all purposes.
La Constante *—an excellent sort, of sprightly flavour.
La Grosse Sucrée *—large, and of excellent flavour.
Loxford Hall Seedling—one of the best late sorts.
Lucas *—a useful fine-flavoured variety.
Myatt's Eliza—very high-flavoured, perhaps in this respect unequalled.
Oscar *—good for a general crop; travels well.
President *—a useful brisk-flavoured sort.
Sir Charles Napier *—a capital market fruit, rather acid.
Sir Harry—a favourite market fruit.
Sir Joseph Paxton *—an excellent large high-flavoured sort.
Vicomtesse Héricart de Thury *—good for all purposes; one of the best.

137. The *Vine*, Vitis vinifera, a native of the shores of the Caspian, and a deciduous climbing shrub, is hardy in Britain so far as regards its vegetation, but not hardy enough to bring its fruit to satisfactory maturity, so that for all practical purposes the vine must be regarded as a tender fruit. Planted against a wall or a building having a south aspect, or trained over a sunny roof, such sorts as the Black Cluster, Black Prince, Pitmaston White Cluster, Royal Muscadine, Sweetwater, &c., will ripen in the warmest English summers so as to be very pleasant eating, but in cold summers the fruit is not eatable in the raw state, and can only be converted into wine or vinegar. For outdoor culture the long-rod system is generally preferred.

When the plant is grown under glass, the vine border should occupy the interior of the house and extend outwards in the front, but it is best made by instalments of 5 or 6 feet as fast as the previous portions become well filled with roots, which may readily be done by packing up a turf wall at the extremity of the portion to be newly made; an exterior width of 15 feet will be sufficient. Inside borders require frequent and thorough waterings. In well-drained localities the border may be partially below the ground level, but in damp situations it should be made on the surface; in either case the firm solid bottom should slope outwards toward an efficient drain. A good bottom may be formed by chalk rammed down close. On this should be laid at least a foot thick of coarse hard rubbly material, a layer of rough turf, grass side downwards, being spread over it to prevent the compost from working down. The soil itself, which should be 2½ or 3 feet deep, never less than 2 feet, should consist of five parts rich turfy loam, one part old lime rubbish or broken bricks, including a little wood ashes or burnt earth (ballast), one part broken charcoal, and about one part of half-inch bones, the whole being thoroughly mixed, and kept dryish till used.

Young vines raised from eyes are generally preferred for planting. The eyes being selected from well-ripened shoots of the previous year are planted about the end of January, singly, in small pots of light loamy compost, and after standing in a warm place for a few days should be plunged in a propagating bed, having a bottom heat of 75°, which should be increased to 85° when they have produced several leaves, the atmosphere being kept at about the same temperature or higher by sun heat during the day, and at about 75° at night. As soon as roots are freely formed the plants must be shifted into 6-inch pots, and later on into 12-inch ones. The shoots are trained up near the glass, and, with plenty of heat (top and bottom) and of water, with air and light, and manure water occasionally, will form firm strong well-ripened canes in the course of the season. To prepare the vine for planting, it should be cut back to within 2 feet of the pot early in the season, and only 3 or 4 of the eyes at the base should be allowed to grow on. The best time for planting is in spring, when the young shoots have just started. The vines should be planted inside the house, from 1 to 2 feet from the front wall, the roots being placed an inch deeper in the soil than before, carefully disentangled and spread outwards from the stem, and covered carefully and firmly with friable loam, without manure. When the shoots are fairly developed, the two strongest are to be selected and trained in. When forcing is commenced, the vinery is shut up for two or three weeks without fire heat, the mean temperature ranging about 50°. Fire heat must be at first applied very gently, and may range about 55° at night, and from 65° to 70° by day, but a few degrees more may be given them as the buds break and the new shoots appear. When they are in flower, and onwards during the swelling of the berries, 85° may be taken as a maximum, running up to 90° with sun heat, and the temperature may be lowered somewhat when the fruit is ripe. As much ventilation as the state of the weather will permit should be given. A moist growing atmosphere is necessary both for the swelling fruit and for maintaining the health of the foliage. A due amount of moisture may be kept up by the use of evaporating troughs and by syringing the walls and pathways two or three times a day, but the leaves should not be syringed. When the vines are in flower, and when the fruit is colouring, the evaporating troughs should be kept dry, but the aridity must not be excessive, lest the red spider and other hurtful insects should attack the leaves. In the course of the season the borders (inside) will require several thorough soakings of warm water,—the first when the house is shut up, this being repeated when the vines have made young shoots a few inches long, again when the vines are in flower, and still again when the berries are taking the second swelling after stoning. Outside borders require watering in very dry summer weather only.

There are three principal systems of pruning vines, termed the *long-rod*, the *short-rod*, and the *spur* systems, and good crops have been obtained by each of them. It is admitted that larger bunches are generally obtained by the long-rod than by the spur system. The principle of this mode of pruning is to train in at considerable length, according to their strength, shoots of the last year's growth for producing shoots to bear fruit in the present; these rods are afterwards cut away and replaced by young shoots trained up during the preceding summer; and these are in their turn cut out in the following autumn after bearing, and replaced by shoots of that summer's growth. By the short-rod system, short instead of long rods are retained; they are dealt with in a similar manner. The spur system has, however, become the most general. In this case the vines are usually planted so that one can be trained up under each rafter, or up the middle of the sash, the latter method being preferable. The shoots are cut back to buds close to the stem, which should be encouraged to form alternately at equal distances right and left, by removing those buds from the original shoot which are not conveniently placed. The young shoots from these buds are to be gently brought to a horizontal position, by bending them a little at a time, and usually opposite about the fourth leaf the rudiments of a bunch will be developed. The leaf directly opposite the bunch must in all cases be preserved, and the young shoot is to be topped at one or two joints beyond the incipient fruit, the latter distance being preferable if there is plenty of room for the foliage to expand; the lateral shoots, which will push out after the topping, must be again topped above their first or second joints. If the bunches are too numerous they must be thinned before the flowers expand, and the berries also must be properly thinned out and regulated as soon as they are well set, care being taken, in avoiding overcrowding, that the bunches be not made too thin and loose.

The cultivation of vines in pots is very commonly practised with good results, and pot-vines are very useful to force for the earliest crop. The plants should be raised from eyes, and grown as strong as possible in the way already noted, in rich turfy loam mixed with about one-third of horse dung and a little bone dust. The temperature should be gradually increased from 60° to 80°, or 90° by sun heat, and a bottom heat a few degrees higher must be maintained during their growth. As the roots require more room, the plants should be shifted from 3-inch pots into those of 6, 12, or 15 inches in diameter, in any of which larger sizes they may be fruited in the following season, but, to be successful in this, the young rod produced must be thoroughly matured after it has reached its limit of growth.

The vine, both indoors and out, is very subject to the vine-mildew, which appears to the naked eye like a white powder; when this is visible there is no effectual remedy, but if taken at the earliest stage it may be destroyed by dusting the whole plant, stem, leaves, and fruit, with sulphur. An equally destructive enemy is the vine louse, *Phylloxera vastatrix*. No certain easily applied cure has yet been discovered, and practically the only sure remedy is to destroy the vines, clear out the old infested soil, and cleanse the structures thoroughly in every part.

The number of varieties of grapes possessing some merit is considerable, but a very few of them will be found sufficient to supply all the wants of the cultivator. For general purposes nothing approaches the Black Hamburg (including Frankenthal) in merit. Those named below are more or less in requisition:—

Outdoor Grapes.

Black Cluster—small, roundish-oval, black berries.
Black Prince—largish, oval, purplish-black berries.
Early Ascot Frontignan—round, amber-coloured berries; musky flavour.
Early Saumur Frontignan—medium, round, pale-amber berries; musky.
Early White Malvasia (Grove-end Sweetwater)—roundish, whitish-green berries.
July Frontignan—medium, round, blue-black berries; musky flavour.
Miller's Burgundy (The Miller)—small, roundish-oval, black berries.
Royal Muscadine (Chasselas de Fontainebleau)—large, round, greenish-yellow berries; one of the best white grapes, indoors or out.

Indoor Grapes.

Alicante—large, oval, blue-black berries; late, and a good keeper.
Black Hamburg—large, roundish-oval, black berries; A 1 in every respect.
Black Monukka—medium, obovate-oblong, brownish-black, seedless, crackling berries; very pleasant eating; may be grown as a curiosity.
Buckland Sweetwater—large, roundish, pale amber berries.
Canon Hall Muscat—large, roundish, amber berries; high musky flavour.
Chasselas Musqué—medium, round, pale amber berries; rich musky flavour.
Duchess of Buccleuch—small, round, greenish-white berries; musky.

Duke of Buccleuch—very large, roundish, greenish-amber berries.
Foster's White Seedling—largish, roundish-oval, greenish-yellow berries.
Frankenthal (Victoria Hamburg)—large, roundish-oblate, black berries.
Grizzly Frontignan—medium, round, grizzly red berries; musky.
Gros Colman—very large, round, black berries; late, requires to hang long.
Gros Maroc—large, oval, purple-black berries; very fine, late.
Lady Downe's—largish, roundish-oval, black berries; late, a good keeper.
Madresfield Court—large, oval or oblong, black berries; slightly musky.
Mill Hill Hamburg—very large, round or oblate, hammered, blue-black.
Muscat of Alexandria—large, oval, pale-amber berries; musky flavour.
Muscat Hamburg—large, oval, black berries; musky flavour.
Raisin de Calabre—large, round, transparent white berries; late.
Trebbiano—medium, roundish-oval, greenish-white berries; late.
Venn's Black Muscat—medium, oval, brownish-black berries; musky.
West's St Peter's—largish, roundish-oval, blue-black berries; late.
White Frontignan—medium, round, greenish-yellow berries; musky.

For the open wall, the Early Ascot Frontignan, Early White Malvasia, and Royal Muscadine may be preferred of the white sorts; and July Frontignan and Black Cluster of the blacks. For a greenhouse vinery, Black Hamburg and Madresfield Court, black; and Foster's White Seedling, Buckland Sweetwater, and Royal Muscadine, white. For early forcing, Black Hamburg and Muscat Hamburg, black; Foster's White Seedling, Royal Muscadine, White Frontignan, and Duke of Buccleuch, white. For a general midseason crop, Black Hamburg or Frankenthal, and Lady Downe's, black; Grizzly Frontignan, reddish; and Muscat of Alexandria and Raisin de Calabre, white. For hanging late, Alicante, Gros Colman, Gros Maroc, Lady Downe's, and West's St Peter's, black; and Muscat of Alexandria and Trebbiano, white.

Walnut. 138. The *Walnut*, Juglans regia, is a lofty tree, native of Persia and Asia Minor. The fruit, whilst young and tender, is much used for pickling, and when ripe is a favourite article of the dessert. The tree succeeds in deep sandy or calcareous loams, and in stiff loams resting on a gravelly bottom. It requires free exposure to air and light. It is propagated by seeds, and occasionally by budding, grafting, or inarching for the perpetuation of special varieties. The trees form their heads naturally, and therefore little pruning is required, it being merely necessary to cut off straggling growths, and to prevent the branches from interlacing. The best time for performing this is in the autumn, just after the fall of the leaf. Plants raised from the seed seldom become productive till they are twenty years old. The fruit is produced at the extremities of the shoots of the preceding y ar; and therefore, in gathering the crop, care should be taken not to injure the young wood. In some parts of England the trees are thrashed with rods or poles to obtain the nuts, but this is far from being a commendable mode of collecting them.

Besides the common walnut, there are several varieties cultivated, particularly the Thin-shelled and the Thetford or Highflyer, which last is by far the best walnut grown.

Orchard-house trees. 139. *Orchard-house Trees.*—The fruits that may be successfully grown in unheated orchard-houses are peaches, nectarines, apricots, plums, figs, cherries, pears, and apples; and all, except the last two, are more readily obtained in those which are judiciously heated.

The trees are sometimes planted out, and sometimes grown in pots. The potted trees are decidedly to be preferred, for those which are planted out are less at the command of the cultivator, and unless the houses are large are apt to outgrow the space; they do not indeed require so much attention as regards water, while pot trees entail very much labour in this respect from the time the fruit is fairly set until it is near the ripening stage; but on the other hand a much greater variety may be grown in this way, and the trees can be shifted from place to place, as required, with the utmost facility. While at rest in winter they can be set close together without injury, and may be continued in this way until they come into flower. After the setting of the fruit, the hardier sorts, as plums, pears, and apples, can be taken out, and put under temporary awnings till it is safe to plunge them beside the walks in the open quarters of the garden, where they grow and swell, if duly watered, as well as if established in the ground. In dry summer weather they need a good watering two or three times a day, and besides this should have a dose of liquid manure occasionally. This removal of the hardier plants to the open air leaves more space under glass for the tenderer sorts.

The trees are most convenient when trained in the pyramidal form, or as compact bushes; and the summer treatment should consist in pinching back the points of all the growing shoots after they have formed two or three leaves.

The vigour of pot fruit trees is greatly due to judicious surface-dressing during the summer months. It should be applied at intervals of ten or twelve days, and should be made up of equal parts of horse-droppings, turfy loam, and malt dust, the whole being laid up in a heap and frequently turned. The dressing should not, however, be applied within three weeks of the ripening of the fruit.

The trees should be repotted in autumn as soon as the leaves have done their work, in similar compost to that first employed—good turfy loam, with about a sixth of rotted manure, and a sprinkling of bone dust. They are to be turned out of the pot, and a slice of about an inch in thickness pared off with a sharp knife, and are then to be replaced in a pot of the same size as that in which they previously grew, unless in those cases where a larger one may be afforded, and then the roots need not be cut away. This disrooting may sometimes be done before the leaves are quite ready to fall, in which case care is necessary to prevent the tree from flagging; and, if the weather be hot, the tops should be kept moist by frequently dewing the foliage with the syringe, but no water must be given at the root for a day or two after repotting. If the wood has been well ripened, trees treated in this way will bear freely during the following season. Whether placed on the floor of the house, or plunged outdoors, the pots should stand on two bricks placed a little apart, so that worms cannot gain admittance by the draining-hole.

The fruit obtained from trees well cultivated in pots in an orchard-house will compare, as regards size and quality, with the best fruit ripened on an open wall or in a forcing-house; but, when grown without fire heat, it is of course but little in advance of the outdoor crops. To the amateur this mode of culture will be found to present many attractions.

VII. *Vegetables.*

140. Under this head we include those esculents which are largely eaten as "vegetables" or as "salads," while the various "herbs" which are used chiefly for flavouring or garnishing will be referred to in a supplementary paragraph.

141. The *Artichoke*, Cynara Scolymus, is a stout-growing hardy perennial, cultivated for the sake of the immature flower-heads. In France the whole of the leaves of the involucre are eaten when in a young and tender state, *en poivrade*, or with pepper, salt, and vinegar; but the only parts of the flower-head used in England are the base of the leaves of the involucre, and the immature floral receptacle called the *bottom*, freed from the bristly seed-down which is called the *choke*. In old plantations about to be destroyed the central leaves are sometimes blanched and eaten; this edible part, like that of the nearly related cardoon (par. 150), is called the *chard*. Ar-cho[ke.]

The artichoke requires a deep cool dry soil, well enriched, and deeply trenched. It is propagated by parting the roots in April, the sets being planted in rows 4 or 5 feet asunder, and 2 feet apart in the rows. As the young plants afford a crop which succeeds that of old plants, a new plantation is made in some gardens every year. During summer the artichokes require little other attention than to be kept clear of weeds. In November the decayed stems and leaves are removed, the ground cleared, and a cone of a foot deep of sifted coal-ashes, or rotten tan, or littery dung, is placed close round the base to defend the stools from frost. In April this is taken away, the stocks are examined, and two or three only of the strongest shoots are permitted to remain; a dressing of manure is given—well-rotted hotbed dung or seaweed—and the ground between the rows is forked over. The offsets, carefully removed, afford materials for young plantations. The heads are cut when nearly full grown, before the scales of the involucre open out.

The varieties most esteemed in England are the Green or French, which has conical heads, and is considered the highest flavoured; the Globe, which has dull purplish heads, and is well adapted for a general crop; and the Purple, which is the earliest. The Laon is that most widely grown at Paris.

142. The *Asparagus*, Asparagus officinalis, is one of the most delicate of our esculents, possessing well-marked diuretic properties, and is grown extensively in private gardens as well as for market. The asparagus prefers a loose light deep sandy soil; the depth should be 3 feet, the soil being well trenched, and all surplus water got away. A considerable quantity of well-rotted dung or of recent seaweed should be laid in the bottom of the trench, and another top-dressing of manure should be dug in preparatory to planting or sowing. Nitrate of soda appears to be the best artificial manure, and salt applied at the rate of 2 lb to the square yard is a good dressing while the plants are growing. The beds should be 3 feet or 5 feet wide, with intervening alleys of 2 feet, the narrower beds taking two rows of plants, the wider ones three rows. The beds should run east and west, so that the sun's rays may strike against the side of the bed. In some cases the plants are grown in equidistant rows 3 to 4 feet apart. Where the beds are made with plants already prepared, either one-year old or two-year old plants may be used, for which a trench should be cut sufficient to afford room for spreading out the roots, the crowns being all kept at about 2 inches below the surface. Planting is best done in May, after the plants have started into growth. To prevent injury to the roots, it is, however, perhaps the better plan to sow the seeds in the beds where the plants are to remain. As-pa[ragus.]

The seed should be sown in March in slight drills; and it is a good precaution to sow more than is necessary, and to thin out towards the end of the first summer, to the distance of about 6 inches in the rows. The ground must be hoed and kept clear of weeds. Frequently slight crops of lettuce are taken from the surface of the beds, and of cauliflower from the spaces between them. The asparagus heads should not be cut before the third spring, and are not in perfection till the fourth or fifth.

The manuring of asparagus, which can scarcely be overdone, should be performed in the end of autumn, when the dead stems are removed. When the plants are in beds, the surface should be stirred with a fork; a layer of well-rotted hotbed dung should then be laid on, and the whole covered with a sprinkling of earth from the alleys. If the plants are grown in rows, the manure is simply dug in between them by means of a digging fork, care being taken not to injure the roots. These operations are repeated annually, and no other culture is required; but it is necessary to observe a due moderation in reaping the crop, as the shoots, when cut too freely, become gradually smaller. A considerable quantity of ground is consequently required to keep up a supply. It is a general rule never to gather asparagus after peas have come into season. To experience the finest flavour of asparagus, it should be eaten immediately after having been gathered; if kept longer than one day, or set into water, its finer flavour is altogether lost. If properly treated, asparagus beds will continue to bear well for many years.

The asparagus grown at Argenteuil, near Paris, has acquired much notoriety for its large size and excellent quality. The French growers plant in trenches, instead of raised beds.

Forcing.—The most common method of forcing asparagus is to prepare, early in the year, a moderate hotbed of stable litter with a bottom heat of 70°, and to cover it with a common frame. After the heat of fermentation has somewhat subsided, the surface of the bed is covered with a layer of light earth or exhausted tan-bark, and in this the roots of strong mature plants are closely placed. The crowns of the roots are then covered with 3 to 6 inches of soil. A common three-light frame may hold 500 or 600 plants, and will afford a supply for several weeks. After planting, linings are applied when necessary to keep up the heat, but care must be taken not to scorch the roots; air must be occasionally admitted. Where there are pits heated by hot water or by the tank system, they may be advantageously applied to this purpose. A succession of crops must be maintained by annually sowing or planting new beds. Mr Lindegard, of the Royal Gardens at Copenhagen, recommends the plan of forcing asparagus on the ground on which it grows, but the results obtained in this way are not so satisfactory.

The principal varieties are the Red-topped and the Green-topped, of which there are several reputed sub-varieties, as the Battersea, Gravesend, Giant, Colossal, &c., which differ but slightly from each other.

ean. 143. The *Bean*, Faba vulgaris, is an annual plant. The seeds are sown about 4 inches apart, in drills 2½ feet asunder for the smaller and 3 feet for the larger sorts. The soil should be a rather heavy loam, deeply worked and well enriched. For an early crop Marshall's Early Dwarf Prolific and the Dwarf Crimson-seeded may be sown in November, and protected during winter in the same manner as early peas. An early crop may also be obtained by dibbling in the seeds in November, sheltering by a frame, and in February transplanting them to a warm border. Successional crops of Early Seville or Early Longpod should be sown in January and February, and the Longpods or Green Windsor in March, April, and May, for a general crop, while for later crops the Dutch Longpod may be sown in June or early in July. All the culture necessary is that the earth be drawn up about the stems. The plants are usually topped when the pods have set, as this not only removes the black aphides which often settle there, but is also found to promote the filling of the pods.

The following are some of the best sorts:—

Early.—Dwarf Crimson-seeded, Marshall's Early Dwarf Prolific, Early Seville, Early Longpod.

Late.—Windsor, Green Windsor, Dutch Longpod.

See BEAN, vol. iii. p. 460, and AGRICULTURE, vol. i. p. 360.

et. 144. The *Beet*, Beta vulgaris, is a hardy biennial, native of the south of Europe, on the sea-coast. The boiled root is eaten cold, either by itself or as a salad; it is also often used as a pickle. The beet prospers in a rich deep soil, well pulverized by the spade. If manure is required, it should be deposited at the bottom of the trench in preparing the ground. The seeds should be sown in drills 15 inches asunder, in April or early in May, and the plants are afterwards to be thinned to about 8 inches apart in the lines, but not more, as moderate-sized roots are preferable. The plants should grow on till the end of October or later, when a portion should be taken up for use, and the rest laid in in a sheltered corner, and covered up from frost. The roots must not be bruised, and the leaves must be twisted off—not closely cut, as they are then liable to bleed. In the north the crop may be wholly taken up in autumn, and stored in a pit or cellar, beyond reach of frost. If it is desired to have fresh roots early, the seeds should be sown at the end of February or beginning of March; and if a succession is required, a few more may be sown by the end of March.

The Yellow Beets are not appreciated at table, and the White Sugar Beets are not suitable for garden culture. We shall only name a selection of the red-fleshed sorts:—Turnip-rooted or Egyptian (very early), Red Castelnaudary (the type of our best beets), Pine-apple Short-top, Nutting's Selected, Carter's Perfection of Beets, Sutton's Dark Red, Dell's Crimson or Osborn's Select.

The White Beet, Beta Cicla, is cultivated for the leaves, which are used as spinach; but for this they are a very sorry substitute. The midribs and stalks of the leaves are also stewed and eaten as seakale, under the name of Swiss chard. The culture does not differ materially from that of the red beet, but more space is required.

See BEET, vol. iii. p. 504, and AGRICULTURE, vol. i. p. 381.

recole. 145. The *Borecole* or *Kale*, Brassica oleracea acephala, includes several varieties which are amongst the hardiest of our esculents, and seldom fail to yield a good supply of winter greens. They require well-enriched soil, and sufficient space for full exposure to air; and they should also be sown early, so as to be well established and hardened before winter.

The main crops should be sown about the first week of April, or, in the north, in the third week of March, and a succession a month later. The Buda kale is sown in May, and planted out in September, but a sowing for late spring use may be made in the last week of August, and transplanted towards the end of September. To prevent overcrowding, the plants should be transplanted as soon as they are of sufficient size, but if the ground is not ready to receive them a sufficient number should be pricked out in some open spot. In general the more vigorous sorts should be planted in rows 2½ feet or 3 feet and the smaller growers 2 feet apart, and 18 inches from plant to plant. In these the heads should be first used, only so much of the heart as is fresh and tender being cut out for boiling; side shoots or sprouts are afterwards produced for a long time in succession, and may be used so long as they are tender enough to admit of being gathered by snapping their stalks asunder.

The best of the borecoles or kales are—Dwarf Green Curled or Scotch Kale, very hardy, and from its dwarf habit often sheltered by snow; Cottager's Kale, very hardy, one of the most prolific and well-flavoured; Purple Borecole, very hardy. The following are less vigorous in growth, but are of excellent quality:—Jerusalem Kale, Egyptian Kale, Buda Kale,—the last two very hardy.

146. The *Broccoli*, Brassica oleracea botrytis asparagoides, is supposed to have sprung from the cauliflower, being, like it, of Italian origin, and differing chiefly in possessing greater hardiness of constitution. Miller indeed states (*Gardeners' Dictionary*) that the broccolis known in his time were imported from the island of Cyprus. Broccoli

The broccoli succeeds best in a fresh, loamy soil, somewhat firm in texture. For the autumn broccolis the ground can scarcely be too rich, but the winter and spring sorts, on ground of this character, are apt to become so succulent and tender that the plants suffer from frost even in sheltered situations, while plants less stimulated by manure and growing in the open field may be nearly all saved, even in severe winters. The main crops of the early sorts, for use in autumn, such as the Capes and Grange's, should be sown early in May, and planted out while young, to prevent them coming too early into flower; in the north they may be sown a fortnight earlier. The later sorts, for use during winter and spring, should be sown about the middle or end of May, or about ten days earlier in the north. The seed beds should be made in fresh light unexhausted soil; and if the season be dry, the ground should be well watered before sowing. If the young plants are crowding each other, they should be thinned. The ground should not be dug before planting them out, as the firmer it is the better; but a shallow drill may be drawn to mark the lines. The larger growing sorts may be put in rows 3 feet apart, and the plants about 2½ feet apart in the rows, and the smaller-growing ones at from 2 to 2½ feet between, and 1½ to 2 feet in the rows. If the ground is not prepared when young plants are ready for removal, they should be transferred to nursery beds and planted at 3 to 4 inches apart, but the earlier they can be got into their permanent places the better.

It is of course the young flower-heads of the plant which are eaten. When these form, they should be shielded from the light, by bending or breaking down an inner leaf or two. In some of the sorts the leaves naturally curve over the heads. To prevent injury to the heads by frost in severe winters, the plants should be laid in with their heads sloping towards the north, the soil being thrown back so as to cover their stems; or they may be taken up and laid in closely in deep trenches, so that none of the lower bare portion of the stem may be exposed. Some dry fern may also be laid over the tops.

The spring varieties are extremely valuable, as they come at a season when the finer vegetables are scarce. They afford a supply from March to May inclusive. In all cases great care should be taken to procure the seed true, as it is very liable to become deteriorated through crossing by insect agency.

The following are good types of broccoli, but the varieties are frequently changing, in name at least, the supposed novelties being often merely good and pure stocks of older kinds:—

For autumn and winter use: Early Purple Cape, Early White Cape, Grange's, Veitch's Self-protecting Autumn, Snow's Superb Winter White, Osborn's Winter White, Backhouse's Winter.

For late winter and spring use: Knight's Protecting, Cooling's Matchless, Leamington, Chappel's Cream, Ellotson's Mammoth, Sutton's Perfection, Penzance, Purple Sprouting.

For the latest supply: Cattell's Eclipse, Carter's Champion, Lauder's Goshen, Late White Protecting, Miller's Dwarf Late White.

147. The *Brussels Sprouts*, Brassica oleracea bullata gemmifera, have long been cultivated near Brussels. There appears to be no information as to the plant's origin, but, according to the late Dr Van Mons, it is mentioned in the year 1213, in the regulations for holding the markets of Belgium, under the name of *spruyten* (sprouts). It is very hardy and productive, and is much esteemed for the table on account of its flavour and its sightly appearance. Brussels sprouts.

The seed should be sown about the middle of March, and again in the first or second week in April for succession. Any good garden soil is suitable. For an early crop it may be sown in a warm pit in February, pricked out and hardened in frames, and planted out in a warm situation in April. The main crop may be planted in rows 2 feet asunder, the plants 18 inches apart. They should be got out early, so as to be well established and come into use before winter. The head may be cut and used after the best of the little rosettes which feather the stem have been gathered; but, if cut too early, it exposes these rosettes, which are the most delicate portion of the produce, to injury, if the weather be severe.

The earliest sprouts become fit for use in November, and they continue good, or even improve in quality, till the month of March following. Van Mons mentions that by successive sowings the sprouts are obtained in Brussels for the greater part of the year.

The most reliable crop is perhaps obtained from seed of the ordinary variety imported from Holland; but good English-raised seed, represented by Carter's Perfection, may also be obtained. Scrymger's Giant is a vigorous dwarf kind. We doubt, however, the policy of planting dwarf kinds, as the taller ones with longer stems, if sufficiently vigorous, must yield a larger produce.

In this place may be noted two hybrid sprouts, both raised by Mr Melville, at Dalmeny Park, near Edinburgh. They are the Albert Sprouts, a hardy green, long in running to seed, the result of a cross between the savoy and Brussels sprouts; and the Dalmeny Sprouts, which grow 6 inches or 8 inches high, with a compactly cabbaged head of moderate size, and a stem thickly set with cabbage-like sprouts, a cross obtained between the cabbage and Brussels sprouts. Both may be grown in the same way as the borecoles.

Cabbage. 148. The *Cabbage*, Brassica oleracea capitata, has sprung from the biennial B. oleracea of the British sea-coasts. The cabbage requires a well-manured and well-wrought loamy soil. It should have abundant water in summer, liquid manure being specially beneficial. Round London, where it is grown in perfection, the ground for it is dug to the depth of two spades or spits, the lower portion being brought up to the action of the weather, and rendered available as food for the plants; while, the top-soil, containing the eggs and larvæ of many insects, being deeply buried, the plants are less liable to be attacked by the club. Farm-yard manure is that most suitable for the cabbage, but artificial manures such as guano, superphosphate of lime or gypsum, together with lime-rubbish, wood-ashes, and marl, may, if required, be applied with advantage.

The first sowing of cabbage should be made about the beginning of March, and should consist of Nonpareil or Enfield Market (also known as the Early Battersea); these will be ready for use in July and August, following the autumn-sown crops. Another sowing of the same sorts, or of the St John's Day, should be made in the last week of March or first week of April, and will afford a supply from August till November; and a further crop of such sorts as Early York, Little Pixie, Atkins's Matchless, or other kinds that heart quickly, may be made in May to supply young-hearted cabbages in the early part of winter. The autumn sowing, which is the most important, and affords the supply for spring and early summer use, should be made about the last week in August, in warm localities in the south, and about a fortnight earlier in the north; or, to meet fluctuations of climate, it is as well in both cases to anticipate this sowing by another two or three weeks earlier, planting out a portion from each, but the larger number from that sowing which promises best to stand without running to seed. The sorts should be Enfield Market, Nonpareil, or Winnigstadt. These later sown plants will be ready for transplanting by the end of September or early in October, and may be placed in the ground previously occupied by the pea or bean crop.

The cabbages grown late in autumn and in the beginning of winter are denominated Coleworts (vulg. Collards), from a kindred vegetable no longer cultivated. Two sowings are made, in the middle of June and in July, and the seedlings are planted a foot or 15 inches asunder, the rows being 8 or 10 inches apart. The sorts employed are the Rosette and the Hardy Green.

About London the large sorts, as Enfield Market, are planted for spring cabbages 2 feet apart each way; but a plant from an earlier sowing is dibbled in between every two in the rows, and an intermediate row a foot apart is put in between the permanent rows, these extra plants being drawn as coleworts in the course of the winter. The smaller sorts of cabbage may be planted 12 inches apart, with 12 or 15 inches between the rows. The large sorts should be planted 2 feet apart, with 2½ feet between the rows. The only culture required is to stir the surface with the hoe to destroy the weeds, and to draw up the soil round the stems.

The *Red Cabbage*, Brassica oleracea capitata rubra, of which the Red Dutch is the most commonly grown, is much used for pickling. It is sown about the end of July, and again in March or April. The Dwarf Red and Utrecht Red are smaller sorts. The culture is in every respect the same as in the other sorts, but the plants have to stand until they form hard close hearts.

The *Couve Tronchuda* or *Portugal Cabbage*, Brassica oleracea acephala costata, is of a distinct type and of excellent quality. The fleshy ribs of the leaves, cooked like sea-kale, are the only parts eaten. It is somewhat tender, and requires to be sown early in spring for use during the autumn.

The names of the varieties of cabbage are very numerous, but, on comparing them at Chiswick, Mr Barron reduces the garden varieties to about seventeen types, the best of which are:—*Early sorts*: Atkins's Matchless, Early York, Little Pixie, Nonpareil, St John's Day. *Mid-season*: Enfield Market (Battersea or Fulham), Rosette Colewort, Winnigstadt. *Late sorts*: Bacalan, Hardy Green Colewort, Pomeranian. See CABBAGE, vol. iv. p. 617.

Capsicum. 149. The *Capsicum* is the produce of several species of the genus Capsicum cultivated for the sake of their pods, which in a green state are used in salads and in pickles, and when ripe are powdered to form cayenne pepper. The pods, either green or ripe, are also used to make Chili vinegar.

The *Annual Capsicum, Spanish Pepper*, or *Guinea Pepper*, Capsicum annuum, is the sort most commonly grown. The seeds should be sown in a hotbed in February, the young plants being transferred successively into 3-inch, 5-inch, and 8-inch pots. They require a warm genial atmosphere, and a light rich soil, and should be assisted with liquid manure or such artificial fertilizers as Clay's or Jackman's. In the south of England they may be grown in the open air, on a warm sunny border, if planted out towards the end of June. The fruit ripens in September, and may be kept two or three years in a dry room. The *Bird Pepper*, C. baccatum, and the *Chili*, C. frutescens, are both sub-shrubby plants, requiring stove heat. They should be grown in peaty soil, should not be overpotted, and should be kept dryish at the root in winter. The best cayenne pepper is prepared from C. frutescens, and C. baccatum is much relished by some persons. The *Bell Pepper*, C. grossum, and the *Large Sweet Spanish*, are milder in flavour than the other sorts, and are much eaten in salads and also with cold meats. See CAYENNE PEPPER, vol. v. p. 280.

Cardoon. 150. The *Cardoon*, Cynara Cardunculus, a perennial from the south of Europe and Barbary, is a near relation of the artichoke (par. 141). The edible part, called the *chard*, is composed of the blanched and crisp stalks of the inner leaves. Cardoons are found to prosper on light deep soils. The seed is sown annually about the middle of May, in shallow trenches, like those for celery, and the plants are thinned out to 10 or 12 inches from each other in the lines. In Scotland it is preferable to sow the seed singly in small pots, placing them in a mild temperature, and transplanting them into the trenches after they have attained a height of 8 or 10 inches. Water must be copiously supplied in dry weather, both to prevent the formation of flower stalks and to increase the succulence of the leaves. In autumn the leaf-stalks are applied close to each other, and wrapped round with bands of hay or straw, only the points being left free. Earth is then drawn up around them to the height of 15 or 18 inches. Sometimes cardoons are blanched by a more thorough earthing up, in the manner of celery, but in this case the operation must be carried on from the end of summer. During severe frost the tops of the leaves should be defended with straw or litter. Besides the common and Spanish cardoons, there are the prickly-leaved Tours cardoon, the red-stemmed cardoon, and the Paris cardoon, all of superior quality, the Paris being the largest and most tender. The common artichoke is also used for the production of chard.

Carrot. 151. The *Carrot*, Daucus Carota, has been much improved and transformed from the wild state; it is probably a native of the sea-coasts of southern Europe, but is now abundant throughout Europe and Asiatic Russia. The carrot delights in a deep sandy soil, which should be well drained and deeply trenched. In regard to the preparation of the ground, one of our best northern gardeners has said—"Trench in autumn; trench deep and lay the manure at the bottom of the trench; in spring rake down, lay on an inch of wood ashes, and dig them lightly in." For the long-rooted sorts the soil should be at least 3 feet deep, but the Short Horn varieties may be grown in about 6 inches of good compost laid on the top of a less suitable soil. Peat earth may be usefully employed in lightening the soil. Good carrots of the larger sorts may be grown in unfavourable soils by making large holes 18 inches deep with a crowbar, and filling them up with sandy compost in which the seeds are to be sown. The main crop is sown at the end of March or beginning of April. After sowing, it is only necessary to thin the plants, and keep them clear of weeds. The roots are taken up in autumn and stored during winter in a cool shed or cellar.

Forcing.—For a supply of young carrots in winter, a hotbed composed of 3 or 4 feet thick of leaves, or of 18 inches of dung, or of 2 feet of dung and leaves mixed, should be prepared about the end of November or beginning of December, and covered with a frame and lights. The bed should be surfaced with 8 or 9 inches of light soil, of which leaf-mould may form a considerable proportion, and the seed of Early Short Horn, Early Nantes, or French Forcing should be sown in drills 3 inches apart, and covered to the depth of ½ inch. The young plants should be thinned to 1½ inches apart. The temperature should range from 60° to 65°, as much light and air being given as possible, but the sashes should be covered at night, especially in frosty weather. For succession sow again on a gentle hotbed under glass early in February, and follow this by another sowing on a warm sheltered south border early in March. The seed bed should be made up of light rich compost, in a situation well exposed to the sun. If these quick-growing sorts are preferred, small successional sowings should be made in May and again in July, James's Intermediate being substituted at the last sowing. Where a little protection can be given by a frame in winter, some of the Early Short Horn may be sown in August for spring use.

The following are good garden carrots:—*Early*: French Forcing, Early Nantes, Early Short Horn. *Mid-season*: James's Intermediate, Long Blunt Red. *Main Crop*: Long Surrey, Altrincham. See AGRICULTURE, vol. i. p. 369.

Cauliflower. 152. The *Cauliflower*, Brassica oleracea botrytis cauliflora, is said by our old authors to have been introduced from Cyprus, where, as well as on the Mediterranean coasts, it appears to have been cultivated for ages. It is one of the most delicately flavoured of vegetables, the dense cluster formed by its incipient succulent flower-buds being the edible portion.

The sowing for the first or spring crop, to be in use in May and June, should be made from the 15th to the 25th of August for England, and from the 1st to the 15th of August for Scotland. In the neighbourhood of London the growers adhere as nearly as possible to the 21st day. A sowing to produce heads in July and August takes place in February on a slight hotbed. A late spring sowing to produce cauliflowers in September or October or later, should be made early in April, and another about the 20th of May.

The cauliflower succeeds best in a rich soil and sheltered position; but, to protect the young plants in winter, they are sometimes pricked out in a warm situation at the foot of a south wall, and in severe weather covered with hoops and mats. A better method is to plant them thickly under a garden frame, securing them from cold by coverings, and giving air in mild weather. For a very early supply, a few scores of plants may be potted and kept under glass during winter, and planted out in spring, defended with a hand-glass. Sometimes patches of three or four plants on a south border are sheltered by hand-glasses throughout the winter. It is advantageous to prick out the spring-sown plants into some sheltered place, before they are finally transplanted in May. The later crop, the transplanting of which may take place at various times, is treated like early cabbages. After planting, all that is necessary is to hoe the ground, and draw up the soil about the stems.

It is found that cauliflowers ready for use in October may be kept in perfection over winter. For this purpose they are lifted carefully with the spade, keeping a ball of earth attached to the roots. Some of the large outside leaves are removed, and any points of leaves that immediately overhang the flower are cut off. They are then placed either in pots or in hotbed frames, the plants being arranged close together, but without touching. In mild dry weather the glass frames are drawn off, but they are kept close during rain storms; and in severe frost they are thickly covered with mats.

The late Mr Barnes of Bicton informs us in the *Gardeners' Magazine* that his cauliflowers for spring are sown the first week of October, in pans, in a little bottom heat; and about the end of the month, or the beginning of November, are potted into 3-inch pots, and plunged close to the glass. The plants are kept shifted on in some old melon-bed mould until the beginning of January, when they are shifted finally into 7-inch pots. In the first week in February the ground is prepared. If wet, a little of the soil is taken out where each hand-glass is to stand, and replaced with dry dusty rubbish, in order to prevent the cauliflowers from getting the disease of "black legs." Four plants are turned out under each hand-glass. If the weather proves dry, a liquid manure, consisting of ¼ lb of nitrate of soda to 1 hogshead of cow-dung water, with the addition of a few gallons of hot water, is applied, which causes the plants to grow in March as in May, and produce fine cauliflowers early in April. Mr Barnes states that by shifting on the plants until they are in 12-inch pots, and then placing them in a vinery or peach-house, he has had cauliflowers early in March.

Some of the best varieties of cauliflower are—the Walcheren, which, if true, is of excellent quality, and the most generally useful for autumn; Dwarf Erfurt, which is very dwarf and early, and good for summer and early autumn use; Early London, rather tall, but with a fine compact curd; Lenormand's, a second early; Snowball, dwarf, compact, and quick-heading; and Veitch's Autumn Giant, which is an excellent hardy sort for autumn.

Celeriac. 153. The *Celeriac*, Apium graveolens rapaceum, the *céleri-navet* of the French, is a variety of celery in which the stem forms an irregular knob, which is the part used, either sliced in salads or cooked. It is a hardy substitute for other kinds of celery. The roots grow to 3 lb or 4 lb weight. The plants should be reared like those of celery; and, some time before winter sets in, they should be taken up and stored amongst sand in a shed or cellar.

Celery. 154. The *Celery*, Apium graveolens, has been so much improved by cultivation as to have lost its acrid deleterious properties, and is now a stout succulent plant, with a mild and agreeable flavour, and in the finer varieties with the stalks solid instead of hollow and pipy. The blanched portions only should, however, be used.

Celery is usually sown at three different times,—on a hotbed in the beginning of March, and in the open ground in March, and again in April. The seedlings, when about 2 inches high, are pricked into rich soil, in which they are allowed to stand till they are 4 or 5 inches high. The first crop is defended by frames or hand-glasses, and is planted wide to admit of being lifted with balls of earth adhering to the roots. Towards the end of May trenches for blanching the celery are prepared 3½ or 4 feet apart, 15 inches wide at the bottom, and about a foot below the natural level of the surface. The soil at the bottom of the trench is to be carefully dug and manured, and a single row of plants placed in each trench. Sometimes, where a large supply is required, the trenches are made 6 feet wide, and rows 15 or 18 inches apart are planted across the trenches. As the plants advance in growth, earth is laid up about the stalks of the leaves, and this is repeated at the end of every ten or fifteen days. Many delay the earthing-up until the plants have nearly attained their full size, when the operation is performed at once; but it is better to commence the earthing-up when the crop is half-grown, and to complete it by adding a little more soil at short intervals. Successional crops should be planted out from the 1st of June till the 1st of August. Celery loves a rich light soil, and will bear to be flooded with water at the root while growing.

The varieties of celery include some with red stalks and some with white. The latter, as they blanch more perfectly than the red, are sometimes preferred, but the red varieties blanch to a very delicate pink, and are generally better flavoured. Some of the best varieties are:—*Whites*: Early Dwarf Solid White (Incomparable White), Williams's Matchless White, Wright's Grove White. *Reds*: Leicester Red (Major Clarke's Solid), Ivery's Nonesuch, Sulham Prize Pink, Williams's Matchless Red. See CELERY, vol. v. p. 290.

155. The *Chicory* or *Succory*, Cichorium Intybus, is much esteemed by the French as a winter salad, and when blanched is known by the name of *Barbe de Capucin*. When intended for winter use, it is sown in May or June, commonly in drills, and the plants are thinned out to 4 inches apart. If at first the leaves grow very strong, they are cut off, perhaps in the middle of August, about an inch from the ground, so as to promote the production of new leaves, and check the formation of flower-stems. About the beginning of October the plants are raised from the border, and all the large leaves cut off; the roots are also shortened, and they are then planted pretty closely together in boxes filled with rich light mould, and watered when needful. When frost comes on, the boxes are protected by any kind of litter or haulm. As the salad is wanted, they are removed into some place having a moderately increased temperature, and where there is no light. Each box affords two crops of blanched leaves, and these are reckoned fit for cutting when about 6 inches long. Chicory.

Another mode of obtaining the young leaves of this plant in winter is to sow seeds in a bed of light rich mould, or in boxes in a heat of from 55° to 60°, giving a gentle watering as required. The leaves will be fit to cut in a fortnight after sowing, and the plants will afford a second crop.

In Belgium a variety of chicory called *Witloef* is much preferred as a salad to the French *Barbe de Capucin*. The seeds are sown and the plants thinned out like those of the ordinary sort. They are eventually planted in light soil, in succession, from the end of October to February, at the bottom of trenches a foot or more in depth, and covered over with from 2 to 3 feet of hot stable manure. In a month or six weeks, according to the heat applied, the heads are fit for use, and should be cut before they reach the manure. The plants might easily be forced in frames on a mild hotbed, or in a mushroom-house, in the same way as sea-kale.

The sorts cultivated are the Common, the Improved, and the Witloef. That grown for mixing with coffee is a variety with larger fleshy roots. See CHICORY, vol. v. p. 614.

156. The *Chives*, Allium Schœnoprasum, is a hardy perennial, found in the North of England and in Cornwall, and growing in rocky pastures throughout temperate and northern Europe and Asiatic Russia, and also in the mountain districts of southern Europe. It is cultivated for the sake of its leaves, which are used in salads and soups as a substitute for young onions. It will grow in any good soil, and is propagated by dividing the roots into small clumps in spring or autumn; these are planted from 8 to 12 inches apart, and soon form large tufts. The leaves should be cut frequently so as to obtain them tender and succulent. Chives.

157. The *Corn-Salad* or *Lamb's Lettuce*, Valerianella olitoria, is a weedy annual, native of southern Europe, but naturalized in corn-fields in central Europe, and not unfrequent in Britain. In France it is used in salads during winter and spring as a substitute for lettuces, but it is less esteemed in England. The plant is raised from seed sown on a bed or border of light rich earth, and should be weeded and watered, as occasion requires, till winter, when it should be protected with long litter during severe frost. The largest plants should be drawn for use in succession. Sowing may be made every two or three weeks from the beginning of August till October, and again in March, if required in the latter part of the spring. The sorts principally grown are the Round-leaved and the Italian, which last is sometimes referred to Valerianella eriocarpa. Corn-salad.

158. The *Cress*, or *Garden Cress*, Lepidium sativum, is an annual plant, native of western Central Asia. It is used in salads, the young plants being cut and eaten while still in the seed-leaf, forming, along with plants of the white mustard in the same stage of growth, what is commonly called "small salad." The seeds should be sown thickly broadcast or in rows in succession every ten or fourteen days, according to the demand. The sowings may be made in the open ground from March till October, the earliest under hand-glasses, and the summer ones in a cool moist situation; but Cress.

during winter they must be raised on a slight hotbed, or in shallow boxes or pans placed in any of the glass-houses where there is a temperature of 60° or 65°.

The *Golden* or *Australian Cress* is a dwarf, yellowish green, mild-flavoured sort, which is cut and eaten when a little more advanced in growth, but while still young and tender. It should be sown at intervals of a month from March onwards, the autumn sowing, for winter and spring use, being made in a sheltered situation.

The *Curled* or *Normandy Cress* is a very hardy sort, of good flavour. In this, which is allowed to grow like parsley, the leaves are picked for use while young; and, being finely cut and curled, they are well adapted for garnishing. It should be sown thinly in drills, in good soil in the open borders, in March, April, and May, and for winter and spring use at the foot of a south wall early in September, and about the middle of October.

Cucumber. 159. The *Cucumber*, Cucumis sativa, a tender annual, is cultivated both for stewing and pickling, but more usually and extensively for salads. Being an annual plant, it is usually increased by seeds, but it may be readily raised from cuttings, which should consist of the tops of the leading branches, and should be planted in deep pots, half-filled with a compost of leaf-mould and sand, the pots being then covered with a pane of glass, and plunged in a brisk heat. To grow these plants successfully through the winter, a tropical heat must be maintained, for the method of doing which see p. 264. If properly heated hot-water pits or houses cannot be had, and hotbeds have to be employed, it is better not to attempt very early forcing, but to defer sowing till about the first week in February.

In hotbed culture, the preparation of materials for the seed-bed, which should consist of stable dung in a full state of fermentation, should be set about towards the middle of January. The dung should be turned over, well shaken, and mixed about three times at intervals of a few days. The bed should be made up in a sheltered situation open to the sun. The frame should then be set on, and the sashes kept closed till the heat rises to 85° or so, when they should be tilted to allow the steam to pass off. In a few days the surface of the bed should be covered with a layer a few inches in thickness of light soil; and as soon as the heat of the bed ranges about 70° the seeds may be sown singly in 3-inch pots of sifted leaf-mould, with a lump of fibrous turf at the bottom for drainage, the seed being moderately pressed into the soil, and covered to the depth of about half an inch. The heat of the bed should range from 75° to 80°. After germination, the plants should be placed within 6 inches of the glass. When the plants have formed two joints, the growing point should be stopped above the second joint, the succeeding young shoots being stopped above the second or third joint. Subsequently three or four of the shoots, as nearly equal in strength as possible, should be selected for principal branches, and the laterals from these should be allowed to fill out the frame and bear fruit; they should be stopped at one or two joints above the fruit, and all weak shoots removed, being pinched off with the finger and thumb rather than cut, to avoid loss of sap by bleeding. The cucumber is a monœcious plant, and at one time, in order to secure the swelling of the fruit, the female flowers were carefully fertilized; but it is found that this is not necessary unless seed is required.

The fruiting-bed is to be made up in the same way as the seed-bed, only, as it is required to be more lasting, it is better to mix up tree leaves with the dung. The bed may be made up in the first week in February, and should be 4 feet high in front, and 4½ feet at back. The frame should be put on at once, and the lights or sashes kept closed till the heat has risen to the surface. If dry the dung may require watering to keep up fermentation; if it is moist and hot it may be found necessary to make holes with a stake in the sides of the bed to moderate the heat; but unless it rises above 85° there is no danger of its injuring the roots. A few days before the plants are introduced some hillocks of soil should be put into the frame, in order that they may become thoroughly warmed. These should be so arranged that the plant is within 6 inches of the glass. The plants themselves should be removed to the frame for a day or two before turning them out, the soil being moist, but not wet. A good medium compost may consist of two parts of turfy loam, one of peat, and one of leaf-mould, with the addition of some clean coarse sand; or of two parts turfy friable loam, two of turfy heath-mould, three of leaf-mould, and one of clean coarse sand. If the loam be of a less fibrous nature, more peat or leaf-mould or some decayed dung should be used. The bottom heat should range from 75° to 80°, and the atmosphere should be kept moist, and at a temperature ranging from 70° to 80°, the latter by sun-heat. An abundance of light is also essential, but in very bright sunshine a thin shading is beneficial. The water used both at the roots and at the tops should always be warmed, and, while ventilation is to be duly attended to, a cold draught should be avoided.

Winter cucumbers are generally grown in small houses set apart for them (see p. 224). The seeds are sown in August, and planted out so as to become well established before the dull weather sets in. In the case of culture in houses or pits, the heat, bottom and top, is maintained by hot-water pipes or tanks, and the branches are trained over trellises placed about a foot from the glass. The plants must in this case be run up with a single stem, till they reach the upper side of the trellis, when the leader should be stopped in order to produce the branches necessary for covering the allotted space, and these must also be stopped when fruit-bearing laterals are required. These last should be stopped at one joint beyond the fruit, till it can be seen whether or not a shoot will push from the same joint as the fruit, in which case the joint above the fruit is also to be pinched off.

The hardier varieties of cucumber, especially the short prickly sorts, known as *gherkins*, and used for pickling, are often grown under hand-glasses, a cavity having been made in a warm situation, and filled with hot dung and a small covering of earth. In the southern counties of England, pickling cucumbers are sown in drills in the open ground. The earth is made fine and level, and at distances of 3½ feet, in rows 6 feet apart, shallow circular hollows are formed with the hand, a foot wide, and half an inch deep in the middle, in each of which, about the beginning of June, eight or ten seeds are deposited. When the plants appear, they are thinned out to three or four, the weakest or least healthy being rejected, and all the further attention they require is occasional cleaning and watering, according to the state of the weather.

Some of the most popular varieties of the cucumber are:—

Spineless: Rollisson's Telegraph, Carter's Champion.
White-spined: Kenyon's Improved, Empress Eugenie, Improved Manchester Prize, Latter's Victory of England.
Black-tipped White-spined: Tender and True, Hamilton's Market Favourite, Blue Gown.
Black-spined: Dr Livingstone, Henderson's A1, Weedon's Black Spine.
See CUCUMBER, vol. vi. p. 687.

160. The *Egg Plant*, Solanum Melongena, the *Aubergine* or *Brinjal* of the French, is a tender annual, native of South America and of the tropical parts of Asia and Africa. In France it is cultivated for the fruits, which are cooked before they are eaten. The seed should be sown early in February in a warm pit, where the plants are grown till shifted into 8-inch or 10-inch pots, in well-manured soil. Manure water should be given occasionally while the fruit is swelling, about four fruits being sufficient for a plant. The French growers sow them in a brisk heat in December, or early in January, and in March plant them out four or eight in a hotbed with a bottom heat of from 60° to 68°, the sashes being gradually more widely opened as the season advances, until they may be taken off by about the end of May. The two main branches which are allowed are pinched to induce laterals, but when the fruits are set all young shoots are taken off in order to increase their size. The best variety is the Large Purple, which produces oblong fruit, sometimes reaching 6 or 7 inches in length, and 10 or 12 inches in circumference. The Chinese is also an oblong-fruited sort, with white fruit and more juicy flesh than some of the other sorts. The fruit of the ordinary form almost exactly resembles the egg of the domestic fowl. Egg plant.

161. The *Endive*, Cichorium Endivia, is a hardy annual, native of the northern provinces of China and other parts of Asia. As in the case of the lettuce, the blanched hearts are used for salads and in soups. The main crop should be sown about the middle of June, on a seed-bed of light rich soil, and the early crop about the middle of May. The seeds should be scattered sparsely, that the plants may not come up in clusters. The seedlings should be transplanted into a rich soil in an open situation, at about a foot apart in rows, which for the curled-leaved sorts should be a foot asunder, and for the broad-leaved sorts 15 inches. When the plants have reached their maturity, the leaves are gathered up and tied together a little below the tips, and a few days later about the middle of the plant, and in two or three weeks they are found sufficiently blanched for use. Endive.

For winter use the seed should be sown about the middle of July, and a little additional in August. They should be planted in the same way as the earlier crops, but it is advisable, as they approach maturity, to draw the earth quite up about the leaves. At that season, too, the plants may be advantageously planted on sloping banks of earth facing south. They may be blanched by inverting a garden pot with the drainage hole closed, or a common garden saucer 10 or 12 inches in diameter, over the centre of the plants as they grow flat on the earth. Later on they may be blanched in boxes in the mushroom-house, or in a cellar, or by using blanching pots, such as are provided for sea-kale. The time occupied in blanching varies from ten days in summer to three weeks in winter. A sufficient quantity to afford a supply for a week may be operated on at one time.

For protection during the winter it is a good plan to plant the endive on November, at 6 or 8 inches apart, on sloping sheltered banks facing the south, covering it with litter in severe weather, but leaving it uncovered at all other times. A more certain method to obtain a supply during that season is, however, either to take up the late-sown plants before frost sets in, and to plant them in dry earth or sand in a frame, or to place a frame over them where they grow. The early winter crops are sometimes planted at the back of a south wall, and when covered up for blanching they will endure a considerable amount of cold.

There are two races of endives, the Curled (*Chicorée frisée* of the French), with crispy much-cut leaves, and the Batavian (*Scarole* of the French), with broad lettuce-like leaves. Some of the favourite sorts are—

Curled: French Small Green Curled, early; Large Green Curled; Staghorn, for late crops; and Curled Picpus.

Batavian: Small Batavian, Round-leaved Batavian; Lettuce-leaved, early; and Fraser's Broad-leaved Batavian, for late crops.

Garlic. 162. The *Garlic*, Allium sativum, a hardy bulbous perennial, is propagated by separating the cloves of which the bulbs are composed, and planting them 2 to 3 inches deep in spring, at a few inches apart, in rows a foot asunder, in a light, rich, and rather dry soil, and in a warm situation. A few short rows will suffice in most cases, and, if required early, a small patch may also be planted about the end of October. After the leaves have ripened, the bulbs may be taken up, sun-dried, tied in bunches by the stalks, and hung up in a dry airy cool store-room till wanted. Garlic is used for flavouring.

Gourds. 163. The *Gourds* cultivated in gardens for their esculent produce are varieties of several species of Cucurbita, the most commonly used being the vegetable marrow and the pumpkin.

The *Vegetable Marrow*, Cucurbita Pepo var., is the most important of the gourds used as an esculent, and furnishes in good seasons a very large supply for the table. The fruits are best when eaten quite young and not over-boiled, the flesh being then tender, and the flavour sweet and nutty.

Vegetable marrows require a warm situation and a rich soil free from stagnant moisture. They do well on a rubbish or old-dung heap, or in a warm border on little hillocks made up with any fermenting material, to give them a slight warmth at starting. The seeds should be sown in a warm pit in April, and forwarded under glass, but in a very mild heat; the plants must be shifted into larger pots, and be gradually hardened previous to being planted out, when the mild weather sets in in May or June. The use of hand-glasses makes it possible to transplant earlier than would otherwise be advisable. The seeds may be sown early in May in pots under a hand-glass, or towards the end of May in the open ground, if heat is not at command. The true vegetable marrow or succade gourd bears fruit of an oblong-elliptical shape, about 9 inches long, pale-greenish while young, with whitish flesh, and scarcely any indication of ribs; when mature it is of a pale yellow colour. There is a variety which is more oblong, grows to 15 or 18 inches, and has the surface slightly marked by irregular longitudinal obtuse ribs. The shoots may be allowed to run along the surface of the ground, or they may be trained against a wall or paling, or on trellises. As the gourds cross readily, care is necessary to keep any particular variety true. One of the best vegetable marrows is called Moore's Vegetable Cream.

The *Custard Marrow*, one of the Patissons or Crown Gourds, bears a peculiar-looking flattened fruit with scolloped edges, which has a sweeter and less nutty flavour than the true marrow.

The *Pumpkin*, Cucurbita maxima, grows to a very large size, some of the varieties, as the large yellow or *Potiron jaune*, sometimes producing fruit over 200 lb in weight. The flesh of this is yellow, the ripe fruit, in which state only it is used, being of a pale salmony buff colour exteriorly. It will keep for some months in a dry airy place, and is used in soups or stews, or mashed like potatoes, or baked in pies. There are several varieties of this type. The cultivation of the pumpkin resembles that of the vegetable marrow, but it requires abundance of space for its spreading vines.

Many of the other gourds (of which some are very ornamental) produce edible fruits, but as some, notably the orange gourd and the bottle gourd, are cathartic and deleterious, they should not be indiscriminately eaten.

Horse-radish. 164. The *Horseradish*, Cochlearia Armoracia, or Armoracia rusticana, a hardy perennial, is cultivated for its long roots, or more properly underground rootstocks, which when scraped into shreds, or grated and made into a delicious sauce, are eaten with roast beef. Its properties are antiscorbutic. The horseradish requires a deep, rich, and rather moist sandy loam or alluvial soil, the object being to obtain long straight roots. One method of producing new plants is to plant the sets, consisting of the crowns of old roots, or of 1 or 2 inch lengths of the root itself, at the bottom of a trench 2½ feet deep, the lower half of the soil being well manured; only a single shoot should be retained, so as to produce one thick vigorous stick. The roots planted in spring are sometimes taken up in the winter following; if left to grow another year they become very much thicker, though less tender. In digging the roots the soil should be thrown back so as to lay them bare. Those that spring from the set are cut off, and it is manured and left to grow up again the following year. Before the ground becomes frost-bound, a supply should be dug up, and stored in damp sand for use during that emergency.

Jerusalem Artichoke. 165. The *Jerusalem Artichoke*, Helianthus tuberosus, a hardy tuberous perennial, a species of sunflower, derives its epithet *Jerusalem* from a corruption of the Italian *Girasole*, a sunflower, and its name of *Artichoke* from the resemblance in flavour which its tubers bear to that of the receptacles or "bottoms" of that plant. It is propagated by means of its tubers planted in the manner of potatoes, in rows 3 or 4 feet asunder, some time in February or March; by the autumn the new tubers will be fit for use. As a matter of convenience, though the tubers themselves are hardy enough to bear the frosts of winter, they may be dug up about November, and stored in dryish sand. They should have a well-manured soil, and the stems should not be allowed to be too crowded, which is in great measure obviated by planting them annually.

166. The *Kidney Bean* includes what is commonly known as the French Bean, Phaseolus vulgaris, and the Scarlet Runner, Phaseolus multiflorus, both very productive vegetables of excellent quality. Kidney bean.

The *Common Kidney Bean* or *French Bean*, Phaseolus vulgaris, is a tender annual, and should be grown in a rich light loamy soil and a warm sheltered situation. The soil should be well enriched with hotbed dung. The earliest crop may be sown by the end of March or beginning of April. If, however, the temperature of the soil is below 45°, the beans make but little progress. The main crops should be got in early in May; and a later sowing may be made early in July. The earlier plantings may be sown in small pots, and put in frames or houses, until they can be safely planted out-of-doors. The earliest out-of-doors crop may be sheltered by means of thatched hurdles, placed sloping on bearers supported by posts. The seeds should be covered 1½ or 2 inches deep, the distance between the rows being about 2 feet, or for the dwarfest sorts 18 inches, and that between plants from 4 to 6 inches. The pods may be used as a green vegetable, in which case they should be gathered whilst they are so crisp as to be readily snapped in two when bent; but when the dry seeds are to be used, the pods should be allowed to ripen. As the green pods are gathered others will continue to be formed in abundance; but if old seed-forming pods are allowed to remain, the formation of young ones will be greatly checked.

Forcing.—The kidney bean may be easily forwarded in pots in a forcing-house, or in prepared soil in a heated pit. The bottom heat should range about 70°, and the atmospheric temperature should show a minimum of 60°, and a maximum of 70°, running up to 80° by sun-heat. The seed should be sown three or four in a 10-inch pot, nearly filled with light turfy soil and leaf-mould, or decomposed cow dung, the stems being earthed up after the true leaves are formed; and they must be well syringed and watered daily. To keep down the red spider, the under side of the leaves should be thoroughly moistened by syringing early in the morning with water at 60°; the house being then kept shut up till the air is raised to 75° or 80°, both surfaces will, in consequence of condensation, become thoroughly wetted. When the plants come into flower, plenty of air must be admitted. Kidney beans may thus be obtained fit for use, in six weeks or two months from the time of sowing. It may therefore be desirable to sow some seed in August to succeed the crops in the open ground, and, for succession, in September and October; for spring use sow in January, February, and March. The early dwarf sorts are the best for forcing, such as Fulmer's Early, Newington Wonder, Osborn's Forcing, Williams's Early Prolific, Syon House, and White Advancer.

The varieties of French beans being numerous, we here add the names of some of the most desirable for general cultivation:—

Early: White Canterbury, Fulmer's Forcing, Minier's First Early, Osborn's Forcing, Sir Joseph Paxton, White Advancer.

Second Early: Canadian Wonder, bears late; Negro Long-podded, bears late; New Mammoth Negro, earlier than Canadian Wonder; Newington Wonder; Pale Dun; Syon House; Williams's Prolific, bears late.

The *Scarlet Runner Bean*, Phaseolus multiflorus, differs from the common French bean in being a perennial, and in having tuberous roots, which, it may be stated, are narcotic and poisonous. These may be preserved through the winter in dryish earth in a frost-proof cellar, for an early crop the following season. The late Mr Cuthill mentions having found from experiment that plants raised from roots come into bearing just one month earlier than those raised from seed. The seeds of the runner beans should be sown in an open plot,—the first sowing in May, another at the beginning of June, and a third about the middle of June. In the London market-gardens they are sown 8 to 12 inches apart, in 4 feet rows if the soil is good. The twining tops are pinched or cut off when the plants are from 2 to 2½ feet high, to save the expense of staking. It is better, however, in private gardens to have the rows standing separately, and to support the plants by stakes 6 or 7 feet high and about a foot apart, the tops of the stakes being crossed about one-third down. If the weather is dry when the pods are forming abundantly, plenty of tepid water should be supplied to the plants. In training the shoots to their supports, they should be twined from right to left, contrary to the course of the sun, or they will not lay hold.

The ordinary Scarlet Runner is most commonly grown, but there is a white-flowered variety which has also white seeds; this is very prolific and of excellent quality, and is now much grown for market. Another variety called Painted Lady, with the flowers red and white, is very ornamental, but not so productive. Carter's Champion is a large-podded productive variety.

167. The *Kohl Rabi*, or *Turnip Cabbage*, Brassica oleracea caulo-

Kohl Rabi. rapa, is a biennial, the upper part of whose stem swells into a round fleshy mass, resembling a turnip, but produced above ground. Kohl Rabi is exceedingly hardy, withstanding both severe frosts and drought. It is not much grown in English gardens, though when used young it forms a good substitute for turnips. The seeds should be sown in May and June, and the seedlings should be planted shallowly in well-manured ground, 8 or 10 inches apart, in rows 15 inches asunder; and they should be well watered, so as to induce quick growth. The bulbs will be fit for use when they are as large as—not larger than—an early turnip. The best sorts are Early White Vienna, and Early Purple Vienna.

Leek. 168. The *Leek*, Allium Porrum, a hardy biennial, is said to be a native of Switzerland, but more probably comes from the East. The leeks, which prefer a light soil, are sown in beds about the middle of March, and later for a succession, and in June or July are planted out 6 inches asunder; and in rows 15 or 18 inches apart. When the weather is moist the plants are dropped upright into the hole made by the dibble, and no more earth than will just cover the fibres is allowed to fall in, the hole being left open to encourage the stem to swell out, and blanching is effected gradually by the earth washing into the hole. They are also planted in trenches like celery, and earthed up when they have made their growth. The leeks will be fit for use in September, and will last till the spring.

The best sorts are—Early Netherlands, for early use; Large Rouen, one of the very best; London Flag, and Musselburgh, the latter being reputedly the hardiest; and Carentan, a very large hardy French sort.

Lettuce. 169. The *Lettuce*, Lactuca sativa, is a hardy annual, highly esteemed as a salad plant, while its milky juice forms the *lactucarium* of the materia medica. The London market-gardeners make preparation for the first main crop of Cos lettuces in the open ground early in August, a frame being set on a shallow hotbed, and, the stimulus of heat not being required, this is allowed to subside till the first week in October, when the soil, consisting of leaf-mould mixed with a little sand, is put on 6 or 7 inches thick, so that the surface is within 4½ inches of the sashes. The best time for sowing is found to be about the 11th of October. When the seeds begin to germinate the sashes are drawn quite off in favourable weather during the day, and put on, but tilted, at night in wet weather. Very little watering is required, and the aim should be to keep the plants gently moving till the days begin to lengthen. In January a more active growth is encouraged, and in mild winters a considerable extent of the planting out is done, but in private gardens the preferable time would be February. The ground should be light and rich, and well manured below, and the plants put out at 1 foot apart each way. In planting at this early season, the dibble, in closing in the soil, should be inserted on the south side of the plant. Frequent stirring of the ground with the hoe greatly encourages the growth of the plants. A second sowing should be made about the 5th of November, and a third in frames about the end of January or beginning of February. In March a sowing may be made in some warm situation; successional sowings may be made in the open border till August, about the middle of which month a crop of Brown Cos and Hardy Hammersmith should be sown, the latter being the most reliable in a severe winter. These plants may be put out early in October on the sides of ridges facing the south or at the front of a south wall, beyond the reach of drops from the copings, the Hardy Hammersmith being planted 6 or 8 inches apart. Young lettuce plants should be thinned before they crowd or draw each other, and transplanted as soon as possible after two or three leaves are formed. Some cultivators prefer that the summer crops should not be transplanted, but sown where they are to stand, the plants being merely thinned out; but transplanting checks the running to seed, and makes the most of the ground.

Forcing.—For a winter supply by gentle forcing, the Hardy Hammersmith and Brown Dutch Cabbage lettuces, and the Brown Cos and Green Paris Cos lettuces, should be sown about the middle of August and in the beginning of September, in rich light soil, the plants being pricked out 3 inches apart in a prepared bed, as soon as the first two leaves are fully formed. About the middle of October the plants should be taken up carefully with balls attached to the roots, and should be placed in a mild hotbed of well-prepared dung (about 55°) covered about 1 foot deep with a compost of sandy peat, leaf-mould, and a little well-decomposed manure. The Cos and Brown Dutch varieties should be planted about 9 inches apart. Give plenty of air when the weather permits, and protect from frost.

There are two races of the lettuce, the Cos lettuce, with erect oblong heads, and the Cabbage lettuce, with round or spreading heads,—the former generally crisp, the latter soft and flabby in texture. Some of the best lettuces for general purposes of the two classes are the following:—

Cos: White Paris Cos, best for summer; Green Paris Cos, hardier than the white; Alphange Cos, stands well; Brown Cos, one of the hardiest and best for winter; Hicks's Hardy White Cos; Sugarloaf Bath Cos.

Cabbage: Hammersmith Hardy Green, very hardy, good for winter; Tom Thumb; Brown Dutch; Neapolitan, best for summer; Grand Admiral, stands the winter well; Stanstead Park.

Mushroom. 170. The *Mushroom*, Agaricus campestris, is a well-known fungus of a specially savoury character; it grows wild in Great Britain on upland pastures, and appears to be indigenous to most regions of the globe. The plant is propagated by spores, the fine black dust seen to be thrown off when a mature specimen is laid on white paper or a white dish; these give rise to what is known as the "spawn" or mycelium, which consists of whitish threads permeating dried dung or similar substances, and which, when planted in a proper medium, runs through the mass, and eventually appears in the form of the mushroom. This spawn may be obtained from old pastures, or decayed mushroom beds, and is purchased from nurserymen in the form of bricks charged with the mycelium, and technically known as mushroom spawn. When once obtained, it may, like leaven, be indefinitely preserved. It may be produced by placing quantities of horse dung saturated with the urine of horses, especially of stud horses, with alternate layers of rich earth, and covering the whole with straw, to exclude rain and air; the spawn commonly appears in the heap in about two months afterwards. The droppings of stall-fed horses, or of such as have been kept on dry food, should be made use of.

The old method of growing mushrooms in ridges out of doors, or on prepared beds either level or sloping from a back wall in sheds or cellars, may generally be adopted with success. The beds are formed of horse droppings which have been slightly fermented and frequently turned, and may be made 2 or 3 feet broad, and of any length. A layer of dung about 8 or 10 inches thick is first deposited, and covered with light dryish earth to the depth of 2 inches; and two similar layers with similar coverings are added, the whole being made narrower as it advances in height. When the bed is finished, it is covered with straw to protect it from rain, and also from parching influences. In about ten days, when the mass is milkwarm, the bed will be ready for spawning, which consists of inserting small pieces of spawn bricks into the sloping sides of the bed, about 6 inches asunder. A layer of fine earth is then placed over the whole, and well beaten down, and the surface is covered with a thick coat of straw. When the weather is temperate, mushrooms will appear in about a month after the bed has been made, but at other times a much longer period may elapse. The principal things to be attended to are to preserve a moderate state of moisture and a proper mild degree of warmth; and the treatment must vary according to the season.

Mr Cuthill describes a very simple mode of culture. The ridge is built up of dung as it is brought fresh from the London stables; in this fermentation soon sets in, and, when the heat of the bed declines to 80°, pieces of spawn bricks are inserted, a foot apart, in the sides of the bed, which is then moulded over, 2 inches thick, pressed with the feet, and beaten with the spade, then watered, and beaten again with the spade, and finally smoothed down. The more the mould is pressed, the finer the crop, and the more solid the texture of the mushroom.

These ordinary ridge beds furnish a good supply towards the end of summer, and in autumn. To command a regular supply, however, at all seasons, the use of a mushroom-house (see par. 13, p. 226) will be found very convenient. The material employed in all cases is the droppings of horses, which should be collected fresh, and spread out in thin layers in a dry place, a portion of the short litter being retained well moistened by horse urine. It should then be thrown together in ridges and frequently turned, so as to be kept in an incipient state of fermentation, a little dryish friable loam being mixed with it to retain the ammonia given off by the dung. With this or a mixture of horse-dung, loam, old mushroom-bed dung, and half-decayed leaves, the beds are built up in successive layers of about 3 inches thick, each layer being beaten firm, until the bed is 9 or 10 inches thick. If the heat exceeds 80°, holes should be made to moderate the fermentation. The beds are to be spawned when the heat moderates, and the surface is then covered with a sprinkling of warmed loam, which after a few days is made up to a thickness of 2 inches, and well beaten down. The beds made partly of old mushroom-bed dung often contain sufficient spawn to yield a crop, without the introduction of brick or cake spawn, but it is advisable to spawn them in the regular way. The spawn should be introduced an inch or two below the surface when the heat has declined to about 75°, indeed the bed ought never to exceed 80°. The surface is to be afterwards covered with hay or litter. The atmospheric temperature should range from 60° to 65° till the mushrooms appear, when it may drop a few degrees, but not lower than 55°. If the beds require watering, water of about 80° should be used, and it is preferable to moisten the covering of litter rather than the surface of the beds themselves. It is also beneficial, especially in the case of partially exhausted beds, to water with a dilute solution of nitre. For a winter supply the beds should be made towards the end of August, and the end of October.

Mustard. 171. The *Mustard*, Sinapis alba, or Brassica alba, is a hardy annual, used as a small salad—generally accompanied by garden cress—while still in the seed-leaf. To keep up a supply, the seed should be sown every week or ten days. The sowings in the open ground may be made from March till October, earlier or later according to the season. The ground should be light and rich, and the situation warm and sheltered. Sow thickly in rows 6 inches apart, and slightly cover the seed, pressing the surface smooth with the back of the spade. When gathering the crop, cut the young plants off even with the ground, or pull them up and cut off the roots, commencing at one end of a row. From October to March the seeds should be sown thickly in shallow boxes and placed in a warm house or frame, with a temperature not below 65°.

Nasturtium. 172. The *Nasturtium*, or *Indian Cress*, Tropæolum majus, is a perennial climber, native of Peru, but in cultivation treated as a hardy annual. The flowers are sometimes eaten in salads, and are used for garnishing, and the leaves and young green fruits are pickled in vinegar as a substitute for capers. The plant should have a warm situation, and the soil should be light and well enriched; sow thinly early in April, either near a fence or wall, which may be utilized for its support, or in an open spot, where it will require stakes 6 to 8 feet high. Its flowers are no less ornamental than useful.

New Zealand Spinach. 173. The *New Zealand Spinach*, Tetragonia expansa, is a half-hardy annual, native of New Zealand, sometimes used as a substitute for spinach during the summer months, but in every way inferior to it. The seeds should be sown in March, on a gentle hotbed, having been previously steeped in water for several hours. The seedlings should be potted, and placed under a frame till the end of May, and should then be planted out, in light rich soil. The young leaves are those which are gathered for use, a succession being produced during summer and autumn.

Onion. 174. The *Onion*, Allium Cepa, is a hardy bulbous biennial, which has been cultivated in Britain from time immemorial, but the native country of which is unknown. The onion should be grown in an open situation, and on a light, rich, well-worked soil, which has not been recently manured. The principal crop may be sown at any time from the middle of February to the middle of March, if the weather is fine and the ground sufficiently dry. The seed should be sown in shallow drills, 10 inches apart, the ground being made as level and firm as possible, and the plants should be regularly thinned, hoed, and kept free from weeds. At the final thinning they should be set from 3 to 6 inches apart, the latter distance in very rich soil. About the beginning of September the crop is ripe, which is known by the withering of the leaves; the bulbs are then to be pulled, and exposed on the ground till well dried, and they are then to be put away in a store-room or loft, where they may be perfectly secured from frost and damp.

About the end of August a crop is sown to afford a supply of young onions in the spring months. Those which are not required for the kitchen, if allowed to stand, and if the flower-bud is picked out on its first appearance, and the earth stirred about them, frequently produce bulbs equal in size and quality to the large ones that are imported from the Continent. A crop of very large bulbs may also be secured by sowing about the beginning of September, and transplanting early in spring to very rich soil. Another plan is to sow in May on dry poor soil, when a crop of small bulbs will be produced; these are to be stored in the usual way, and planted in rich soil about February, on ground made firm by treading, in rows about a foot apart, the bulbs being set near the surface, and about 6 inches asunder. The White Spanish and Tripoli are good sorts for this purpose.

To obtain a crop of bulbs for pickling, seed should be sown thickly in March, in rather poor soil, the seeds being very thinly covered, and the surface well rolled; these are not to be thinned, but should be pulled and harvested when ripe. The best sorts for this crop are the Silver-skinned, Early Silver-skinned, Nocera, and Queen.

Forcing.—Onions may be forced like mustard and cress if required for winter salads, the seeds being sown thickly in boxes which are to be placed in a warm house or frame. The young onions are of course pulled while quite small.

The *Potato Onion*, Allium Cepa aggregatum, is propagated by the lateral bulbs, which it throws out, under ground, in considerable numbers. This variety is very prolific, and is useful when other sorts do not keep well. It is sometimes planted about midwinter, and then ripens in summer, but for use during the spring and early summer it is best planted in spring. It is also known as the underground onion, from its habit of producing its bulbs beneath the surface.

The *Tree Onion* or *Egyptian Onion*, Allium Cepaproliferum, produces small bulbs instead of flowers, and a few offsets also underground. These small stem bulbs are excellent for pickling.

The *Welsh Onion* or *Ciboule*, Allium fistulosum, is a hardy perennial, native of Siberia. It forms no bulbs, but, on account of its extreme hardiness, is sown in July or early in August, to furnish a reliable supply of young onions for use in salads during the early spring. These bulbless onions are sometimes called Scallions, a name which is also applied to old onions which have stem and leaves but no bulbs.

The following are among the best varieties of onions for various purposes:—

For summer and autumn.—Queen; Early White Naples: these two sorts are also excellent for sowing in autumn for spring salading. Silver-skinned; Tripoli, including Giant Rocca.

For winter.—Brown Globe, including Magnum Bonum; White Globe; Yellow Danvers; White Spanish, in its several forms; Trébons, the finest variety for autumn sowing, attaining a large size early, ripening well, and keeping good till after Christmas; Strasburg (Deptford); Weathersfield Red; Blood Red, strong-flavoured.

For pickling.—Queen, Early Silver-skinned, White Nocera, Egyptian.

175. The *Orach* or *Mountain Spinach*, Atriplex hortensis, native of Tartary, is a tall-growing hardy annual, whose leaves, though coarsely flavoured, are used as a substitute for spinach, and to correct the acidity of sorrel. The White and the Green are the most desirable varieties. The plant should be grown quickly in rich soil. It may be sown in rows 2 feet apart, and about the same distance in the row, about March, and for succession again in June. If needful, water must be freely given, so as to maintain a rapid growth. Orach.

176. The *Oxalis crenata*, Oca of the South Americans, is a tuberous-rooted half-hardy perennial, native of Peru. Its tubers are comparatively small, and somewhat acid; but if they be exposed to the sun from six to ten days, they become sweet and floury. In the climate of England they can only be grown by starting them in heat in March, and planting out in June in a light soil and warm situation. They grow freely enough, but few tubers are formed, and these of small size. The fleshy stalks, which have the acid flavour of the family, may, however, be used in the same way as rhubarb for tarts. The leaves may be eaten in salads. It is easily propagated by cuttings of the stems, or by means of sets like the potato. Oxalis crenata.

177. The *Oxalis Deppei*, a bulbous perennial, native of Mexico, has scaly bulbs, from which are produced fleshy, tapering, white, semi-transparent roots, about 4 inches in length, and 3 to 4 inches in diameter. They strike down into the soil, which should therefore be made light and rich with abundance of decayed vegetable matter. The bulbs should be planted about the end of April, 6 inches apart, in rows 1 foot asunder, being only just covered with soil, and having a situation with a southern aspect. The roots should be dug up before they become affected by frost, but if protected they will continue to increase in size till November. When taken up, the bulbs should be stored in a cool dry place for replanting, and the roots for use. The roots are gently boiled with salt and water, peeled and eaten like asparagus with melted butter and the yolks of eggs, or served up like salsafy and scorzonera with white sauce. Oxalis Deppei.

178. The *Parsnip*, Pastinaca sativa, is a hardy biennial, found in temperate regions. Its long tapering fleshy whitish nutritious roots have a peculiar but agreeable flavour. It succeeds best on a free sandy loam, which should be trenched and manured in the previous autumn, the manure being well buried. The seed should be sown thinly in March, in rows, 18 inches apart, and finally thinned out to 1 foot apart. The leaves will decay in October or November, when a portion of the roots may be taken up and stored in dryish sand for immediate use, the rest being left in the ground, to be taken up as required, but the whole should be removed by February to a dry cool place, or they will begin to grow. The best sorts are the Hollow-crowned, the Maltese, and the Student. Parsnip.

179. The *Pea*, Pisum sativum, is a hardy annual, climbing by means of the tendrils of its leaves, and has been cultivated from time immemorial. The seeds or pulse are very nutritious, whether eaten green or ripe, and those of the early crops are esteemed as luxuries. Pea.

The pea prefers a friable calcareous loam, deeply worked, and well enriched with good hotbed or farm-yard manure. The early crops require a warm sheltered situation, but the later are better grown 6 or 8 feet apart, or more, in the open quarters, dwarf crops being introduced between the rows. The dwarf or early sorts may be sown 3 or 4 feet apart. The deep working of the soil is of importance, lest the plants should suffer in hot dry weather from mildew or arrest of growth. The first sowing should be made about the beginning or middle of November, in front of a south wall, the plants being defended by spruce fir branches or other spray throughout the winter. In February sowings are sometimes made in flower-pots or boxes, and the young plants afterwards planted out. The main crop should be sown towards the end of February, and moderate sowings should be made twice a month afterwards, up to the beginning of July for the north, and about the third week in July for warmer districts. During dry hot weather late peas derive great benefit from mulching and watering. The latest sowings, at the middle or end of August, should consist of the best early sorts, as they are not so long in producing pods as the larger and finer sorts, and by this means the supply may be prolonged till October or November. As they grow up the earth is drawn to the stems, which are also supported by stakes, a practice which in a well-kept garden is always advisable, although it is said that the early varieties arrive sooner at maturity when recumbent. Where space permits, all the taller sorts are best sown in single rows at wide intervals of 20 or 30 feet.

Peas grown late in autumn are subject to mildew, to obviate which Mr Knight proposed to dig over the ground in the usual way, and to soak the spaces to be occupied by the rows of peas thoroughly with water,—the earth on each side to be then collected so as to form ridges 7 or 8 inches high, these ridges being well watered, and the seed sown on them in single rows. If dry weather at any time set in, water should be supplied profusely once a week.

To produce very early crops the French market-gardeners sow early in November, in frames, on a border having a good aspect, the seeds being covered very slightly. The young plants are transplanted into other frames in December, the ground inside being dug out so as to be 18 or 20 inches below the sashes, and the earth thus removed placed against the outside of the frames. The young plants, when 3 or 4 inches high, are planted in patches of three or four, 8 inches asunder, in four longitudinal rows. The sashes are covered at night with straw mats, and opened whenever the weather is sufficiently mild. When 8 or 10 inches high, the stems are inclined towards the back of the frame, a little earth being drawn to their base, and when the plants come into blossom the tops are pinched out, above the third or fourth flower, to force them into bearing. As soon as they begin to pod, the soil may have a gentle watering, whenever sufficiently warmed by the sun, but a too vigorous growth at an earlier period would be detrimental. Thus treated the plants bear pods fit for gathering in the first fortnight in April.

A very convenient means of obtaining an early crop is to sow in 5-inch pots, a few seeds in each, the plants to be ultimately planted out on a warm border. Peas may also be obtained early if gently forced in frames, in the same way as kidney beans, the dwarfest varieties being preferable.

For the very early peas the rows should range east and west, but for the main crops north and south. The average depth of the drills should be about 2 inches for small sorts, and a trifle more for the larger kinds. The drills should be made wide and flat at bottom, so that the seeds may be better separated in sowing. The large sorts are the better for being sown 3 inches apart. Chopped furze may be advantageously scattered in the drill before covering in, to check the depredations of mice, and before levelling the surface the soil should be gently trodden down over the seeds.

A good selection of sorts may be made from the following:—

Early: Dillistone's Early (Sutton's Ringleader, Carter's First Crop), the earliest sort; Sangster's No. 1, a good form of Early Frame; William I., fine; Laxton's Alpha, the earliest wrinkled pea; Dickson's First and Best; Maclean's Little Gem, a very dwarf wrinkled pea; Tom Thumb (Beck's Gem), a very dwarf round pea. The last two are useful for forcing and for pots.

Second Early: Maclean's Advancer, Standish's Criterion, Laxton's Marvel, Carter's Telephone, Dr Maclean, Premier, Carter's Stratagem.

Late: James's Prolific, Carter's G. F. Wilson, Veitch's Perfection; Ne Plus Ultra, the finest of all late peas, but a little delicate in cold wet soils and seasons; General Wyndham, continues to produce very late; British Queen, Champion of England, Laxton's Omega.

otato. 180. The *Potato*, Solanum tuberosum, is a half-hardy perennial, producing underground tubers, largely used as an esculent. It thrives best in a rather light friable loam; and in thin sandy soils the produce, if not heavy, is generally of very good quality. Soils which are naturally wet and heavy, as well as those which are heavily manured, such as old garden ground, are not suitable. Indeed it is best, except when there is ample space, to grow only the earlier kinds in gardens. If the soil is of fair quality, the less manure used upon it the better, unless it be soot or lime. Gypsum, bone-dust, superphosphate of lime, and nitrate of soda may also be used, and wood ashes are advantageous if the soil contains much vegetable matter.

Potatoes are commonly propagated by dividing the tubers, leaving to each segment or "set" one or two eyes or buds. The "sets" are then planted by the aid of the dibble or spade, in rows at a distance varying from 15 inches to 3 feet, the distance being regulated by the height of the stems, and that between the sets varying from 6 to 12 inches, 8 inches being a good average space for garden crops, with 2 feet between the rows. The sets may be put in 6 inches deep. The late T. A. Knight suggested the planting of whole tubers or sets, at greater distances apart, by which means, he argued, a larger produce would be obtained; he proposed to leave 4 feet between the rows, but that distance, except with the larger varieties, has been found to be too great. Though the planting of whole tubers instead of the cut sets has been thus highly recommended, yet according to some experiments made in the garden of the Horticultural Society at Chiswick the cut sets yield a much better return than whole ones. The full-sized tubers are, however, preferable to smaller ones, as their larger buds tend to produce stronger shoots. It has also been found that the best returns are obtained from sets taken from the points of the tubers—not from their base. Mr Thomas Dickson of Edinburgh long ago observed that the most healthy and productive crop was to be obtained by planting unripe tubers, and proposed this as a preventive of the disease called the "curl," which sometimes attacks the young stems, causing them and also the leaves to become crumpled, and few or no tubers to be produced. It has also been noted that the sprouting of the eyes of the potato may be accelerated if, while still unripe, it is taken up and exposed for some weeks to the influence of a scorching sun. The best sets are those obtained from plants grown in elevated and open situations, and it is also beneficial to use sets grown on a different soil.

The earliest crops should, if possible, be planted in a light soil and in a warm situation, towards the end of February, or as early as possible in March. In some cases the tubers for early crops are sprouted on a hotbed, the plants being put out as soon as the leaves can bear exposure. If the young sprouts are about 2 inches long, they may be planted out towards the end of March; if they are protected young potatoes will be procured in seven or eight weeks. It will improve the crop if, when the stems have grown a few inches above ground, the earth is drawn up to them, but the operation will delay its maturity for two or three weeks. Mr Knight recommends removing the flowers as they appear, in order to increase the produce. The fine early varieties, however, scarcely produce any flowers.

The main crop should be planted by the middle of March, late planting being very undesirable. Those intended for storing should be dug up as soon as they are fairly ripe, unless they are attacked by the dire disease, in which case they must be taken up as soon as the murrain is observed; or if they are then sufficiently developed to be worth preserving, but not fully ripe, the haulms or shaws should be pulled out, to prevent the virus passing down them into the tubers; this may be done without disturbing the tubers, which can be dug afterwards. See AGRICULTURE, vol. i. p. 364.

Forcing.—The best forcing sorts are the Ash-leaf as a kidney, and the Early Market or Rector of Woodstock for a round. The earliest crop may be planted in December, and successional ones in January and February. The mode of cultivation adopted by the London market gardeners is thus in substance explained by Mr Cuthill. A long trench, 5 feet wide and 2 feet deep, is filled with hot dung, on which soil to the depth of 6 inches is put. The sets employed are middle-sized whole potatoes, which are placed close together over the bed, covered with 2 inches of mould, and then hooped and protected with mats and straw, under which conditions they will sprout in about a month. A bed of the requisite length (sometimes 100 yards) is then prepared of about 2 feet thickness of hot dung, soil is put on to the depth of 8 inches, and the frames set over all. The potatoes are then carefully taken up from the striking bed, all the shoots being removed except the main one, and they are planted 4 inches deep, radishes being sown thinly over them and covered lightly with mould. When the haulm of the potato has grown to about 6 inches in height, the points are nipped off, in order to give the radishes fair play; and, although this may stop growth for a few days, still the potato crop is always excellent. After planting nothing more is required but to keep up the temperature to about 70°, admitting air when practicable, and giving water as required. The crop is not dug up until it has come to maturity.

Potatoes are also grown largely in hooped beds on a warm border in the open ground. The sets after having been sprouted, as above, are planted out in January in trenches 2 feet deep filled with hot dung, the sets being planted 5 inches deep, and over all radishes are sown. The ridges are then hooped over, allowing about 2 feet of space in the middle, between the mould and the hoop, and are covered with mats and straw, but as soon as the radishes come up they are uncovered daily, and covered again every night as a protection against possible frosts. This is continued till the potatoes are ready for digging in May.

Potatoes are sometimes grown in pots in heat, sprouted sets being planted in 11-inch pots about two-thirds full of soil, and placed near the glass in any of the forcing-houses, where a temperature of from 65° to 70° is to be maintained. The plants are duly watered and earthed up as they advance in growth.

Small supplies of young waxy tubers are produced during winter, in boxes placed in a mushroom-house or in a common cellar. If in October old seed tubers are placed in layers, alternately with a mixture of tree leaves and light mould, the young tubers before mid-winter will often attain the size and appearance of early potatoes; they are, however, watery, and possess little flavour.

The varieties of the potato are very numerous, and much attention has been paid during the last few years to the production of new and improved kinds. The following are named as a limited selection of a few of the standard sorts in the several groups, those marked * having coloured skins, the rest being white:—

Early.—Round: Early Market, Rector of Woodstock, Porter's Excelsior, *Triumph, *Radstock Beauty, Bedfont Prolific, Breesee's Climax. *Kidney*: Old Ash-leaf, Myatt's Ash-leaf, Avalanche, Snowflake, International Kidney, *Bountiful, *Beauty of Hebron.

Main Crop and Late.—Round: Schoolmaster, Regent, *Vicar of Laleham, Victoria, *Grampian, *Vermont Beauty, Champion. *Kidney*: Covent Garden Perfection, Lapstone, Woodstock Kidney, *Trophy, Magnum Bonum, *Late American Rose, Cattell's Eclipse.

181. The *Radish*, Raphanus sativus, is a fleshy-rooted annual, unknown in the wild state. Some varieties of our wild radish, R. Raphanistrum, however, met with on the Mediterranean coasts, come so near to it as to suggest that it may possibly be a cultivated race of the same species. It is very popular as a raw salad. There are two principal forms, the spindle-rooted and the turnip-rooted. Radish.

The radish succeeds in any well-worked not too heavy garden soil, but requires a warm sheltered situation. The seed is generally sown broadcast, in beds 4 to 5 feet wide, with alleys between, the beds requiring to be netted over to protect them from birds. The earliest crop may be sown about the middle of December, the seed-beds being at once covered with litter, which should not be removed till the plants come up, and then only in the daytime, and when there is no frost. If the crop succeeds, which depends on the state of the weather, it will be in use about the beginning of March. Another sowing may be made in January, a third early in February, if the season is a favourable one, and still another towards the end of February, from which time till October a small sowing should be made every fortnight or three weeks in spring, and rather more frequently during summer. About the end of October, and again in November, a late sowing may be made on a south border or bank, the plants being protected in severe weather with litter or mats. The winter radishes, which grow to a large size, should be sown in the beginning of July and in August, in drills from 6 to 9 inches apart, the plants being thinned out to 5 or 6 inches in the row. The roots become fit for use during the autumn. For winter use they should be taken up before severe frost sets in, and stored in dry sand.

Forcing.—To obtain early radishes a sowing should be made about the beginning of November, and continued fortnightly till the middle or end of February; the crop will generally be fit for use about six weeks after sowing. The seed should be sown in light rich soil, 8 or 9 inches thick, on a moderate hotbed, or in a pit with a temperature of from 55° to 65°. Gentle waterings must be given, and air admitted at every favourable opportunity; but the sashes must be protected at night and in frosty weather with straw mats or other materials. Some of these crops are often grown with forced potatoes. The best forcing sorts are Wood's Early Frame, and the Early Rose Globe, Early Dwarf-top Scarlet Turnip, and Early Dwarf-top White Turnip.

Those best suited for general cultivation are the following:—

Spindle-rooted: Long Scarlet, including the sub-varieties Scarlet Short-top, Early Frame Scarlet, and Wood's Early Frame; Long Scarlet Short-top, best for general crop.

Turnip-rooted: Early Rose Globe-shaped, the earliest of all; Early Dwarf-top Scarlet Turnip, and Early Dwarf-top White Turnip; Earliest Erfurt Scarlet, and Early White Short-leaved, both very early sorts; French Breakfast, olive-shaped; Red Turnip, and White Turnip, for summer crops.

Winter sorts: Black Spanish, White Chinese, Californian Mammoth.

Rampion. 182. The *Rampion*, Campanula Rapunculus, is a tap-rooted biennial, native or naturalized in the south of England, and found on banks and in pastures in central and southern Europe, extending to the Caucasus. The white fleshy roots, known as "ramps," are used raw as a salad, or boiled like asparagus. It is but little cultivated in England. The seed, which is very minute, and should be mixed with sand before sowing to secure even distribution, is sown in drills 6 to 8 inches apart, about the end of May or beginning of June, in deeply worked ground, and in a cool situation, and the young plants are merely to be thinned and kept clear of weeds. The roots, which somewhat resemble small radishes, will be fit for use about November, and on the approach of frost, if taken up and stored in sand, they will keep fresh and firm till spring.

Rhubarb. 183. The *Rhubarb* of gardens is derived from different species of Rheum, especially R. Rhaponticum and R. undulatum. The parts chiefly utilized are the fleshy foot-stalks of the leaves, which are much used for preserves, puddings, and tarts, as well as for stewing.

Rhubarb requires an open situation and a rich deep soil, which should be well manured, and prepared by deep trenching. To form a plantation, divisions of the old roots, each provided with a bud or crown, should be put in early in spring, the crown being set about 2 inches below the surface. They should stand 3 to 4 feet apart each way, according to the habit of the variety. The plants will afford a supply in the following spring. It is desirable to renew the plantation in the course of four or five years, shifting to new ground. When gathering the crop, the leaf-stalks should be bent downwards, and pulled off sideways, not cut. The flower-stems should be cut off as soon as they make their appearance, in order to strengthen the root. Established sorts must be increased by division, as seedlings do not reproduce the variety. Rhubarb may, however, be grown from seeds—a flower stem or two being allowed to grow up for the purpose of producing them. The seeds should be sown on a slight hotbed in spring, and transplanted out in rows in the month of May, no stalks being gathered from them for the first two years.

Forcing.—Rhubarb may be forced in a variety of ways for early or winter use; it may have a pot or box set over the crown and covered up by warm litter, dung, or leaves like sea-kale; or the roots may be taken up, potted, and set into any forcing-house at work, the crowns being kept in the dark so as to blanch the stalks; or they may be planted closely in long narrow boxes of moderate depth, and set in a mushroom-house or cellar, where there is a considerable temperature. The rhubarb will soon throw up its stalks, and these, being partially etiolated, possess a delicacy and flavour superior to those grown in the open air. It is easy, by varying the time of subjecting the boxes to the increased temperature, to keep up a succession of rhubarb stalks, from the period at which kitchen apples become scarce or begin to lose their flavour, till green gooseberries come into season.

The favourite old sorts of rhubarb were the Tobolsk and the Elford or Buck's; the latter comes from R. undulatum, and is one of the best in flavour, as well as of a fine red colour. Other good sorts of more modern date are Mitchell's Royal Albert, Dancer's Early Scarlet, Myatt's Linnæus, and Myatt's Victoria, the last a large-growing thick-stalked kind, the others being all earlier sorts. Johnson's St Martin's and Salt's Crimson Perfection are also favourite kinds; and Stott's Monarch grows to a very large size.

184. The *Rocambole*, Allium Scorodoprasum, is a hardy bulbous perennial, occurring in a wild state in sandy pastures and waste places throughout Europe, but not common in the south; in Britain it is found chiefly in the north of England and the south of Scotland. The plant is grown for the sake of its bulbs, which are smaller and milder than those of garlic, and consist of several cloves chiefly produced at the roots. The cloves should be planted about the end of February or in March, and treated like the garlic or shallot. When mature, the bulbs should be taken up, dried, and stored for use. Rocambole.

185. The *Salsafy* (or *Salsify*), Tragopogon porrifolius, is a hardy biennial, with long cylindrical fleshy esculent roots, which, when properly cooked, are extremely delicate and wholesome; it occurs in meadows and pastures in the Mediterranean region, and, in Britain, is confined to the south of England. The salsafy requires a free rich deep soil, which should be trenched in autumn, the manure used being placed at two spades' depth from the surface. The first crop should be sown in March, and the main crop in April, in rows a foot from each other, the plants being afterwards thinned to 8 inches apart. In November the whitish roots should be taken up and stored in sand for immediate use, others being secured in a similar way during intervals of mild weather. Salsafy.

186. The *Savoy*, Brassica oleracea bullata major, is a near ally of the cabbage, but has bullate or blistered leaves; it is more hardy, and, except in very severe seasons, instead of suffering is rather improved in flavour by frost. The savoys come into use in autumn, and continue until the spring. The early crop should be sown in February, the main crop about the middle of March, and a month afterwards the latest crop. The rows of the smaller sorts should be 15 inches, and those of the larger ones 2 feet, apart. Savoy.

The best sorts of savoys for garden culture are:—

Tours, early and hardy; Ulm, early, but not so hardy; Little Pixie, small, early, and good; Dwarf Green Curled, best for a general crop; Golden, handsome and excellent. The large Drumhead savoy is more suitable for field culture, unless bulk of produce is required.

187. The *Scorzonera*, Scorzonera hispanica, is a hardy perennial, a native of Spain, but cultivated in gardens for its fleshy cylindrical roots, which resemble those of salsafy except in being black outside, and which are used in the same manner. They should be treated in every respect like salsafy (par. 185). Scorzonera.

188. The *Sea-kale*, Crambe maritima, is a hardy perennial, growing spontaneously along the coasts of England, of Ireland, and of the Scotch lowlands, along the western coasts of Europe, and on the Baltic, reappearing on the Black Sea. Sea-kale.

Sea-kale prefers a light dry soil, and when manure is necessary it should consist of sea-weed or well-rotted dung; or a dressing of salt or of nitrate of soda may be given. When it is raised from seeds, they should be sown in March or April in rows a foot asunder, the plants being thinned to 6 inches apart. In the following March these should be planted out in trenched well-prepared ground, 2 feet asunder, in rows 2½ to 3 feet apart. The top with the crown buds should be cut off before planting to prevent them from running up to seed. In the spring of the second year the young shoots if blanched will be fit for use, and therefore the summer growth should in every way be promoted by the use of water and liquid manure. Tolerably blanched stalks may be produced by plants only nine months old from the seed, and after two summers seedling plants will have acquired sufficient strength for general cropping. The seeds, instead of being sown in rows and transplanted, may be deposited in patches of three or four together, where they are to remain. In the autumn, after the leaves have been cleared off, the ground should be forked up, and 6 or 8 inches' depth of leaves or of light sandy soil laid over the plants, by either of which means they will be blanched, though not forced. The blanched sprouts should be cut for use whilst they are crisp, compact, and from 3 to 6 inches in length, the stem being cut quite down to the base.

Sea-kale beds may be made equally well from cuttings of the roots, the extremities of the roots, technically called "thongs," being the parts best adapted for this purpose. They should be taken up in autumn, cut into lengths of about 4 inches, and laid aside in a heap of sand or earth till spring, when they should be planted out like the seedlings. Cuttings should not be taken from any but very healthy plants.

Forcing.—Sea-kale may be forced in the open beds by the aid of sea-kale pots or covers, which are large enough to cover a plant, contracted a little at top, with a movable lid or cover. In the autumn the stalks are cut over, the decayed leaves removed, the ground loosened about the eyes, and a thin stratum of coal-ashes mixed with salt laid on the surface to keep down earth-worms. One of the earthenware pots or covers, or failing these a large inverted flower-pot, is placed over each plant or each patch of plants, and leaves of trees are closely packed round the pots, and raised to about a foot above them. When fermentation commences, a thermometer should be occasionally introduced into a few of the pots, to ascertain that the temperature within does not exceed 60° Fahr., and the thickness of the leaves is to be regulated accordingly. In a month or six weeks the shoots will be ready for cutting, and by means of the movable lids they can be examined and the shoots gathered without materially disturbing the covering. If the crowns are thus covered up by about the end of October, the crop may be cut by about the third week of December, and by starting a batch at various times a supply may be kept up till the middle of May.

Strong plants may also be taken up and planted on hotbeds, the sashes being kept covered close; or they may be set thickly in boxes as recommended for rhubarb (par. 183), and placed in any heated structure, or in the mushroom house; but, to have the shoots crisp and tender as well as blanched, light must be completely excluded. Besides the common purple-leaved, there is a green-leaved sort, which is said to blanch better.

Shallot. 189. The *Shallot*, Allium ascalonicum, is a native of Palestine, and is much used in cookery for high-flavoured soups and gravies, besides which it is excellent when pickled. It is a hardy bulbous perennial, and is propagated by offsets, which are often planted in September or October, but the principal crop should not be got in earlier than February or the beginning of March. The mixing of soot with the manure has been recommended as a protection against maggots. In planting, the tops of the bulbs should be kept a little above ground, and it is a commendable plan to draw away the soil surrounding the bulbs when they have got root-hold. They should not be planted on ground recently manured. They require the same general treatment as garlic and rocambole, and should be stored in a similar manner. They come to maturity about July or August. There are two sorts—the Common, and the Jersey or Russian, the latter being much larger and less pungent.

Skirret. 190. The *Skirret*, Sium Sisarum, is a fleshy-rooted perennial, native of China and Japan, the roots of which are boiled, and afterwards served up like salsafy. It requires a free, deep, and much enriched soil, and is generally raised from seeds, which should be sown in drills a foot apart about the end of March, the bed being well-watered in dry weather. The roots will be in use about November, and will continue fresh through the winter if carefully stored.

Sorrel. 191. The *Sorrel*, Rumex Acetosa, is a hardy perennial, found throughout Europe, in Asiatic Russia, and in North America. The leaves are used, more so on the Continent than in Britain, in soups, salads, and sauces. Sorrel grows freely in any good garden soil, and is increased by dividing the roots during the early part of spring. They should be planted in rows 15 to 18 inches apart. The leaves, when fully grown, are gathered singly.

The common garden sorrel is much superior to the wild plant; but the Belleville, which is the kind generally cultivated near Paris, is still better, its leaves being larger and not so acid. The Blistered-leaved, which has large leaves with a blistered surface, has the advantage of being slow in running to seed.

The *French Sorrel*, Rumex scutatus, is a hardy perennial, native of France and Switzerland, with densely-branched trailing stems. The leaves are roundish heart-shaped and glaucous; they are more acid than those of the common sorrel.

Spinach. 192. The *Spinach*, Spinacia oleracea, is an annual plant, which has been long cultivated for the sake of its succulent leaves. It should be grown on good ground, well worked and well manured; and for the summer crops abundant watering will be necessary.

The first sowing of winter spinach should be made early in August, and another towards the end of that month, in some sheltered but not shaded situation, in rows 18 inches apart,—the plants, as they advance, being thinned, and the ground hoed. By the beginning of winter the outer leaves will have become fit for use, and if the weather is mild successive gatherings may be obtained up to the beginning of May. The Prickly-seeded and the Flanders are the best for winter; and these should be thinned out early in the autumn to about 2 inches apart, and later on to 6 inches. The Lettuce-leaved is a good succulent winter sort, but not quite so hardy.

To afford a succession of summer spinach, the seeds should be sown about the middle of February, and again in March; after this period small quantities should be sown once a fortnight, as summer spinach lasts but a very short time. They are generally sown in shallow drills between the lines of peas. If a plot of ground has to be wholly occupied, the rows should be about a foot apart. The Round-leaved is the best sort for summer use.

Tomato. 193. The *Tomato* or *Love Apple*, Lycopersicum esculentum or Solanum Lycopersicum, is a tender annual from South America, much esteemed in England as an esculent, either raw or cooked.

Tomatoes were formerly raised from seed sown in gentle heat in February or early in March, potted singly into small pots, shifted on into larger pots, and gradually exposed to the air till about the end of May, when, if the season was favourable, they were planted out against a wall with a south aspect, or in the warmest situation at command. As they grew, they were nailed to the wall, or otherwise supported. Only the earlier of the fruit ripened out of doors in an average season; and when a fair quantity had set, the plants were stopped, the secondary branches being also stopped above the fruit, and laterals removed gradually. Under these circumstances the fruit began to ripen in August, successively coming to maturity, at which stage, and when perfectly dry, it had to be gathered and hung up or laid on shelves. The partially ripened fruit had to be got in before it was injured by frost, its maturation being completed in a vinery or other heated house, and, though not acquiring the full flavour, the forwardest of these late fruits thus became usable.

Forcing.—The outdoor treatment remains as above sketched out, but, owing to the precarious nature of the crop in bad seasons, large quantities are now grown under glass. Mr G. T. Miles, of Wycombe Abbey Gardens, has explained in the *Gardeners' Chronicle* his mode of culture, of which the following is an abstract:—

"To grow it properly, it requires considerable heat and every possible ray of sunshine, as well as a free circulation of dry warm air. The compost should consist of about one-half rough turfy loam, one-fourth of roadside scrapings, and one-fourth of decomposed manure or horse-droppings, moderately fresh. For planting out, a ridge of soil 2 feet wide and 15 inches deep should be placed on a warm bed of tan or leaves. For pot cultivation those from 12 to 15 inches in diameter are most appropriate, and these should not be quite filled, in order that surface dressings of the same material or of pure manure may be applied afterwards. For early work a sowing should be made in January, and the plants moved onwards until they have moderately filled 5-inch pots with roots, when they are transferred to the beds or fruiting-pots; in each case the plants are kept about 2 feet apart. Other sowings may be made at intervals till about the end of August. From the last sowing a supply is obtained for a considerable period onwards through the winter months. The plants are restricted to one main stem, which is allowed a run of 6 feet or more, as the position may admit, and from this all laterals are removed in an early stage of growth. Top-dressings of rich materials should be applied when the surface soil becomes full of roots; copious supplies of stimulating manure-water are also necessary, and the fruits should be kept perfectly free from damp while they are ripening. For this purpose, if close confined pits are used, a chink of air should be kept on continuously."

Tomatoes may also be allowed to run freely over the back wall of a forcing house, and, if sufficiently fed, will bear fruit abundantly.

Mr Miles observes that these plants, when grown out of doors, are generally placed in an excellent position, but the main point—the enrichment of the soil—is overlooked or not sufficiently attended to. A portion of good soil should be provided for each plant, and heavy mulchings of manure should be placed upon the surface as soon as practicable after planting, in order to prevent the soil becoming dry and parched. In these cases three or more main shoots are allowed to each plant, because it often happens that the space will not allow a good run, and a certain amount of growth with foliage is essential to the well-doing of the plants.

The following varieties afford considerable choice:—

Red-fruited: Early Gem, small, but a good cropper, and the quickest to ripen; Vick's Criterion, small and free-bearing, particularly adapted for growing in small pots; Vilmorin's Dwarf Early, dwarf and free-bearing; Hathaway's Excelsior, one of the finest, a great cropper; Trophy, large and very fine; Conqueror, large and prolific.

Yellow-fruited: Carter's Green Gage, of a distinct yellow colour, and of fine flavour.

Smaller-fruited: Cherry Red and Burghley Pet, round, prolific, and agreeably flavoured; Dickson's Queen of Tomatoes, with pear-shaped, and Nesbit's Victoria, with plum-shaped fruits, both being prolific sorts.

194. The *Turnip*, Brassica campestris Rapa, is a hardy biennial, found in corn-fields in various parts of England. The cultivated varieties have bulbiform roots, much esteemed as an esculent. Turnip.

Turnips should be grown in a rich friable sandy loam, such as will produce medium-sized roots without much aid from the manure heap, and are better flavoured if grown in fresh soil. In light dry soils well decomposed hotbed or farmyard manure is the best that can be used, but in soils containing an excess of organic matter, bone dust, superphosphate of lime, wood-ashes, or guano, mixed with light soil, and laid in the drills before sowing the seed, are beneficial by stimulating the young plants to get quickly into rough leaf, and thus to grow out of reach of the so-called turnip fly. To get rid of this pest, it has been found beneficial to dust the plants with quicklime, and also to draw over the young plants nets smeared with some sticky substance like treacle, by which large numbers will be caught and destroyed. It has been also recommended as a palliative to sow thick in order to allow for a percentage of loss from this and other causes, and, as a preventive, to scatter gas-lime over the surface after the seed has been sown. Mr Thompson (*Gardeners' Assistant*) also recommends the following remedy:—"In the first place, let a supply of water be brought close to hand, or say to each end of the quarter; then let one person move steadily along one side of the piece of ground from one end to the other, delivering the water through a rose as he proceeds. The fleas will jump forward as the water approaches them, and a second person, following the first, will keep them on the hop forward, whilst a third will drive them still further, and so on till the whole are driven off the ground."

The first sowing should be made on a warm border with the protection of a frame or matted hoops, in January or February, the second on a well-sheltered border in March, after which a sowing once a month will generally suffice. In May and June the plot should be in a cool moderately shaded position, lest the plants should suffer from drought. The principal autumn and winter sowings, which are the most important, should be made about the end of June in the northern districts, and in the beginning of July in warmer districts; a small sowing may be made at the end of August to come in before the spring-sown crops are ready. If the weather is showery at the time of sowing, the seed speedily germinates, and the young plants should be kept growing quickly by watering with rain or pond water and by surface stirrings. The drills for the earliest sorts need not be more than 15 inches apart, and the plants may be left moderately thick in the row; the late crops should have at least 2 feet between the rows, and be thinned to 12 inches in the row, a free circulation of air about them being very important in winter. As a provision against prolonged periods of severe weather, it has been recommended to lay the finest roots in rows, covering them well with soil, and leaving intact the whole of the foliage. The very latest sown crops of half-grown roots will prolong the supply until the earliest spring-sown crops are fit for use.

The following are the best sorts of turnips for garden crops:—

Early Purple-top Munich, the earliest and best of all; Early White Strap-leaf, very quick growing, and good; Early Snowball, for summer use; Early White Stone, for summer sowing; Orange Jelly, for summer sowing; Yellow Finland, for winter use; Chirk Castle, for winter use. In addition to these, which have round roots, there are the Jersey Navet, an excellent oblong variety, and very hardy, and the Teltow, a small tapering-rooted sort, employed, on account of its piquant flavour, in ragouts, and for seasoning. The latter should be sown in April and July in sandy soil.

ater ess. 195. The *Water Cress*, Nasturtium officinale, is a hardy perennial, occurring wild in Britain, and also throughout Europe and Asiatic Russia, except the extreme north. It is highly prized as a salad, and accredited with powerful antiscorbutic properties. It may be propagated from seed, but in forming plantations rooted divisions are usually employed. They should occupy positions where they can be supplied with water from a spring, as this will be rarely frozen. The plant will not grow freely on a muddy bottom; hence this has to be replaced by gravel or chalk. A constant current of water is absolutely necessary; and the plants should be disposed in rows parallel with the course of the stream. They thrive best in water about $1\frac{1}{2}$ inch in depth; this increases to about 3 inches when the plants begin to grow, and thereby check the current. In summer the tops of the plants must be kept closely cut, and under proper conditions of water and soil they will yield a gathering once a week. In winter the water should be 4 to 5 inches deep, to obtain which the plants are left with more head. The time for the renewal of the beds is in May and June, and from September to November, the planting being done in succession; those planted in May are fit to cut by August, and those planted in November are ready to gather in the spring. When collected for sale, the shoots are cut, not broken off, the latter plan being injurious. The water cress may also be grown in a shady border of rich light soil, kept constantly moist; but the surface should be covered with a thin layer of sand to keep the leaves clean. It may be also grown in tubs partially filled with soil which is covered with water, in which case the water should be frequently changed, or in shallow pans set in stands of water. If protected from frost in a brick pit with a slight service of hot-water piping, it may be had in use through the winter. To secure this, pans are filled with loamy soil in October or November, and planted with the tops of outdoor cresses; in about six weeks they will be fit to cut, and will furnish successional gatherings.

m. 196. The *Chinese Yam*, Dioscorea Batatas, is a fleshy-rooted perennial climber, native of China. It has annual stems, and deeply penetrating thick club-shaped fleshy roots, or rhizomes, full of starch, which when cooked acquire a mild taste like that of a potato, but have besides somewhat of a medicinal flavour. The roots grow 3 feet or upwards in length, and sometimes acquire a weight of more than $1\frac{1}{2}$ lb. The plant grows freely enough in deep sandy soil, moderately enriched. The sets, consisting of pieces of the roots, may be planted in March or April, and require no other culture than the staking of the climbing stems. They should not be dug up before November, the chief increase in their size taking place in autumn. They sometimes strike downwards 2 or 3 feet into the soil, and must be carefully dug out, the upper slender part being reserved for propagation, and the lower fleshy portion eaten after having been allowed a few days to dry.

197. CULINARY HERBS.—Besides the foregoing esculent and salad plants, there are several minor herbs used for flavouring and garnishing. For the most part they are dwarf perennial plants requiring to be grown on a dry warm soil in an open sunny aspect, or annuals for which a warm sheltered border is the most suitable place; and they may therefore be conveniently grown together in the same compartment—an herb garden. The perennials should be transplanted either every year or every second year.

For winter use the tops of the most useful kinds of herbs should be cut when in flower or full leaf and quite dry, and spread out in an airy but shady place so as to part slowly with the moisture they contain, and at the same time retain their aromatic properties. When quite dry they should be put into dry wide-mouthed bottles and kept closely corked. In this way such herbs as basil, marjoram, mint, sage, savory, and thyme of the aromatic class, balm, chamomile, horehound, hyssop, and rue of the medicinal class, as well as parsley, may be had throughout the season with almost the full flavour of the fresh herb.

Angelica, Archangelica officinalis.—A stout biennial umbellifer; sow in April, in deep rich soil. The stems and leaf-stalks are candied.

Anise, Pimpinella Anisum.—A slender umbelliferous annual; sow in May in light warm soil; English summers are scarcely warm enough to bring it to perfection.

Balm, Melissa officinalis.—A hardy labiate perennial; divide the roots in October; dry for winter use.

Basil, Ocymum Basilicum.—A fragrant labiate annual; sow in a gentle heat in March, and plant out on a warm border; or sow in a warm sheltered place in April or May; or in winter sow in heat (65°-70°) in pots or boxes in rich light soil, once a month from November onwards; that sown in April or May should be cut when in blossom, and dried slowly for winter use.

Borage, Borago officinalis.—A stout native British annual, used for garnishing; sow in March and May in an open place, in good soil.

Burnet, Poterium Sanguisorba.—A hardy native perennial; divide the roots in October or February. It tastes like cucumber.

Caraway, Carum Carui.—A hardy umbelliferous biennial; sow in April or May to flower the following summer.

Chamomile, Anthemis nobilis.—A hardy native British composite perennial of prostrate habit; divide the plants in autumn or spring, planting in rather poor dry soil; the flower-heads should be gathered successively as they open, and carefully dried and stored.

Chervil, Anthriscus Cerefolium.—A hardy annual umbellifer; sow in March, and again in October if required for spring use.

Coriander, Coriandrum sativum.—A hardy annual umbellifer; sow in March in light loamy soil.

Dill, Anethum graveolens.—A hardy annual umbellifer; sow in March on a warm border, in rich light soil.

Fennel, Fœniculum vulgare.—A hardy perennial umbellifer; sow in March, or divide the roots at the same season.

Finochio, Fœniculum dulce.—A somewhat tender kind of fennel, with two-ranked leaves, fleshy at the base, which part is blanched by earthing up like celery; sow in March and successionally if required, in light very rich soil.

Horehound, Marrubium vulgare.—A hardy native labiate perennial, best raised annually from seeds sown early in March, or by selecting self-sown autumn seedlings.

Hyssop, Hyssopus officinalis.—A hardy evergreen suffruticose labiate plant; sow in March or April, young plants being more vigorous than older ones; it may also be divided in spring.

Lavender, Lavandula vera.—An aromatic undershrub of the labiate order, requiring a light warm dry soil, and increased by cuttings, or by slips taken off with roots about March or April.

Marigold, Calendula officinalis.—A hardy composite annual; sow in March, in any garden soil.

Marjoram, Origanum Majorana.—A tender labiate, usually treated as an annual, and known as Knotted Marjoram; sow in March in a slight heat, and plant out on a warm sunny border. The *Pot Marjoram*, Origanum Onites, and *Winter Sweet Marjoram*, Origanum heracleoticum, are hardy perennials, growing best in dry warm soils; divide and transplant in autumn or spring; a winter supply is provided by cutting the stems, when the plant is in flower, and drying in an airy shady place.

Mint, Mentha viridis.—A hardy native labiate perennial, often called Spear-Mint. The running underground roots should be taken up in February or March, and replanted in fresh good soil. The young tops may be obtained early by forcing; the leafy stems may also be cut when at their full growth in summer, and dried for winter use. The *Peppermint*, Mentha piperita, is cultivated like the spear-mint, only its runners grow above instead of beneath the ground, and require planting accordingly.

Parsley, Petroselinum sativum.—A hardy umbelliferous biennial; sow in February, again in May, and again in July to have a good supply, a portion of the last-sown crop being protected by frames or hand-lights, so as to be accessible in frosty weather; it likes a free soil of good quality, but not too richly manured.

Pennyroyal, Mentha Pulegium.—A hardy native labiate perennial, growing in moist situations, and best cultivated on a north border, is propagated freely enough by its running rooting stems, which should be well established early in autumn.

Rosemary, Rosmarinus officinalis.—An evergreen undershrub of the labiate order, just tender enough to be killed in all but the most sheltered situations by the most severe British winters, but surviving uninjured through those of ordinary severity. It requires a light dry soil and a sheltered situation, and is increased by cuttings or rooted slips taken off in spring.

Rue, Ruta graveolens.—A hardy evergreen rutaceous undershrub, which will grow freely in ordinary garden soil, and is propagated by cuttings or slips, or very freely by seeds, which ripen abundantly.

Sage, Salvia officinalis.—A hardy evergreen undershrub, belonging to the labiates, of which there are two varieties, the green-leaved and the red-leaved, the latter being somewhat the hardiest; it is increased by earthing up the outside stems, which after the lapse of a year may be taken off as rooted plants in the following April or May.

Savory, Satureja hortensis.—A hardy labiate annual; sow on a warm border in April; when the plants reach the flowering stage, dry a portion for winter use. The *Winter Savory*, Satureja montana, a hardy evergreen undershrub, is propagated by cuttings taken off in April and May, or by dividing the plant about April.

Tansy, Tanacetum vulgare.—A hardy composite native perennial, which soon grows thick and exhausts the soil, and should therefore be divided and transplanted every second year. If required earlier than the natural season, a root or two may be potted and set in a mild forcing-house or hotbed.

Tarragon, Artemisia Dracunculus.—A hardy perennial composite plant, which grows freely in light dryish soil, and is increased by division in October or March; it should be transplanted every year or two. Tarragon may be had during the winter by potting a root or two early in December, and placing them in heat.

Thyme, Thymus vulgaris.—A hardy evergreen undershrub, requiring a light dry warm soil, and an open but sheltered situation; it may be raised from seeds sown in April, and thinned out; or the old roots may be divided also in April. The tops should be cut in summer, and preserved for winter use in the same way as savory and marjoram. The *Lemon Thyme*, Thymus citriodorus, is of a more decumbent habit, and may be parted and transplanted in spring in genial weather during the month of April.

Wormwood, Artemisia Absinthium.—A hardy native composite perennial, which will grow in any soil, but is most aromatic on those which are dry and poor. The plants should be replaced annually in autumn, when self-sown plants are generally to be found round about the old ones; if not so produced, they can be provided by sowing the seeds during the summer.

VIII.—*CALENDAR OF GARDEN OPERATIONS FOR GREAT BRITAIN.*[1]

JANUARY.

Kitchen Garden.—Wheel out manure and composts during frosty weather; trench vacant ground not turned up roughly in autumn. Sow early peas in a cold frame for transplanting. Sow also Dillistone's Early, Alpha, or other first-crop peas, early in the month, and William I. and Advancer towards the end; Early Seville and Early Longpod beans; and short-topped radish in two or three sowings, at a week's interval, all on a warm border; also Hardy Green and Brown Dutch lettuce in a frame or on south border. Plant shallots and Ashleaf potatoes on a warm border. Protect broccoli as it becomes fit for use, or remove to a dry shed or cellar; lettuces and endive, which are best planted in frames; and parsley in frames so as to be accessible.

Fruit Garden.—Plant fruit trees in open weather, if not done in autumn, which is the proper season, mulching over the roots to protect them from frost, and from drought which may occur in spring. Prune fruit trees in mild weather or in moderate frosts, nailing only in fine weather. Wash trees infested with insects, with a mixture of soap-suds, black sulphur, and tobacco water, or with Gishurst Compound. Take off grafts, and lay them aside in moist earth in a shady place.

Forcing.—Prepare manure for making up hotbeds for early cucumbers and melons, where pits heated with hot water are not in use; also for Ashleaf potatoes. Sow also in heat mustard and cress for salads, onions for salads; celery to be pricked out for an early crop; and Early Horn carrot and kidney-beans on slight hotbeds. Force asparagus, sea-kale, and rhubarb, in hotbeds, in pits, in the mushroom-house, or in the open garden by the use of covers surrounded with warm litter. For pines keep up a bottom heat of 80°, and water sparingly; for cucumbers a top heat of 75°; for vines in leaf and flower a temperature ranging from 65° to 75°. Keep forced strawberries with swelling fruit well watered. Plant vine eyes for propagation in a brisk heat.

Plant Houses.—Give abundance of air to the greenhouse, conservatory, and alpine frame in mild weather, but use little water. A supply of roses, kalmias, rhododendrons, &c., and of hardy flowers and bulbs, as lily of the valley, hyacinths, &c., should be kept up by forcing.

Flower Garden.—Plant out tubers and bulbs of border flowers, where neglected in autumn, deferring the finer florists' flowers till next month. Transplant herbaceous plants in light soils, if not done in autumn; also deciduous trees, shrubs, and hedges. Lay edgings in fine weather. Sow mignonette, stocks, &c., in pots; sow sweet peas, and a few hardy annuals, on a warm border. Give auriculas and carnations abundance of air, but keep the roots rather dry, to prevent damping off.

FEBRUARY.

Kitchen Garden.—Sow successional crops of Early Seville beans, and William I., Advancer, Criterion, and other peas in the beginning and end of the month; early cabbages, to follow the last sowing in August; red cabbages and savoys towards the end. Sow also Early Horn carrot; Early Purple-top Munich turnip; onions for a full crop in light soils, with a few leeks and some parsley. Sow lettuce for succession, with radishes and Round-leaved spinach, twice in the course of the month; and small salads every fortnight. Plant Jerusalem artichokes, shallots, garlic, horse-radish, and early potatoes. Transplant for seed, if not done before, all the brassica tribe, including cabbage, cauliflower, turnip, &c.; also carrots, onions, beet, celery, endive, leeks, and parsnips. Transplant to the bottom of a south wall a portion of the peas sown in pots in frames in November and January for the first crop. Sow Brussels sprouts in gentle heat for an early crop.

Fruit Garden.—Prune apricots, peaches, nectarines, and plums, before the buds are much swelled; finish pruning apples, pears, cherries, gooseberries, currants, and raspberries, before the end of the month; also the dressing of vines. Keep the fruit-room free from spoiled fruit, and shut it close. Cut down the double-bearing raspberries to secure strong autumn-fruiting shoots. Head back stocks preparatory to grafting.

Forcing.—Sow melons and cucumbers on hotbeds and in pits. Sow carrots, turnips, early celery, also aubergines or egg-plants, capsicums, tomatoes, and successional crops of kidney-beans; cauliflower and Brussels sprouts, in gentle heat, to be afterwards planted out. Plant early potatoes on slight hotbeds. Continue the forcing of asparagus, rhubarb, and sea-kale. Pine-apple plants require little water; plants in dung-frames especially should be kept free from damp; shift the fruiting plants by the middle of the month, if not done in August. Commence or continue the forcing of the various choice fruits, as vines, peaches, figs, cherries, strawberries, &c. Pot roots of mint and place in heat to produce sprigs for mint sauce. Be careful to protect the stems of vines that are outside the forcing-houses.

Plant Houses.—Let the greenhouse and conservatory have plenty of air in mild weather. Pot and start tuberous-rooted begonias. Pot young plants of amaryllis, and start the established ones. Put plants of fuchsias, petunias, verbenas, heliotropes, salvias, and other soft-wooded subjects, into a propagating house to obtain cuttings, &c., for the flower garden. Sow stocks, dahlias, and a few tender and half-hardy annuals, on a slight hotbed, or in pots. Propagate old roots of dahlias by cuttings of the young shoots in a hotbed. Sow petunias in heat, and prick out and harden for bedding out; also gloxinias to be grown on in heat till the flowering season.

Flower Garden.—In dry open weather plant dried roots, including most of the finer florists' flowers; continue the transplanting of hardy biennial flowers and herbaceous plants. Sow in the last week mignonette, and hardy annuals, in a warm border, for subsequent transplanting.

MARCH.

Kitchen Garden.—Sow main crops of wrinkled marrow peas; Longpod and Windsor beans; Nonpareil or St John's day cabbages; onions, leeks, Early Horn carrots, parsnips, salsafy, scorzonera, Brussels sprouts, borecoles, lettuces, and spinach. In the beginning and also at the end of the month sow Early Strap-leaf and Early Snowball turnips, and savoys. In the last fortnight sow asparagus, cauliflower, chervil, coriander, dill, fennel, finochio, hyssop, marigold, savory; also sea-kale, radishes, celery, celeriac, and most of the culinary aromatics, as parsley. Small salads should be sown

---

[1] *CALENDAR FOR THE UNITED STATES (chiefly for the Latitude of New York).*

JANUARY.

Flower Garden and Greenhouse.—Little is to be done in either. In the greenhouse care must be used to protect against frost. Ventilate but little, and with care; raise the ventilating sash only high enough to let the heated air from the greenhouse drive back the outer air so as not to chill the plants. To destroy the red spider, syringe the plants copiously at night, and splash the paths with water. The aphis, or "green fly," must also be destroyed; tobacco may be used. At this season roses, grape vines, and other plants are often affected by mildew; an effectual remedy is to paint the hot-water pipes with a mixture of sulphur and lime, put on as thick as ordinary whitewash, once each week until it is checked; but care must be taken not to apply it on any surface at a higher temperature than 212°. Hyacinths and other bulbs that have been kept in a cellar or other dark cool place may now be brought into the light of the greenhouse or sitting room, provided they have filled the pots with roots. If they are not well rooted, leave them until they are, or select such of them as are best, leaving the others. In the outside flower garden little can be done except that shrubs may be pruned, or new work, such as making walks or grading, performed, if weather permits.

Fruit Garden.—Pruning, staking up, or mulching can be done if the weather is such that the workmen can stand out. No plant is injured by being pruned in cold weather.

Grapery.—Graperies used for the forcing of foreign grapes may be started, beginning at a temperature of 50° at night, with 10° or 15° higher during the day. The borders must be covered sufficiently deep with leaves or manure to prevent the soil from freezing, as it would be destruction to the vines to start the shoots if the roots were frozen; hence, when forcing is begun in January, the covering should be put on in November, before severe frosts begin.

Vegetable Garden.—But little can be done in the Northern States except to prepare manure, and get sashes, tools, &c., in working order; but in sections of the country where there is little or no frost the hardier kinds of seeds and plants may be sown and planted, such as asparagus, cabbage, cauliflower, carrot, leek, lettuce, onion, parsnip, peas, spinach, turnip, &c. In any section where these seeds can be sown in open ground, it is an indication that hotbeds may be started for the sowing of such tender vegetables as tomatoes, egg and pepper plants, &c.; though, unless in the extreme Southern States, hotbeds should not be started before the beginning or middle of February.

FEBRUARY.

Flower Garden and Greenhouse.—The directions for January will in the main apply to this month, except that now some of the hardier annuals may be sown in hotbed or greenhouse, and also the propagation of plants by cuttings may be done rather better now than in January, as the greater amount of light gives more vitality to the cutting.

Fruit Garden.—But little can be done in most of the Northern States as yet, and in sections where there is no frost in the ground, it is likely to be too wet to work; but in many Southern States this will be the best month for planting fruit trees and plants of all kinds, particularly strawberries, raspberries, blackberries, pear and apple trees, while grape vines will do, though they will also do well quite a month later.

Grapery.—The graperies started last month at 50° at night may now be increased to 60°, with a correspondingly higher day temperature. Great care must be taken to syringe the leaves thoroughly at least once a day, and to deluge the paths with water, so as to produce a moist atmosphere. Paint the hot-water pipes with sulphur mixture, as recommended in January.

Vegetable Garden.—Leaves from the woods, house manure, or refuse hops from breweries may be got together towards the latter part of this month, and mixed and turned to get "sweetened" preparatory to forming hotbeds. Cabbage, lettuce, and cauliflower seeds, if sown early this month in hotbed or greenhouse, will make fine plants if transplanted into hotbed in March. This is preferable to the use of fall-sown plants. Manure that is to be used for the crop should be broken up as fine as possible, for the more completely manure of any kind can be mixed with the soil the better the crop will be, and, of course, if it is dug or ploughed in in large unbroken lumps it cannot be properly commingled.

MARCH.

Flower Garden and Greenhouse.—The long days and bright sunshine will now begin to tell on the plants under glass. Examine all plants that are vigorous and healthy; if the roots have matted the "ball" of earth they must be shifted into a larger-sized pot. Plants from cuttings struck last every ten days. Make up beds for mushrooms with well-prepared dung towards the end of the month. Plant early potatoes in the first week, and a main crop during the last fortnight. Jerusalem artichokes, sea-kale, asparagus, and peas raised in frames, may now be planted; also garlic and shallots. Full crops of cabbages should be planted out; also cauliflowers under hand-glasses. Propagate by slips, or by earthing up the old stems, the various pot-herbs, as sage, savory, thyme, &c., and increase mint by dividing the roots.

Fruit Garden.—Finish the pruning of fruit trees before the middle of the month. Protect those coming into blossom. Begin grafting in the third week; dig and dress between the rows of gooseberries, currants, and other fruit trees, if not already done. Kill wasps assiduously, as soon as they appear.

Forcing.—Continue the forcing of melons and cucumbers, and the various fruits. Pot pine-suckers and crowns that have been kept in tan during winter, repotting those that require large pots, and about the middle of the month shifting them to the succession pit; give a top-dressing to the fruiting plants, turning the tan, and adding new bark to the pits, to keep up bottom-heat, where that is used. In the vinery and peach-house, attend to the keeping down of insects by syringing; and promote the growth of the young shoots, by damping the walls and paths morning and evening. Sow capsicum, egg-plant, and tomato; also in slight heat such tender herbs as basil and marjoram.

Plant Houses.—More water may be given than formerly. Sow seeds of greenhouse and hothouse plants; also the different sorts of tender annuals; pot off those sown last month; sow cineraria for the earliest bloom; also Chinese primulas. Shift heaths and other hard-wooded subjects and stove-plants; plant tuberoses in pots for forcing. Begin to propagate greenhouse plants by cuttings; also coleuses by cuttings in heat, and chrysanthemums in moderate heat, potting them off as soon as rooted.

Flower Garden and Shrubbery.—In the last week, sow hardy annuals in the borders, with biennials that flower the first season, as also perennials. Plant anemone and ranunculus roots; plant the corms of gladiolus. Transplant from the nursery to their final sites annuals sown in autumn, with biennials and herbaceous plants. Propagate perennials from root-slips and offsets. Protect tulips, hyacinths, and choice flowers from severe weather. Continue to propagate the finer sorts of dahlias, both by cuttings and by division of the roots. Finish the pruning of all deciduous trees and hedges as soon as possible. Attend to the dressing of shrubberies; lay turf-edgings, and regulate the surface of gravel walks.

April.

Kitchen Garden.—Sow asparagus, sea-kale, Turnip-rooted beet, salsafy, scorzonera, skirret, carrots, and onions on heavy soils; also marrow peas, Longpod and Windsor beans, turnips, spinach, celery, Enfield Market cabbage, savoys, Brussels sprouts, and German greens, for succession. Sow broccoli and kidney beans both in the second and in the last week, and lettuces and small salads twice or thrice during the month; sow angelica, caraway, also all sweet herbs, if not done last month. Sow vegetable marrow. Plant cauliflower, cabbages, sea-kale, lettuce; and finish the planting of the main crops of potatoes; divide and replant artichokes. Propagate all sorts of pot-herbs, and attend to the hoeing and thinning of spinach, onions, turnips, &c. Earth up cabbages, cauliflower, peas, beans, and early potatoes. Stake up peas; blanch sea-kale and rhubarb in the open air, by covering with straw or leaves.

Fruit Garden.—If vines have been neglected to be pruned, rub off the buds that are not wanted; this is safer than pruning now. Protect the finer sorts of fruit trees on the walls. The hardier orchard-house fruits should now be moved outdoors under temporary awnings, to give the choicer fruits more space,—the roots being protected by plunging the pots. Mulch all newly-planted fruit trees, watering abundantly in dry weather.

Forcing.—Continue the preparation of succession beds and pits for cucumbers and melons. Sow basil in slight heat; pot and push on tomatoes and capsicums. Attend to the routine culture of the pinery, giving water and air when necessary. In the forcing-houses, from the variable state of the weather, considerable vigilance is required in giving air. Keep down red spider (*Acarus*) in the more advanced houses by frequent syringings and a well-moistened atmosphere. Continue the usual operations of disbudding and thinning of fruit, and take care to keep up the proper temperatures.

Plant Houses.—Still sow tender annuals if required; sow cinerarias and primulas. Proceed with all necessary shiftings. Propagate rare and fine plants by cuttings or grafting; increase bouvardias by cuttings, and grow on for winter flowering. Pot off tender annuals, and cuttings of half-hardy greenhouse plants put in during February to get them well established for use in the flower garden.

Flower Garden and Shrubbery.—Sow main or successional crops of annuals of all sorts—half-hardy annuals in warm borders, or on slight hotbeds. Biennials and perennials should be sown before the middle of the month. Plant out gladioli, if not done, tigridias, and fine stocks. Finish the transplanting of herbaceous plants by the end of the first week. Protect stage auriculas and hyacinths from extremes of every description of weather; and tulips from hoar-frosts and heavy rains. Plant out tender deciduous trees and shrubs raised in pots; plant out tea-roses, mulching the roots. Remove part of the coverings of all tender shrubs and plants in the first week, and the remainder at the end of the month. Form and repair lawns and grass walks, by laying turf and sowing perennial grass-seeds; mow the lawns frequently; plant evergreens.

May.

Kitchen Garden.—Sow Pine-apple or Nutting's beet in the first week, small salads every week, radishes and lettuces thrice, spinach once a fortnight, carrots and onions for late drawing, kidney beans in the first week and together with scarlet runners in the last fortnight; endive for an early crop; also peas and Longpod and Windsor beans, cauliflowers, Early York or Little Pixie cabbages, Brussels sprouts, borecole, broccoli, savoys, Buda kale, and German greens, for late crops. Sow anise and basil on a warm border; and borage and parsley on open spots. Sow vegetable marrows and hardy cucumbers on a warm border in the last week; sow cardoons in trenches, or (in the north) in pots under glass shelter; sow chicory for salading. Plant asparagus. Continue hoeing and earthing up the several crops.

Fruit Garden.—Disbud peaches, nectarines, and other early trees against the walls; also attend to the thinning of fruit. Give occa-

CALENDAR FOR THE UNITED STATES—Continued.

month may now be shifted, and the propagation of all plants that are likely to be wanted should be continued. Hardier kinds of annuals may be sown; it is best done in shallow boxes, say 2 inches deep. Lawns can be raked off and mulched with short manure, or rich garden earth where manure cannot be obtained. Flower beds on light soils may be dug up so as to forward the work of the coming busy spring season.

Fruit Garden.—In many sections, planting may now be done with safety, provided the soil is light and dry, but not otherwise. Again at this season, although a tree or plant will receive no injury when its roots are undisturbed in the soil should a frost come after planting, the same amount of freezing will and very often does greatly injure the plant if the roots are exposed.

Grapery.—The grapery started in January will have set its fruit, which should be thinned by one-third. The temperature may now be farther advanced to 70° at night, with 15° higher in the daytime. The same precautions must be used against mildew and insects as given in January. Graperies wanted for succession may be started in February or this month.

Vegetable Garden.—This is a busy month. In localities where the frost is out of the ground, if it is not wet, seeds of the hardier vegetables can be sown. The list of seeds given for the Southern States in January may now be used at the North, while for most of the Southern States tender vegetables, such as egg plant, okra, sweet potatoes, melon, squash, potatoes, tomatoes, &c., may be sown and planted. Hotbeds must now be all started.

April.

Flower Garden and Greenhouse.—Window and greenhouse plants require more water and ventilation. Due attention must be paid to shifting well-rooted plants into larger pots; and, if space is desired, many kinds of hardier plants can be safely put out in cold frames. Towards the end of the month it may be necessary to slightly shade the glass of the greenhouse. All herbaceous plants and hardy shrubs may be planted in the garden. The covering of leaves or litter should be taken off bulbs and tender plants that were covered up for winter, so that the beds can be lightly forked and raked. Sow tender annual flower seeds in boxes inside.

Fruit Garden.—Strawberries that have been covered up with straw or leaves should be relieved around the plants, leaving the covering between them. Raspberries, grape vines, &c., that have been laid down, may now be uncovered and tied up to stakes or trellises, and all new plantations of these and other fruits may now be made.

Vegetable Garden.—Asparagus, rhubarb, spinach, &c., should be uncovered, and the beds hoed or dug lightly. Hardier sorts of vegetable seeds and plants, such as beets, cabbage, cauliflower, celery, lettuce, onions, parsley, parsnip, peas, potatoes, radishes, spinach, turnip, &c., should all be sown or planted by the middle of the month if the soil is dry and warm, and in all cases, where practicable, before the end of the month. It is essential, in sowing seeds now, that they be well firmed in the soil. Any who expect to get early cabbage, cauliflower, lettuce, or radishes, while planting or sowing is delayed until the time of sowing tomato and egg plant in May, are sure to be disappointed of a full crop.

May.

Flower Garden and Greenhouse.—Window and gree house plants should be in their finest bloom. Firing may be entirely dispensed with, though care must still be exercised in ventilating. Every precaution must be used to keep the air moist. "Moss culture" may be tried, the common sphagnum or moss of the swamps, mixed with one-twentieth of its bulk of bone-dust, being laid as a mulch on the top of the earth of the flower-pots; its effect is to shield the pots from the sun, and at the same time stimulate the roots to come to the surface. By the end of the month all of the plants that are wanted for the summer decoration of the flower border may be planted out, first loosening a little the ball of earth at the roots. If the weather is dry, water freely after planting. When the greenhouse is not to be used during the summer months, camellias, azaleas, and plants of that character should be set out of doors under partial shade; but most of the other plants usually grown in the conservatory or window garden in winter may be set in the open border. Flower beds should be kept well hoed and raked, to prevent the growth of weeds next month. Lawns should be mown, and the edgings trimmed. Pelargoniums, pinks, monthly roses, and all the half hardy-kinds of flowering plants should be planted early; but coleus, heliotrope, and the more tender plants should be delayed until the end of the month. Annuals that have been sown in the greenhouse or hotbed may be planted out, and seeds of such sorts as mignonette, sweet alyssum, phlox Drummondii, portulaca, &c., may be sown in the beds or borders.

sional washings with the engine to keep down insects. Pick caterpillars from gooseberries and wall trees on their first appearance. Remove from raspberries and strawberries all suckers and runners that are not wanted.

Forcing.—Plant melons and cucumbers, and some basil, on the hotbeds prepared for vegetables in February, and now free. Plant out vegetable marrows and pumpkins on dung-ridges, under hand-glasses. Sow late crops of cucumbers and melons. Continue the routine culture of the pinery, shifting those intended for autumn and winter fruiting; give abundance of heat and water, keeping down insects.

Plant Houses.—Turn out hardy plants about the middle, and the more tender at the latter end of the month. Sow tender annuals for succession, potting and shifting those sown at an earlier period; sow cinerarias for succession; and a few hardy annuals and ten-week stock, &c., for late crops. Pot off all rooted cuttings. Put in cuttings of the different desirable species which are now fit for that purpose. Plant out in rich soil Richardias, to be potted up in autumn for flowering.

Flower Garden.—Sow annuals for succession in the last week, also biennials and perennials in the nursery compartment, for planting out next year. Propagate plants of which more stock is required, either by cuttings or by dividing the roots. Plant out, during the last week, dahlias, hardy pelargoniums, stocks, and calceolarias, protecting the dahlias from slight frosts. By the end of the month, masses of the following plants may be formed with safety in warm localities:—pelargonium, heliotropium, fuchsia, petunia, nierembergia, salvia, verbena, bouvardia, and lobelia. Protect tulips, ranunculuses, and anemones from the mid-day sun, and from rains and winds. Remove the coverings from all tender plants in the open air.

Shrubbery.—Transplant all kinds of evergreens, this month and September being the proper seasons. The rarer conifers should be planted now and in June, after they have commenced to grow. Proceed with the laying down of lawns and gravel-walks; and keep the former regularly mown.

JUNE.

Kitchen Garden.—Sow kidney beans for succession; also the wrinkled marrow peas, and Seville Longpod, and Windsor beans for late crops. Sow salading every ten days; also carrots, onions, and radishes for drawing young; and chicory for salads; sow endive for a full crop. In the first week sow Early Munich and Yellow Finland turnips for succession, and in the third week for a full autumn crop. Sow scarlet and white runner beans for a late crop, and cabbages for coleworts. Make up successional mushroom beds early in the month. Plant full crops of broccoli, Brussels sprouts, savoys, German greens, leeks, and early celery, with successional crops of cabbage and cauliflower. In the first fortnight of the month, plant hardy cucumbers for pickling, in a warm border, placing hand-glasses over them towards the end of the month. Plant out capsicums on a warm border (south of England), also tomatoes along the bottom of a south wall. Pull and store winter onions, if ripe.

Fruit Garden.—Train and prune the summer shoots of wall and trellis and other trained trees. Mulch and water fruit trees and strawberries in dry weather,—desisting when the fruit begins to ripen. Net over cherry-trees. Destroy aphides and other insects by syringing with tobacco water, or by fumigating, or by dusting with tobacco powder.

Forcing.—Proceed with planting melons and cucumbers raised from seeds and cuttings, for late crops. Keep up the necessary temperatures for the ripening of the various fruits. Continue the routine operations in the pinery; but, if very large-sized fruit is desired, remove the suckers from the stem, and apply heat and water in abundance. Shift suckers and succession plants in the beginning and middle of the month, as the state of the plants may require. The other forcing-houses must still have the necessary heat, but little water and abundance of air must be given to those wherein the fruit is beginning to ripen, and those in which the fruit is past ought to be constantly under a system of thorough ventilation.

Plant Houses.—These will now be occupied with tender greenhouse plants and annuals, and the more hardy plants from the stove. Shift, repot, and propagate all plants that are desirable. Sow fragrant or showy annuals, to flower in pots during winter; and grow on a set of decorative plants for the same object.

Flower Garden.—Plant out dahlias and other tender subjects if risk of frost is past. Take up bulbs and tuberous roots, and dry them in the shade before removing them to the store-room. Fill up with annuals and greenhouse plants those beds from which the bulbs and roots have been raised. After this season, keep always a reserve of annuals in pots, or planted on beds of thin layers of fibrous matter, so as to be readily transplanted. Layer carnations and pipe pinks in the end of the month. Keep the lawns closely mown.

JULY.

Kitchen Garden.—Watering will be necessary in each department, if the weather is hot and dry. In the first week, sow peas for the last crop of the season; also Dutch Longpod beans, and French beans. In the last week, sow Yellow Finland turnip for a full winter crop, spinach for an early winter supply, and Enfield Market or Winnigstadt cabbage for early summer use. Sow endive, for autumn and winter use, in the beginning and end of the month; also successional crops of lettuce and small salads. Make up successional mushroom beds. Plant full crops of celery, celeriac, endive, about the middle and end of the month; late crops of broccoli, cauliflower, and coleworts in the last week. Gather and dry medicinal and pot herbs; also propagate these by slips and cuttings.

Fruit Garden.—Continue the pruning and training of wall and espalier trees, and the destruction of noxious insects. Plant strawberries in pots for forcing next winter, and make new beds out of doors as soon as well-rooted runners can be obtained. Propagate the different sorts of stone fruit trees, by budding on other trees, or on prepared stocks. Gather fruits of all kinds as they ripen.

Forcing.—Prune melons and cucumbers, giving air and water, and maintaining heat, &c. Continue the routine treatment in the pinery, but withhold water when the fruit begins to ripen; push on the growth of the suckers on old plants, which will materially advance the fruiting period. The forcing-houses ought to have abundance of fresh air and moisture, along with the necessary heat.

Plant Houses.—Ventilation will be necessary to keep down excessive heat; and attention must be paid to potting, shifting, and putting in cuttings, and giving abundance of water to the potted plants, both indoors and out. Sow calceolarias; shift heaths, if

---

CALENDAR FOR THE UNITED STATES—Continued.

Fruit Garden.—The hay or leaf mulching on the strawberry beds should be removed and the ground deeply hoed, after which it may be placed on again to keep the fruit clean and the ground from drying. Where it has not been convenient before, most of the smaller fruits may yet be planted during the first part of the month. Tobacco dust will dislodge most of the numerous kinds of slugs, caterpillars, or worms that make their appearance on the young shoots of vines or trees.

Vegetable Garden.—Attention should be given to new sowings and plantings for succession. Crops sown last month will have to be thinned out if large enough. Hoe deeply all transplanted crops, such as cabbage, cauliflower, lettuce, &c. Tender vegetables, such as tomatoes, egg and pepper plants, sweet potatoes, &c., can be planted out. Seeds of Lima beans, sweet corn, melon, okra, cucumbers, &c., should be sown; and sow for succession peas, spinach, lettuce, beans, radishes, &c., every ten days.

JUNE.

Flower Garden and Greenhouse.—Tropical plants can now be used to fill up the greenhouse during the summer months. It should be well shaded, and fine specimens of fancy caladiums, dracænas, coleus, crotons, palms, ferns, and such plants as are grown for the beauty of their foliage, will make a very attractive show. The "moss culture" will be found particularly valuable for these plants. Hyacinths, tulips, and other spring bulbs may be dug up, dried, and placed away for next fall's planting, and their places filled with bedding plants, such as coleus, achyranthes, pelargoniums, and the various white and coloured leaf plants. It will be necessary to mow the lawn once a week.

Fruit Garden.—The small fruits should be mulched about the roots, if this has not yet been done. Grape vines outside as well as in should be disbudded.

Vegetable Garden.—Beets, beans, carrots, corn, cucumbers, lettuce, peas, and radishes may be sown for succession. This is usually a busy month, as many crops have to be gathered, and, if hoeing is not promptly seen to, weeds are certain to give great trouble. Tomatoes should be tied up to trellises or stakes if fine-flavoured and handsome fruit is desired, for if left to ripen on the ground they are apt to have a gross earthy flavour.

JULY.

Flower Garden and Greenhouse.—Watering, ventilating, and fumigating (or the use of tobacco in other forms for destruction of aphides) must be attended to. The atmosphere of the greenhouse must be kept moist. Watch the plants that have been plunged out of doors, and see if any require repotting. All plants that require staking, such as dahlias, roses, gladioli, and many herbaceous plants, should now be looked to. Carnations and other plants that are throwing up flower stems, if wanted to flower in winter, should be cut back, that is, the flower stems should be cut off to say 5 inches from the ground.

Fruit Garden.—If grape vines show any signs of mildew, dust them over with dry sulphur, selecting a still warm day. The fruit having now been gathered from strawberry plants, if new beds are to be formed, the system of layering the plants in small pots is the best. Where apples, pears, peaches, grapes, &c., have set fruit thickly, thin out at least one-half to two-thirds of the young fruit.

Vegetable Garden.—The first ten days of this month will yet be time enough to sow sweet corn, beets, lettuce, beans, cucumbers, and ruta-baga turnips. Such vegetables as cabbage, cauliflower, celery, &c., wanted for fall or winter use, are best planted this month, though in some sections they will do later. Keep sweet potatoes hoed to prevent the vines rooting at the joints.

AUGUST.

Flower Garden and Greenhouse.—But little deviation is required in these departments from the instructions for July.

Fruit Garden.—Strawberries that have fruited will now be making "runners" or young plants. These should be kept cut off close to the old plant, so that the full force of the root is expended in making the "crowns" or fruit buds for next season's crop. If plants are required for new beds, only the required number should be allowed to grow, and these should be layered in pots as recommended in July. The old stems of raspberries and blackberries that have borne fruit should be cut away, and the young shoots thinned to three or four canes to each hill or plant. If tied to stakes and topped when 4 or 5 feet high, they will form three or four branches on a cane, and will make stronger fruiting plants for next year.

they require it; cut down pelargoniums past flowering, and plant the cuttings.

Flower Garden and Shrubbery.—Take up the remaining tuberous roots, such as anemones, ranunculuses, &c., by the end of the first week; fill up their places, and any vacancies that may have occurred, with annuals or bedding plants from the reserve ground. Repot auriculas, and sow auricula seed in boxes under glass. Propagate herbaceous and other plants that have gone out of flower, by means of cuttings and slips, especially those required for spring bedding; propagate also the various summer bedding plants increased by cuttings. Increase roses and American shrubs, by layering, budding, or cuttings, and go on with the layering of carnations and picotees. Stake and tie up dahlias and strong herbaceous plants.

August.

Kitchen Garden.—Sow winter and spring spinach in the beginning and about the end of the month; parsley and winter onions, for a full crop, in the first week; cabbages about the middle of the month, for planting out in spring; cauliflower in the first half (Scotland) and in the second half (England) of the month; Hardy Hammersmith and Brown Cos lettuce in the first and last week; small salads occasionally; and Black Spanish radish, for winter crops. Plant out kales and broccoli for late crops; plant celery (earthing up the advancing crops as required), endive for succession, and a few coleworts. Take up shallots, garlic, &c.

Fruit Garden.—Proceed in training and regulating the summer shoots of all fruit trees as directed for the last three months. Net up, in dry weather, gooseberry and currant bushes, to preserve the fruit till late in the autumn. Make new strawberry beds if required. Preserve the ripening fruits on the wall and other trees from insects, and destroy wasp nests. Gather fruits as they ripen.

Forcing.—The routine of cultivation in hotbeds and pits may be continued. Sow, and propagate by cuttings, in the beginning of the month, cucumbers, to be afterwards grown in hot-water pits, or in boxes in the front of the pine-stove, for a winter crop. Make up mushroom beds for winter crop. In the pinery most of the summer fruit will be cut by the middle of the month, when a general shifting of succession plants will take place; as also a potting of suckers; but these will be strengthened by being allowed to remain on the old plants until the end of the month. In the forcing-houses, where the crops are past, part of the sashes may be removed, so as to permit thorough ventilation.

Plant Houses.—Attend to the propagation of all sorts of greenhouse plants by cuttings, and to the replacing in the greenhouse and stoves the more tender species, by the end of the month in ordinary seasons, but in wet weather in the second week. Sow half-hardy annuals, as Nemophila, Collinsia, Schizanthus, Rhodanthe, &c., to flower during winter.

Flower Garden and Shrubbery.—Sow in the second and the last week, on a warm border of a light sandy soil, with an east aspect, any free-flowering hardy annuals as Silene pendula, Nemophila, &c., for planting in spring; and auricula and primula seeds in pots and boxes. Propagate all sorts of herbaceous plants by rooted slips; layer chrysanthemums; take off layers of carnations, picotees, and pansies. Plant cuttings of bedding plants, and of bedding pelargoniums in boxes for convenience of removal. Layer the tops of chrysanthemums, to obtain dwarf flowering plants. Transplant evergreens in moist weather, about the end of the month; and propagate them by layers and cuttings. Pot Neapolitan violets for forcing; or plant out on a mild hotbed. Clip box edgings.

September.

Kitchen Garden.—Sow small salading for late crops; and lettuce and spinach, if not done last month, for spring crops. Plant endive and lettuce at the foot of a south wall to stand the winter; plant out cabbages from the chief autumn sowing. Plant cauliflowers on a warm border in spaces such as can be protected by hand-lights. Thin the winter spinach, when large enough, that it may have space to grow. If broccoli be too rank or tall to withstand the winter, lift and lay nearly up to the neck in the earth, the heads sloping towards the north. Lift onions, and lay them out to ripen on a dry border or gravel-walk. Lift potatoes and store them.

Fruit Garden.—Finish the summer pruning and training. Where the walls are heated, assist the maturing of peaches and nectarines, and the ripening of the young wood for next year, by fires during the day. Gather and lay up in the fruit-room with care the autumnal sorts of apples and pears. Prepare borders and stations for fruit trees during dry weather. Plant strawberries for a main crop. Repot orchard-house trees, disrooting if necessary.

Forcing.—Take care that late melons and cucumbers be not injured by getting too much water, and too little air. Sow a few kidney beans for an early forced crop. In the pinery at once take off and pot all strong suckers not done last month; the remainder may be taken off at the end of the month, and planted in old tan in a frame or pit. Expel damp, and assist the ripening of late grapes and peaches, with fires during the day. Prune early vines and peaches.

Plant Houses.—The various pot plants should now be put in their winter quarters. Keep up moderate temperatures in the stove, and merely repel frosts in the greenhouse, guarding against damp, by ventilation and by the cautious use of water. Pot hyacinths, tulips, and other bulbs for forcing; and propagate half-hardy plants by cuttings.

Flower Garden, &c.—Sow in the beginning of this month all half-hardy annuals required for early flowering; also mignonette in pots, thinning the plants at an early stage; the different species of primula; and the seeds of such plants as, if sown in spring, seldom come up the same season, but if sown in September and October, vegetate readily the succeeding spring. Put in cuttings of bedding pelargoniums in boxes, which may stand outdoors exposed to the sun, but should be sheltered from excessive rains. Continue the propagation of herbaceous plants, taking off the layers of carnations, picotees, pansies, and chrysanthemums, by the end of the month; choice carnations and picotees may be potted and wintered in cold frames if the season is wet and ungenial. Plant evergreens; lay and put in cuttings of most of the hard-wooded sorts of shrubby plants.

October.

Kitchen Garden.—Sow small salading and radishes in the first week, and lettuces in frames on a shallow hotbed for planting out in spring. If the winter prove mild they will be somewhat earlier

---

CALENDAR FOR THE UNITED STATES—Continued.

Vegetable Garden.—Hoe deeply such crops as cabbage, cauliflower, and celery. The earthing up of celery this month is not to be recommended. Onions in many sections can be harvested. The proper condition is when the tops are turning yellow and falling down. They are dried best by placing them in a dry shed in thin layers. Sow spinach for fall use, but not yet for the winter crop. Red top, white globe, and yellow Aberdeen turnips should now be sown; ruta-baga turnips sown last month will need thinning, and in extreme Southern States they may yet be sown.

September.

Flower Garden and Greenhouse.—The flower beds in the lawn should be at their best. If planted in "ribbon lines" or "massing," strict attention must be given to pinching off the tops, so that the lines or masses will present an even surface. Tender plants will require to be put in the greenhouse or housed in some way towards the end of this month; but be careful to keep them as cool as possible during the day. Cuttings of bedding plants may now be made freely if wanted for next season, as young cuttings rooted in the fall make better plants for next spring's use than old plants, in the case of such soft-wooded plants as pelargoniums, fuchsias, verbenas, heliotropes, &c.; with roses and plants of a woody nature, however, the old plants usually do best. Dutch bulbs, such as hyacinths, tulips, crocus, &c., and most of the varieties of lilies, may be planted. Violets that are wanted for winter flowering will now be growing freely, and the runners should be trimmed off. Sow seeds of sweet alyssum, candytuft, daisies, mignonette, pansies, &c.

Fruit Garden.—Strawberry plants that have been layered in pots may yet be planted, or in southern districts the ordinary ground layers can be planted. The sooner in the month both are planted the better crop they will give next season; and, as these plants soon make runners, it will be necessary to trim them off. Attend to raspberries and blackberries as advised for last month, if they have not already been attended to.

Vegetable Garden.—If cabbage, cauliflower, and lettuce are wanted to plant in cold frames, the seed should be sown from about the tenth to the twentieth of this month; but judgment should be exercised, for, if sown too early, cabbage and cauliflower are apt to run to seed. The best date for latitude of New York is September 15th. The main crop of spinach or sprouts that is wanted for winter or spring use should be sown about the same date. The earth should be drawn up to celery with a hoe preparatory to earthing up with a spade. Onions that were not harvested and dried last mouth must now be attended to. Turnips of the early or flat sorts may yet be sown the first week of this month in the Northern States, and in the South from two to four weeks later.

October.

Flower Garden and Greenhouse.—In northern sections of the United States, tender plants that are still outside should be got under cover as early as possible. Delay using fire heat as long as possible, unless the nights become so cold as to chill the plants inside the house. Roses, carnations, camellias, azaleas, pelargoniums, and the hardier sorts of plants will do better if placed in a cold frame or pit until the middle of November than they would in an ordinary greenhouse. Look out for insects. Fall bulbs of all kinds may be planted. Take up summer-flowering bulbs and tubers, such as dahlias, tuberoses, gladioli, cannas, caladiums, tigridias, and dry them off thoroughly, stowing them away afterwards in some place free from frost and moisture during winter.

Fruit Garden.—Strawberries that have been grown from pot-grown layers may yet be planted in Southern States; keep the runners trimmed off. Fruit trees and shrubs may be set out; but, if planting is deferred to the last of the month, the ground around the roots should be mulched to the thickness of 3 or 4 inches with straw, leaves, or rough manure, as a protection against frost.

Vegetable Garden.—Celery will now be in full growth, and will require close attention to earthing up, and during the last part of the month the first lot may be stored away in trenches for winter. All vegetable roots not designed to be left in the ground during the winter should be dug up, such as beets, carrots, parsnips, sweet potatoes, &c. The cabbage, cauliflower, and lettuce plants grown from seed sown last month should be pricked out in cold frames. If lettuce is wanted for winter use, it may now be planted in the greenhouse or cold frame, and will be ready for use about Christmas. If asparagus or rhubarb is wanted for winter use, it should be taken up and stowed away in pit, frame, shed, or cellar for a month or two. It may then be taken into the greenhouse and packed closely together under the stage, and will be fit for use from January to March, according to the temperature of the house.

than those sown next month or in January. Plant parsley in pots or boxes to protect under glass in case very severe weather occurs. Plant cabbages in beds or close rows till wanted in spring; and cauliflowers in the last week, to receive the protection of frames, or a sheltered situation. Store potatoes, beet, salsafy, scorzonera, skirret, carrots, and parsnips, by the end of the month. Band and earth up cardoons.

Fruit Garden.—Such fruit trees as have dropped their leaves may be transplanted; this is the best season for transplanting (though with care it may be done earlier), whether the leaves have fallen or not. Protect fig-trees, if the weather proves frosty, as soon as they have cast their leaves. Plant out raspberries. The orchard-house trees should be got under glass before the end of the month. Gather and store all sorts of apples and pears, the longest-keeping sorts not before the end of the month, if the weather be mild.

Forcing.—Maintain the heat in hotbeds and pits by means of fresh dung linings. Give abundance of air in mild bright weather. Dress vines and peaches. Clean and repair the forcing-houses, and overhaul the heating apparatus to see it is in good working condition. Plant chicory or witloef in boxes or on hotbeds for blanching. Sow kidney beans. Make up successional winter mushroom beds.

Plant Houses.—Replace all sorts of greenhouse plants. Fill the pits with pots of stocks, mignonette, and hardy annuals for planting out in spring, along with many of the hardy sorts of greenhouse plants; the whole ought to be thoroughly ventilated, except in frosty weather. From this time till spring keep succulent plants almost without water. Sow cyclamens. Begin to force roses, hyacinths, and a few other bulbs, for winter and early spring decoration. Plant hyacinths in glasses for windows.

Flower Garden.—Sow a few pots of hardy annuals in a frame, or on a sheltered border, for successional spring use if required. Plant the greater part of the common border bulbs as hyacinths, narcissi, crocuses, and early tulips, about the end of the month, with a few anemones for early flowering. Transplant strong plants of biennials and perennials to their final situations; also the select plants used for spring bedding. Protect alpine plants, stage auriculas, and carnations and picotees with glass frames; and half-hardy greenhouse plants, such as fuchsias, &c., about the end of the month, with coverings of broom or spruce-fir, preferring the latter. Take up, dry, and store dahlias and all tender tubers in the end of the month; pot lobelias and similar half-hardy plants from the open borders. Transplant all sorts of hardy evergreens and shrubs, especially in dry soils, giving abundance of water. Put in cuttings of all sorts of evergreens, &c. Plant out the hardier sorts of roses.

November.

Kitchen Garden.—Trench up all vacant ground as soon as cleared of its crops, leaving the surface as rough as possible. Sow Dillistone's Early peas and Early Dwarf Prolific beans, in the second week, for an early crop; also in frames for transplanting. Protect endive, celery, artichoke, and sea-kale, with stable-litter or fern, or by planting the former in frames; take up late cauliflower, early broccoli, and lettuces, and place them in sheltered pits or lay them in an open shed; earth up celery; manure and dress up asparagus beds.

Fruit Garden.—Plant all sort of fruit trees in fine weather—the earlier in the month the better. Protect fig-trees. Commence pruning and nailing. Gather and store the latest apples and pears. Examine the fruit room, and remove all decayed fruit.

Forcing.—Keep up the requisite degree of heat in hotbeds and pits. Cucumbers and pines, on hotbeds, will require more than ordinary attention, to prevent them damping off from too much moisture; hence the advantage of hot-water heating. Force asparagus, rhubarb, and sea-kale, in the mushroom-house, in pits, or in the open border under boxes or cases surrounded and covered by well-fermented stable dung and leaves. Sow Early Horn carrot; also kidney beans and radishes, on hotbeds. In the forcing-houses prune and train the trees; fork over and dress the borders of such houses as have not been already done.

Plant-Houses.—The directions for the greenhouse and conservatory in January apply also to this month generally. Continue the forcing of roses, hyacinths, &c.

Flower Garden, &c.—Plant dried tubers of border flowers, but the finer sorts had better be deferred till spring. Plant tulips in the early part of the month. Put in cuttings of bedding calceolarias, choosing the shoots that will not run up to flower. Protect such half-hardy plants as are not already sheltered. Plant deciduous trees and shrubs so long as the weather continues favourable, and before the soil has parted with the solar heat absorbed during summer. Dig and dress such flower borders and shrubberies as may now be cleared of annuals and the stems of herbaceous plants.

December.

Kitchen Garden.—Collect and smother-burn all vegetable refuse, and apply it as a dressing to the ground. Sow a few peas and beans, in case of accident to those sown in November, drawing up the soil towards the stems of those which are above ground as a protection; earth up celery; blanch endive with flower-pots; sow radishes in a very sheltered place. Attend to trenching and digging in dry weather.

Fruit Garden.—Plant all sorts of fruit trees in mild weather. Proceed with pruning and nailing wall-trees. Examine the fruit-room every week, removing promptly all decaying fruit.

Forcing.—The same degree of attention to hotbeds and pits will be necessary as in the last month. Continue the forcing of asparagus, rhubarb, and sea-kale, in pits and in the mushroom-house. Proceed with the usual routine of culture commenced last month. Make the necessary preparations to begin forcing early or succession crops by the last week of this or the first of next month.

Plant-Houses, Frames, &c.—Carnations and picotees in pots must be kept rather dry to prevent damping off. Heaths and Australian plants must be very sparingly watered, and kept with only fire heat enough to repel frost.

Flower Garden, &c.—Plant shrubs in open weather. Prune hardy roses and other hardy shrubs. Sweep and roll the lawns, and put in repair the gravel-walks, keeping the surface frequently rolled. (T. MO.)

CALENDAR FOR THE UNITED STATES—Continued.

November.

Flower Garden and Greenhouse.—Plants intended to be grown inside should now all be indoors. Keep a sharp look out for cold snaps, as they come very unexpectedly in November, and many plants are lost thereby. In cases where it is not convenient to use fire heat, 5° to 10° of cold can be resisted by covering the plants over with paper, and by using this before frost has struck the plants valuable collections may be saved. When fire heat is freely used, be careful to keep up the proper amount of moisture by sprinkling the paths with water. Little can be done in the flower garden, except to clean off all dead stalks, and straw up tender roses, vines, &c., and, wherever there is time, to dig up and rake the borders, as it will greatly facilitate spring work. Cover up all beds in which there are hyacinths, tulips, and other bulbs with a litter of leaves or straw to the depth of 2 or 3 inches. If short thoroughly-decayed manure can be spared, a good sprinkling spread over the lawn will help it to a finer growth next spring.

Fruit Garden.—Strawberry beds should be covered (in cold sections) with hay, straw, or leaf mulching, to a depth not exceeding 2 inches. Fruit trees and grape vines generally should be pruned; and, if the wood of the vine is wanted for cuttings, or scions of fruit trees for grafts, they should be tied in small bundles and buried in the ground until spring.

Vegetable Garden.—Celery that is to be stored for winter use should be put away before the end of the month in all sections north of Virginia; south of that it may be left in most places where grown throughout the winter if well covered up. The stalks of the asparagus bed should be cut off, and burned if there are berries on them, as the seeds scattered in the soil sometimes produce troublesome weeds. Mulch the beds with 2 or 3 inches of rough manure. All vegetable roots that are yet in the ground, and not designed to be left there over winter, must be dug up in this latitude before the middle of the month, or they may be frozen in. Cover up onions, spinach, sprouts, cabbage, or lettuce plants with a covering of 2 or 3 inches of leaves, hay, or straw, to protect them during the winter. Cabbages that have headed may usually be preserved against injury by frost until the middle of next month, by simply pulling them up and packing them closely in a dry spot in the open field with the heads down and roots up. On approach of cold weather in December they should be covered up with leaves as high as the tops of the roots, or, if the soil is light, it may be thrown over them, if leaves are not convenient. Cabbages will keep this way until March if the covering has not been put on too early. Plough all empty ground if practicable, and, whenever time will permit, do trenching and subsoiling. Cabbage, cauliflower, and lettuce plants that are in frames should be regularly ventilated by lifting the sash on warm days, and on the approach of very cold weather they should be covered with straw mats or shutters. In the colder latitudes, and even in the Middle States, it is absolutely necessary to protect cauliflower in this way, as it is much more tender than cabbage and lettuce plants.

December.

Flower Garden and Greenhouse.—Close attention must be paid to protecting all tender plants, for it is not uncommon to have the care of a whole year spoiled by one night's neglect. Vigilance and extra hot fires will have to be kept up when the thermometer falls to 34° or 35° in the parlour or conservatory. It is well to set the plants under the benches or on the walks of the greenhouse; if they are in the parlour, move them away from the cold point and protect them with paper; this will usually save them even if the thermometer falls to 24° or 26°. Another plan in the greenhouse is to dash water on the pipes or flues, which causes steam to rise to the glass and freeze there, stopping up all the crevices. With plants outside that require strawing up or to be mulched, this will have now to be finished.

Fruit Garden.—In sections where it is an advantage to protect grape vines, raspberries, &c., from severe frost, these should be laid down as close to the ground as possible, and covered with leaves, straw, or hay, or with a few inches of soil.

Vegetable Garden.—Celery in trenches should receive the final covering for the winter, which is best done by leaves or light stable litter; in the latitude of New York it should not be less than 12 inches thick. Potatoes, beets, turnips, or other roots in pits, the spinach crop in the ground, or any other article in need of protection, should be attended to before the end of the month; manure and compost heaps should be forwarded as rapidly as possible, and turned and mixed so as to be in proper condition for spring. Remove the snow that accumulates on cold frames or other glass structures, particularly if the soil which the glass covers was not frozen before the snow fell; it may remain on the sashes longer if the plants are frozen in, since they are dormant, and would not be injured if deprived of light for eight or ten days. If roots have been placed in cellars, attention must be given to ventilation, which can be done by making a wooden box, say 6 by 8 inches, to run from the ceiling of the cellar to the eaves of the building above. (P. H.)

Horticulture.—Index of Principal Subjects.

HOSEA, the son of Beerî, the first in order of the minor prophets. The name Hosea (הוֹשֵׁעַ, LXX. 'Ωσηέ, Vulg. *Osee*, and so our English version in Rom. ix. 25) ought rather to be written Hoshea, and is identical with that borne by the last king of Ephraim, and by Joshua in Num. xiii. 16, Deut. xxxii. 44. Of the life of Hosea we know nothing beyond what can be gathered from his prophecies. That he was a citizen of the northern kingdom appears from the whole tenor of the book, but most expressly from i. 2, where "the land," the prophet's land, is the realm of Israel, and vii. 5, where "our king" is the king of Samaria. The date at which Hosea flourished is given in the title, i. 1, by the reigning kings of Judah and Israel. He prophesied (1) in the days of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah; (2) in the days of Jeroboam the son of Joash, king of Israel. As Jeroboam II. died in the lifetime of Uzziah, these two determinations of the period of Hosea's prophetic activity are not strictly coincident, and a question arises whether both are from the same hand or of equal authority. There is no doubt that the date of Jeroboam II. applies to chaps. i. and ii., which were written before the downfall of the dynasty of Jehu (i. 4), and while the nation was still enjoying the prosperity that distinguished Jeroboam's reign. On the other hand, it seems equally certain that chaps. iv.-xiv. are in their present form a continuous composition dating from the period of anarchy subsequent to that king's death. Thus it seems natural to suppose, with Ewald and other scholars, that the name of Jeroboam originally stood in a special title to chaps. i., ii. (or to these along with chap. iii.), which was afterwards extended to a general heading for the whole book by the insertion of the words "of Uzziah . . . . and in the days of." As Hosea himself can hardly be supposed to have thus converted a special title into a general one, the scholars who take this view suppose further that the date by Judæan reigns was added by a later hand, the same perhaps which penned the identical date in the title to Isaiah. On this view the Judæan date merely expresses knowledge on the part of some Hebrew scribe that Hosea was a contemporary of Isaiah. The plausibility of this hypothesis is greatly increased by the fact that there does not appear to be anything in the book of Hosea that is clearly as late as the reign of Hezekiah. On the contrary, the latter part of the book seems to have been written before the expedition of Tiglath Pileser against Pekah in the days of Ahaz. In that war Gilead and Galilee were conquered and depopulated (2 Kings xv. 29), but Hosea repeatedly refers to these districts as still forming an integral part of the kingdom of Israel (v. 1, vi. 8, xii. 11; contrast Micah vii. 14). Assyria is never referred to as a hostile power, but as a dangerous ally, from which some of the godless Ephraimites were ready to seek the help which another party expected from Egypt, but which in truth was to be found only in Jehovah (v. 13, vii. 11, viii. 9, xii. 1, xiv. 3). This picture precisely corresponds with what we read in 2 Kings xv. of the internal dissensions which rent the northern kingdom after the fall of the house of Jehu, when Menahem called in the Assyrians to help him against those who challenged his pretensions to the throne. Under Pekah of Israel, and Ahaz his contemporary in Judah, the political situation was altogether changed. Israel was in alliance with Damascus, and Assyria made open war on the allies (2 Kings xvi.). This new situation may be said to mark a crisis in the history of Old Testament prophecy, for to it we owe the magnificent series of Isaiah's Assyrian discourses (Isa. vii. *seq.*). But the events which stirred Judæan prophets so deeply have left no trace in the book in which Hosea sums up the record of his teaching. He foresees that captivity and desolation lie in the future, but even in his last words of pathetic exhortation he speaks to a nation which looks to Assyria for help and victory (xiv. 3). The received chronology of the kings of Judah and Israel is notoriously precarious, and a comparison of the Assyrian monuments and eponym lists with the Biblical data makes it probable that the period from the accession of Zachariah, son of Jeroboam II., to the fall of Samaria must be shortened by as much as twenty years, and that the interregnum which is commonly supposed to have followed Jeroboam's death must also be cancelled. This correction may be held to remove one difficulty in the title of our book, which on the current chronology assigns to Hosea some sixty years of prophetic activity. On the other hand, most Assyriologists agree that the expedition of Sennacherib, which fell in the fourteenth year of Hezekiah (2 Kings xviii. 13), took place in 701 B.C. In that case Hezekiah did not come to the throne till after the fall of Samaria (722–719); which the book of Hosea predicts as a future occurrence (ch. xiii. 16)—another argument against the authority of the title. There is still, however, a large element of uncertainty in the reconstruction of Hebrew chronology by the aid of the monuments. One date bearing on our book may be taken as certain, viz., the war of Tiglath Pileser with Pekah in 734, and, according to our argument, Hosea committed his prophecies to writing before that year.[1] A more exact determination of the date of the book has been sought by comparing viii. 9, 10, with the statement on the monuments that Tiglath Pileser received tribute from King Menahem (Minhimmi) of Samaria in 738 B.C. That Minhimmi of the monuments is the Menahem of the Bible there seems no good reason to doubt, in spite of the objections of Oppert and G. Smith. But it cannot be assumed that tribute was paid by him in 738 for the first time. The narrative in 2 Kings xv. 19 seems to indicate that the relations of Menahem to Assyria began earlier in his reign,[2] perhaps not long after his accession, which may be dated with probability *c.* 750 B.C.

To sum up, the first part of Hosea's prophetic work, corresponding to chaps i.–iii., lay in the years of external prosperity immediately preceding the catastrophe of the house of Jehu in or near the year 750. The second part of the book is a summary of prophetic teaching during the subsequent troublous reign of Menahem, and must have been completed before 734 B.C. Apart from the narrative in chaps i.–iii., to which we shall presently recur, the book throws little or no light on the details of Hosea's life. It appears from ix. 7, 8, that his prophetic work was greatly embarrassed by opposition, "As for the prophet, a fowler's snare is in all his ways, and enmity in the house of his God." The enmity which had its centre in the sanctuary probably proceeded from the priests (comp. Amos vii.), against whose profligacy and profanation of their office our prophet frequently declaims—perhaps also from the degenerate prophetic guilds which had their seats in the holy cities of the northern kingdom, and with whom Hosea's elder contemporary Amos so indignantly refuses to be identified (Amos vii. 14). In chap. iv. 5 Hosea seems to comprise priests and prophets in one condemnation, thus placing himself in direct antagonism to all the leaders of the religious life of his nation. Under such circumstances, and amidst the universal dissolution of social order and morality to which every page of his book bears testimony, the prophet was driven to the verge of despair (ix. 7), and only the sovereign conviction of Jehovah's infinite love and tender compassion to His people, even in their faithlessness and sin, upheld him in the sure hope of the final repentance and restoration of Israel, which finds such exquisitely pathetic expression in the closing sentences of his prophecy. The hypothesis of Ewald, that he was at last compelled by persecution to retire from the northern kingdom, and composed his book in Judea, rests mainly on an improbable exegesis of several passages, and derives no valid support from the fact that the prophet, to whom the ideal unity of all the tribes of Jacob and the legitimate sovereignty of the house of David are cardinal doctrines, follows the house of Judah with constant interest and growing acquaintance with its internal condition.

The most interesting problem of Hosea's history lies in the interpretation of the story of his married life (chaps. i.–iii.). We read in these chapters that God's revelation to Hosea began when in accordance with a divine command he married a profligate wife Gomer, the daughter of Diblaim. Three children were born in this marriage and received symbolical names, illustrative of the divine purpose towards Israel, which are expounded in chap. i. In chap. ii. the faithlessness of Israel to Jehovah, the long-suffering of God, the moral discipline of sorrow and tribulation by which He will yet bring back His erring people and betroth it to Himself for ever in righteousness, love, and truth, are depicted under the figure of the relation of a husband to an erring spouse. The suggestion of this allegory lies in the prophet's marriage with Gomer, but the details are worked out quite independently, and under a rich multiplicity of figures derived from other sources. In the third chapter we return to the personal experience of the prophet. His faithless wife had at length left him and fallen, under circumstances which are not detailed, into a state of misery, from which Hosea, still following her with tender affection, and encouraged by a divine command, brought her back and restored her to his house, where he kept her in seclusion, and patiently watched over her for many days, yet not readmitting her to the privileges of a wife.

In these experiences the prophet again recognizes a parallel to Jehovah's long-suffering love to Israel, and the discipline by which the people shall be brought back to God through a period in which all their political and religious institutions are overthrown. Throughout these chapters personal narrative and prophetic allegory are interwoven with a rapidity of transition very puzzling to the modern reader; but an unbiassed exegesis can hardly fail to acknowledge that chaps. i. and iii. narrate an actual passage in the prophet's life. The names of the three children are symbolical, but Isaiah in like manner gave symbolical names to his sons, embodying prominent points in his prophetic teaching (Shear-jashub, Isa. vii. 3, comp. x. 21; Maher-shalal-hash-baz, viii. 3). And the name of Gomer bath Diblaim is certainly that of an actual person, upon which all the allegorists, from the Targum, Jerome, and Ephrem Syrus downwards, have spent their arts in vain, whereas the true symbolical names in the book are perfectly easy of interpretation.[3] That the ancient interpreters take the whole narrative as a mere parable is no more than an application of their standing rule that everything in the Biblical history is allegorical which in its literal sense appears offensive to propriety (comp. Jerome's proem to the book). But the supposed offence to propriety

[1] Some writers, including Dr Pusey, claim a later date for the book, identifying Shalman in x. 14 with Shalmaneser IV., the successor of Tiglath Pileser. This identification is altogether arbitrary. If Beth-Arbel is Arbela beyond Jordan (*Onom.*, ed. Lagarde, p. 88), the reference, as Schrader has shown (*Keilinschr. und A. T.*, p. 283), may be equally well to Shalmaneser III., or to a king Shalamanu of Moab, who appears on the monuments as a tributary of Tiglath Pileser.

[2] See on the whole chronology of the period, Schrader, *Keilinschriften und A. T.*, Giessen, 1872; Id., *Keilinschriften und Geschichtsforschung*, *ibid.*, 1878; G. Smith, *Assyrian Eponym Canon*, London, 1875; Wellhausen's article in *Jbb. f. Deutsche Theol.*, 1875, pp. 607 *sq.*; Oppert, *Salomon et ses Successeurs*, Paris, 1877.

[3] Theodorus Mops. remarks very justly, *καὶ τὸ ὄνομα καὶ τὸν πατέρα λέγει, ὡς μὴ πλάσμα ψιλόν τι δοκοίη τὸ λεγόμενον, ἱστορία δὲ ἀληθὴς τῶν πραγμάτων.*

seems to rest on mistaken exegesis and too narrow a conception of the way in which the Divine word was communicated to the prophets. There is no reason to suppose that Hosea knowingly married a woman of profligate character. The point of the allegory in i. 2 is plainly infidelity after marriage as a parallel to Israel's departure from the covenant God, and a profligate wife (אשת זנונים) is not the same thing with an open prostitute (זונה). The marriage was marred by Gomer's infidelity; and the struggle of Hosea's affection for his wife with this great unhappiness—a struggle inconceivable unless his first love had been pure and full of trust in the purity of its object—furnished him with a new insight into Jehovah's dealings with Israel. Then he recognized that the great calamity of his life was God's own ordinance and appointed means to communicate to him a deep prophetic lesson. The recognition of a divine command after the fact has its parallel, as Wellhausen observes, in Jeremiah xxxii. 8.

This explanation of the narrative, which is essentially Ewald's, has commended itself to not a few recent expositors, as Valeton, Wellhausen, and Nowack. It has the great advantage of supplying a psychological key to the conception of Israel or the land of Israel (i. 2) as the spouse of Jehovah, which dominates these chapters, but in the later part of the book gives way to the personification of the nation as God's son. This conception has, indeed, formal points of contact with notions previously current, and even with the ideas of Semitic heathenism. On the one hand, it is a standing Hebrew usage to represent the land as mother of its people, while the representation of worshippers as children of their god is found in Num. xxi. 29, where the Moabites are called children of Chemosh, and is early and widespread throughout the Semitic field (*cf. Trans. Bib. Arch.*, vi. p. 438; *Jour. of Phil.*, ix. p. 82). The combination of these two notions gives at once the conception of the national deity as husband of the land. On the other hand, the designation of Jehovah as Baal, which, in accordance with the antique view of marriage, means husband as well as lord and owner, was current among the Israelites in early times (see BAAL), perhaps, indeed, down to Hosea's age (ii. 16). Now it is highly probable that among the idolatrous Israelites the idea of a marriage between the deity and individual worshippers was actually current and connected with the immorality which Hosea often condemns in the worship of the local Baalim, whom the ignorant people identified with Jehovah. For we have a Punic woman's name, ארישתבעל, "the betrothed of Baal" (Euting, *Punische Steine*, pp. 9, 15), and a similar conception existed among the Babylonians (Herod., i. 181, 182). But Hosea takes the idea of Jehovah as husband, and gives it an altogether different turn, filling it with a new and profound meaning, based on the psychical experiences of a deep human affection in contest with outraged honour and the wilful self-degradation of a spouse. It can hardly be supposed that all that lies in these chapters is an abstract study in the psychology of the emotions. It is actual human experience that gives Hosea the key to divine truth. Among those who do not recognize this view of the passage, the controversy between allegory and literalism is carried on chiefly upon abstract assumptions. The extreme literalists, of whom Dr Pusey may be taken as the modern representative in England, will have it that the divine command justified a marriage otherwise highly improper, and that the offensive circumstances magnify the obedience of the prophet. This is to substitute the Scotist and Neo-Platonic notion of God for that of Scripture. On the other hand, the allegorists, who argue that God could not have enjoined on His prophet a marriage plainly improper and fitted to destroy his influence among the people, are unable to show that what is repulsive in fact is fit subject for a divine allegory. A third school of recent writers, led by Hengstenberg, and resting on a thesis of John Smith, the Cambridge Platonist, will have it that the symbolical action was transacted in what they allow themselves by a *contradictio in adjecto* to call an objective vision. This view has been adopted by Fairbairn (*Prophecy*, ch. v. sec. ii.). The recent Continental literature of the controversy is catalogued by Nowack in his *Commentary*, p. xxxvi.

It was in the experiences of his married life, and in the spiritual lessons opened to him through these, that Hosea first heard the revealing voice of Jehovah (i. 2). Like Amos (Amos iii. 8), he was called to speak for God by an inward constraining voice, and there is no reason to think that he had any connexion with the recognized prophetic societies, or ever received such outward adoption to office as was given to Elisha. His position in Israel was one of tragic isolation. Amos, when he had discharged his mission at Bethel, could return to his home and to his friends; Hosea was a stranger among his own people, and his home was full of sorrow and shame. Isaiah in the gloomiest days of Judah's declension had faithful disciples about him, and knew that there was a believing remnant in the land. Hosea knows no such remnant, and there is not a line in his prophecy from which we can conclude that his words ever found an obedient ear. For him the present condition of the people contained no germ or pledge of future amendment, and he describes the impending judgment, not as a sifting process (Amos ix. 9, 10) in which the wicked perish and the righteous remain, but as the total wreck of the nation which has wholly turned aside from its God. In truth, while the idolatrous feasts of Ephraim still ran their joyous round, while the careless people crowded to the high places, and there in unbridled and licentious mirth flattered themselves that their many sacrifices ensured the help of their God against all calamity, the nation was already in the last stage of internal dissolution. To the prophet's eye there was "no truth, nor mercy, nor knowledge of God in the land—nought but swearing, and lying, and killing, and stealing, and adultery; they break out, and blood toucheth blood" (iv. 1, 2). The root of this corruption lay in total ignorance of Jehovah, whose precepts were no longer taught by the priests, while in the national calf-worship, and in the local high places, this worship was confounded with the service of the Canaanite Baalim. Thus the whole religious constitution of Israel was undermined. And the political state of the realm was in Hosea's eyes not more hopeful. The dynasty of Jehu, still great and powerful when the prophet's labours began, is itself an incorporation of national sin. Founded on the bloodshed of Jezreel, it must fall by God's vengeance, and the state shall fall with it (i. 4, iii. 4). This sentence stands at the head of Hosea's predictions, and throughout the book the civil constitution of Ephraim is represented as equally lawless and godless with the corrupt religious establishment. The anarchy that followed on the murder of Zachariah appears to the prophet as the natural decadence of a realm not founded on divine ordinance. The nation had rejected Jehovah, the only helper. And now the avenging Assyrian is at hand. Samaria's king shall pass away as foam on the water. Fortress and city shall fall before the ruthless invader, who spares neither age nor sex, and thistles shall cover the desolate altars of Ephraim. But the ultimate theme of all prophecy is not judgment but redeeming love, and the deepest thought of every Hebrew seer is the sovereignty of Jehovah's grace in Israel's sin. Hosea could discern no faithful remnant in Ephraim, yet Ephraim in all his corruption is the son of Jehovah, a child nurtured with tender love, a chosen people, whose past history declares in every episode the watchful and patient affection of his father. And that father is God and not man, the Holy One who will not and cannot sacrifice His love even to the justest indignation (chap. xi.). To the prophet who knows this love of Jehovah, who has learned to understand it in the like experience of his own life, the very ruin of the state of Israel is a step in the loving guidance which makes the valley of trouble a door of hope (ii. 15), and the wilderness of tribulation as full of promise as the desert road from Egypt to Canaan was to Israel of old. Of the manner of Israel's repentance and conversion Hosea presents no clear image, nay, it is plain that on this point he had nothing to tell. The certainty that the people will at length return and seek Jehovah their God and David their king rests, not on any germ of better things in Israel, but on the invincible supremacy of Jehovah's love And so the two sides of his prophetic declaration, the passionate denunciation of Israel's sin and folly, and the not less passionate tenderness with which he describes the final victory of divine love, are united by no logical bond. The unity is one of feeling only, and the sob of anguish in which many of his appeals to a heedless people seem to end, turns once and again with sudden revulsion into the clear accents of evangelical promise, which in the closing chapter swell forth in pure and strong cadence out of a heart that has found its rest with God from all the troubles of a stormy life.

Traditions about Hosea.—Beêrî, the prophet's father, is identified by the Rabbins with Beêrah (1 Chron. v. 6), a Reubenite prince carried captive by Tiglath Pileser. This view is already expressed by Jerome, *Quæst. in Paralip.*, and doubtless underlies the statement of the Targum to Chronicles that Beêrah was a prophet. For it is a Jewish maxim that when a prophet's father is named, he too was a prophet, and accordingly a tradition of R. Simon makes Isa. viii. 19, 20 a prophecy of Beêrî (Kimchi *in loc.*; *Leviticus Rabba*, par. 15). According to the usual Christian tradition, however, Hosea was of the tribe of Issachar, and from an unknown town, Belemoth or Belemon (pseudo-Epiphanius, pseudo-Dorotheus, Ephrem Syr., ii. 234; *Chron. Pasch.*, Bonn ed., i. 276). As the tradition adds that he died there, and was buried in peace, the source of the story lies probably in some holy place shown as his grave. There are other traditions as to the burial-place of Hosea. A Jewish legend in the *Shalsheleth haqqabala* (Carpzov, *Introd.*, pt. iii. ch. vii. § 3) tells that he died in captivity at Babylon, and was carried to Upper Galilee, and buried at צפת, that is, Safed (Neubauer, *Géog. du Talmud*, p. 227); and the Arabs show the grave of Neby 'Osha, east of the Jordan, near Es-Salt (Bädeker's *Palestine*, p. 337; Burckhardt's *Syria*, p. 353).

Literature.—Of the older commentaries on Hosea which have been fully catalogued by Rosenmüller in his *Scholia*, it is sufficient to name, as books still practically useful, Le Mercier's Latin annotations, embodying a translation of the chief rabbinical expositions, and the English commentary of E. Pococke, Oxford, 1685, which is not surpassed in learning and judgment by any subsequent work. Among recent expositions the most important are those in Ewald's *Propheten*, Bd. i. (2d ed., Göttingen, 1867; Eng. trans., London, 1876); Hitzig's *Kleine Propheten* (3d ed., Leipsic, 1863); Keil's *Kleine Propheten* (Leipsic, 1866; Eng. trans., Edinburgh, 1868); Pusey's *Minor Prophets*, London, 1860; Reuss's *Bible*, part ii. (Paris, 1876); the *Speaker's Commentary*, vol. vi. (by Huxtable, London, 1876); Heilprin's *Historical Poetry*, vol. ii. (New York, 1880); and the separate publications of Simson (Hamburg and Gotha, 1851), Wünsche (Leipsic, 1868), and Nowack (Berlin, 1880). The last gives a list of recent Continental commentaries and monographs, to which may be added Houtsma's "Bijdrage" (*Theol. Tijdsch.*, 1875, p. 55 *sq.*). The English commentary of Williams (London, 1866) is of little importance; Schmoller's commentary in Lange's *Bibelwerk* (1872; Eng. trans., 1874) is adapted for homiletical purposes. The theology of Hosea is ably discussed by Duhm, *Theol. der Propheten* (Bonn, 1875), with which an essay by Smend (*Stud. u. Krit.*, 1876) may be advantageously compared.

Texts and Versions.—The best edition of the Massoretic text is that with notes by S. Baer (Leipsic, 1878). From the great facsimile of the *Codex Babylonicus Petropolitanus* Hosea and Joel have been separately published (St Petersburg, 1875). The most recent helps to the use of the VSS. are Nestle's appendix to the 6th edition of Tischendorf's Septuagint (Leipsic, 1880), Lagarde's edition of the Targum from the *Cod. Reuch.* (Leipsic, 1872), Ceriani's facsimile editions of the great Ambrosian MSS. of the Syro-Hexaplar (Milan, 1874) and Peshito (Pars iii., Milan, 1879), and Field's *Hexapla* (vol. ii. 1870). An Arabic version directly translated from the Hebrew was published by Schroeter from a Bodleian codex in Merx's *Archiv*, 1869. A convenient and accessible edition of the Hebrew text of Hosea, with Targum and Rabbinical commentaries, is H. v. d. Hardt's reprint (Göttingen, 1775) of R. Stephen's Paris text of 1566. (W. R. S.)

HOSHANGÁBÁD, a British district in the chief commissionership of the Central Provinces of India, lying between 21° 40′ and 22° 59′ N. lat. and between 76° 38′ 30″ and 78° 45′ 30″ E. long. It is bounded N. by the Narbadá (Nerbudda), which separates it from the territories of Bhopál, Sindhia, and Holkar; E. by the Dudhi river, dividing it from Narsinghpur district; S. by the districts of Western Berar, Betúl, and Chhindwára; and W. by Nimár. Hoshangábád may be described as a valley of varying breadth, extending for 150 miles between the Nerbudda and the Sátpura mountains. The soil consists chiefly of black basaltic alluvium, often more than 20 feet deep; but along the banks of the Nerbudda the fertility of the land compensates for the tameness of the scenery. Towards the west, low stony hills and broken ridges cut up the level ground, while the Vindhyás and the Sátpuras throw out jutting spurs and ranges. In this wilder country considerable regions are covered with jungle. On the south the lofty range which shuts in the valley is remarkable in mountain scenery, surpassing in its picturesque irregularity the Vindhyán chain in the north. Many streams take their rise amid its precipices, then, winding through deep glens, flow across the plain between sandy banks covered with low jungle, till they swell the waters of the mighty Nerbudda. None of the streams are of any importance except the Tawá, which is interesting to the geologist on account of the many minerals to be found along its course. The boundary rivers, the Nerbudda and Tapti, are the only considerable waters in Hoshangábád. At Chárwá a dense low jungle extends over a large region, but by far the finest timber is found at Borí and Denwa.

The census of 1877 showed a population of 463,625 (Europeans, 86; Eurasians, 10; aboriginal tribes, 89,029; Hindus, 364,679; Mahometans, 21,765; Buddhists and Jains, 1132). There are only four towns with a population exceeding 5000, viz., Hoshangábád, 11,613; Harda, 9170; Seoni, 7579; and Sohágpur, 7552. The total revenue in 1876–77 was £69,842; the total cost of officials and police, £14,733. There were 11 civil and revenue judges, and 22 magistrates. The number of police was 582. There were 94 Government schools, attended by 4024 pupils.

Of the total area of 4376 square miles only 1442 are cultivated, and of the portion lying waste 825 are returned as cultivable; 2455 acres are irrigated entirely by private enterprise. Wheat forms the staple crop of the district; the other products are inferior grains, cotton, and sugar-cane. Hoshangábád does a considerable export trade in agricultural produce, receiving in return English piece-goods, spices, cocoa-nuts, salt, and sugar. The extent of made roads in Hoshangábád is returned at 498 miles. The Great Indian Peninsula Railway intersects the whole district from east to west, with stations at the principal towns. Besides roads and railway, the Nerbudda, with its tributaries, supplies means of communication by water for 150 miles during part of the year. The district is generally free from violent alternations of temperature, hot winds are rare, and the nights during the sultry weather and rains are always cool. The rainfall is exceedingly variable, ranging between the limits of 40 and 60 inches for the year. The prevailing diseases are fevers and bowel complaints. In 1876 five charitable dispensaries afforded medical relief to 18,206 in-door and out-door patients.

History.—Little is known of the history of Hoshangábád prior to the Marhattá invasion. When the Mughal troops occupied Handiá, the eastern part of the district inhabited by Gonds, who still retain their possession, maintained a rude independence. About 1720 Dost Muhammad, the founder of the Bhopál family, captured the town of Hoshangábád, and annexed a considerable territory with it. In 1750 Rájá Raghují Bhonslá of Nágpur reduced the country east of Handiá and south of the Nerbudda, except the portion held by Bhopál. In 1795 the rival dynasties of Bhopál and Nágpur came into conflict, and the town and fort of Hoshangábád were captured by the Nágpur forces. In 1802 the Bhopáls retrieved their loss. The Nágpur army again besieged the fort, but failed in their attack, and contented themselves with burning the town. In 1809 Hoshangábád was again assailed by a Nágpur force, and the Bhopáls, finding their communications with Bhopál cut off, surrendered. Overcome by these disasters, the Bhopáls called in the Pindháris to their help, and till they were finally extirpated in 1817 the whole of this fertile region became a prey to ravage and massacre. Under the order which the British Government has restored, the prosperity of the country is gradually returning. In 1818 that part of the district held by Nágpur was ceded under an agreement. In 1844 the region of Harda Handiá was made over by Sindhiá in part payment of the Gwalior contingent, and by the treaty of 1860 became British territory.

HOSHANGÁBÁD, the headquarters town of the above district, 22° 45′ 30″ N. lat., 77° 46′ E. long., is situated on the south side of the Nerbudda. Population (1877) 11,613. It is supposed to have been founded by Hoshang Sháh, the second of the Ghorí kings of Málwá; but it remained an insignificant place till the Bhopál conquest about 1720, when a massive stone fort was constructed, with its base on the river, commanding the Bhopál road. It sustained several sieges, and passed alternately into the hands of the Bhopál and Nágpur troops. From 1818 it has been the residence of the chief British officials in charge of the district. A church has been built, and a first-class jail constructed. The town has a dispensary and school-houses. It is the chief seat of the English piece-goods trade of the district, and has a brisk trade in cotton, grain, and bills of exchange.

HOSIERY. Under this name is embraced a wide range of manufactured textiles, which are classed together more on account of their manner of fabrication than from similarity of application or use. The term, as is quite obvious, has its origin in hose or stockings; but although stockings continue to be one of the staples of hosiery, that department is only one of a very numerous and diversified range of applications of the entire industry, it having been officially stated that not fewer than 5000 distinct articles are made in the trade. All kinds of hosiery proper are made by the process of knitting, and the industry has principally to deal with the fabrication of knitted under-clothing.

The art of knitting is the youngest of all the important textile manufactures, and, compared with the others, its origin is quite modern. No certain allusion to the art occurs before the beginning of the 15th century. In an Act of Parliament of Henry VII. (1488) knitted woollen caps are mentioned. It is supposed that the art was first practised in Scotland, and thence carried into England, and that caps were made by knitting for some period before the more difficult feat of stocking-making was attempted. In an Act of Edward VI. (1553) "knitte hose, knitte peticotes, knitte gloves, and knitte slieves" are enumerated, and the trade of hosiers is, among others, included in an Act dated 1563. Spanish silk stockings were worn on rare occasions by Henry VIII., and the same much-prized articles are also mentioned in connexion with the wardrobe of Edward VI.

The peculiarity of knitting consists in the use of a single thread for the entire texture, and in the formation therewith of a singularly elastic yet strong and firm looped web.

The process of hand-knitting is universally known, and the endless details of fancy stitches and loops whereby ornamented work can be produced do not come within the scope of hosiery proper. While a vast quantity of the best and most comfortable hosiery is made with implements so simple and inexpensive as four knitting wires or needles, the manufacturing industry is carried on with machinery of unsurpassed ingenuity and complexity. Moreover, domestic knitting machines, mostly of American origin, have of late years been introduced, and, although these can never be expected to attain the popular favour of the sewing-machine, yet they have been widely adopted.

In the year 1589 the stocking-frame, the machine which mechanically produces the looped stitch in hosiery, was invented by the Rev. William Lee, a graduate of Cambridge, and native of Woodborough, near Nottingham. The fundamental principle of the apparatus consists in the substitution of a separate hooked or barbed needle for the support and working of each loop, in place of the system whereby an indefinite number of loops are skewered on one or more wires or needles. The method on which the machine is worked will be easily comprehended by aid of the accompanying diagram (fig. 1), which represents a few of Lee's peculiar barbed needles from a frame with yarn in process of knitting. At R is seen a thread of yarn passed over the needle stalks and within the terminal hooks. The yarn, it will be observed, is waved or depressed between each pair of needles, whereby sufficient yarn is secured to form the separate loops of uniform size, and thus produce a regular equal fabric. The waving or depression of the yarn is produced by allowing thin plates of shaped metal termed sinkers to fall between each pair of needles after the yarn has been thrown across the whole range, and these sinkers, according to their depth of fall, carry down material for a large or small loop as the case may be. The elastic points of the needle-hooks are next pressed into a groove in the stem by means of a presser bar which acts on the whole row of barbs, and thus a range of temporarily closed metallic hooks is formed, through which the waved yarn is threaded. Over these hooks the loops of the already formed web SS have only to be drawn to form with the material R a new series of loops; the pressure is then relieved, and now R forms a new row in the work in place of S, and the operation is ready to be repeated for a succeeding row. It is not necessary here to enter into a description of the various mechanical devices by which Lee perfected the complex movements of his stocking-frame. It is sufficient to say that so perfectly did he succeed in his adaptations that to this day the essential features of his machine continue in use for the class of work to which he applied it. At first Lee was only able to work a flat even web, which when joined at the selvages made an unshapen cylinder; but he soon learned to shape the work at pleasure by removing loops from time to time from the outer edges of the web for narrowing or taking in, and to reverse that process for widening or letting out.

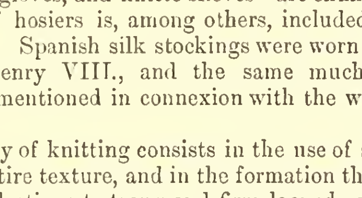

Fig. 1.

Neither Lee nor any of his relatives during their lifetime reaped an adequate reward for the great boon he conferred on mankind. His stocking-frame came gradually into extensive use, and an important industry was thereby created. No improvement of essential consequence was effected on the apparatus till in 1758 Mr Jedediah Strutt, originally a Derbyshire farmer, adapted it to the production of ribbed work. Mr Strutt's invention consisted of an addition to the original frame, which could be brought into use or not according as plain or ribbed work was desired. The addition consisted of a set of ribbing-needles placed at right angles to Lee's plain needles, and at the intervals required for producing ribbed courses. On the completion of a row of plain loops, the rib needles are raised; at their respective intervals they lay hold of the last-formed loop, and, bringing that through the loop which was on the rib-needle itself before, they give an additional or double looping or twisting, which reverses the line of chaining, and produces the ribbed appearance characteristic of this variety of work. For his invention Strutt in conjunction with his brother-in-law Woollett, a hosier, secured a patent, and they commenced the manufacture at Derby, where their "Derby-ribs" became exceedingly popular. The idea of adding parts to the plain frame of Lee, thus originated by Strutt, became the fertile source of a great number of the later adaptations and modifications of the apparatus. Strutt's invention was the starting-point of a great and most honourable business in the hands of himself and his family, and the elevation of his grandson, Lord Belper, to the peerage was a direct tribute to the industrial interests of the nation.

Down till almost the middle of this century only a flat web could be knitted in the machines in use, and for the finishing of stockings, &c., it was necessary to seam up the selvages of web shaped on the frame (fashioned work), or to cut and seam them from even web (cut work). The introduction of any device by which seamless garments could be fabricated was obviously a great desideratum, and it is a singular fact that a machine capable of doing that in a perfect manner should have been patented in 1816, while it was not seen in actual use in Nottingham, the capital of the hosiery trade, till 1845. The inventor of the round stocking-frame was no other than Sir Marc I. Brunel, who in 1816 patented his machine under the name of the *Tricoteur*. In Brunel's apparatus the needles are fixed on the rim of a rotating wheel. The yarn is delivered, the loops formed, the beards of the needles pressed down, and all the other operations performed by means of a series of arms and wheels which act on the circumference of the ring or circle of needles. As the working of such a machine is continuous, and as several sets of wheels and arms may work simultaneously around a ring of sufficient diameter, Brunel's machine was really capable of doing work with very great rapidity. He appears not, however, to have regarded his invention as worthy of being pushed into notice, and it was not till 1845 that in an improved form it was brought forward as an original invention by Mr Peter Claussen, who, however, reaped no profit from his undoubted ingenuity and merit.

Another improvement of very great importance in the hosiery trade was effected through the invention of the tumbler needle, patented by Mr M. Townsend in 1858. The tumbler needle (fig. 2) consists of a stem somewhat bulged near the point. The bulged part contains a groove in which there is hinged a short pin. The pin is so placed that, when turned to the hooked or curved point, its own point falls into a spoon-like indent, thus forming a smooth metal loop. When reversed the pin falls into the groove of the stem, making a smooth stalk. In this way, as will be clear from the figure, when the yarn is caught in the curved point of the needles, the already formed loops in being brought forward to pass off the needles carry forward the hinged pin and close the steel loop, over which they pass quite smoothly. The newly-formed loop then pushes over the tumbler pin into its groove, and the hook is once more ready to seize the yarn as it passes along. The tumbler needle and the revolving frame together form the basis of the various domestic machines which are now in the market. In machines in which the tumbler needle is adopted the needles themselves move in grooves, each being carried forward in succession as the feed of yarn comes opposite its position.

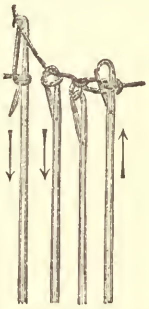

Fig. 2.

The varieties of frame now in use are embraced under narrow hand-machines, wide hand-machines, power rotary-frames, and power round-frames, the first two being exclusively used in the houses of the operatives, while the latter are factory machines driven by steam. "It will be an explanation of some interest," says the late Mr Felkin, in a paper before the British Association (Nottingham meeting, 1866), "to those who are strangers to the process of these trades, to state that the hand-knitter of a stocking, if assiduous and clever, will knit 100 loops a minute, and that Lee on his first machine made 1000 of worsted, and on his second 1500 loops of silk per minute. The visitor may now see on the round frame, patented by Brunel in 1816, but since modified and improved, without any effort but to supply yarn, 250,000 loops of the finest textures made, in various colours, per minute, with safety,—an advance of 2500-fold upon the hand-knitter."

The principle centre of the hosiery trade of the United Kingdom is Nottingham town and county; and in Leicestershire and Derbyshire the industry is also of importance. It was computed by Mr Felkin that the English hosiery trade gave employment in 1866 to about 150,000 persons, of whom about 100,000 were occupied in the preliminary and finishing operations of winding, cutting, mending, seaming, &c. At that time the industry was largely domestic, frames being hired out to operatives; but the trade tends steadily towards factories. According to a parliamentary return issued 31st July 1879, there were in the United Kingdom 186 hosiery factories, giving employment to 14,992 persons, 6683 males and 8309 females. Of these, 175 factories were in England, 10 in Scotland, and 1 in Ireland; and centred in Nottingham, Leicester, Lincoln, Rutland, and Derbyshire there were 173 of the establishments employing 13,680 of the operatives. The exports in 1878, which of course represent only a small proportion of the total output, amounted in value to £860,318. In the United States the industry is conducted on a manufacturing scale in New York State, Massachusetts, New Hampshire, Rhode Island, Vermont, Connecticut, and Maine; besides which family machines are extensively employed in that country. In Saxony also the trade is an important industrial feature, and there its development has been strikingly rapid. Throughout France, Spain, and Italy there are numerous frames at work, and indeed the trade may be regarded as in some degree commensurate with civilized industrial communities. (J. PA.)

HOSIUS, or OSIUS, bishop of Cordova, the friend of Athanasius, and the favourite of Constantine, was born about 256 A.D., most probably at Cordova, although from a passage in Zosimus it has sometimes been conjectured that he was believed by that writer to be a native of Egypt. Elected to the see of Cordova before the end of the 3d century, he narrowly escaped martyrdom in the persecution of Maximian (303–305); in 305 or 306 he attended the council of Illiberis or Elvira, his name appearing second in the list of those present; and in 313 we find him already at the court of Constantine, he being expressly mentioned by name in a constitution directed by the emperor to Cæcilianus of Carthage in that year. In 323 he was the bearer and not impossibly the writer of Constantine's letter to bishop Alexander of Alexandria and Arius his deacon, designed to promote the cause of peace; and, on the failure of the negotiations in Egypt, it was doubtless with the active concurrence of Hosius that the council of Nice was convened. He certainly took part in its proceedings; according to some Roman Catholic writers he presided, and did so as representing the bishop of Rome, but both these statements are made on totally inadequate grounds. Equally doubtful is the assertion that he was the principal author of the Nicene creed; but manifestly he powerfully influenced the judgment of the emperor in favour of the orthodox party. After a period of retirement in his diocese, Hosius presided in 347 at the fruitless synod of Sardica, which showed itself so hostile to Arianism; and afterwards he spoke and wrote in favour of Athanasius in such a way as to bring upon himself a sentence of banishment to Sirmium (355). From his exile he wrote to Constantius II. his only extant composition, a letter not unjustly characterized by Tillemont as displaying gravity, dignity, gentleness, wisdom, generosity, and in fact all the qualities of a great soul and a great bishop. Subjected to continual pressure, the old man, who was approaching, if he had not already passed, his hundredth year, was weak enough to sign the Arian formula adopted by the second synod of Sirmium in 357. Shortly afterwards he was permitted to return to his diocese, where he died in 359. Apart from some human touches of worldliness and latterly of weakness, Hosius was a consistent and creditable as well as prominent defender of orthodoxy, and as such he is recognized even by those who most bitterly resent his apostasy.

See Tillemont, *Mémoires*, vol. vii. 300–321 (1700), and Hefele, *Conciliengeschichte*, vol. i.

HOSPITAL is derived from the Latin *hospitalis* (adj.), and this again from the noun *hospes*, a host or guest. The place in which a guest was received was in Latin *hospitium* (hence the French, *hospice*), but in course of time the adjective became used as a noun, and the words *hospitalis*, *hospitale*, and *hospitalia* were adopted in the same sense as *hospitium*, by dropping the nouns *domus*, *cubiculum*, or *cubicula*. In this sense Vitruvius uses *hospitalia* to mean the chambers where guests were received. The English word *hospital* (often reduced to *spital*) comes from the old French *hospital*, now *hôpital*, of which Littré says that it was remade from the Latin many centuries ago, although originally *hospitalis* had given rise quite regularly to *hostel*, now *hôtel*. The three words, *hôpital*, *hospice*, and *hôtel*, although from the same source, are used now in very different meanings, the first being usually restricted to establishments for temporary occupation by the sick and hurt, for the purposes of medical and surgical treatment; the second (*hospice*) to places for permanent occupation by the poor, the infirm, the incurable, or the insane; and the last (*hôtel*) to dwellings, either public or private, for ordinary occupation. To the last, however, there is one exception, viz., when the term *hôtel-Dieu* (that is, *hôtel de Dieu*) is applied to the chief hospital or infirmary of a town or city. In English we have no equivalent to *hospice*, so that the word *hospital* has been, and is still, used in the double sense, viz., as a place for medical treatment, and also as a retreat or almshouse for the poor, the infirm, &c. On the other hand the word *infirmary*, which originally meant a place or room set apart in an establishment (such as a monastery) for the reception of the sick members, and also for those who were through age or infirmity incapacitated from work, is not infrequently employed in the same sense as *hospital*, namely, as a separate establishment for the treatment of the sick.

Although in ancient times there may have been places for the reception of strangers and travellers, it seems at least doubtful if there was anything of the nature of a charitable institution for the reception of the sick, such as existed after the introduction of Christianity. The Bethesda of Scripture (Aramaic, from בֵּית, a house, and חֶסְדָּא, charity) was probably no more than a collection of mere sheds built round the pool to whose waters miraculous healing powers were attributed. Among the Greeks there seems little evidence of the existence of establishments for the sick; ξενών, described by Plato as a place of shelter for travellers, is also explained as a νοσοκομεῖον, or hospital, by Suidas; but that lexicographer is a late writer (10th or 11th century A.D.), and the word νοσοκομεῖον itself does not appear to be earlier in use than the 4th century A.D. The word is used by St Jerome in the 4th century, and in the Code of Justinian in the 6th, from which it is possible Suidas may have got his definition, although ξενοδοχεῖον is distinctly used by Justinian as a shelter for travellers, as indeed its name implies. Even for sick and wounded soldiers but little provision seems to have been made, although we do not know much of the *valetudinarium*, which appears to have existed in a Roman camp. That the Romans had a medical staff has been shown by the monuments discovered in Great Britain, and the subject has been carefully examined by the late Sir James Simpson (*Transactions of the Society of Antiquaries of Scotland*, *Edinburgh Monthly Journal of Medicine*, &c.). Among the earliest hospitals on record are that said to have been founded by Valens in Cæsarea 370–80 A.D., and the one built at Rome by Fabiola, a Roman lady and friend of St Jerome, although like most others of that and even later times both were probably almshouses as well.

The origin of our present hospitals must, however, be looked for in the monastic arrangements for the care of the sick and indigent. Every monastery had its *infirmaria*, managed by an *infirmarius*, in which not only were sick and convalescents treated, but also the aged, the blind, the weak, &c., were housed.[1] In course of time separate buildings were erected for the purpose, and special revenues, augmented from time to time by benefactions, appropriated for their maintenance. In numerous instances, however, the hospitals were converted into benefices by the priests, and the scandal had to be dealt with by the authority of general councils, which, like that of Vienne, forbade the practice. About the earliest distinct record of the building of a hospital in England is in the life of Lanfranc, archbishop of Canterbury, who in 1080 founded two, one for leprosy and one for ordinary diseases. The former is referred to in the *Vie de St Thomas le Martyr*, a work of the 12th century. The establishments for the sick remained in the hands of the clergy until the Reformation, when some of the monasteries and church property were appropriated and set apart for the use of the sick. Of those the most noted instances were St Bartholomew's in Smithfield, St Thomas's in the Borough, Bethlehem or Bedlam, Bridewell, and Christ's Hospital, which were long known as the "Five Royal Hospitals." St Bartholomew's was a priory, founded by Rahere, a minstrel, in 1102, and the ancient hospital chapel is still the parish church of St Bartholomew the Less. It was handed over to the citizens of London as a hospital in 1547; it escaped the fire of 1666, and was rebuilt in 1729. St Thomas's was founded by Richard, prior of Bermondsey, in 1213, surrendered in 1538, and purchased by the mayor and citizens of London in 1551, and opened for 260 sick. It was incorporated in 1553, rebuilt in 1693, added to in 1732, removed temporarily to Surrey Gardens in 1862, and finally transferred to Lambeth, its present site, in 1871. Bethlehem (or Bedlam) was a priory, founded by Simon Fitzmary, in 1247. In 1547 it was handed over by Henry VIII. for the reception of lunatics. It was rebuilt in 1676, and wings were added in 1733. The present building was constructed in 1810. Bridewell and Christ's Hospital early ceased to be receptacles for the sick. (For further information regarding charitable institutions see ENGLAND, vol. viii. p. 253.)

But the great movement in hospital building took place in the 18th century, and the following table from Dr Steele's paper, "On the mortality of Hospitals" (Howard prize essay for 1876), gives a list of the chief institutions founded during that period :—

London.	Date of Foundation.	Provincial.	Date of Foundation.	Irish.	Date of Foundation.
Westminster	1719	York	1710	*Dublin.*	
Guy's	1723	Salisbury	1716	Jervis Street	1726
St George's	1733	Cambridge	1719	Steevens's	1733
London	1740	Bristol	1735	Mercer's	1734
Middlesex	1745	Edinburgh	1736	Meath	1756
		Windsor	1736	House of Industry	1774
		Aberdeen	1739		
Special Hospitals.		Northampton	1743		
		Exeter	1745	*Special (Dublin).*	
The British Lying-in	1749	Worcester	1745		
		Newcastle	1751	The Rotunda Lying-in	1745

[1] *Liber ordinis Sancti Victoris Parisiensis*, MS. cap. 40. See Ducange's *Glossary*, *s.v.* "Infirmaria."

During the present century the increase of hospitals has continued, seven general and many special having been founded in London alone. Dr Steele gives statistics of 27 metropolitan hospitals, having an aggregate of nearly 6000 beds, and receiving about 46,000 in-patients annually. This does not take into account the infirmaries attached to the workhouses or the metropolitan asylums hospitals. In addition to this probably from ten to twelve times the number of out-patients are treated in the course of the year.

Hospitals are usually divided into *General* and *Special*. In *General Hospitals* cases of all kinds are admitted in some, whilst in others certain classes are excluded. Thus cases of contagious zymotic disease are not admitted now in many instances, especially in London since the establishment of the metropolitan asylums, fever and small-pox hospitals. Lying-in cases, venereal cases, &c., are also frequently excluded.

Special Hospitals are of various kinds, such as lying-in hospitals, ophthalmic, lock (for venereal diseases), cancer, consumption, &c., besides fever and small-pox hospitals. At the end of the last and beginning of this century fever hospitals were generally called "houses of recovery," with a view of not alarming the people too much who had to resort to them. Special hospitals are also set apart for the treatment of diseases of children.

Besides the various civil hospitals there are also naval and military hospitals for the cure of sailors and soldiers.

Although hospitals have been intended as a blessing and benefit to the poor, they have too often proved the reverse, on account of the ignorance, on the part of their administrators, of the true principles of health. So much was this the case formerly that it has been not infrequently debated whether hospitals are or are not gigantic evils; and even where it is admitted that they are of value in cases of actual disease, it is still doubtful if they are really of benefit in cases of confinement It may be of use to consider briefly the statistics of mortality at different times and in different places. It is very difficult to compare former death-rates with present or recent if we consider cases in bulk, because previous to the present century it was but little the custom to classify cases; so that a preponderance of surgical cases might exist at one period and of medical at another, with a corresponding variation of the death-rate. Of course in some exceptional instances we can point to remarkable differences due to known causes of unhealthiness. Thus in the Hôtel Dieu of Paris, in the last century, a terrible mortality occurred, amounting to 1 in 4½, or 220 per 1000 (Tenon);—and in the British hospitals at Scutari the mortality reached between 400 and 500 per 1000. In both of those cases there was inordinate crowding, such as is hardly likely to be met with again. But in dealing with ordinary hospitals there are so many modifying causes that the comparison, without careful analysis, may be misleading. Thus Dr Steele has shown that in the last century (1730–1800) the death-rate of St Thomas's was 86 per 1000, whilst that of Guy's was 119; but this, as he points out, may have arisen from the latter being looked upon as an asylum for incurables. In 1875 the death-rates of the general hospitals in London ranged from 72 per 1000 in the Royal Free to 127 in King's College; in the Edinburgh Royal Infirmary it was 92, and in the Glasgow 118. But it is when we examine the mortality of special cases that the most instructive lessons are to be learned; and the best for this purpose are surgical cases and lying-in cases. From these we gather that the mortality is pretty generally in the ratio of the size of the hospital and the consequent aggregation of patients, the crowding together of patients in the wards, the deficiency of ventilation, defective sewerage arrangements, and the want of constant attention to the details of cleanliness. Thus Sir James Simpson showed in his paper on "Hospitalism" the following statistics of mortality from amputations:—

	Deaths per 1000.
St Bartholomew's	366
London Hospital, Whitechapel	473
Guy's	382
St George's	388
Nine London hospitals	411
Royal Infirmary, Edinburgh	433
,, ,, Glasgow	391
Eleven large and Metropolitan hospitals	410

On the other hand, amputations in country practice give a death-rate of only 108 per 1000.

Comparing the results with the size of the hospital, that is, the aggregation of cases, we find:—

	Deaths per 1000.
Large Parisian hospitals, with more than 600 beds (Husson)	620
English hospitals, 301 to 600 beds	410
,, ,, 201 to 300 ,,	300
,, ,, 101 to 200 ,,	230
,, ,, 25 to 100 ,,	180
Cottage hospitals under 25 beds	140
Isolated rooms in country practice	108

The question of lying-in cases is even more remarkable. Dr Lefort, having collected the statistics of 888,302 delivered in hospitals, and of 934,781 delivered at home, shows that in hospitals 35 per 1000 die, and at home 4¾.

Dr Steele gives the statistics of the four great lying-in hospitals of London, compared with the "extern-maternity" charities of Guy's, St Bartholomew's, and St Thomas's:—

	Queen Charlotte's Lying in.	British Lying-in.	General Lying in.	City of London Lying-in.	Guy's.	St Bartholomew's.	St Thomas's.
Deaths per 1000	28·2	15·7	14·8	13·5	4·1	3·1	3·5

Baron Meydell, chief of the sanitary department of St Petersburg, has shown that in the largest lying-in hospital there, in which 2000 women are confined in a year, the death-rate is from 30 to 40 per 1000; in the second, in which about 1000 women per annum are received, only 25 die; in the third, where 400 are received, only 20 die per 1000; in the small detached asylums of 2 or 3 beds, of which there are 11 in different parts of the city, giving accommodation to 1600 women per annum, or about 155 each, only 9 per 1000 die; whilst amongst those confined in their own homes, including the poorest and most wretched, only 5 per 1000 die (*Rapport du Congrès International d'Hygiène et de Sauvetage*, Brussels, 1876, vol. i. p. 226). These numbers correspond with the observations above.

It can also be shown that outbreaks of disease are coincident with individual overcrowding, whether the hospital be large or small. Thus the terrible mortality of the Hôtel-Dieu of Paris in the last century was due as much to actual overcrowding as to the enormous aggregation of patients. The extraordinary spectacle was to be seen there of two or three small-pox patients, or several surgical cases, or sometimes even four parturient women, lying in one bed. A large proportion of the beds were purposely made for four patients, and six were frequently crowded in. In the Salle St Charles and St Antoine there were 139 large beds (intended for four patients each, but often holding six), and 38 small beds for one patient each. Those beds were generally full, giving under ordinary conditions 558 patients, and in times of pressure 836. To this might be added the Salle St Roch, opening directly from and really forming part of the great ward; this contained 35 large beds and 3 small,—normal number of patients 143, with a possible increase to 213. This gives a grand total of 701 patients as a normal amount, with a possible increase to 1049.

There was thus collected in one enormous ward a larger number of patients than any hospital in England contained altogether, if we except the Royal Naval Hospital at Haslar. In addition, however, to the above inordinate number, there were in the three stories placed above this great ward 1926 patients, which number might be increased to 2596,—without reckoning the serving staff of the institution;—or (including the wards on the Pont Double) a total in one block of building equal to 3418, which might be increased to 4320. The law forbade the hospital authorities to refuse admission to any one, and in 1773 there were 5000 patients in the hospital, which occupied a space of little more than 3 English acres,—giving a total gross area of only 30 square feet per head. The gross area per bed of the modern Hôtel-Dieu is just ten times this amount, being 311 square feet, according to M. Tollet; but even this is much too small, 100 square metres (1076 square feet) being the minimum proposed by Tollet, who estimates the general average per inhabitant of Paris at 430 square feet, whereas that of London is nearly double. We cannot point to any such overcrowding in England as that of the old Hôtel-Dieu, but in many cases there has been enough to produce very grave results. The ill effects are seen in outbreaks of erysipelas, hospital gangrene, and surgical fever among surgical cases, and in puerperal fever in lying-in cases,—whilst in all communicable diseases the danger of spreading is greatly intensified. It was observed in 1877 in the General Lying-in Hospital, the year before it was closed for alterations, that when only two or three women were in a ward, puerperal disease rarely showed itself, but that when, in consequence of pressure of applications, five or six were put in, disease generally broke out. Similar results have been observed elsewhere.

Another great cause of mortality has been inefficient ventilation. If we can scatter our sick population and give them individually plenty of space in their wards, we shall have done much,—but, if we do not also change the air sufficiently often we may still have evil results with all our care. Formerly no arrangements were made for ventilation in hospitals, schools, barracks, churches, or indeed in any buildings whatsoever. An immense deal remains to be desired in this direction still, but in recent hospitals, at least, more or less efficient means have been introduced, whilst efforts have been made to improve the conditions of the old. The want of fresh air aggravates all diseases, increases the power of infection, retards the convalescence, and hastens the death of patients; moreover, it lowers the tone of the healthy, and is the most potent of all agents in the propagation of phthisis or destructive lung disease. The labours of the Royal Commission of 1857, appointed to inquire into the health of the army, brought out in full relief the disastrous effects of want of proper ventilation in the sleeping rooms of our soldiers. It was there shown that the death-rate of Her Majesty's Foot Guards was more than 20 per 1000 per annum, 67 per cent. greater than the death-rate at the same ages in Manchester, our most unhealthy town, double the general death-rate of England, and nearly three times that of the most healthy country districts. As regards phthisis alone the death-rate was 10·8 per 1000 from 1830–1836, and 11·9 from 1837 to 1846, or an average of 11·4 per 1000 for the period, an amount more than the total mortality of the civil male population of England and Wales at the same ages. In the army generally the proportion was 7·86. Since the evil was recognized steps have been taken to remedy the conditions, particularly in the direction of giving more space in barrack-rooms, and securing a certain standard of air renewal. The results are seen in the present death-rate from phthisis, which is reduced to 2·5 per 1000, about one-third of the old, and not much above that of the best districts in England. It is still, however, too high, as a large number of men are invalided for disease who go to swell the returns of sickness and mortality in civil life. That this is mainly owing to defective air renewal is evident from the fact that in civil life starvation, crowding, and poverty are insufficient to produce the same evil results we have seen in our army,—because, in all likelihood, the very wretchedness of the dwellings of the poor has brought about an amount of involuntary air renewal, which has been their safeguard.

Defective arrangements for the removal of excreta have constituted another cause of mortality. Water closets opening directly out of wards, and sinks, waste-pipes, bath-pipes, &c., in direct communication with the sewers, have been the means of introducing sewer poison into hospitals, producing surgical and puerperal diseases, enteric fever, and diphtheria, and aggravating every other form of malady.

A want of constant attention to the details of cleanliness has been a fertile source of hospital disease. Dr B. W. Richardson has traced out in a very instructive way the remarkable immunity of the Jews from epidemic and other diseases, and has shown that their religious attention to the details of the periodic cleansing enjoined by the Mosaic law appears to be the main cause of this notable circumstance. An instructive instance of the importance of this point is recorded by Mr W. Cadge, surgeon of the Norwich Infirmary, which institution had long suffered from surgical diseases, such as erysipelas, pyæmia, and the like. These, it was supposed, were mainly due to the age and structural defects of the building, so that it was determined to pull it down and reconstruct it throughout. In the meantime a change of administration took place, and a new matron was introduced, who effected an entire alteration in the arrangements, and in particular insisted on an absolute and unremitting attention to every detail of cleanliness, both of building, clothing, bedding, and person. The result was an immediate cessation of the dreaded complications which had so vexed the hospital, and from that time there has been no return of them.

Faulty diet had also, doubtless, its influence on mortality, although its effects would be less easy to trace. One singular feature in the last century was the enormous allowance of beer given to patients in hospital,—from two to three pints being common, and the allowance sometimes reaching half a gallon per diem. The absence of fresh vegetables from the diet, not only of hospitals but also of the populace at large, probably introduced a scorbutic taint which may have had some part in aggravating or modifying disease.

Some influence must also be allowed to the indiscriminate mixture of cases. The evil of this, especially in the more or less crowded state of the older hospitals, was recognized even in the last century, and was referred to by Tenon among others Although the danger is materially lessened when ample space per bed is allowed, it is still unadvisable, not to say unfair, to place contagious cases with other patients. The argument has been advanced that by distributing infectious cases there is less danger of concentration of poison than when they are congregated together by themselves. With proper hygienic precautions, however, this concentration may be minimized, whilst the isolation of such cases gives the greatest immunity to others.

This question of concentration has been pushed still further, so as to bear against the existence of all hospitals whatsoever, and so far as lying-in hospitals are concerned we have seen that the objections are well founded. But when we consider the subject in its various aspects it must be admitted that it would be difficult to do without hospitals in some form or another. It would hardly be possible to afford people the same advantages of treatment, attendance, nursing, and comforts at their own homes, although in some cases the system of home treatment might be advantageously substituted, as has been done for so many years with so much success in Edinburgh and other towns of Scotland on the dispensary system. Another most important aspect of the question is the necessity for hospitals as places of instruction for those entering the profession of medicine. Although it would be wrong to subordinate in any serious way the claims of patients of any class to the requirements of teaching, it must yet be admitted that the only sound way of learning medicine and surgery is by clinical or bedside instruction, and we may therefore reasonably demand that those who owe their treatment and care to public charity should be willing so far to contribute to the general welfare. Now it is clear that in dealing with large classes of students it would hardly be possible to convey proper clinical instruction except in a hospital. For this purpose the provincial hospitals ought to be more largely utilized, in addition to the metropolitan; at present the resources of the former are to a great extent wasted for teaching purposes.

Assuming then the necessity for hospitals, there still remains the question of the kind of hospital that should be constructed or approved of. It is certainly open to doubt whether we should continue to build monumental hospitals, and not rather construct slighter buildings, which may be destroyed and rebuilt from time to time, thus both scattering patients over a wider area and lessening the risk from long accumulation of infective material. This latter has been named the cottage or hut system of construction. The difficulties attending it are chiefly connected with original expense of site and with the current expenses of nursing and administration. On the other hand, it may be urged with some reason that with correct hygienic management there is no reason why a large hospital should not be kept in a healthy condition.

We may now consider the principles of hospital construction.

1. *Locality and Site.*—Hospitals are required for the use of the community in a certain locality, and to be of use they must be within reach of the centre of population. Formerly the greater difficulty of locomotion made it necessary that they should be actually in the midst of towns and cities, and to some extent this continues to prevail. It is at least doubtful if this be the best plan. Fresh and pure air being a prime necessity, as well as a considerable amount of space of actual area in proportion to population, it would certainly appear to be better to place hospitals as much in the outskirts as is consistent with considerations of usefulness and convenience. In short, the best site would be open fields; but, if that be impracticable, a large space—a "sanitary zone," as it is called by Tollet—should be kept permanently free between them and surrounding buildings, certainly never less than double the height of the highest building. The difference between the expense of purchase of land in a town and in the environs is generally considerable;—and this is therefore an additional reason for choosing a suburban locality. Even with existing hospitals it would be in most cases pecuniarily advantageous to dispose of the present building and site and retain only a receiving house in the town. St Thomas's in London, the Hôtel-Dieu in Paris, and the Royal Infirmary in Manchester are all good examples where this might have been carried out. In none, however, has this been done, the first two having been rebuilt, at enormous outlay, in the cities as before, although not exactly in the same locality, while the last is still retained with a few structural alterations. In Edinburgh, on the other hand, an open space of a much more favourable character has been obtained, which, although within the limits of the city, is almost rural in character.

As regards the actual site itself, where circumstances admit of choice, a dry gravelly or sandy soil should be selected, in a position where the ground water is low and but little subject to fluctuations of level, and where the means of drainage are capable of being effectually carried out. There should also be a cheerful sunny aspect, and some protection from the coldest winds.

2. *Form of Building.*—A form of building must be selected which answers the following conditions:—(*a*) the freest possible circulation of air round each ward, with no *cul-de-sac* or enclosed spaces where air can stagnate; (*b*) free play of sunlight upon each ward during at least some portion of the day; (*c*) the possibility of isolating any ward, or group of wards, effectually, in case of infectious disease breaking out; (*d*) the possibility of ventilating every ward independently of any other part of the establishment. Those conditions can only be fulfilled by one system, viz., a congeries of houses or pavilions, more or less connected with each other by covered ways, so as to facilitate convenient and economical administration. The older plans of huge blocks of building, arranged in squares or rectangles, enclosing spaces without free circulation of air, are obviously objectionable. Even when arranged in single lines or crosses they are not desirable, as the wards either communicate with each other or with common passages or corridors, rendering separation impossible. On this point it may be remarked that some of the buildings of the last century were more wisely constructed than many of those in the first half of the present, and that the older buildings have been from time to time spoilt by ignorant additions made in later times. The question next arises —Is it better to have pavilions of two or more stories high, or to have single-storied huts or cottages, scattered more widely? Where land is expensive the former plan is of course more economical, but where land is easily got the latter ought to be adopted. The pavilions may be arranged in various ways: they may be joined at one end by a corridor, or may be divided by a central corridor at right angles to them, &c. In fact, the plan is very elastic, and adapts itself to almost any circumstances. A certain distance, not less than twice the height of the pavilions, ought to be preserved between them. By this means free circulation of air and plenty of light are secured, whilst separation or isolation may be at once accomplished if required.

3. *Foundations, Building Materials, &c.*—It is of the first consequence that a hospital should be dry; therefore the foundation and walls ought to be constructed so as to prevent the inroads of damp. An impervious foundation has the further advantage of preventing emanations from the soil rising up in consequence of the suction force produced by the higher temperature of the internal atmosphere of the building itself. There should be free ventilation in the basement, and the raising of the whole on arches is a good plan, now generally carried out in hot climates. If the pavilions are two or more stories high it is advisable to use fire-proof material as much as possible, but single-storied huts may be of wood. In any case effectual means of excluding damp must be employed. The interiors of wards ought to be rendered as non-absorbent as possible, by being covered with impervious coatings, such as glazed tiles (parian, though much used, is apt to crack), silicate paint, soluble glass, or the like. The ceilings ought to be treated in the same way as the walls, or, perhaps better still, they might be made like the deck of a ship, without any lath and plaster, so as to have nothing but the floor itself between room and room. For the floors themselves various materials have been suggested: in France there is a preference for flags (dalles), but in England wood is more liked; and indeed hard well-fitting wood, such as teak, oak, or pitch-pine, leaves nothing to be desired. The surface should be waxed and polished or varnished. Even deal floors can be rendered non-absorbent by waxing, by impregnating them with solid paraffin as recommended by Dr Langstaff, or by painting with soluble glass as suggested by Dr Luther of Philadelphia.

4. *Shape and Arrangement of Wards.*—It is now generally agreed that wards should have windows on at least two opposite sides, and three main shapes have been proposed, viz., (*a*) long wards with windows down each side, and (generally) one at the further end; (*b*) wards nearly square, with windows on three sides; and (*c*) circular wards, with windows all round. The first (*a*) is the form usually adopted in pavilions; (*b*) is recommended by Dr Folsom (*Plans for the Johns Hopkins Hospital*); and (*c*) has been suggested by Mr John Marshall, F.R.S. (*Nat. Assoc. for Promotion of Social Science*, 1878). Of these (*b*) seems the least to be commended, and (*c*) has not yet been tried in practice; we may therefore confine our attention to the long or oblong wards. The length is to be determined chiefly by the number of patients to be accommodated, but the breadth admits of less variation. Each bed should be a little distance, say from 8 inches to 1 foot from the wall, and each bed may be reckoned as 6½ feet long; this gives 7½ feet on each side. Between the ends of the beds about 10 feet space is necessary, so that 25 or 26 feet of total breadth may be taken as a favourable width. The wards of the Herbert Hospital are 26 feet; but some exceed this, as, for instance, St Thomas's, London, and the New Royal Infirmary, Edinburgh, 28; New Hôtel-Dieu, 29; and Lariboisière, 30. There seems no necessity for exceeding 26, but if the breadth be greater there ought to be more window-space,—the great difficulty being to get a wide space thoroughly ventilated. There ought to be only two rows of beds, one down each wall, with if possible a window to each bed, and never less than one to every two beds.

5. *Ventilation, Warming, and Lighting.*—For ventilation two things are required,—sufficient space and sufficiently frequent change or renewal of air. As regards space, this must be considered

with reference both to total space and to lateral or floor space. Unless a minimum of floor space be laid down, we shall always be in danger of overcrowding, for cubic space may be supplied vertically with little or no advantage to the occupier. If we allow a minimum distance of 4 feet between the beds and 10 feet between the ends of the beds, this gives 100 square feet of space per bed ; less than this is undesirable. In severe surgical cases, fever cases, and the like, a much larger space is required ; and in the Edinburgh New Infirmary 150 square feet is allowed. Cubic space must be regulated by the means of ventilation ; we can rarely change the air oftener than three times an hour, and therefore the space ought to be at least one-third of the hourly supply. This ought not to be less than 4000 cubic feet per bed, even in ordinary cases of sickness,—and the third of that is 1333 cubic feet of space. With 100 square feet of floor space a ward of 13½ feet high would supply this amount, and there is but little to be gained by raising the ceiling higher,—ndeed, 12 feet is practically enough. The experiments of Drs Cowles and Wood of Boston (see *Report of State Board of Health of Massachusetts* for 1879) show that above 12 feet there is little or no movement in the air except towards the outlet ventilator; the space above is therefore of little value as ventilation space. Additional height adds also to the cost of construction, increases the expense of warming, makes cleaning more difficult, and to some extent hampers ventilation. Whatever be the height of wards, the windows must reach to the ceiling, or there must be ventilators in the ceiling or at the top of the side walls. If this be not arranged for a mass of foul air is apt to stagnate near the ceiling, and sooner or later to be driven down upon the inmates. The reasons for a large and constant renewal of air are of course the immediate removal and dilution of the organic matter given off by the inmates ; and, as this is greater in quantity and more offensive and dangerous in sickness than in health, the change of air in the former case must be greater than in the latter. Hence in serious cases an amount of air practically unlimited is desirable,—the aim of true ventilation being to approach as near as possible to the condition of pure external air. Without going too much into details, a few general rules may be laid down :—(1) Fresh air ought if possible to be brought in at the lowest part of the ward, warmed if necessary; (2) foul air ought to be taken out at the highest part of the ward ; (3) fresh air should reach each patient without passing over the bed of any other ; (4) the vitiated air should be removed from each patient without passing over the bed of any other ; (5) 4000 cubic feet of fresh air per head per hour should be the minimum in ordinary cases of sickness, to be increased without limit in severer cases ; (6) the air should move in no part of a ward at a greater rate than 1½ feet per second, except at the point of entry, where it should not exceed 5 feet per second, and at the outlet, where the rate may be somewhat higher ; about 64 square inches of inlet and outlet sectional area ought to be supplied per head as a minimum ; (7) every opportunity ought to be taken of freely flushing the wards with air, by means of open windows, when this can be done with safety.

Warming is a question of great importance in most climates, especially in such a climate as ours, where every system of ventilation must involve either the warming of some portion of the incoming air, or the contriving its delivery without too great lowering of temperature ; at the same time it cannot be too strongly insisted upon that the tendency is too much in the direction of allowing warmth to supersede freshness of air. There are very few cases of disease (if any) that are not more injured by foul air than by low temperature ; and in the zymotic diseases, such as typhus, enteric fever, small-pox, &c., satisfactory results have been obtained even in winter weather by almost open-air treatment. At the same time a reasonable warmth is desirable on all grounds if it can be obtained without sacrificing purity of atmosphere. For all practical purposes 60° to 63° F. is quite sufficient, and surgical and lying-in cases do well in lower temperatures. Various plans of warming have been recommended, but probably a combination is the best. It is unadvisable to do away altogether with radiant heat, although it is not always possible to supply sufficient warmth with open fireplaces alone. A portion of the air may be warmed by being passed over a heating apparatus before it enters the ward, by having an air chamber round the fire-place or stove, or by the use of hot-water pipes in the ward itself. In each case, however, the air must be supplied independently to each ward, so that no general system of ventilation is applicable.

The lighting of wards at night will be most conveniently done by means of gas, in the form of a jet over each bed, with a special ventilator to carry off combustion products, as in the Edinburgh New Infirmary.

6. *Furniture of Wards.*—This should be simple, clean, and non-absorbent; the bedsteads of iron, mattresses hair, laid on spring bottoms without sacking. No curtains should be permitted.

7. *Water.*—The water-supply ought to be on the constant system, and plentiful ; 50 gallons per head per diem may be taken as a fair minimum estimate.

8. *Closets, Baths,* &c.—The closets ought to be of the simplest construction, the pans of earthenware all in one piece, the flushing arrangements moved by opening the door,—the supply of water ample. Each ward should have its own closets, lavatories, &c., built in small annexes, with a cross-ventilated vestibule separating them from the ward. All the pipes should be disconnected from the drains, the closets by intercepting traps, the sink and waste pipes by being made to pour their contents over trapped gratings. The soil pipes should be ventilated, and placed outside the walls, protected as may be necessary from frost. Each ward should have a movable bath which can be wheeled to the patient's bedside.

9. Each ward should have attached to it a room for the nurse from which she can look into the ward, a small kitchen for any special cooking that may be required, a room for the physician or surgeon, and generally a room with one or two separate beds. No cooking should be done in the wards, nor ought washing, airing, or drying of linen to be allowed there.

10. *Nursing.*—The arrangements for nursing the sick have greatly improved in recent times, although controversy still goes on as to the best method of carrying it out. In arranging for the nursing in a hospital both efficiency and economy have to be considered. Miss Nightingale recommends large wards of 32 beds each, as at the Herbert Hospital, on the ground that one head-nurse is sufficient for such a number by day and one nurse by night. In the Edinburgh New Infirmary the wards are not so large, the medical being arranged for 21, and the surgical for 14 patients. Circumstances must to a large extent determine the arrangement, but it seems desirable on the whole that the work of a nurse should be confined to a single ward at a time if possible. The duties of nurses ought also to be distinctly confined to attendance on the sick, and no menial work, such as scrubbing floors and the like, should be demanded of them ; a proper staff of servants ought to be employed for such purposes. It is also desirable that a separate pavilion for lodging the nurses should be set apart, and that fair and reasonable time for rest and recreation should be allowed. Some discussion has taken place as to the advisability of placing the nursing of a hospital in the hands of a sisterhood or separate corporation. It will, however, be admitted that the best plan is for the nursing staff of each hospital to be special and under one head within the establishment itself, even although it may be connected with some main institution outside. The nursing must of course be carried on in accordance with the directions and treatment of the physicians and surgeons.

11. The kitchen, laundry, dispensary, and other offices must be in a separate pavilion or pavilions, away from the wards, but within convenient access.

12. A separate pavilion for isolation of infectious cases is desirable. This may be a wooden hut, or in some cases even a tent ; either is probably preferable to a permanent block of building.

13. A *Disinfecting Chamber* ought to be provided, where heat can be applied to clothes and bedding, for the destruction both of vermin and of the germs of disease. It is advisable to expose all bedding and clothing to its influence after each occasion of wear. Although this may entail additional expense from deterioration of fabric, it is worth the outlay to secure immunity from disease. This plan is rigidly followed at the Royal South Hants Infirmary at Southampton.

14. It is of great importance that the wards should be periodically emptied, and kept unoccupied for not less than one month in each year, and longer if possible. During such period thorough cleansing and flushing with air could be carried out, so as to prevent any continuous deposit of organic matter.

Up to quite lately hospital accommodation was confined to the larger towns, but the desirability of having it more accessible in smaller towns and villages has made itself more and more felt. Accordingly in many places *cottage hospitals* have been established with advantage. One great advantage of the pavilion system is that the principles of its construction and arrangements are equally applicable to large and small establishments, so that we may either look upon a large hospital as an extension of a cottage hospital, or upon a small one as a section of a pavilion one. The importance of increased accommodation for the reception of infectious cases is now very generally acknowledged, as shown not only by the establishment of the Metropolitan Asylums Hospitals, but also of others in various parts of the country. In some instances they have apparently been the means of arresting the spread of disease and protecting the locality from epidemics.

Paying Hospitals, Pay-Wards, Provident Dispensaries.—The general object for which hospitals have been established may be stated to be the gratuitous medical and surgical treatment of the indigent sick. Many abuses have, however, crept in, and large numbers of persons yearly receive medical treatment gratuitously who are quite able to pay for it. The numbers have been stated at one in four in London and one in two in Liverpool of the entire population. To obviate this evil the establishment of paying institutions has been much recommended. There is a large class above the very poor who are but ill able to afford the most skilled attendance and nursing at their own homes, which in most cases do not supply the accommodation necessary for sickness. It is not desirable, nor is it always their own wish, that those persons should be objects of charity, and the establishment of hospitals and dispensaries at which they could contribute something towards the expense of their treatment and attendance would meet the difficulty to some extent. Numerous arrangements of the kind are to be found on the continent of Europe, in America, and in the British colonies. Attempts have recently been made to introduce the system into England, and it is highly desirable that it should be accomplished, if it can be done with fairness to all concerned.

Administration.—In the civil hospitals of Britain this is usually carried on by a body of governors, who are either specially appointed or are benefactors of the institution. From them an executive committee is chosen, or the executive power may be vested in a single official, often the treasurer. A secretary or superintendent is usually charged with the financial and general management of the affairs of the hospital, whilst an apothecary superintends the pharmaceutic department. The treatment of the sick is of course entirely in the hands of the physicians and surgeons, whose appointments are for the most part honorary, in the sense of being unpaid, and under whom resident medical officers act. The medical staff ought always to be represented on the governing body as a means of preventing unnecessary friction. The appointment seems desirable in every hospital of a sanitary officer, whose duty it should be to watch and supervise the carrying out of every detail of ventilation, warming, cleanliness, disinfection, &c.

On the Continent hospitals are more directly under state control, and their arrangement is therefore considerably modified.

Naval and Military Hospitals.—These are provided in all civilized countries for the care of the sailors and soldiers of the state. The two great English hospitals of Greenwich and Chelsea were founded as asylums for disabled and superannuated sailors and soldiers, but the former is now given up for that purpose, although a part is appropriated as a hospital for sick merchant seamen of all nations. The chief naval hospitals are those of Haslar, Plymouth, and Chatham. Haslar is the largest hospital in the country, having been originally intended for 2000 sick, and even now, with increased allowance of space per bed, accommodating 1500 patients. There are also hospitals in most of the principal naval stations abroad, such as Malta, Jamaica, Halifax, Hong-Kong, &c. The principal military hospitals are the Royal Victoria Hospital at Netley (the invaliding hospital of the army and the locality of the army medical school), the Herbert Hospital at Woolwich, the Cambridge Hospital at Aldershott, and numerous others at the principal stations. The cubic space allotted by regulation is 1200 cubic feet at home and 1500 to 2000 cubic feet in the tropics per bed. Formerly every regiment of cavalry and infantry and each battery or troop of artillery had its own hospital, but this plan is now given up, and station hospitals with a fixed staff are being arranged at the chief centres of military districts. In both the army and the navy the regulations place the administration and command of hospitals in the hands of the respective medical departments; in the army this is as yet only partially carried out, but it has been accomplished in the navy with the advantage of both efficiency and economy. In time of war general hospitals are established at the base of operations, whilst field hospitals move with the troops as the campaign progresses.

In France there have long been hospitals established for the navy, such as those at Rochefort, Toulon, Brest, &c., as well as schools of instruction for medical officers. The chief military hospital is the Val de Grâce at Paris, formerly a convent; it is there that the medical school for the army is located. Large hospitals are also established in all the great stations. Great attention to military hospitals is also paid in Germany, Austria, and other countries of Europe. In most of them the administration is in the hands of the medical department, except in France, where the intendance still holds the reins, much to the disadvantage of efficiency and good working.

In the United States of America the army is small and chiefly employed on frontier duties, so that the hospitals are all what are called post hospitals, and as a rule are wooden huts or temporary structures, built to last ten years, and to hold 12 to 24 beds. There are, however, two permanent hospitals, one for cadets at West Point, and the other, the Barnes Hospital, at the Soldier's Home near Washington. All the arrangements are under the army medical department. The navy and the mercantile marine were long amalgamated in America, so far as hospital arrangements went. The Marine Hospital Service was formed in 1798, and the navy was not separated from it until 1811, although it was not for some years after that special naval hospitals were built. In connexion with the marine hospital service, hospitals have been established at a great number of ports, both sea, river, and lake. Up to 1870 each of these hospitals had its own organization, but since that time a regular service has been established under a supervising surgeon-general. A tax of 40 cents a month is levied for the service upon all seamen or members whatsoever of a ship's company. One of the finest hospitals is the Mercantile Marine Hospital at Chicago, a pavilion building of several stories, and of considerable architectural pretensions. But in America, as in Europe, the tendency has latterly been to abandon such monumental hospitals, and to construct single-storied pavilions on the hut or "barrack" principle,—the word barrack being employed in this sense as equivalent to the French *baraque*, a wooden hut. Accordingly the new marine hospital at San Francisco has been thus constructed, three one-storied pavilions of Californian redwood radiating from the outside of a curved corridor, from the ends and inner centre of which project the administrative blocks. The cost is about £120 ($600) per bed, whereas the average cost of the older ones was fully seven times that amount, with the drawback that in course of time they became extremely unhealthy, and showed all the evils of hospitalism.

A brief notice may be added here of the history of hospital construction in recent times, particularly with reference to the pavilion system. It is to France that we must look for the commencement of that system, although it has been carried out with even greater success in other countries. Its origin may be traced to the discussions which arose from time to time as to the advisability of reconstructing the Hôtel-Dieu at Paris. So long ago as the 17th century, Desgodets, architect to Louis XIV., presented a plan for reconstructing the hospital in "rayons." But it was after the fire that took place in 1772 that the question was taken up with real interest. In 1773 it was proposed to transfer the hospital to the plain of Grenelle, and in 1774 M. Petit proposed a radiating building of four stories at the base of the hill of Belleville (probably at no great distance from the existing hospital of Ménilmontant). M. le Roi presented a plan for a hospital at Chaillot, consisting of long single-story pavilions, arranged alternately, with the roof open at intervals,—each patient to be screened off by partitions. Finally, the committee of the Académie des Sciences reported favourably in 1788 on a proposal of M. Poyet's to construct a hospital on the Ile des Cygnes (between Grenelle and Passy), consisting of isolated pavilions radiating from a central rotunda, the hospital to hold 5000 patients,—each pavilion to be 115 feet long, by 24 broad and 14 to 15 high, to contain 34 to 36 patients, and to have windows to the ceiling. These proportions would give 77 to 80 square feet of floor space, 6½ to 6¾ feet of wall space, and 1080 to 1200 cubic feet of total space, an immense advance upon then existing arrangements. The Revolution put a stop to those projects, and half a century elapsed before a pavilion building, as now understood, was actually constructed. Curiously enough, revolution again stepped in to arrest the movement, for the first building of the kind, the Hôpital Louis-Philippe, was begun in the last years of that monarch's reign, and suspended in consequence of the revolution of February 1848. Some years later, in 1854, it was completed and renamed Lariboisière, from the name of the benefactress whose munificence helped to bring it to a successful conclusion. The building is oblong, enclosing a space in the centre, the front (south end) containing the administration, and the opposite (north) end the chapel, kitchens, &c. From the two sides the pavilion wards jut out. The building is on the whole not a good one; the distance between the pavilions is only half what is required, and the wards are frequently overcrowded. Unfortunately most of the defects, with some additional ones, have been reproduced in the new Hôtel-Dieu. The new hospital at Ménilmontant, in the north-east of Paris, is also a pavilion one, differing somewhat in detail, but of great size, each pavilion having numerous stories. The military hospital at Vincennes is a good specimen of modern construction. A small experimental pavilion, built on the suggestions of Dr Tarnier in the garden of the Maternité in Paris, merits notice. It consists of two stories, each containing four wards for one parturient woman each. The kitchen, office, &c., are in the centre, but the only access to each ward is by the verandah direct from the open air. The walls, floors, and ceilings are non-absorbent, and there is a space of 56 cubic metres, or nearly 2000 cubic feet for each inmate. The chief objection is that there are no means of ventilation except by the door or window;—otherwise the plan is excellent. This plan of making each ward open directly from the open air was proposed by the late Sir James Simpson, as a means of improving the sanitary state of existing old hospitals. The plans of M. Tollet ought not to be passed unnoticed. In addition to the ordinary principles of pavilion construction, he insists upon the ogival or Gothic form of architecture, which he thinks was adopted in the Middle Ages as much for sanitary as for architectural reasons.

In England the question of hospital improvement slept until the disasters at Scutari, in 1854–55, roused the attention of the Government and the public to the necessities of the case, and the report of the Army Sanitary Commission and of the Barrack and Hospital Committee, and Miss Nightingale's *Notes on Hospitals*, led the way in advocating hospital reform. Unfortunately just before this movement the plans of Netley Hospital were made, and the building begun on the corridor system. Efforts were made to arrest its progress, but unhappily without effect, and the country which has led the van in sanitary science has as its chief military hospital a building far from satisfactory. The first pavilion hospital in England was the Blackburn Infirmary, built rather more than twenty years ago. The pavilions are there at right angles to a centre corridor, and are alternate; a similar arrangement is followed out at the Children's Hospital at Pendlebury, near Manchester. St Thomas's at Westminster Bridge consists of a row of parallel pavilions united by a corridor at one end. A plan practically identical was proposed for a new hospital at Valetta (Malta), but this building, though frequently referred to in books, has never been constructed. The Herbert Hospital at Woolwich consists of parallel pavilions jutting out from the sides of a centre corridor at right angles; although it is now nearly twenty years old, it is still one of the best examples of a pavilion hospital. The latest pavilion hospital is the New Royal Infirmary at Edinburgh, to which reference has already been made. Every care seems to have been bestowed on its construction and arrangement; the space allowed per head is ample and the site excellent.

In Germany the Friedrichshain Hospital at Berlin is one of the best specimens of a pavilion building. The pavilions are 160 feet apart, six two-storied and four one-storied, with isolation wards and the necessary administrative buildings. The hut hospital erected during the late war at Tempelhof near the same city was a good example of how the pavilion system may be indefinitely extended, the huts being placed in échelon in wide zigzag lines.

In America great attention has been paid to the question of hospitals, especially since its importance was so roughly thrust upon the country's notice in the great civil war of 1861–64. During that time numerous plans were tried, and among others the old plan of Petit, Poyet, &c., namely, radiating pavilions from a circular or oval centre, which contained the offices and administration. This plan was found not to be a good one, as it interfered with both lighting and ventilation. The earliest American hospital of any size was the Pennsylvanian Hospital of Philadelphia, which was begun in 1755, under the auspices of Dr Thomas Bond and Benjamin Franklin, and finished in 1805. It was also in Philadelphia that the first pavilion hospital of a permanent character was erected, the corner stone being laid in 1860; in it the pavilions are parallel, two stories besides basement and attics. The space allowed is ample, but the wards are too wide, nearly 31 feet. In New York there is a large amount of hospital accommodation—about 6000 beds, or about 1 in 1500 of the population. The New York Hospital new pavilions give 112 square feet of floor space and 1800 cubic feet of total space. The Roosevelt Hospital has somewhat the same dimensions, but with a much greater space for surgical patients. One peculiarity of arrangement in that building is that the closets are not at the end of the wards as usual, but in the centre, grouped round a central shaft which extends through all the stories, cellar and basement. In this the water and steam pipes are placed, as also the foul linen shafts; the closets are cleaned by a steam jet. This plan does not seem very commendable. The Massachusetts General Hospital at Boston is the oldest in America, except the Pennsylvania Hospital. Since 1872 four new pavilions have been built on peculiar plans: two are square, one containing one large ward for 20 patients, and the other divided into small rooms of 2 beds each, giving each about 97 feet of floor space and 1500 to 1850 feet of total space; the other two are oblong, divided into rows of single rooms, with a dividing corridor, something like an arrangement of prison cells. The floor space is about the same, with less height. The Johns Hopkins Hospital at Baltimore will be memorable for the care bestowed upon the consideration of its plans. The one finally adopted is on the pavilion principle, scattered over a wide space of ground.

HOSPITIUM. The power the Greeks possessed of travelling safely among other Greek states depended on the feeling which made hospitality a matter of religion, and looked on strangers as under the protection of Zeus Xenios. A stranger was received and protected during his stay. Violation of the duties of hospitality was likely to provoke the wrath of the gods; but it does not appear that anything beyond this religious sanction existed to guard the rights of a traveller. There is, however, no ground for the common statement that a stranger was *ipso facto* considered as an enemy. In truth he was a guest. The roads were all sacred; he who passed over them was the guest of the land; he found along their courses statues of the tutelary deity of the road, generally Hermes; and the offerings of food, &c., in front of these he was at liberty to appropriate. Hence the word ἕρμαιον was used in the sense of a lucky find. (See Curtius, "Griech. Wegebau," *Berlin Abhandl.*, 1854.) When the guest parted from his host he was often presented with gifts (ξένια), and sometimes a die (ἀστράγαλος) was broken between them. Each then took a part, a family connexion was established, and the broken die served as a symbol of recognition; thus the members of each family found in the other hosts and protectors in case of need. As the foreigner was not recognized by the law of the state in which he travelled, he could appear in a court of justice only through his host. Similar customs seem to have existed among the Italian races. In Rome there was a tie recognized by the law between host and guest, almost as strong as that which connected patron and client. Jupiter Hospitalis watched over the jus hospitii. As in Greece the connexion often became hereditary; and a tessera hospitalis was broken between the parties.

Besides this private connexion there was a custom according to which a state appointed among the citizens of another state one man called πρόξενος to protect any of their citizens travelling in his country. Sometimes an individual came forward voluntarily to perform these duties on behalf of another state (ἐθελοπρόξενος). Many cases occur where such an office was hereditary; thus the family of Callias at Athens were proxenoi of the Spartans. We find the office mentioned in a Corcyræan inscription dating probably from the 7th century B.C., and it continued to grow more important and frequent throughout Greek history. There is no proof that any direct emolument was ever attached to the office, while the expense and trouble entailed by it must often have been very great. Probably the honours which it brought with it were sufficient recompense. These consisted partly in the general respect and esteem paid to a proxenos, and partly in many more substantial honours conferred by special decree of the state whose representative he was, such as ἐπιγαμία, γῆς ἔγκτησις, ἀτέλεια, ἀσυλία, προεδρία, and sometimes full citizenship. Public hospitium seems also to have existed among the Italian races; but the circumstances of their history prevented it from becoming so important as in Greece.

HOTCH-POT (or HOTCH-POTCH, HODGE-PODGE), in law, is the name given to a rule of equity whereby a person, interested along with others in a common fund, and having already received something in the same interest, is required to surrender what has been so acquired into the common fund, on pain of being excluded from the distribution. The following is an old example given in Coke on Littleton:—"If a man seized of 30 acres of land in fee hath issue only two daughters, and he gives with one of them 10 acres in marriage to the man that marries her, and dies seized of the other 20; now she that is thus married, to gain her share of the rest of the land, must put her part given in marriage into hotch-pot; *i.e.*, she must refuse to take the profits thereof, and cause her land to be so mingled with the other that an equal division of the whole may be made between her and her sister, as if none had been given to her; and thus for her 10 acres she shall have 15, or otherwise the sister will have the 20." In the common law this seems to have been the only instance in which the rule was applied, and the reason assigned for it is that, inasmuch as daughters succeeding to lands take together as coparceners and not by primogeniture, the policy of the law is that the land in such cases should be equally divided. The law of hotch-pot applies only to lands descending in fee-simple. The same principle is noticed by Blackstone as applying in the customs of York and London to personal property. It is also expressly enacted in the Statute of Distributions (§ 5) that no child of the intestate, except his heir-at-law, who shall have any estate in land by the settlement of the intestate, or who shall be advanced by the intestate in his life time by pecuniary portion equal to the distributive shares of the other children, shall participate with them in the surplus; but if the estate so given to such child by way of advancement be not equivalent to their shares, then such part of the surplus as will make it equal shall be allotted to him. It has been decided that this provision applies only to advancements by *fathers*, on the ground that the rule was founded on the custom of London, which never affected a widow's personal estate. The heir-at-law is not required to bring any land which he has by descent or otherwise from the deceased into hotch-pot, but advancements made to him out of the personal property must be brought in. The same principle is to be found in the *collatio bonorum* of the Roman law: emancipated children, in order to share the inheritance of their father with the children unemancipated, were required to bring their property into the common fund. It is also found in the law of Scotland. "It seemeth," says Littleton, "that this word *hotch-pot* is in English a pudding; for in a pudding is not commonly put one thing alone, but one thing with other things together."

HOTHO, HEINRICH GUSTAV, was born at Berlin in 1802, and died in his native city on Christmas day 1873. He made a name for himself in Germany as an historian rather than as a critic of art. Yet he remained second to his contemporary Waagen in experience, grasp of subject matter, and subtlety of eye. Nor had he the good fortune which accompanied Waagen through life to find patrons and friends in all countries of Europe. No one could have foreseen that Hotho would one day be an authority on art. During boyhood he was affected for two years with blindness consequent on an attack of measles. But recovering his sight he studied so hard as to take his degree at Berlin in 1826. A year of travel spent in visiting Paris, London, and the Low Countries determined his vocation. He came home delighted with the treasures which he had seen, worked laboriously for a higher examination, and passed as "docent" in æsthetics and art history. In 1829 he was made professor at the university of Berlin. In 1833 Waagen accepted him as assistant in the museum of the Prussian capital; and in 1858, after the death of Schorn, he was promoted to the directorship of the print-room. This was Hotho's last step in life. When Waagen died he had hopes of succeeding him, but these hopes were disappointed, not because in this walk Hotho was unfitted for the duties he was ambitious of performing, but probably because his experience was not considered sufficiently extensive. During a long and busy life, in which his time was divided between literature and official duties, Hotho's ambition had always been to master the history of the schools of Germany and the Netherlands. Accordingly what he published was generally confined to those countries. In 1842–43 he gave to the world his account of German and Flemish painting. From 1853 to 1858 he revised and published anew a part of this work, which he called "the school of Hubert van Eyck, with his German precursors and contemporaries." His attempt later on to write a history of Christian painting overtasked his strength, and was far from finished when the last sickness fell on him. Hotho's name will be honourably remembered as that of an amiable and industrious man, earnest from the first in his effort to throw light on an obscure and recondite subject. His training unfortunately confined him to one section of the field in which art history is comprised, and his comparative ignorance of Italian painting was the cause why he did not climb the last step to which Waagen had been able to ascend.

HOTMAN, or HOTTOMAN, FRANÇOIS (1524–1590), one of the most learned of French civilians, and a brilliant publicist, was born at Paris in 1524, of a family which had come, in the days of his grandfather, from Silesia. His father a counsellor of the parliament of Paris, naturally hoped to see his eldest son his successor, and gave him a legal education at Orleans. After three years' study he was made a doctor of laws, and immediately began to practise at the Paris bar. But the quibbles of pleading soon disgusted him, and to his father's annoyance he turned to the calmer study of jurisprudence. At the age of twenty-two he was named public lecturer with Baudouin at Paris, and at once gained high repute. The fortitude of Anne Dubourg under torture roused his latent enthusiasm for the Reformed opinions; he at once gave up his career, and went in 1547 to Lyons, the outpost of Genevan theology, and thence to Geneva and Lausanne. At Lausanne he became professor of belles-lettres and history, and married a French refugee from Orleans; in 1550 we find him in high repute as a teacher at Strasburg, where he lectured for several years to large crowds of students. In 1560, in the beginning of the civil troubles, he attached himself to Antony of Navarre, and was trusted with delicate missions from the Huguenot chiefs to German princes; he even at one time carried credentials from Catherine de' Medici, and his speech at the Frankfort diet, which is extant, is "a model of eloquence and political shrewdness." After a while we find him professor at Valence, expounding the civil law with such success as to restore the failing credit of that university. Three years later he succeeded Cujas at Bourges; but the civil war drove him to Orleans for refuge, whence he was sent down to Blois to negotiate the peace of 1568. He returned to Bourges only to encounter another outbreak of war and another flight, this time to Sancerre, where in the tedium of the obstinate siege he composed his *Consolatio*, a striking work drawn from the Bible and St Augustine. The peace of 1570 restored him once more; but the St Bartholomew drove him away again; and with wife and family he fled to Geneva, turning his back for ever on his country. As he went he shot at Charles IX. a Parthian shaft in his celebrated *Franco-Gallia*, a treatise much censured by Catholics and Huguenots alike. It breathed the true spirit of research and of Huguenot independence and even republicanism; for it boldly appealed, in the very citadel of hereditary succession, from rights of blood to popular election, and declared that the French monarchy rested on that foundation; the use soon made of the book by the Jesuits in their pamphlet war against Henry IV. added to its unpopularity. At Geneva Hotman was appointed professor of Roman law, and taught in peace for six years; in 1579, however, the threatening approach of the duke of Savoy frightened him away to Basel. Thence the plague sent him to Montbéliard in 1582, where he lost his faithful wife. After making trial of Geneva once more, he again in 1589 fled to Basel, where he died in 1590, and was buried in the cathedral.

Hotman was a man of unfeigned piety, nor were his firm and lofty ideas on religion ever shaken; the purity of his home-life, his devotion to wife and family, his courageous endurance of poverty and trouble, made him one of the finer characters of his age. His very timidity and restlessness were but the results of a parent's anxiety for the safety of his children; the infinite horrors of unbridled war filled him with fears for them. It was his quick intelligence and passionate temperament that made him a wanderer, and even laid him open to the suspicion of cowardice. As an author, if not original, he certainly was not Scaliger's "vulgare ingenium." His criticism is sound and acute, his learning beyond question scholarly and legal, his Latinity admirable, even eloquent; he is one of the best writers of his age; and it is not to be urged severely against him that he cheated himself with that snare of clever and needy men, alchemy, and sought to achieve the transmutation of metals.

His chief works were—the *Anti-Tribonien* (1567), a treatise to show that French law could not be based on Justinian; the *Franco-Gallia* (1573), with the pamphlets in its defence; his *Controversia patrui et nepotis* (1585); his *Brutum Fulmen* (1585), against the bull of Pope Sixtus; the *Consolatio* (published in 1593); *A Treatise on the Eucharist* (1566); *A Life of Coligny* (1575), with many other works on law, history, politics, or classical scholarship. These are mostly forgotten; but in their day they placed Francis Hotman in the first rank among the learned and accomplished authors of France. A collection of his letters was published at Amsterdam in 1700.

HOT SPRINGS, a post village in Hot Springs county, Arkansas, United States, is situated on a tributary of the Washita river, 55 miles S.W. of Little Rock. It is much resorted to by strangers on account of its hot springs, which are about sixty in number, and together have a daily flow of about 500,000 gallons. They vary in temperature from 93° to 150° Fahr., and their beneficial effects depend chiefly upon external application. The principal diseases in which they are efficacious are affections of the skin, malarial fever, and rheumatism. The number of persons who make use of them is about 20,000 annually. The town is well supplied with hotels and churches. The population, which in 1870 was 1276, was 5179 in 1880.

HOTTENTOTS was the generic name given by Europeans to the native tribes inhabiting the southern extremity of Africa. Some early writers termed them Hodmadods or Hodmandods, and others Hot-nots and Ottentots—all corruptions of the same word. The common denomination adopted by themselves was Khoi-Khoin (men of men), or Quæ Quæ, Kwekhena, t'Kuhkeub, the forms varying according to the several dialects.

These aborigines, totally distinct as they were in their primitive state from all other African races, have been generally regarded as the most ancient inhabitants of the land. A little more than two centuries ago they were a numerous people, whose nomadic tribes or clans and families were spread over the territory now distinguished as the Cape Colony; and tradition, as well as the evidence afforded by names of places and surviving peculiarities of manners and language, points to their having in prehistoric times extended much further to the north-westward and eastward, where they have been supplanted by the Kaffre or Negro tribes. The freedom, security, and protection enjoyed by the Hottentots since the Cape of Good Hope became a portion of the British empire have in no small degree arrested the process of extermination of the race which was rapidly proceeding at the close of last century. When Sir John Barrow described their condition in 1798, he estimated their numbers at about 15,000 souls. In 1806 the official return gave a population of 9784 males and 10,642 females. In 1824 they had increased to 31,000. At the census of 1865 they numbered 81,589; and the census of 1875 gave the Hottentot population within the Cape Colony at 98,561. In the returns for the last-mentioned periods, however, the designation "Hottentot" has no doubt embraced many persons of mixed race. It is only at the mission stations or in their vicinity that any genuine descendants of the early tribes are now to be met with. Beyond the colonial borders, however, they are numerically strong. Dr Theophilus Hahn gives the following as an approximate statement of their numbers (amounting in all to nearly 17,000) in Great Namaqualand and Damaraland:—*Pure Namaquas*—Geikous, or Red Nation, 2500; Topnaars, 750; Kharo-oas, 300; Khogeis, 100; Ogeis, or Great Deaths, 800; Khau-goas, or Young Red Nation, 1000; Habobes, or Velschoendragers, 1800; Karagei-Khois, 800; Gaminus, or Bondlezwaarts, 2000; Gunungu, or Lowlanders, 200. *Namaqua Hottentots* or *Oerlaams*—Eicha-ais, or Afrikaaners, 800; Kowisis, 2500; Amas, 2000; Khauas, 700; Gei-Khauas, or Gobabis people, 600.

The pure Namaquas claim to be the aboriginal tribes, while the "Oerlaam" are the new-comers, or those who migrated across the Orange river from the southern part of Cape colony. The latter tribes and many of the former may be said to be in a semi-civilized state, and have in a great measure adopted the customs, habits, language, and pursuits of the colonists. Some are in good circumstances, rich in waggons, horses, cattle, and sheep; while others retain all the improvident, idle, nomadic habits of the aborigines.

The primitive character of the Hottentot or Khoi-Khoin has been greatly changed by their forced migrations, and their gradual adoption of the habits of civilized life. The best information as to their original manners and customs is therefore to be obtained from the descriptions given of them by the older writers. The observations of Kolben, who was a resident at the Cape in the early part of last century, are by far the most complete; and, although doubts have been thrown upon some of his statements, yet travellers and missionaries who have resided among the tribes in Great Namaqualand confirm and endorse the greater part of them.

All authorities agree in representing the natural disposition of the Hottentots as mild, placable, and ingenuous. Mutual affection was the greatest of their virtues. They held in contempt the man who could eat, drink, or smoke alone. They were hospitable to strangers; indeed, their munificence often left them scarcely anything for themselves. Another characteristic was indolence. While not deficient in talents or capacity, they seemed to lack the energy to call them into action. They did not, however, disdain to look after their cattle. Hunting they pursued for pleasure as well as sustenance, and when once aroused they were nimble and active, as well as bold and ardent. In personal appearance they were of a medium height, the females rather smaller than the men. Their bodies were slender but well proportioned, with small hands and feet. Their skin was of a leathery brown colour; their face oval, with prominent projecting cheekbones; eyes dark chestnut or black and wide apart; nose broad and thick and flat at the root; chin pointed, and mouth large, with thick turned-up lips. Their woolly hair grew in short thick curly tufts on their head, and the beard very scanty. The women, especially as they advanced in years, had flabby breasts hanging down low; abnormal developments of fat were somewhat common among them; and cases occurred of extraordinary elongation of the *labia minora* and of the *præputium clitoridis*.[1]

The dress of the men was very simple. A cloak or kaross, varying according to the fashion of the tribe, was usually thrown across the shoulders and a smaller one across the loins. Those of the chiefs or captains were usually of tiger or wild-cat skins, those of the commonalty of sheep skins. They wore the cloaks all the year round, turning the hairy side inward in winter and outward in summer; they slept in them at night, and when they died they were interred in them. They had suspended around their necks little bags or pouches, containing their knives, their pipes and tobacco or daccha (*Cannabis*, or hemp), and an amulet of burnt wood. On their arms were rings of ivory. When they drove their herds to pasture they wore sandals on their feet, and some of them carried a jackal's tail fastened on a stick to wipe their face with when heated and drive away the flies. The women also wore karosses, a lesser under a greater, fashioned much like those of the men, but with the addition of a little apron, to which were appended their ornaments. In a leather bag suspended round their neck they carried daily, whether at home or abroad, some victuals, together with their daccha, tobacco, and pipe. They also wore an ornamented skin cap on their heads, armlets of iron or copper on their arms, strings of beads round their wrists, and round their legs thongs of ox-hide sometimes covering half the leg or more.

They loved to besmear their bodies and their dress with greasy substances. The wealthy Hottentots were very lavish in the matter of butter and fat, the use of which was the grand distinction between rich and poor. They also perfumed themselves with the powdered leaves of a shrub called by them bucchu (*Diosma crenata*). An ointment formed of soot and grease and the powder of bucchu was held in very high estimation.

The sites of their villages or kraals were usually on green meadow grounds. They never entirely exhausted the grass or herbage, but kept moving at intervals from one spot to another. The huts or tents, which they could strike, carry, or pitch where they chose, were ranged in circles, the area of which varied with the pastoral wealth of the community. The small cattle were placed inside the circle, and the larger cattle outside. In the centre of the huts a hole served for a fire-place, around which the members of the family were fond of squatting upon their haunches while they passed the tobacco pipe from one to another. On each side of the hearth small excavations an inch or two deep were made in the ground, and thereon mats were spread upon which the men, women, and children rolled up in their karosses lay down and slept. Their household effects consisted only of some earthen vessels for cookery, tortoise shells for spoons and dishes, and calabashes, bamboos, and skins for holding milk and butter. The weapons for hunting or warfare—the assegai, the bow and poisoned arrows, the shield, and the kerrie (a stick with a large knob at one end)—were also part of the furniture. Women were held in high repute: the most sacred oath a Khoi-Khoi could take was to swear by his sister or mother; yet the females ate apart from the men, and did all the work of the kraal. Their usual food consisted of milk, the flesh of the buffalo, hippopotamus, antelope, or other game, and edible roots and bulbs or wild fruits. Cows' milk was commonly drunk by both sexes, but ewes' milk only by the women, and when cows' milk was scarce the women were obliged to keep to ewes' milk or water. Meats were eaten either roasted or boiled, but for the most part half raw, without salt, spices, or bread. Some meats they carefully abstained from, such as swine's flesh. Hares and rabbits were forbidden to the men, but not to the women; while the pure blood of beasts and the flesh of the mole were forbidden to the women, but not to the men.

Their social pleasures consisted in feasting, smoking, dancing, and singing. Every signal event of life, and every change of abode and condition was celebrated with a feast. On the formation of a new kraal an arbour was constructed in the centre, and the women and children adorned and perfumed it with flowers and branches of trees and odoriferous herbs. The fattened ox was killed and cooked, and the men partook of it in the arbour, while the women sitting apart regaled themselves with broth. Upon such occasions they indulged in no other intoxication than what arose from their smoking tobacco or daccha.

Circumcision, which is common to the Kaffre tribes, was unknown to them, but when a youth entered upon manhood a particular ceremony was performed. One of the elders or officiating priests, using a knife of sharp quartz, made incisions on the young man's body, and afterwards besprinkled the same with urine. When a man for the first time distinguished himself by killing an elephant, hippopotamus, or rhinoceros, similar marks were made on his body, and were regarded as insignia of honour. There was no purchase of wives, but in every case of marriage the consent of the parents had to be first obtained. If his proposals were accepted, the suitor accompanied by all his kindred drove two or three fat oxen to the house from which he was to take his destined bride. There her assembled relations received them with kindly greetings and caresses; the oxen were then immediately slain, and

[1] See paper by Messrs Flower and Murie in *Journ. Comp. Anat. and Physiology*, 1867; and Fritsch, *Die Eingebornen Süd-Afrikas*, Breslau, 1873.

every one participated in the bridal feast. The nuptial ceremony was concluded by the priest besprinkling the happy pair. Among the colonial Hottentots these ancient usages have long been set aside; but they are still continued among some of the surviving tribes north of the Orange river. Polygamy was practised, but not to any great extent. Divorce was much more common. Family names were perpetuated in a peculiar manner—the sons took the family name of the mother, while the daughters took that of the father. Thus if the father's and mother's names were respectively Hagub and Daimūs, the sons would be called, according to their age, Daimūb geib (big one), Daimūb ! naga mab (of lower standing), and Daimūb ‡ Kham (younger); and the daughters, Hagu-geis (eldest), Hagu ! nagamas (second), and Hagu ‡ Khams (younger). The children were very respectful to their parents, by whom they were kindly and affectionately treated. Yet the superannuated or aged father or mother was sometimes exposed and left to die. Namaquas say this was done by very poor people if they had no food for their parents. But even when there was food enough, aged persons, especially women, who were believed to be possessed of the evil spirit or devil were placed in an enclosure of bushes with some meat and water, intended to be their last nourishment.

The Hottentots had neither warlike nor pastoral songs, and their musical instruments were but few and simple. One named the "gorah" was formed by stretching a piece of the twisted entrails of a sheep along a thin hollow stick about three feet in length in the manner of a bow and string. At one end there was a piece of quill fixed into the stick, to which the mouth was applied, and the tones were produced by inspiration and respiration. Another, the "ramkee," was constructed on the same principle as a guitar, with three or four strings stretched over a piece of hollow wood. The "rommel-pot" was a kind of drum. Reeds several feet long were likewise made use of as flutes.[1]

The system of government was patriarchal. Each tribe had its hereditary "khu-khoi" or "gao-ao" or chief, and each kraal or encampment its captain. These met in council whenever any great matters affecting the privileges of the people had to be decided. They had no salary, but their persons were held in great reverence, and they were installed in office with solemnities and feasting. In certain tribes the hind part of every bullock which was slaughtered was sent to the chief, and this he distributed among the males of the village. He also collected sufficient milk at the door of his hut to deal out amongst the poor. A part of every animal taken in hunting was exacted by the chief, even though it was in a state of putrefaction when brought to him.

The captains assisted by the men of each kraal attended to the settlement of disputes regarding property and to the trial of criminals. A murderer was beaten or stoned to death; but if one escaped and was at large for a whole year, he was allowed to go unpunished. Adultery seldom occurred; if any one found parties in the act and killed them he was no murderer, but on the contrary received praise for his deed. Women found offending were burnt. Theft, especially cattle-stealing, was severely punished.[2]

The religious ideas of the Hottentots were very obscure. Vaillant says they had "neither priests nor temples, nor idols, nor ceremonials, nor any traces of the notion of a deity." Kolben, Tachart, and others, however, assure us that they believed in an invisible deity or "Great Captain," whom they named Tik-guoa (*Tsu-goab*), a good man who did them no harm, and of whom therefore they need not be afraid. They also spoke of other captains of less power, and of a black captain named Gauna, who was the spirit of evil. The moon was a secondary divinity, supposed to have the disposal of the weather; and on each occasion of the appearance of the crescent moon in the sky they assembled from night till morning, dancing, clapping hands, and singing their hymns.[3] Schmidt, the first missionary to the Hottentots, says they also celebrated the anniversary of the appearance of the Pleiades above the eastern horizon. Hahn states that at the present day the Topnaars of Sandwich Harbour and of the ! Khomab mountains worship a being whom they name Tusib, the rain god. He also reports that he heard an old Namaqua saying, "The stars are the souls of the deceased," and mentions a form of imprecation, "Thou happy one, may misfortune fall on thee from the star of my grandfather."

Their notion of the supreme being and their relations to a life hereafter also took the form of ancestor-worship. The deified hero was named *Heitsi-Eibib*; and of him endless stories are told. The one most generally accepted is that he was a notable warrior of great physical strength, who once ruled the Khoi-Khoin, and that in a desperate struggle with one of his enemies, whom he finally overcame, he received a wound in the knee, from which event he got the name of "the wounded knee." He was held in high repute for extraordinary powers during life, and after death he continued to be invoked as one who could still relieve and protect. According to the tradition still preserved among the Namaquas, Heitsi-Eibib came from the east. Therefore they make the doors of their huts towards the east, and those who possess waggons and carts put their vehicles alongside the mat-house with the front turned towards the east. All the graves are in true west-easterly direction, so that the face of the deceased looks towards the east. The spirit of Heitsi-Eibib is supposed to exist in the old burial places, and, whenever a heathen Hottentot passes them, he throws stones on the spot as an offering, at the same time invoking the spirit's blessing and protection. Hahn asserts that there are many proofs which justify the conclusion that, to the minds of the Khoi-Khoin, Heitsi-Eibib and Tsu-goab (the supreme being) were identical. Both were higher powers who took great care of men. Both were believed to have died and risen again. They killed the bad beings and restored peace on earth; they promised men immortality, understood the secrets of nature, and could foretell the future. The Heitsi-Eibega are to be found all over South Africa.[4]

Various ceremonies were practised to ward off the evil influence of ghosts and spectres, and charms were freely

[1] These were always played at the reed-dance, which was commenced by a leader blowing on his reed, with head bent forwards, and stamping his feet violently on the ground to beat time. He was followed by the other musicians, who, forming a circle, also stooped forward and stamped. The women first ran round the circle of reed-players, clapping their hands and singing, and giving their bodies various odd twists. Then they got into the circle, and the men stamped and blew the reeds around them, and thus they continued frequently a whole night with but little interruption. On some occasions the performers described with appropriate action any incident of late occurrence, and in doing so the utmost poetical licence, as well as perfect freedom of speech, was permitted.

[2] The thief was bound hand and foot, and left on the ground without food for a long time; then, if his offence was slight, he received some blows with a kerrie or stick, but if the case was an aggravated one, he was severely beaten, and then unloosed and banished from the kraal. The family of even the worst criminal suffered nothing on his account in reputation, privilege, or property.

[3] An interesting notice of this form of worship occurs in the journal of an expedition which the Dutch governor, Ryk van Tulbagh, sent to the Great Namaquas in 1752, which reached as far as the Kamob or Lion river (about 27° S. lat.).

[4] On the religion and antiquities see Hahn's papers, "Graves of the Heitsi-Eibib," in *Cape Monthly Magazine*, 1879, and "Der Hottentotische Zai-goab und der Griechische Zeus," in *Zeitschr. für Geogr.*, Berlin, 1870.

employed.[1] There was also a belief that in every fountain there was a snake, and that as long as the snake remained there water would continue to flow, but that if the snake was killed or left the fountain it would cease. Offerings were sometimes made to the spirit of the fountain. Like all people sunk in barbarism, the Hottentots had great faith in witch-doctors, or sorcerers. When called to a sick-bed, these ordered the patient to lie on his back, and then pinched, cuffed, and beat him all over until they expelled the illness. After that they produced a bone, small snake, frog, or other object which they pretended to have extracted from the patient's body. If the treatment did not prove efficacious, the person was declared bewitched beyond the power of any one to cure him. Sometimes a joint of a finger was cut off from the idea that the disease would thereby pass away. If death occurred, the corpse was interred on the day of decease. It was wrapt in skins, and placed in the ground in the same position it once occupied in the mother's womb. Death was generally regarded in a very stoical manner.

Language.

The Hottentot language was regarded by the early travellers and colonists as an uncouth and barbarous tongue. The Portuguese called the native manner of speaking stammering; and the Dutch compared it to the "gobbling of a turkey-cock." These phonetic characteristics arose from the common use of "clicks,"—sounds produced by applying the tongue to the teeth or to various parts of the gums or roof of the mouth, and suddenly jerking it back. Three-fourths of the syllabic elements of the language begin with these clicks, and combined with them are several hard and deep gutturals and nasal accompaniments. The difficulty a European has in acquiring an accurate pronunciation is not so much in producing the clicking sound singly as in following it immediately with another letter or syllable. The four recognized clicks, with the symbols generally adopted to denote them, are as follows:—Dental = | ; palatal = ǂ ; lateral = || ; cerebral = !. According to Tindall, one of the best grammarians of the language, the dental click (similar to a sound of surprise or indignation) is produced by pressing the top of the tongue against the upper front teeth, and then suddenly and forcibly withdrawing it. The palatal click (like the crack of a whip) is produced by pressing the tongue with as flat a surface as possible against the termination of the palate at the gums, so that the top of the tongue touches the upper front teeth and the back of the tongue lies towards the palate, and then forcibly withdrawing the tongue. The cerebral click (compared to the popping of the cork of a bottle of champagne) is produced by curling up the tip of the tongue against the roof of the palate, and withdrawing it suddenly and forcibly. The lateral click (similar to the sound used in stimulating a horse to action) is articulated by covering with the tongue the whole of the palate and producing the sound as far back as possible; European learners imitate it by placing the tongue against the side teeth and then withdrawing it. The easiest Hottentot clicks, the dental and cerebral, have been adopted by the Kaffres; and it is a striking circumstance, in evidence of the past Hottentot influence upon the Kaffre languages, that the clicking decreases amongst these tribes almost in proportion to their distance from the former Hottentot domain.

The language in its grammatical structure is beautiful and regular. Dr Bleek describes it as having the distinctive features of the suffix-pronominal order or higher form of languages, in which the pronouns are identical with and borrowed from the derivative suffixes of the nouns. The words are mostly monosyllables, always ending, with two exceptions, in a vowel or nasal sound. Among the consonants neither *l*, *f*, nor *v* are found. There are two *g*'s, *g* hard and *g* guttural, and a deeper guttural *kh*. Diphthongs abound. There is no article, but the definite or indefinite sense of a noun is determined by the gender. In the fullest known dialect (that spoken by the Namaqua) nouns are formed with eight different suffixes, which in nouns designating persons distinguish masc. sing. (*-b*), masc. plur. (*-ku*), masc. dual (*kha*), fem. sing. (*-s*), fem. plur. (*-ti*), com. sing. (*-i*), com. plur. (*-u*), com. dual (*-ra*). The adjective is either prefixed to a noun or referred to it by a suffixed pronoun. This grammatical division of the nouns according to gender led to the classification of the language as "sex-denoting," thus suggesting if not identifying its relationship, in original structure, with the North-African species of the same family, such as the Coptic and Old Egyptian, Galla, Berberic, Houssa, Ethiopic, and others.

There are four dialectical varieties of the language, each with well-marked characteristics:—the Nama dialect, spoken by the Namaqua as well as by the Hau-Koin or Hill Damaras, a supposed Bantu or negro people who in some past period were conquered and enslaved by the Namaquas; the Kora dialect, spoken by the Korannas, or Koraquas, dwelling about the middle and upper part of the Orange, Vaal, and Modder Rivers; the Eastern dialect, spoken by the Gona or Gonaquas on the borders of Kaffreland; and the Cape dialect, now no longer spoken but preserved in the records of early voyagers and settlers. Of these dialects the Nama is the purest. It is described in three grammars:—Wallmann's (1857) and Hahn's in German, and Tindall's (1871) in English, the last being the best; and the four Gospels, with a large amount of missionary literature, have been published in it. This dialect is commonly spoken by a native population of not less than 100,000 souls south and north of the Orange river, and in parts of Damaraland (or Hereroland) and the Kaokoveld.

The vocabulary is not limited merely to the expression of the rude conceptions that are characteristic of primitive races. It possesses such words as *koi*, human being; *khoi-si*, kindly or friendly; *koi-si-b*, philanthropist; *khoi-si-s*, humanity; ǂ *ei*, to think; ǂ *ei-s*, thought; *amo*, eternal; *amo-si-b*, eternity; *tsa*, to feel; *tsa-b*, feeling, sentiment; *tsa-kha*, to condole; *amu*, true; *ama-b*, the truth; *anu*, sacred; *anu-si-b*, holiness; *esa*, pretty; *anu-xa*, full of beauty.

Folkl

A considerable mass of floating traditionary literature—fables, myths, and legends—exists amongst the Khoi-Khoin,—a fact which was first made known by Sir James Alexander, who in his journeyings through Great Namaqualand in 1835 jotted down the stories told him around the camp fire by his Hottentot followers. Since then missionaries and officials stationed in the country have made collections of them, and the result has been an unlooked for mine of literary lore among a nation whose mental qualifications it was customary to regard as of a very low grade. These Hottentot tales generally have much of the character of fables; some are in many points identical with northern nursery tales, and suggestive of European origin or of contact with the white man; but the majority bear evidence of being true native products. Bleek's *Reynard the Fox in South Africa* (1864) contains a translation of a legend written down from the lips of the Namaquas by the Rev. G. Krönlein, which is regarded as an excellent specimen of the national style. Another legend relating to the moon and the hare conveys the idea of an early conception of the hope of immortality. It is found in various versions, and, like many other stories, occurs in Bushman as well as in Hottentot mythology.

Ethno- graphi relatio

The supposed affinity of the Hottentot with the North African nations was first guessed at by the Rev. Dr Moffat from the resemblance between the language of the Namaquas and that of some slaves in the market of Cairo. This relationship was afterwards suggested by the Rev. Dr James Adamson, of Cape Town, from the identity of the signs of gender in Namaqua and Coptic, and the appearance of persons of the Hottentot form and colour, with their grease and *sibilo* dye, among the representations on Nubian tombs. Then came Dr Bleek's philological researches, showing that the Hottentot language from the sexual gender of its nouns was one of the very extensive "sex-denoting" family which has spread itself over North Africa, Europe, and part of Asia, and that it moreover surpassed all the others in a faithful preservation of the primitive type. This association of the language of the people of South Africa with that of their northern cousins promised to solve the problem of their pedigree and ancestry, for it at once suggested and implied early migrations of Hottentot and Bushmen from their primal home, and the intrusion upon them at some time or other of the Bantu or negroid tribes, who probably came from the west and drove the Hottentots on the eastern side of Africa southward before them. But the assumed kinship of the Old Egyptians and Hottentots has been disputed by other eminent authorities, such as Von Gabelentz, Pott, Fr. Müller, and Hahn, who have pronounced against it on ethnological and philological grounds. Hahn stoutly maintains that the Hottentots and Bushmen are but divisions of a single race—"the children of the same mother"—who formed the primeval inhabitants of the whole of South Africa as far as the Zambezi.[2]

Histor

The earliest accounts which we have of the Hottentots occur in the narratives of Vasco da Gama's first voyage to India round the Cape in 1497. They are described as small, of a brownish yellow complexion, and an ugly appearance; they freely bartered their sheep, but would not part with their cattle, on which the women

[1] If a Khoi-Khoi went out hunting his wife kindled a fire, and assiduously watched by it to keep it alive; if the fire should be extinguished her husband would not be lucky. If she did not make a fire, she went to the water and kept on throwing it about on the ground, believing that thereby her husband would be successful in getting game. Charms, consisting of bones, burnt wood, and roots of particular shrubs cut into small pieces, were generally worn round the neck.

[2] See the linguistic part of Dr Fr. Müller's work on the scientific results of the Novara expedition, and Hahn's contributions on the Hottentots in the *Proceedings* of the Geographical Society (Dresden, 1869) and in *Globus* (1870), and his *Sprache der Nama* (Leipsic, 1870).

rode with pack saddles. In 1509 the Portuguese viceroy, Francisco d'Almarda, count of Abrantes, met his death in a dispute with these natives; and down to the early part of the 17th century there was an idea that they were cannibals. Better knowledge was obtained after the Dutch East India Company took possession of the Cape in 1652. According to the accounts given by the early Dutch governors the Hottentots received the Europeans in a friendly manner. The Dutch upon their first settlement were not chargeable with cruelty or oppression to the natives. Their primary intention when they erected a fort and took possession of Table Valley was merely to secure supplies of water, cattle, and other fresh provisions for their passing fleets; and the only mode in which they could accomplish this object was by maintaining friendly relations with the aborigines. These relations continued until 1659, when a collision occurred which led to some bloodshed.

To prevent disputes about pasturage and cattle forays in the future, one of Van Riebeek's successors purchased in 1672, at the cost of goods about £10 value, from two of the Hottentot chiefs, who claimed to be hereditary sovereigns, all the country from the Cape peninsula to Saldanha Bay,—but on the condition that, where the colonists did not occupy the arable lands or pastures, the natives might erect their kraals and pasture their cattle freely.

During the years which followed, the European population, notwithstanding renewed hostilities in 1676 and 1677, considerably increased, and the settlement enlarged its boundaries, while the natives ejected from their former pastures retired upon their neighbours, and waged war among themselves. Simultaneously with the tribal disintegration and impoverishment which ensued, the occurrence of new and infectious diseases made sad havoc; and, while the tide of European occupation was gradually advancing inland from the south, a similar movement by the negro warrior tribes who have received the common appellation of Kaffres was taking place in the east, with the result that about the middle and the end of the last century the former inhabitants of the land were but occupants on sufferance. Straggling remnants still maintained their independence, living in small kraals or societies, but the mass of them voluntarily took service with the colonists as herdsmen, while others became hangers-on about the company's posts and grazing-farms, or roamed about the country. In 1787 the Dutch Government passed a law subjecting these wanderers to certain restrictions. They were required to have a residence, and were forbidden to change their place of abode without "passes" or certificates from the authorities or their masters. Another provision gave their employers the right to the services of their children from eight to eighteen years of age, if born on their estates. At the same time corporal punishment and confiscation of property were threatened against any colonist convicted of ill-treating Hottentots, or of forcibly separating them from their wives and children. The effect of these measures of restraint was to place the Hottentots in more immediate dependence upon the farmers, or to compel them to migrate to the northward beyond the colonial border. Those who chose the latter alternative had to encounter the hostility of their old foes, the Bushmen, who were widely spread over the plains from the Nieuwveld and Sneeuwberg mountains to the Orange river. The colonists also, pressing forward to those territories, came in contact with these aboriginal Ishmaelites,—their cattle and sheep, guarded only by a Hottentot herdsman, offering the strongest temptation to the Bushman. Reprisals followed; and the position became so desperate that the extermination of the Bushmen appeared to the Government the only safe alternative. "Commandoes" or military expeditions were sent out against them, and they were hunted down like wild beasts. Within a period of six years, it is said, upwards of 3000 were either killed or taken. In consequence of certain measures of restraint and conciliation insisted on by the authorities at a later period, the Boers rose in rebellion, and a state of anarchy ensued, which was prevalent when the British Government took possession of the Cape in 1795. No sooner was the English standard raised in the country than the Hottentots abandoned their former masters and joined the British troops, a step which helped to bring about the prompt submission of the Boer insurgents. Tranquillity being thus restored, the Hottentots, fearing to return to their Dutch masters on the withdrawal of the British troops, requested the Government to make some provision for them. This petition and appeal being neglected, many joined their barbarian neighbours, the Kaffres, and together with them fell suddenly upon the colonists all along the border and even as far westward as the district of George. It was not till 1800 that they were ultimately prevailed upon to deliver up their arms. The English governor of that day, General Francis Dundas, showed an earnest desire to do justice to the Hottentots. Such as were disposed to enlist were embodied in a militia corps named the Cape Regiment, afterwards known as the Cape Mounted Rifles.

The Hottentots were not rescued from their state of servitude, or released from the restraints and disabilities imposed upon them by the Dutch authorities until long after the British rule had been permanently established in South Africa. A proclamation issued in 1809 gave them a greater degree of security in their contracts of service with the colonists; and subsequent regulations provided for the better protection of their persons and property. But with the exception of those individuals who found asylums in the missionary institutions of the Moravian Brethren and of the London Missionary Society, or who served in the Cape regiment, they were still in the service of the farmers, subject to indentureship and to rigorous control in moving from place to place. At length in 1828 the representations of English philanthropists prevailed; a law was promulgated effectually emancipating the Hottentots and all free persons of colour from compulsory service and all other disabilities, and declaring them "to be in the most full and ample manner entitled to all and every right, benefit, and privilege to which any other British subjects within the colony were entitled."

Following upon this the Government adopted a measure allotting certain lands for the use of Hottentot families. A tract known as the Kat River Valley, from which the Kaffre chief Macomo had been expelled for his aggressions against the colony, was set apart for them. It was divided into locations, upon which villages were laid out, each family receiving a number of acres as their allotment for cultivation, and the pasturage being reserved for commonage. Numbers of Hottentots soon made their appearance and settled on the spot. Some were possessed of a quantity of live stock, which they had earned in the service of the farmers, or at the mission stations; but most of them owned no property. Those who had cattle assisted their poorer friends and relatives; those who had neither food nor friends lived upon "*veldkost*," *i.e.*, the wild roots and bulbs dug out of the ground until the land they had planted returned them a harvest. Within a few years they surmounted their first difficulties, and their progress and prosperity delighted the friends of the coloured race. Three or four years afterwards, however, they suffered a good deal from Kaffre aggressions, and in 1835 had to bear the brunt of the war, being exposed to the most determined attacks of the followers of Macomo and Tyali. They had scarcely recovered from the disasters then inflicted, when the outbreak of 1846 occurred, and all their able-bodied men had again to leave their homes and join the military encampments. When allowed to return to their locations, they found, like many other frontier inhabitants, the result of all their former labours destroyed; their houses had to be rebuilt, their lands to be cultivated, and their families to be fed. From this time a spirit of dissatisfaction crept in amongst them. They complained that while doing burgher duty they had not received the same treatment as others who were serving in defence of the colony, that they got no compensation for the losses they had sustained, and that they were in various ways made to feel they were a wronged and injured race. The location of a disloyal Kaffre, named Hermanus, with a number of disorderly followers in their neighbourhood, served to corrupt and estrange the feelings of many, and a secret combination was formed with the Kaffres to take up arms to sweep the Europeans away and establish a Hottentot republic. In 1851 about 900 of them broke out into rebellion, and their numbers were increased by deserters from the Hottentot regiment of Cape Mounted Rifles, and by several Hottentots in the service of the frontier farmers. A small body, however, remained loyal, and with the missionaries and the local magistrates withstood the rebels until military aid came to their relief. The Kat River population have since had a long period of peace and good government, and are now as loyal and happy as any subjects of the crown. (W. J. N.)

HOTTINGER, Johann Heinrich (1620–1667), a Swiss philologist and theologian, was born at Zurich, 10th March 1620. He studied at Ghent, Groningen, and Leyden, and after visiting England was in 1642 appointed professor of church history in his native town. To the duties of that chair those of Hebrew at the Carolinum were added in 1643, and in 1653 he was appointed ordinary professor of logic, rhetoric, and theology. Nothwithstanding this plurality of offices he found time to publish a number of pamphlets, chiefly on the original text of the Old Testament, which gained him such a reputation as an Oriental scholar that the elector palatine in 1655 appointed him professor of Oriental languages and biblical criticism at Heidelberg. In 1661 he, however, again returned to Zurich, where in 1662 he was chosen principal of the university. In 1667 he accepted an invitation to become professor in the university of Leyden; but on the journey thither he was drowned along with three of his children by the upsetting of a boat while crossing the river Limmath.

Hottinger was the author of a variety of learned theological works, the principal of which are *Historia ecclesiastica*, 9 vols., 1651–67; *Thesaurus philologicus seu clavis Scripturæ*, originally published in 1649; *Etymologicon orientale, sive Lexicon harmonicum heptaglotton*, 1661. He also wrote a Hebrew and a Chaldee grammar.

HOUBRAKEN, Jacobus (1698-1780), Dutch engraver, was born at Dort, December 25, 1698. All that his father, Arnold Houbraken, bequeathed to him was a fine constitution and a pure love for work. In 1707 he came to reside at Amsterdam, where for years he had to struggle incessantly against difficulties. He commenced the art of engraving by studying the works of Cornelis Cort, Suyderhoef, Edelinck, and the Visschers. He devoted himself almost entirely to portraiture, and as his reputation became known in and beyond the boundary of his country he soon found himself with commissions more than he could conveniently execute. Seeking happiness in the bosom of his family, and being temperate in his habits, he lived to an advanced age, and the work executed the last year of his life shows no failing of his power in the use of the burin. Among his best works are scenes from the comedy of *De Ontdekte Schijndeugd*, executed in his eightieth year, after Cornelis Troost, who was called by his countrymen the Dutch Hogarth, with, however, very small title to such a distinction. Houbraken died on the 14th of November 1780, having nearly completed his eighty-second year.

See A. Ver Hull, *Jacobus Houbraken et son Œuvre* Arnhem, 1875, where 120 engraved works are fully described.

HOUDON, Jean Antoine (1740-1828), was the most distinguished sculptor produced by France in the latter half of the 18th century. He was born at Versailles in 1740, and at the age of nineteen, having learnt all that he could from Michel Ange Slodtz and Pigalle, Houdon carried off the prix de Rome and left France for Italy, where he spent the next ten years of his life. His brilliant talent, which seems to have been formed by the influence of that world of statues with which Louis XIV. peopled the gardens of Versailles rather than by the lessons of his masters, delighted Clement XIV., who, on seeing the St Bruno executed by Houdon for the church of St Maria degli Angeli, said "he would speak, were it not that the rules of his order impose silence." In Italy Houdon had lived in the presence of that second Renaissance with which the name of Winckelmann is for ever associated, and the direct and simple treatment of the Morpheus which he sent to the Salon of 1771 bore witness to its influence. This work procured him his "agrégation" to the Academy of Painting and Sculpture, of which he was made a full member in 1775. Between these dates Houdon had not been idle; busts of Catharine II., Diderot, and Prince Galitzin were remarked at the Salon of 1773, and at that of 1775 he produced, not only his Morpheus in marble, but busts of Turgot, Gluck, and Sophie Arnould, together with his well-known marble relief, "Grive suspendue par les pattes." He took also an active part in the teaching of the academy, and executed for the instruction of his pupils the celebrated Écorché still in use. To every Salon Houdon was a chief contributor; most of the leading men of the day were his sitters; his busts of D'Alembert, Prince Henry of Prussia, Gerbier, Buffon (for Catharine of Russia), and Mirabeau are amongst the most remarkable portraits of modern times; and in 1778, when the news of Rousseau's death reached him, Houdon started at once for Ermenonville, and there took a cast of the dead man's face, from which he produced the grand and lifelike head at present in the Louvre. The celebrated draped statue of Voltaire, now in the vestibule of the Théâtre Français, was exhibited at the Salon of 1781, to which Houdon also sent a statue of Marshal de Tourville, commissioned by the king, and the Diana executed for Catharine II. This work was refused; the jury alleged that a statue of Diana demanded drapery; without drapery, they said, the goddess became a "suivante de Vénus," and not even the proud and frank chastity of the attitude and expression could save the Diana of Houdon (a bronze reproduction of which is now in the Louvre) from insult. Whether Houdon felt annoyance at this folly does not appear; but three years later he very readily accepted an invitation to go to America, there to carry out a statue of Washington. With Franklin, whose bust he had recently executed, Houdon left France in 1785, and, staying some time with Washington at Philadelphia, he modelled the bust, with which he decided to go back to Paris, there to complete the statue destined for the assembly hall of the State of Virginia. After his return to his native country Houdon executed for the king of Prussia, as a companion to a statue of Summer, La Frileuse, a naif embodiment of shivering cold, which is one of his best as well as one of his best-known works. The Revolution interrupted the busy flow of commissions, and Houdon took up a half-forgotten project for a statue of St Scholastica, which had long been put on one side in a corner of his studio. He was immediately denounced to the convention, and his life was only saved by his instant and ingenious adaptation of St Scholastica into an embodiment of Philosophy. Under Napoleon, Houdon received little employment; he was, however, commissioned to execute the colossal reliefs intended for the decoration of the column of the "Grand Army" at Boulogne (but which ultimately found a different destination); he also produced a statue of Cicero for the senate, and various busts, amongst which may be cited those of Marshal Ney, of Josephine, and of Napoleon himself, by whom Houdon was rewarded with the legion of honour. After the fall of the first empire Houdon suddenly aged; he lost his memory, and slept away the closing years of his life. He died at Paris in 1828.

The most striking characteristic of his work is the life by which it is animated, and which is the result of marvellous skill in execution and keenness in observation. He was, in all he did, great. His bust of Voltaire is deservedly one of the most famous in the whole range of modern sculpture, and his genial reading of Rousseau—a splendid yet brute virility tempered with the gift of tears—is a masterpiece of insight into character. But Houdon's power was no less triumphant in rendering the beauty of youth and the beauty of beautiful women. His Diana proved that he could penetrate the secret of an ideal of noble womanhood; his heads of young girls have been compared with the graceful children of his contemporary Greuze, but the innocent candour of Houdon's work is entirely free from the self-consciousness which disturbs the charm of La Cruche Cassée and her companions. Finally, Houdon cannot be claimed, like Greuze, as representing the popular tendencies of the society to which he belonged; for, whereas Greuze, like most men, bore the stamp of his time on all he did, Houdon was one of those rare spirits who, doing the work of their own time, set their own seal thereto.

HOUND. The foxhound, harrier, and beagle are now the only representatives of whatever varieties of hounds existed previously in England. The staghound proper is practically extinct, no pack of them having been kept since 1825, when the Devon and Somerset establishment was broken up and the pack sold. With the exception of Lord Wolverton's black St Huberts, all hounds now used for stag-hunting are simply those of the foxhound breed entered to deer instead of to fox. Most packs of staghounds are composed of hounds of the ordinary size, but it is said that the present master of the Devon and Somerset (1880) uses none under 25 inches, and excludes bitches altogether.

Foxhound

The modern English foxhound is about as near perfection as he can well be, and his excellence is all the more wonderful that less than 200 years ago there does not seem to have been in existence any hound bearing a resemblance to him; for, until fox-hunting by hounds kept for that especial purpose was instituted, there could have been no reason to breed foxhounds. According to old writers on hunting subjects, there appear to have been, amongst other varieties, the slow, plodding, southern hound, with a great square head and wondrous powers of working on a scent, and the lighter northern hound; and as all animals improve under the care and guidance of man, until they assume the character of a distinct breed, it is clear that such has been the case with foxhounds, the earlier breeders of which did their part towards the attainment of perfection, by breeding with much care and judgment from the best specimens at their disposal. Older breeders were satisfied if the result of their crossings possessed good noses, and were up to the standard of beauty of those days; but the time came, in the days of the great Meynell, when pace had to be added to the list of foxhound virtues, owing to the use of better bred horses in the hunting field, and at the present day the development of pace without sacrificing nose is one of the greatest difficulties a breeder has to contend with.

The mastership of a pack of foxhounds is an undertaking of great responsibility. In the article HUNTING mention is made of the difficulties which beset a master when he takes the field; but after all, the greatest exercise of judgment is called for in relation to the kennels, for upon the master, in conjunction to a greater or less extent with the huntsman or kennel huntsman, rests the responsibility of selecting suitable sires and dams for the young hounds he intends to breed; of drafting such hounds as it is thought desirable to part with owing to their being over or under sized, or possessed of some failing; and of obtaining drafts from other establishments. More than one opinion exists as to what is the proper size for a foxhound, but some of the greatest authorities having expressed their conviction that from 21 to 22 inches for bitches and from 23 to 24 inches for dogs is the proper standard, a master could hardly do wrong in adopting it. A hound's head should not be too large, nor, on the other hand, should it be too narrow, or else, like the greyhound, he will possess speed, but be deficient in nose. There was much truth in Mr Warde's remark, who, on overhearing a stranger finding fault with his hounds for having such large heads, said, "Their knowledge boxes (as he called them) are large, but size has this advantage, that when they once put their noses down to the ground they cannot get their heads up again." The neck should be neither too short nor throaty; that is to say, there should be no dewlap. The shoulder should slope like that of the horse, and there should be plenty of muscle in the arm. Below the knee a hound should be quite straight, and the distance should be short between the knee and the foot, which must be short and round like a cat's foot. So, too, with the hind legs; speed and strength alike call for great length from the hip to the hock, and as little as possible from the hock to the foot; the haunches or gaskins should be wide and well furnished with muscle. A flat-sided hound should be drafted at once, as he is sure to be a bad winded one; so should one that stands over at the knee when looked at sideways. How to combine all the good points in one hound requires no little judgment, but appearance is not all that must be thought of; the breeder must have an eye to nose, pace, stoutness, and the avoidance of certain faults in the field. In order to produce a good-looking puppy, dams and sires, perfect enough as regards make and shape, are often selected before they have taken the field long enough to have their good or bad points developed. Three years is quite early enough to begin to breed from any hound, male or female, and by that time it will be pretty well known what are the hunting capabilities of each. Out of every litter of whelps it may be necessary to destroy some,—four or five are quite enough for a mother to rear,—but a diversity of opinion exists amongst huntsmen as to which should be kept. As the points of a very young puppy cannot be seen, the selection is really one of colour; some men prefer light colours, others dark; the majority are in favour of the latter, light-coloured hounds and horses being popularly supposed to have weak constitutions and uncertain tempers.

When the puppies are three or four days old the dew-claws should be severed with a small and sharp pair of scissors, and after another day or two it is usual to cut off about an inch of the tail. Rounding is the last operation that foxhounds are subjected to, and generally takes place as soon as the puppy has quite recovered from the distemper; it consists in cutting off the ends of the ears so that they may not be torn in going through cover. When about ten or twelve weeks old puppies are sent out to walk, and are not again received at the kennel till the beginning of the following April, soon after which date the distemper may be looked for. At this crisis the great aim should be to keep the body in a healthy condition, and not to feed hounds too highly, whey and porridge only being given. After the return from walks, the huntsman and whips should give the young entry plenty of gentle exercise, at first in the couples; and nothing more need be done in the way of training until about eight or nine weeks before cubbing begins, when the young hounds, who should hitherto have been exercised by themselves, should be put into the company of some older ones, and the exercise should be gradually extended until they can keep up for 2 or 3 miles with a horse going at half speed. The first day or two of cub-hunting is certain to be a somewhat unsatisfactory performance; the young entry are sure to run riot; it cannot be helped at first, but they will soon learn better manners under the watchful eyes of the huntsman and whips, and in company of the old hounds, about a dozen of the latter being taken out with twice that number of young ones. The sooner the puppies taste blood the better; it will help to teach them to stick to their proper game. Huntsmen therefore make every effort to bring a brace of cubs to hand the first day they go out, but this thirst after blood should not be indulged to any great extent afterwards, or the stock of foxes in the country may be much impaired, and sport thereby diminished. There is perhaps nothing connected with hunting of more importance, and, it may be added, of greater interest, than good kennel management. First of all it is shown in the formation of a level pack; for where things are done properly it is not enough to get together a lot of hounds that are good in themselves, they must also be, as nearly as possible, of one size. Then again, they must all be equally fast—to use a common expression, a sheet should cover them when running. Lastly, they must be free from certain faults, such as muteness, babbling, and skirting. A mute hound is a terrible nuisance. A fox is found and goes away unperceived; some time afterwards news is brought to the huntsman that a single hound has been seen running hard a mile from cover. This is our mute friend, which got on to the line by himself and gave no notice to anybody. But a young hound that is reticent with his tongue should not be too hastily set down as mute; he may have been flogged for proclaiming a scent, under the mistaken idea that he was running riot, and if so it would have the effect of checking his music. "Babbling" consists in a hound being too free with his tongue: after a fox has been found, the babbler announces the fact for the next ten minutes, and repeats his refrain whenever the least opportunity presents itself. A hound may give tongue too much without being an absolute babbler, but a noisy hound is pretty sure to become a babbler, and when he is so he should be drafted at once. A "skirter" is a hound that will not run with the pack, but is always taking a line of his own; like the babbler he should have every chance, but, if gentle as well as severe measures fail in effecting a reclamation, he too must be sent away. It goes without saying that where good kennel management exists, the hounds will be well disciplined, both in and out of the kennel. To the uninitiated, a visit to the kennel at feeding time is an interesting sight, notwithstanding the somewhat pungent smell of pudding and boiled horse. The hounds, as hungry as the proverbial hunter, stand anxiously awaiting the order to fall to, yet not daring to move until the order is given; and when the huntsman thinks a hound has eaten sufficient, the mere calling out of his name is sufficient to make him return to the benches, in spite of a desire for a more prolonged stay at the trough. An extraordinary instance of discipline in the field is related by Colonel Cook in his work *Observations on Fox-hunting*, p. 202. With hounds as with horses, control over them will be best obtained by kindness: the popular idea is that huntsmen, whips, and feeders never set about their respective duties unless armed with a formidable whip to be used on all possible occasions; but happily this is an entire mistake.

Feeding of hounds. The feeding of a pack of hounds is a matter calling for the exercise of great care and judgment, and cannot be properly carried out unless the establishment enjoy the services of a thoroughly trustworthy feeder. His duty is to cook the food, and to keep the utensils clean and the kennel sweet and wholesome. Hounds' food comprises both animal and vegetable substances. Objections have sometimes been made to admitting the former into the kennel fare at all, on the ground that it is likely to impair the powers of scent, but the exception does not seem to be well-founded, because wild dogs, as also wolves and foxes, are carnivorous animals and live by the use of their scenting powers; in moderation flesh is a necessity. Wheatmeal and barleymeal are eschewed, coarse oatmeal a twelvemonth old being the only thing fit to feed hounds with. The meal is boiled in a large iron boiler (a smaller one of the same metal being reserved for boiling the flesh), and during the cooking the feeder must be on the watch lest any of it stick to the bottom of the boiler. When sufficiently cooked it is turned out into coolers. On meat being given it is cut into small pieces and stirred into the pudding. In the summer young cabbages, given once every four days, form a wholesome food, and are vastly superior to potatoes, swedes, or any other root. With proper diet, an occasional alterative, and plenty of exercise, hounds should seldom or never require to be plastered over with ointment in consequence of skin irritations. The benches should be littered with good dry wheat-straw, which should be taken out of the kennel and shaken up every morning when the hounds are at exercise. Great cleanliness is indispensable; the natural odour of a kennel is none of the sweetest, and if hounds are kept in the midst of dirt their powers of scent will speedily deteriorate.

Harriers. The harrier like the foxhound is a very different animal from what he was one hundred years ago. Then there were several sorts used in hare-hunting; first came the old southern hound, used principally in heavy countries; the second variety was a somewhat faster dog, with a sharp nose and pointed ears, and was best adapted for an open country; thirdly, a rougher-coated hound; and lastly, the old fashioned blue mottled harrier, found in the Weald of Sussex and some parts of Kent. The first and last of the above list are said to have been endowed with wonderful scenting powers, and we are told that when these hounds were in use a run of six hours after a hare was no uncommon occurrence; but they were so slow that the same authority tells us that they fatigued "the healthy foot-man very little." It is probable that the Sussex blue mottled hound was the result of the first attempt to improve the old southern hound, and to obtain a species particularly suitable for hare-hunting, but since then almost all the traces of the old harrier have disappeared, until at the present time the modern harrier is little more than a dwarf foxhound. When pursued by the old-fashioned harrier, the hare had time to indulge in all those wiles in which our forefathers delighted, and of which they wrote at length in the hunting treatises of their time; but with the taste of the day in favour of pace, and with the modern harrier, the "curious and lasting sport" of old has been put an end to, and now the hare must, if the scent be moderately good, simply get away as far and as fast as possible. The late Sir John Dashwood King, of West Wycombe Park, Bucks, is said to have been the breeder to whom the sportsman is indebted for the present race of harriers. His pack did not exceed 18 inches in height. The parent stock was a small foxhound from the duke of Grafton's kennel, named Tyrant, whose blood, form, and character were apparent throughout; and so highly was the pack thought of that Lord Sondes, of Rockingham Castle, gave 700 guineas for it.

Beagle. The beagle (see Dog) is used in hunting the hare, but from its diminutive size it is not possessed of great pace; it is therefore generally followed on foot, but it is a good plan to have one person on horseback, in order that the pack may be stopped if they get away from the field and make for a cover.

Otter hound. The real otter hound bears a strong resemblance to the old southern hound. The head is heavier than that of the foxhound, and the eyes are deeply set as in a blood hound. The coat is rough and somewhat wiry, but it should be thick. The otter hound is not very common, foxhounds being often used for otter hunting; but the Carlisle pack is of the true breed.

The remarks already made on kennel management apply, for the most part, in the cases of hounds other than foxhounds; all varieties need the same cleanliness and attention. The different game for which the hounds are entered of course necessitate some trivial adaptation from the course pursued in foxhound kennels, but speaking generally the management is the same. (E. D. B.)

HOUNSLOW, a township, formerly a market-town, in the parishes of Isleworth and Heston, county of Middlesex, England, is situated on the great western coach road, and on a branch of the London and South-Western Railway, 9 miles from Hyde Park Corner. In the Domesday survey Hounslow is mentioned as *Honeslowe* and *Hundeslawe*. It consists chiefly of one street about a mile in length. In the 17th century it numbered about 120 houses, principally alehouses and inns. Previous to the opening of the railway nearly 500 coaches passed through the town daily. Of late years it has considerably recovered from the depression caused by the opening of the railway, and a number of fine villas have been erected in the neighbourhood. A priory of friars of the Holy Trinity was founded at Hounslow in 1296, and existed till the dissolution of the monasteries. The priory chapel was used as a church till 1830, when it was demolished, and the present church in the later style of English architecture erected. Another church in the Early English style was erected in 1874, and a town-hall in 1857. The surrounding country is flat and uninteresting, and to the west of the town there was at one time an extensive heath, which, according to the survey of 1546, had an area of 4293 acres. It is the site of Roman and old British camps, and in later history was the scene of several important military rendezvous. For many years the heath was a favourite resort of highwaymen, the carcases of whom used to be exposed on gibbets along the road. According to an Act passed in the 53d of George III., the heath has been enclosed, and it is now nearly all cultivated. In 1793 large cavalry barracks were erected upon it, and it also affords a site of extensive powder-mills. The population of the township in 1861 was 5760, and in 1871 it had increased to 9294.

HOUSE-FLY. Although extremely abundant in individual representatives, by habit specially attached to mankind, of widely extended range (North American and Abyssinian exponents are absolutely identical with European), familiar from the earliest times, engrafted upon the literature of all nations by proverbial and poetical allusions, and of later years affording material for much scientific microscopical investigation,—the dipterous species known to naturalists as *Musca domestica* apparently has two peculiarities opposed to these premises:—one, that its lack of salient external features would puzzle any but a profound dipterologist to define its specific attributes with absolute certainty; the other, that its earlier life history and transformations remained practically unknown (at all events to ordinary readers) up to the year 1873. It is scarcely within the province of this work to diagnose species; the instincts of the majority of readers will probably direct them at once to the right insect, which may be roughly described as a quarter of an inch long, black, hairy, with a reddish oval vertical spot and golden orbits, three grey longitudinal bands on the thorax, an interrupted yellowish band at the base of the abdomen, which has lateral and apical golden spots, and the base of the wings yellowish-white. But not only allied species are liable to be confused with the house-fly; representatives of other genera, such as *Anthomyia*, *Tachina*, and *Stomoxys*, are often mistaken for it, and a puncture from the sharp beak of the latter fly has often caused a wrong charge of blood-sucking to be brought against the subject of this notice, which has a short fleshy bilobed tongue incapable of penetrating the skin, though provided with a terminal framework of tracheal tubes, acting like a rasp, by using which it often annoys us in the heat of summer. As regards the second point, Linnæus, who first named the fly, left its transformations undescribed; De Geer in 1776, and Bouché in 1834, described the larva and pupa, and correctly defined their habitat; but it has been reserved for Dr A. S. Packard, jun., the well-known American entomologist and biologist, to make a thorough investigation of their whole economy, which he has published in the *Proceedings of the Boston Society of Natural History*, vol. xvi. (for 1873–74), pp. 136–150, pl. iii.

The minute dull chalky white eggs (usually about 120 in number), elongate oval and cylindrical in shape, are laid by the parent fly in crevices of fresh manure in or about stables,—heat, and especially moisture, being required for their development. The larvæ are hatched in twenty-four hours, and pass through three stages, averaging from five to seven days in all; in the second of its stages, the larva has been observed to increase by one-third of its length in twenty-four hours. They resemble those of the well-known meat fly, *Calliphora vomitoria*, but are smaller, longer, more slender, transparent, smooth, and shining, and regularly conical. The prop-leg at the apex is also much smaller, and cannot be seen from above when the larva is in motion. They eat the decaying parts of the manure, leaving the bits of hay and straw. The puparium, or pupa-case, is a quarter of an inch long, cylindrical, and dark brown, closely resembling that of *Stomoxys calcitrans*, from which it chiefly differs in the larger and squarer anal spiracles and the smoother apex. The enclosed pupa is of the usual type of the cyclorhaphous *Diptera*, and is readily distinguishable from that of *Stomoxys* by its broad spatulate labium and curved maxillary palpi; it rests in the case with the hard framework of the jaws of the old larva skin next the ventral side; and when the fly pushes its way out, after remaining from five to seven days as a pupa, the upper end of the case splits off just behind the suture between the thorax and abdomen. The term "pupa" is here used in a general sense, since intermediate stages of development (variously called "pseudo-nymph" or "semi-pupa") in that condition occur in the *Muscidæ*, as in *Hymenoptera*, *Coleoptera*, &c.

On leaving the pupa-case, the fly runs about with its wings soft, small, and baggy, pressed to the side of the body, much as in the pupa. It is pale, with the colours not set, and the membranous portion of its forehead constantly distends with air as the fly moves, being connected with the tracheæ. From Mr Lowne's observations on the anatomy of the blow-fly, this organ is evidently employed for pushing away the end of the puparium when the pupa slips out of its case.

The whole period of evolution being thus from ten to fourteen days only, and the number of eggs laid by each female fly so numerous, it will be readily seen that any slight personal inconvenience to man, as produced by the habits of the perfect insect, are much more than compensated for by the unceasing labours of its larvæ as scavengers; the benefit being the more direct as the work is invariably done close to human habitations. The workings of the law of nature, by which an excess of increase in any one species is checked, are conspicuously shown in the case of this insect. Not only do the ordinary parasites of its own class (some Hymenopterous, and in one recorded instance Coleopterous) attack it in its earlier stages, but certain common birds are particularly addicted to it in the perfect state (in which also a *Chelifer*, a minute European representative of the scorpions, has also been found parasitically attached to it). The vegetable world also supplies some lethal agents in the shape of fungi (notably *Empusa muscæ*), individuals destroyed by which are constantly to be seen in autumn unable to move, and distended or ruptured by the expansion of the internal growth, the white spores of which are finally to be observed scattered round their victim.

Trivial as the house-fly may appear even to entomologists, it is to be noted that recent observations by the German biologist Weissman on its development have resulted in his discovery of its possessing "imaginal discs" in the early larval state—a structure deemed of sufficient value to suggest a new division of the whole *Insecta* into "Discota" and "Adiscota."

HOUSELEEK, *Sempervivum*, a genus of ornamental evergreen plants belonging to the natural order *Crassulaceæ*. About 30 species are known in gardens, some of which are hardy perennial herbs, and grow well in dry or rocky situations; the others are evergreen shrubs or undershrubs, fit only for cultivation in the greenhouse or conservatory. The genus *Sempervivum* is distinguished from the nearly allied *Sedum* by having about 12 petals, and by the glands at the base of the ovary being laciniated if present. The common houseleek, *S. tectorum*, L. (Germ. *Hauswurzel*; Fr. *Joubarbe*), is often met with in Britain on roofs of outhouses and wall tops, but is not a native. Originally it was indigenous in the Alps, but it is now widely dispersed in Europe, and has been introduced into America. The leaves are thick, fleshy, and succulent, and are arranged in the form of a rosette lying close to the soil. The plant propagates itself by offsets on all sides, so that it forms after a time a dense cushion or aggregation of rosettes. The flowering stem, which is of rather rare occurrence, is about a foot high, reddish, cylindrical, and succulent, and terminates in a level-topped cyme, reflexed at the circumference, of reddish flowers, which bloom from June to September. The houseleek has been known variously as the Houselick, Homewort, Great Houseleek, *Sedum majus*, and *Crassula major altera*, *Sedum acre*, L., being styled the Least Houseleek. In Germany it is sometimes called *Donnerkraut*, from being supposed to protect the house on which it grows from thunder. The leaves are said to contain malic acid in considerable quantity, and are reckoned by herbalists to possess cooling and astringent properties. The leaves, freshly bruised, are applied to hæmorrhoids, boils, wens, and corns, and the expressed juice is used as a remedy for inflammation of the eyes and freckles, and especially for thrush (aphthæ) in children, also for stings and burns, erysipelas and herpes. Internally houseleek is used as a cooling remedy in dysentery and fluxes. The young leaves have also been eaten as salad, like *Portulacca*. *S. glutinosum*, Ait., and *S. balsamiferum*, Webb, natives respectively of Madeira and the Canary Islands, contain a very viscous substance in large quantity, and are used for the preparation of bird-lime; fishermen in Madeira, after dipping their nets in an alkaline solution, rub them with this substance, rendering them as tough as leather. *S. montanum*, L., indigenous in Central Europe, according to Gmelin, causes violent purging; *S. arboreum*, L., τὸ μέγα ἀείζωον of Dioscorides, is employed in Cyprus, the East, and northern Africa as an external remedy for malignant ulcers, inflammations, and burns, and internally for mucous discharges.

See Britten and Holland, *Dictionary of Plant Names*, pp. 265–271; Fristedt, *Joannis Franckenii Botanologia*, p. 60; Rosenthal, *Plantarum Diaphoricarum*, p. 576.

HOUSSA, Housa, Haussa, or Hausa, an important people of the western Soudan, forming a main element in the population of the country between 12° and 13° N. lat., from the Niger in the south-west to Bornu in the east. By Barth they are identified with the Atarantians of Herodotus; and it is certain that at a comparatively early date they attained great political power. The seven original states of Biram, Daura, Gobir, Kano, Rano, Katsena, and Zegzeg, formed a great confederation or empire, which extended its authority over many of the neighbouring countries, and retained its pre-eminence till the beginning of the 19th century, when the Pullo (Fellata or Fulbe) rose upon its ruins. Physically the Houssa may be considered as the most typical of all the negro peoples: they are strongly and somewhat heavily built, and even where there has been a considerable intermixture of Barber or Pullo blood, their racial persistence is very marked. In intellectual qualities they hold the very foremost rank among the negroes; they are excellent agriculturists, and, almost unaided by foreign influence, they have developed a variety of industries, such as the making of cloth, mats, leather, and glass, as well as a very extensive trade. In Sierra Leone and the Gold Coast territory the Houssa form the backbone of the military police, and under Captain Glover, who was the first to enrol them under the British flag, they did good service in the Ashantee campaigns.

The Houssa or Afnu language ranks as one of the richest and most cultivated in Africa; and it is not only the dominant vernacular throughout a large part of the Soudan, but serves as the means of communication in a great many places throughout the region to the south and west of the Lower Niger. At Idda, says Bishop Crowther (*Proc. Roy. Geog. Soc.*, 1877), we found Houssa becoming more generally spoken by the inhabitants, and at Igbegbi it is one of the prevailing languages of the mixed population of that town. From Lagos, Badagry, and Porto Novo, and upwards to the Niger, wherever Mahometans are found, Houssa is spoken by them; through it the Koran is explained in the mosques throughout Yoruba. According to Dr Baikie (*Observations on the Hausa and Fulfulde*, printed for private circulation, Lond. 1861) there are two master dialects—the Daura or eastern, and the Gobir or western. Of these the latter is the more original, the other the more refined. The Katsena form is very pure, and closely resembles the Gobir; that of Kano is extremely corrupt, though not so much so as that of Zariya or Zozari. As an example of the richness of the vocabulary, Dr Crowther mentions that there are eight names for different parts of the day from cockcrow till after sunset.

See El Hage Abd Salam Shabeeny, *Account of Timbuctoo and Haussa Territories*, 1820; Norris, *Dialogues and part of the New Testament in the English, Arabic, Haussa, and Bornu languages*, 1853; Koelle, *Polyglotta Africana*, 1854; Barth, *Travels in North and Central Africa*, vol. ii., London, 1857, and *Central-Afrikanische Vokabularien*, Gotha, 1862 and 1866; Schön, *Grammar of the Hausa Language*, London, 1862; Id., *Hausa Reading Book*, 1877; and Id., *A Dictionary of the Hausa Language*, 1877. Schön has also produced Houssa translations of Gen. (1858), Matt. (1857), and Luke (1858).

HOUSTON, a city of the United States, capital of Harris county, Texas, and the next city in the State to Galveston as regards both population and commercial enterprise, is situated on the left bank of Buffalo bayou at the head of navigation, and at the junction of several railways, 50 miles north-west of Galveston. The bayou is crossed at Houston by several bridges. Most of the streets are shaded by fine avenues of trees, and the principal of them are traversed by tramway cars. The chief buildings are the city-hall and market-house, completed in 1874, at a cost of 400,000 dollars, the masonic temple of the grand lodge of Texas, and the hotels, the largest of which is the finest in the State. The city is well supplied with schools and churches, and has two large public libraries. It is the principal railway centre of the State, and the depôt of an extensive and rich agricultural region, besides being the seat of important and varied manufactures. The recent deepening of the bayou so as to make it navigable for vessels drawing 9 feet of water has considerably increased the shipping trade, which is chiefly in lumber. The town possesses iron and brass founderies, railway machine shops, planing-mills, factories for cars, waggons, and agricultural implements, sheet-iron and tin works, a large flour-mill, beef-packing establishments, and manufactures of cotton, soap, Portland cement, and bone dust. In the neighbourhood there are extensive nurseries. The annual fair of the State of Texas is held at Houston. The city, which was named after Samuel Houston, noticed below, was settled in 1836, and in 1837 it was for a short time the capital of the State. In 1870 the population was 9382, and in 1880 it had increased to 17,000.

HOUSTON, Samuel (1793–1863), an American general and statesman, was born near Lexington, Virginia, 2d March 1793. On the death of his father, a soldier of the revolution, in 1807, he removed with his mother to the frontier, and settling in Blount county, Tennessee, was soon on familiar terms with the Cherokee Indians. For a while he acted as clerk to a trader, and then as village schoolmaster; but in 1813, after a residence of nearly three years among the Indians, he joined the United States army. He served with Jackson in the war against Great Britain, and at the peace of 1815 had risen from the ranks to a lieutenancy. Although conscious of his success, and proud of having won Jackson's friendship by his bravery, he then resigned his commission and turned to the study and practice of law at Nashville. In 1823 Tennessee returned him to congress, and four years later he was elected governor of the State. He married in January 1829, and in the April following, without assigning any reason, he suddenly abandoned his home and his office, and took up his residence among the Cherokees, by whom he was formally adopted as a member of their nation. Returning to Washington, he successfully pleaded their cause against the Government agents who had wronged them. In 1832 he settled in Texas, and was soon after elected a member of the convention called for the purpose of framing a constitution for that State, then in difficulties with the Mexican Government. On March 2, 1836, Texas declared its independence, and, on the 2d of April following, won it on the field of San Jacinto, where Houston, who had been appointed commander-in-chief of the Texas forces, with a body of 783 raw troops, defeated 1600 Mexican veterans led by Santa Anna. On the recognition of the independence of Texas, Houston was elected president of the new republic, and re-elected in 1841; and, when Texas was admitted to the Union in 1845, he was returned as one of its two representatives to the senate. There he distinguished himself as a zealous friend of the Indians, opposing the Kansas and Nebraska bill in a memorable speech (3d March 1854), and voting against the Lecompton constitution of Kansas. His decided opposition to secession obliged him in 1861 to retire from the office of governor of Texas, which he had held from 1859. He died at Huntersville, Texas, 25th July 1863. The hero of San Jacinto was above all things an able soldier, wary, intrepid, and resolute; but he also possessed as a legislator the qualities of rare foresight, cool discrimination, and fearless candour.

See his *Life* (New York, 1855), his *Letters to the People* (1856), and S. L. Knapp's *History of America* (New York, 1875).

HOUWAERT, JEAN BAPTISTA (1533-1599), Flemish poet, was the most prominent of the rhetoricians of his day. He held the title of "Counsellor and Master in Ordinary of the Exchequer to the Dukedom of Brabant." As a patriot and a friend of the prince of Orange he played a prominent part in the revolution of the Low Countries against Spain, and when the prince entered Brussels victoriously, September 23, 1577, Houwaert met him in pomp at the head of the two chambers of rhetoric, the "Book" and the "Garland of Mary." He died at Brussels, March 11, 1599.

His existing works are of an allegorical and highly fantastic order, and prove him to have been a disciple of Matthys de Castelyn. He wrote the *Commerce of Amorosity* (Den Handel der Amourenskeyt), consisting of four plays or moralities in verse, namely, *Æneas and Dido*, *Narcissus and Echo*, *Mars and Venus*, and *Leander and Hero*. His other principal poem is a didactic epic on the vanity of human love, *Pegasides Pleyn, of den Lusthof der Maechden*. These and other laborious and exemplary pieces gained him the title of the "Homer of Brabant" from his contemporaries. Houwaert prided himself on the introduction of classical and mythological names into his poems, but he had little or nothing of the antique spirit.

HOVEDON, ROGER OF, an old English chronicler, was in all probability born at Howden, in the East Riding of Yorkshire, and was possibly a member of a family which had taken its name from the place. The date neither of his birth nor his death is known, and the first notice we have of him is as being sent in 1174 by Henry II., on whom he was in attendance in France, to endeavour to induce the lords of Galloway to withdraw from their allegiance to the king of Scotland. He appears to have been recommended to the notice of Henry from his knowledge of law, and to have occupied a place in his household. It has been conjectured, but without much evidence, that he was a student of Oxford; and the ascription to him of a volume of lectures is also without ground to support it. From the interest manifested in his history regarding the dispute between Archbishop Roger of York and Bishop Hugh of Durham in regard to synodal fees, it has been supposed that he himself held for some time the living of Howden, but this is likewise wholly devoid of direct corroboration. In 1175 he was employed by Henry in the delicate mission of inducing the monastic houses to send deputations to Woodstock for the purpose of choosing their rulers. In 1189, the last year of Henry's reign, he was appointed a justice itinerant for the forests in Northumberland, Cumberland, and Yorkshire; and it is probable that after Henry's death he retired to Howden, since from the number of his references to Yorkshire disputes it is evident that he must have been living in that county during the time that he compiled the latter portion of his Chronicle. As the Chronicle closes abruptly in 1201, it is probable that he did not live long beyond that date.

The work of Roger of Hovedon, which commences with the close of the Chronicle of Bede in 732, is divided by Professor Stubbs into four parts:—the 1st ending with 1148, and consisting chiefly of the *Historia post Bedam*, with a few alterations and additions; the 2d ending with 1169, based principally on the *Melrose Chronicle*, and from 1163 composed mainly of the A Beckett letters contained in the collection made by John of Salisbury and Alan of Tewkesbury; the 3d ending with 1192, and virtually a condensation of Benedict's Chronicle, with the occasional addition of unimportant details and several variations, many of which are inaccurate and of such a kind as to show that he wrote from memory; the 4th ending in 1201, and evidently a narrative of contemporary events. The work of Roger of Hovedon was cited in 1291 by Edward I., when claiming the lordship of Scotland, as one of the authorities in regard to the homage done by the earlier kings to his ancestors. The independent value of the work belongs almost wholly to the last portion, although various documents of interest to be found nowhere else are incorporated in the 2d and 3d portions.

The Chronicle was first printed in 1596 in Sir Henry Saville's collection of the *Scriptores post Bedam*, and was reprinted at Frankfort in 1601. A translation of it by H. F. Riley, B.A., appeared in 1852, and forms part of Bohn's Antiquarian Library; and it has been published in 4 vols., 1868-71, in the series of the Master of the Rolls, under the editorship of Professor Stubbs, whose preface contains an elaborate criticism of the work and a full account of the various MSS.

HOWARD, HENRY. See SURREY, EARL OF.

HOWARD, JOHN (1726-1790), "the philanthropist," was born in 1726, most probably on September 2, and at Enfield, where his father, a moderately wealthy retired London merchant, had a country house. His childhood was spent at Cardington near Woburn, Bedfordshire, where his father had a small estate; for seven years he was under the tuition of the Rev. John Worsley of Hertford (author of a Latin grammar and of a new translation of the New Testament); and he was afterwards placed for a short time at a private academy in London under Mr John Eames, F.R.S. At the close of a very imperfect school education he was apprenticed by his father at a considerable premium to a firm of grocers in the city; but on the death of the elder Howard in September 1742, by which he inherited considerable property, he bought up his indenture and devoted more than a year to foreign travel, during which he acquired some knowledge of French. Never constitutionally strong, he on his return to England settled in lodgings at Stoke Newington as a confirmed valetudinarian, his days being spent for the most part in hypochondriac idleness (for little importance can be attached to what have sometimes been called his studies in medicine and meteorology). Having been nursed through an acute illness by an attentive landlady, a widow of some fifty-three years of age, he felt that he could offer no adequate return short of marriage for her motherly kindness, and they were united accordingly in 1752. Left a widower in less than three years, Howard broke up his establishment at Stoke Newington in 1755, and resolved to go abroad, the recent occurrence of the earthquake at Lisbon attracting him to Portugal. The ship, however, in which he sailed was so unfortunate as to be taken by a French privateer, by whom both crew and passengers were carried to Brest, where they were treated with great harshness and almost starved. At Morlaix and at Carhaix Howard had further opportunities of observing the treatment to which prisoners of war were usually at that time subjected; and when permitted on parole to return to England to negotiate an exchange for himself, he not only accomplished his personal object, but also successfully represented the case of those who had been his fellow-captives. Abandoning for the time his Lisbon scheme, he now retired to his property at Cardington, where he continued to interest himself in meteorological observation, for some slight notes on which he obtained publication in the *Transactions* of the Royal Society, of which he had been admitted a member in 1756. After his marriage (April 1758) to Henrietta, eldest daughter of Edward Leeds of Croxton, Cambridgeshire, he continued to live a secluded life, partly at Cardington and partly on another property which he had purchased at Watcombe, Hampshire. In both places he distinguished himself as a kind landlord, and at Cardington especially he displayed a highly enlightened philanthropy in his efforts to raise the condition of the poor by the construction of model cottages and by the erection of schools. In March 1765 his home was again desolated by the sudden and unexpected death of his wife, a few days after she had given birth to a son, her first and only child; and soon Howard's drooping health and spirits imperatively demanded a change of air and scene. After visiting Bath and London, he in the spring of 1768 crossed to Holland; and another brief stay at Cardington was followed by a prolonged tour in France, Switzerland, and Italy as far as to Naples, whence he returned in 1770 by Germany and the Rhine. Having resumed his former course of life at Cardington, he was in 1773 named high sheriff of Bedford, an office which, although as a nonconformist he was unable to take the usual tests, he resolved to accept. The characteristic work of his life may be said to have now begun. When the assizes were held he did not content himself with sitting out the trials in open court; his inquisitiveness and his benevolence alike impelled him to visit the jail to which the prisoners had been condemned. Howard found it, like all the prisons of the time, wretchedly defective in all its arrangements; but what chiefly astonished and shocked him was an almost incredible abuse arising out of the circumstance that neither the jailer nor his subordinates were salaried officers, but were dependent for their livelihood on fees which they rigorously exacted from the prisoners themselves. He found it to be a fact that some whom the juries had declared not guilty, others in whom the grand jury had not found even such appearance of guilt as would warrant a trial, others whose prosecutors had failed to appear, were frequently detained in prison for months after they had ceased to be in the position of accused parties, until they should have paid the fees of jail delivery. (See Introduction to *The State of the Prisons in England and Wales.*) His prompt application to the justices of the county for a salary to the jailer in lieu of his fees was met by a demand for a precedent for charging the county with such an expense. This he undertook to find if such a thing existed. He went accordingly from county to county until his journey had extended to every town in England which contained a prison, but the object of his search eluded inquiry. He could find no precedent for charging the county with the wages of its servants, but he did find so many abuses in prison management which imagination had never conceived, and so many sufferings of which the general public knew nothing, and of which the law took no account, that he determined to devote to the exposure of those wrongs and the reform of those abuses whatever time and money might be needful. The task cost him a fortune, and the best remaining years of his life. The subject of prison reform, indeed, had not previously been wholly absent from the public mind. As early as the year 1728 the House of Commons had appointed a committee to inquire into the state of Newgate, the Marshalsea, and other London prisons, where abuses had come to light which had caused the house to order the arrest of several governors of jails, who were tried for high misdemeanours (see *Reports of the Committee Appointed to Inquire into the State of the Gaols*, 1729). Much more recently Popham, member for Taunton, had forced the unwilling legislature at least to discuss the propriety of paying fixed salaries to jailers out of the county rates; but in February 1773 the bill after passing the second reading had been withdrawn with a view to its being again brought forward in an amended form. The way had thus been prepared for a friendly reception to anything Howard might have to say as the result of his investigations; and at the close of his first rapid survey of the English prisons he was, through the influence of the supporters of Popham's bill, cited to appear before a committee of the whole house in March 1774. After his report had been received and he himself examined upon it, it was moved and carried, on the house resuming, "that John Howard, Esq., be called to the bar, and that Mr Speaker do acquaint him that the House are very sensible of the humanity and zeal which have led him to visit the several jails of this kingdom, and to communicate to the house the interesting observations which he has made on that subject." Almost immediately an Act was passed which provided for the liberation, free of all charges, of every prisoner against whom the grand jury failed to find a true bill, giving the jailer a sum from the county rate in lieu of the abolished fees. This was followed in June by another requiring justices of the peace to see that the walls and ceilings of all prisons within their jurisdiction were scraped and whitewashed once a year at least; that the rooms were regularly cleaned and ventilated; that infirmaries were provided for the sick, and proper care taken to get them medical advice; that the naked should be clothed; that underground dungeons should be used as little as could be; and generally that such courses should be taken as would tend to restore and preserve the health of the prisoners. It was highly characteristic of the man that, having caused the provisions of the new legislation to be printed at his own private cost in large type, he sent a copy to every jailer and warder in the kingdom, determined that no one should be able to plead ignorance of the law if detected in the violation of its provisions. He then set out upon a new tour of inspection, from which, however, he was brought home by the approach of a general election in September 1774. Siding with those who objected to the American policy of the Government, he had consented to stand as one of the anti-ministerial candidates for Bedford; although, however, he was returned by a narrow majority along with his friend Whitbread, he was unseated after a scrutiny on account of the alleged disqualification of some of those voters who had supported him. He was thus left entirely free for the vigorous prosecution of the special task which he had assigned himself; and he began to have thoughts of publishing the immense mass of facts which he had so industriously collected, and which was still so rapidly accumulating. But after a tour which had extended to Scotland and Ireland, it occurred to him before going into print that his notes would be much enhanced in utility if supplemented with the regulations and arrangements of the more important Continental prisons. In April 1775, accordingly, he set out upon an extended tour through France, the Low Countries, and Germany. At Paris he was at first denied access to the prisons; but by recourse to an old and almost obsolete law of 1717, according to which any person wishing to distribute alms to the prisoners was to be admitted and allowed to dispense his charity with his own hand, he succeeded in inspecting the Bicêtre, the Force l'Évêque, and most of the other places of confinement, the only important exception being the Bastille. With regard to this last, however, he succeeded in obtaining possession of a suppressed pamphlet, which he afterwards translated and published in English, to the unconcealed chagrin of the French authorities. At Ghent he examined with special interest the great Maison de Force, then recently erected; its distinctive features—useful labour, in the profits of which the prisoners had a share, and complete separation of the inmates by night—drew from him the exclamation that it was a "noble institution." At Amsterdam, as in Holland generally, he was much struck with the comparative absence of crime, a phenomenon which he attributed to the industrial and reformatory treatment there adopted. In Germany he found little that was useful and much that was repulsive; in Hanover and Osnabrück, under the rule of a British sovereign, he even found traces of torture. Returning to England in autumn with his copious notes, he determined, before finally reducing them to order and sending them to press, to undertake another tour of England. This lasted for seven months (November 1775 to May 1776), and yielded results so important by way of correction and supplement that he resolved to give his Continental experience the benefit of a similar revision. On this occasion he extended his tour to several of the Swiss cantons. At last in 1777 appeared *The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some Foreign Prisons* (Warrington). It met with a very favourable reception, although its author was fully justified in his statement in the preface that as the journeys were not undertaken for the traveller's amusement, so the results of them were not published for general entertainment. It consists principally of a mass of minute statistical details, somewhat pedantically accumulated and very unmethodically arranged; its most important section

—that relating to "proposed improvements in the structure and management of prisons"—constituting less than a tenth part of the whole. One portion of his subject, indeed,—that relating to the ships used for transportation of convicts,—had been to some extent taken out of his hand by the passing in 1776 of the Act authorizing the hulk system; but even in this connexion the appearance of his work was highly opportune. Following within a few years the publication of Beccaria's work *On Crimes and Punishments*, it called public attention to the practical question of the treatment of criminals in a manner which compelled the adoption of remedial or at least of palliative measures, although the full difficulty and delicacy of the problem had not as yet been thoroughly appreciated. One of the most immediate results was that Sir W. Blackstone and Mr Eden were requested to draft a bill for the establishment of penitentiary houses, where by means of solitary imprisonment, accompanied by well-regulated labour and religious instruction, the object of reforming the criminal and inuring him to habits of industry might be successfully pursued. New buildings were manifestly necessary in order that the provisions of such an Act might be carried into effect; and as no one seemed to know how to set about their construction, Howard volunteered to go abroad again and collect plans and other information. On this errand (April 1778) he first went to Amsterdam, and carefully examined the "spin-houses" and "rasp-houses" for which that city was famous; next he traversed Prussia, Saxony, Bohemia, Austria, and Italy, everywhere inspecting prisons, hospitals, and work-houses, and carefully recording the merits and defects of each. In the course of this tour he was received with marked consideration and respect at more than one court; but the personal incident of greatest consequence was one which befel him on a voyage along the Tuscan coast. A sudden and violent storm had compelled the master of the small vessel in which he had taken a passage for Leghorn to seek the shelter of land; cold, wet, and exhausted, passengers and crew reached a little island harbour, but only to find that through fear of the plague (they having sailed from a port supposed to be infected) a landing was refused them. Driven back again upon the storm, they were carried by its violence to the coast of Algeria, where a similar experience was encountered, permission to enter the harbours there also being peremptorily denied. It was this occurrence which first directed Howard's attention to the subject which engrossed his attention in after years, and in the investigation of which he ultimately lost his life. Leghorn at last reached, he hastened northwards through Lombardy, France, and Flanders, arriving in England in 1779. The information he had obtained having been placed at the service of the House of Commons, a bill was introduced and passed for building two penitentiary houses in Middlesex, Surrey, Kent, or Essex (as might be afterwards determined), and Howard was appointed first supervisor (19 Geo. III. cap. 74). The scheme, however, did not proceed without friction too trying for his patience; and after much time had been lost in interminable discussions with his colleagues as to the sites of the proposed buildings, he in January 1781 wrote to Lord Bathurst resigning his post before anything practical had been achieved. In 1780 he had published a quarto volume of 220 pages as an appendix (the first) to his *State of Prisons*; about the same time also he caused to be printed his translation of the suppressed French pamphlet on the Bastille; but on obtaining release from his employments at home his passion for accumulating statistics urged him to new and more extended Continental tours, as far as to Denmark, Sweden, and Russia in 1781, and to Spain and Portugal in 1783. The results of these journeys (which were full of curious and romantic incidents) were embodied in 1784 in a second appendix, with the publication of which his direct labours in connexion with the subject of prison reform may be said to have ceased. The five remaining years of his life were chiefly devoted to researches on a different though cognate subject, that of the means which ought to be used for prevention of the plague, and for guarding against the propagation of contagious distempers in general. Having at the suggestion of his medical friends provided himself with a list of queries to be put to the physicians in attendance at the lazarettos he proposed to visit, he in November 1785 sailed for Holland, and thence travelling through France inspected the great lazaretto at Marseilles, though with considerable difficulty, owing to the unfriendliness of the authorities. He next passed through Florence, Rome, and Naples to Malta, whence he sailed by Zante to Smyrna, where his reputed medical skill opened all the prisons and hospitals to his inspection, and where he had ample opportunities of studying the plague in its most fatal form. He then went to Constantinople, where the fame of his skill had preceded him, and where some further fortunate practice greatly added to his prestige. Declining the hospitalities of the British ambassador, however, he devoted himself entirely to the care of the neglected poor, and persistently forced his way into infected caravanserais and pest-houses whither physician and dragoman alike declined to follow him. At length his researches seemed to be complete; and with a great accumulation of papers and memoranda, he was preparing to return homewards by Vienna, when it occurred to his scrupulous mind that he still lacked one essential qualification for practically dealing with the matter which he had taken in hand; he had not as yet had any personal experience of quarantine discipline. Altering his plans accordingly, he returned to Smyrna, and, deliberately choosing a foul ship, took a passage to Venice that he might there undergo the usual confinement. A protracted voyage of sixty days, during which an attack by pirates gave Howard an opportunity of manifesting in a new form that personal bravery which was one of his characteristics, was followed by a weary term of confinement which enabled him to gain, though at the cost of considerable hardship and suffering, the experience he had desired. While imprisoned in the Venetian lazaretto he received two pieces of intelligence which from very opposite causes gave him acute pain. One was the announcement of a proposal that a statue should be erected commemorative of his services in the cause of humanity; to Howard as "a private man with some peculiarities," desirous to retire into obscurity and silence, it presented itself as a "hasty and disagreeable measure," "a distressing affair." The other was the information that his only son, a youth of twenty-two years of age, after a course of flagrant misconduct, had lost his reason and had been put under restraint. Returning hastily by Trieste and Vienna (where he had a long and singular interview with the emperor Joseph II.), he reached England in February 1787. His first care related to his domestic concerns; after these had been put into such order as they admitted, he set out upon another journey of inspection of the prisons of the United Kingdom, at the same time busying himself in preparing for the press the results of his recent tour. The somewhat rambling work containing them was published in February 1789 at Warrington, under the title *An Account of the Principal Lazarettos in Europe: with various Papers relative to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and additional Remarks on the present state of those in Great Britain and Ireland.* In the conclusion (p. 235) he committed with some solemnity the result of his past labours to his country, and announced his intention of again visiting Russia, Turkey, and some other countries, and of extending his tour in the East, adding these words, "I am not insensible of the dangers that must attend such a journey. Trusting, however, in the protection of that kind providence which has hitherto preserved me, I calmly and cheerfully commit myself to the disposal of unerring wisdom. Should it please God to cut off my life in the prosecution of this design, let not my conduct be uncandidly imputed to rashness or enthusiasm, but to a serious, deliberate conviction that I am pursuing the path of duty, and to a sincere desire of being made an instrument of more extensive usefulness to my fellow-creatures than could be expected in the narrower circle of a retired life." The execution of the purpose he had thus expressed was delayed for some time by the necessity for making special arrangements with regard to his private affairs in consequence of the confirmed insanity of his son; but early in July 1789 he finally embarked in what proved to be his last journey. Travelling overland from Amsterdam by Hanover, Berlin, Königsberg, and Riga to St Petersburg and Moscow, and so southwards, and visiting in passing the military hospitals that lay on his route, he reached Cherson in November. In the hospitals of this place and of the immediate neighbourhood he found more than enough to occupy his attention while he awaited the means of transit to Constantinople. Towards the end of the year his medical advice was asked in the case of a young lady who was suffering under the camp fever then prevalent, and in attending her he himself took the disease, which terminated fatally on January 20, 1790. "Give me no monument," he had said, "but lay me quietly in the earth; place a sundial over my grave, and let me be forgotten;" but a life like his had made such a burial even in a foreign land impossible, and his remains were followed, respectfully and sorrowfully, by many thousands to the grave, where they now lie near the village of Dauphigny on the road to St Nicolas. A statue by Bacon with a suitable inscription was afterwards erected to his memory in St Paul's, London.

In personal appearance Howard is described as having been short, thin, and sallow,—unprepossessing apart from the attraction of a penetrating eye and a benevolent smile. "There was an animation in his manner and a quickness in his gait which corresponded with the activity of his mental powers. In his address he was dignified, kind, and condescending, always adapting himself to the persons with whom he conversed; as free from a cringing servility amongst his superiors in station as he was from arrogancy towards those of lower rank" (Field). In point of intellectual ability he cannot be said to have been possessed of more than the ordinary endowments; nor had education done all that was possible for the development of those which he had. That he was of a deeply religious temperament is abundantly shown by the meagre remains we have of his letters and diaries; while the greater part of his life shows that his enthusiasm of humanity was the unusual yet normal outcome of the sincerest piety. His benevolent impulses were sustained by a rare degree of energy and determination, while they were guided by a remarkable delicacy of tact and an equally remarkable vigour of practical common sense. It would be idle to speculate how far Howard's work could have been done when it was, and as it was, by a man differently endowed. Doubtless the reforms which he inaugurated were reforms urgently called for by the spirit and enlightenment of his age; but this fact rather enhances than diminishes the imperishable glory which belongs to him of having been the foremost to give an articulate voice to that demand. "In the scale of moral desert the labours of the legislator and the writer are as far below his as earth is below heaven. His kingdom was of a better world; he died a martyr after living an apostle" (Bentham).

See *Anecdotes of the Life and Character of John Howard, written by a Gentleman* (1790); Aikin, *View of the Character and Public Services of the late John Howard*; *Memoirs*, by Baldwin Brown (1818), Taylor (1836), Hepworth Dixon (1849), Field (1850), and Stoughton (1853); and *Correspondence of John Howard, with brief Memoir and Anecdotes* (1855).

HOWE, JOHN (1630–1706), one of the greatest of the later Puritan divines, was born May 17, 1630, at Loughborough, Leicestershire, of which parish his father was minister. When hardly five years old he was removed to Ireland by his father, who, unable to support the ecclesiastical policy of Archbishop Laud, had been ejected from his living. On the outbreak of the Irish rebellion in 1641, the exiles returned to England; and, fixing his abode in Lancashire, the elder Howe conducted in person the studies of his son, who in his seventeenth year (May 19, 1647) entered Christ's College, Cambridge, as a sizar, and in the following year took his degree of B.A. During his residence in this university he made the acquaintance of Cudworth, More, and Smith, from intercourse with whom, doubtless, as Calamy suggests, as well as from direct acquaintance with the *Dialogues* themselves, his mind received that "Platonic tinge" which is so perceptible in his writings. Immediately after graduation at Cambridge, he removed to Oxford, where he took the same degree in the following year, and, after becoming a fellow of Magdalen College, proceeded M.A. in 1652. On leaving Oxford in that year he returned to his father's retreat in Lancashire, and received ordination at Winwick from the hands of Mr Herle, the minister of the parish, who was assisted by the ministers of the neighbouring chapelries. Sometime afterwards "an unexpected conduct of divine providence" bore him to Great Torrington in Devonshire, where he spent some years as pastor. It was there that he preached those discourses which at a later period took shape in his treatises on *The Blessedness of the Righteous* and on *Delighting in God*. There also it was that he married the daughter of "his inner friend" Mr George Hughes. In the beginning of 1657 a journey to London accidentally brought Howe under the notice of Cromwell, who, struck by his appearance and preaching, made him his domestic chaplain. In this prominent position, which he had accepted with very great reluctance, his conduct as the almoner and confidential adviser of the Protector was such as to win the praises of even the bitterest enemies of his party. Without overlooking the due claims of the Puritans, he omitted no opportunity of helping pious and learned men of other denominations, Ward (afterwards bishop of Exeter) and Thomas Fuller having been among the number of those who profited by Howe's kindness, and who were not ashamed subsequently to express their gratitude for it. On the deposition of Richard Cromwell, Howe returned to Great Torrington, where, like all who had played a conspicuous part under the Commonwealth, he soon after the Restoration found himself an object of suspicion and hatred; in 1662 the passing of the Act of Uniformity drove him from his parish. For several years he now led a wandering and uncertain life, preaching in secret as occasion offered to handfuls of trusted hearers. More than once his liberty was in imminent peril; and it is alleged by Calamy, though on doubtful grounds, that for two months in 1665 he was imprisoned in the Isle of St Nicholas in Plymouth Sound. Impelled by the demands of pressing want, he in 1668 published the treatise entitled *The Blessedness of the Righteous*; the reputation which he had acquired by it procured for him in 1669 an invitation from Lord Massarene of Antrim Castle, Ireland, to become his domestic chaplain. At Antrim, where he was soon joined by his family, he accordingly spent six years of quiet, during which he frequently preached in public, with the approval of the bishop of the diocese, and also found time to produce the most eloquent of his shorter treatises, *The Vanity of Man as Mortal*, and *On Delighting in God*; there too he planned the largest (and also in some respect the greatest) of his works, *The Living Temple*. In the beginning of 1676 he accepted an invitation to become pastor of a nonconformist congregation in Silver Street, London; and in the same year he published the first part of *The Living Temple*, entitled *Concerning God's Existence and His Conversableness with Man: Against Atheism or the Epicurean Deism*. In 1677 appeared his tractate *On the Reconcileableness of God's Prescience of the Sins of Men with the Wisdom and Sincerity of His Counsels, Exhortations, and whatsoever means He uses to prevent them*, which was attacked from various quarters, and had Andrew Marvel for one of its defenders. His work *On Thoughtfulness for the Morrow* followed in 1681; those on *Self-Dedication* and *Union among Protestants* in 1682; and that on *The Redeemer's Tears wept over Lost Souls* in 1684. During the earlier years that followed his settlement in London Howe had enjoyed comparative freedom from annoyance on the ground of his nonconformity, and had been on intimate terms with many who already were or who afterwards became eminent in the Established Church, such as Stillingfleet, Tillotson, Sharp, and Kidder; but the greater severity which began to be manifested in 1681, and which continued to be shown during the following years, so interfered with his liberty that in 1685 he gladly accepted the invitation of Philip Lord Wharton to travel abroad with him. The tour extended over the greater part of a year. In 1686, matters still seeming hopeless in England, he determined to settle for a time at Utrecht, where he officiated along with Mead and others in the English chapel, and also read privately with English students at the university. Among his friends there was Burnet, the future bishop of Salisbury, by whose influence he obtained several confidential interviews with the prince of Orange. In 1687 Howe availed himself of the publication by James II. of the declaration for liberty of conscience to return to England, and in the following year he headed the procession of nonconformist ministers who went to congratulate William on his accession to the English throne. The remainder of his life, so far as recorded, was extremely uneventful. In 1693 he published three admirable discourses *On the Carnality of Religious Contention*, suggested by the disputes and divisions that had so abundantly occurred among the nonconformists as soon as liberty of doctrine and worship had been granted. In 1694 and 1695 he published various treatises on the subject of the Trinity, the principal being *A Calm and Solemn Inquiry concerning the Possibility of a Trinity in the Godhead*. The second part of *The Living Temple*, entitled *Animadversions on Spinosa and a French Writer pretending to confute him, with a recapitulation of the former part and an account of the destitution and restitution of God's Temple among Men*, appeared in 1702. About this time he appears to have fallen into shattered health, but he was able in 1705 to give to the world a discourse *On Patience in the Expectation of Future Blessedness*, which proved to be his last work. He died in London on April 2, 1706.

Though excelled by Baxter as a pulpit orator, and by Owen in exegetical ingenuity and in almost every department of theological learning, Howe compares favourably with either as a sagacious and profound thinker, while he was much more successful in combining religious earnestness and fervour of conviction with large-hearted tolerance and cultured breadth of view. His style, moreover, though not altogether free from the literary faults which may almost be called characteristic of Puritanism, has often a stately yet graceful flow which the modern reader will look for in vain in most of Howe's theological contemporaries. The works published in his life-time, including a number of sermons and other occasional pieces besides those specified above, were collected into 2 vols. fol. in 1724, and again reprinted in 3 vols. 8vo. in 1848. A complete edition of the *Whole Works*, including much posthumous and additional matter, appeared with a Memoir in 8 vols. in 1822; this was reprinted in 1 vol. in 1838. The *Memoirs* of Howe by Calamy, originally published in 1724, have been more than once reprinted, and form the basis of *The Life and Character of Howe, with an Analysis of his Writings*, by Henry Rogers (1836; new ed., 1863).

HOWE, Richard Howe, Earl (1725-1799), English admiral, was born in 1725. By his father Emanuel Scrope Howe, second Viscount Howe in the Irish peerage, he was descended from an old family, several members of which attained distinction in war or in politics; and his mother was the daughter of Baron Kielmansegge, master of the horse to George I. when elector of Hanover. Leaving Eton at the age of fourteen, Howe entered the navy as midshipman on board the "Severn," which then formed one of a squadron under Anson destined for an expedition against Spain in the Pacific. Nothing is recorded as to the manner in which he conducted himself in the actions in which the squadron engaged, but he at any rate succeeded in winning the approval of his commander, and in his twentieth year was made lieutenant. Shortly after this he was appointed to the command of a sloop-of-war, the "Baltimore," in which with the aid of the "Greyhound" frigate, commanded by Captain Noel, he signalized himself by defeating off the coast of Scotland two French vessels, of greatly superior metal to his own, which were carrying supplies and reinforcements to the Pretender. On his arrival in England he found that previous to this action he had been raised to the rank of post-captain, and he served in this capacity on the coast of Guinea and on the Jamaica station. In 1748 he returned to England, and after spending three years chiefly in the study of naval tactics, he was in 1751 appointed to the "Glory," of 44 guns, and employed on the coast of Africa. In May 1752 he was commissioned to the "Dolphin" frigate, in which he was employed for some years in protecting the trade in the vicinity of Gibraltar. Shortly after his return to England he was appointed in 1755 to the "Dunkirk," and joined the squadron of Admiral Boscawen, bound for America. In the course of the voyage thither Howe took a prominent part in capturing two French men-of-war, the "Alcide" and the "Lys." This action was virtually the commencement of the seven years' war with France, in the course of which Howe in command of a small squadron succeeded in capturing from the French the island of Chaussé, and, after obtaining a commission to the "Magnanime," distinguished himself in the attacks made on the Isle of Aix, St Malo, and Cherbourg, manifested conspicuous courage and readiness of resource at the disaster of St Cas, and in the action with the French fleet under De Conflans disabled two of the enemy's ships. Shortly before the close of the war Howe had married, and by the death of his brother Viscount Howe had inherited the family titles and estates. From 1758 till 1782 he represented Dartmouth in parliament; in the latter year he was raised to the British peerage as Viscount Howe. In 1763 he received a seat at the board of admiralty, and in June 1765 he was appointed to the important office of treasurer of the navy, which he retained till August 1770. In October of this latter year he was made rear-admiral of the blue, and nominated commander in chief of the fleet intended to be employed in the Mediterranean in view of a probable rupture with Spain, which, however, did not take place. In 1775 he was promoted rear-admiral of the white, and in the following year he received the command of the squadron despatched to America, but owing to the insufficiency of his force he achieved no exploit of importance. After his return to England he was in September 1782 appointed to the command of the Channel fleet, and ordered to proceed to the relief of Gibraltar, then besieged by the combined land and sea forces of France and Spain, when after succeeding in supplying the garrison with stores and provisions he engaged at long ranges the united fleet which numbered 44 sail to his 34, and caused them to retreat to Cadiz. In January 1783 Howe succeeded Keppel as first lord of the admiralty, an office which he resigned in the following April, but again accepted under the Pitt ministry, holding it till July 1788. In July 1787 he was made admiral of the white, and shortly afterwards was raised to an earldom. In 1790 he was appointed to the command of a fleet intended to operate against the Spaniards, but peace was concluded before any action took place. On the commencement of the war with France after the Revolution he obtained the chief command in the Channel, and on the 1st of June 1794 gained a great victory over the French fleet off Ushant, dismasting ten of the enemy's ships and taking seven, one of which, the "Vengeur," sank as she was being towed away. On the 9th August of the same year he resumed the command of the Channel fleet, but in none of his cruises was he fortunate enough to meet any of the enemy's vessels; and during the greater part of 1795 and 1796 ill health compelled him to remain on shore. In May 1797 he resigned his command. In the same year he was appointed with full powers to treat with the mutineers in the British fleet at Portsmouth and Spithead, and completely succeeded, through the confidence they had in the friendliness of his intentions, and by the firm and judicious measures he adopted, in eradicating the causes of discontent. During the latter years of his life Lord Howe suffered much from ill health; and he died under a violent attack of gout, August 5, 1799. A splendid monument was erected to Howe in St Paul's Cathedral.

Lord Howe is entitled to the exceptional praise of never having failed to bear himself with credit and success in any of his enterprises. The qualities in which he excelled were coolness, firmness, seamanship, and caution—an excess of the latter virtue, however, tending perhaps on some occasions to diminish the lustre and completeness of his victories. He introduced a new and thorough system of naval tactics, evolutions, and signals, and bestowed careful and minute attention on all the details of the service. In person he was tall and well-proportioned. His countenance was strongly marked, somewhat harsh in expression except when softened by his genial smile, and dark in complexion—although the *sobriquet* of Black Dick by which he was known in the navy was not due to this circumstance, but to a mezzotinto portrait of himself which hung in his cabin. The benevolent friendliness of his disposition secured him the strong affection and confidence as well as respect of his seamen, while no professional jealousy prevented him from doing full justice to the achievements of his officers.

HOWELL, James (1594-1666), a voluminous English author, best known by his collection of letters (*Epistolæ Ho-Elianæ*) and his *Instructions for Forreine Travell*, which, in Mr Arber's phrase, form our first handbook for the Continent. Howell, as he was proud to acknowledge, was a Welshman; he was born probably at Abernant in Carmarthenshire, where his father was minister. From the free grammar school at Hereford he proceeded to Jesus College, Oxford, in 1610, and there he took his degree of B.A. in 1613. About 1617 we find him holding the post of steward in Sir Robert Mansell's glass-works in Broad Street, and in the following year he was commissioned to go abroad to procure the services of some high-class workmen. It was not till 1622 that he returned home, having visited Holland, France, Spain, and Italy; and these three or four years of foreign experience made a lasting impression on his character and his career. Not long after his return he was despatched to Spain in company with Lord Digby's embassy to try and settle a dispute about the unlawful seizure of an English vessel; but though he remained till the end of 1624 he was obliged to return without success: the Spaniards, irritated at the breaking off of the famous match, were in no mood for concessions. For some time Howell had no stable employment, but at length, in 1626, he went to York as secretary to Lord Scroop, lord president of the north, and for a season he appears to have been wonderfully fortunate. In 1627 he was elected M.P. for Richmond; in 1632 he was sent as orator with the embassy of the earl of Leicester to Denmark; and in 1642 the king appointed him one of the clerks of the privy council. On suspicion of royalist leanings he was committed to the Fleet prison by the Parliament in 1643, and, though he professed himself most humbly submissive to its authority, he was allowed to languish in confinement till 1648. He had acquired considerable fame by his allegorical Δενδρολογία, published in 1640, and his *Instructions for Forreine Travell*, 1642; and now he was driven to maintain himself by his pen. He edited and supplemented Cotgrave's French and English dictionary, compiled *Lexicon Tetraglotton, or an English, French, Italian, and Spanish Dictionary* (London, 1660), translated various works from Italian and Spanish, and wrote a life of Louis XIII. In 1660 he presented a petition for confirmation in the place of clerk of the privy council; and, though this was not granted him, the post of historiographer royal was created for his benefit. In 1661 he made application for the office of tutor in foreign languages to the infanta Catherine of Braganza, and in the following year published an *English Grammar translated into Spanish*. He died in 1666, having realized to the last his favourite motto, "*Senesco non segnesco.*" Howell had no small ability and learning; and all his writings are imbued with a certain simplicity and quaintness. His elaborate allegories, *Discourses of Trees* and the like, are now dead to the root; his linguistic labours, though of worth in their time, are a hundred times superseded; but his *Letters* (10th ed., 1737) are still almost models of their kind, and his *Instructions*, with their subtle observations and pithy parallels, are well worthy of their place in Mr Arber's series (London, 1869).

HOWITT, William (1795–1879), a popular writer and poet, was born in 1795 at Heanor, Derbyshire, where the Howitts had long been settled. His mother and father being members of the Society of Friends, William was brought up, with his brothers, in the faith of that sect, and educated at the local schools of the society. What he thus learned was supplemented by studies in natural science and modern literature and languages; and his leisure, spent in the woods and by the brook, fostered that love of nature which brightened every page he wrote and won his readers' sympathy. A poem, published in 1814, on the *Influence of Nature and Poetry on National Spirit*, was, so far as we know, his first printed work. He married in 1823 a Quaker lady, Mary Botham of Uttoxeter, who as poetess and prose-writer occupies a place in literature no less distinguished than her husband's. The first joint book appeared in the year of their marriage under the title, *The Forest Minstrel, and other Poems*. After a pedestrian excursion to Scotland, they took up their residence at Nottingham, Howitt engaging in the business of an apothecary. In 1824 he printed *A Poet's Thoughts at the Interment of Lord Byron*. We now find that both he and his wife had become known by their contributions, chiefly in rustic verse, to *The Literary Souvenir*, *The Amulet*, and other serial volumes of the day; these were collectively issued with additions in 1827 as *The Desolation of Eyam* (founded on the plague), *The Emigrant, and other Poems*. In 1831 Howitt produced a work of the class specially his own, *The Book of the Seasons, or the Calendar of Nature*, in which he drew a picture, from his own observations, of the appearances of mother earth in the garden, in the field, and by the stream during each of the twelve months. Of quite a different character was *A Popular History of Priestcraft* (1833), which ran through several editions, and gained him the favour of the active Liberals of his time, and the office of alderman of Nottingham. It was followed, in 1835, by a cognate work in 2 vols., entitled, *Pantika, or Traditions of the most Ancient*

Times. Having removed in 1837 to Esher, to be near the literary circles of the metropolis, Howitt there wrote in succession *The Rural Life of England*, 2 vols., 1838; *Colonization and Christianity*, 1838; *The Boy's Country Book*, 1839; and the first series (afterwards extended) of *Visits to Remarkable Places, Old Halls, Battlefields, and Scenes illustrative of striking passages in English History and Poetry*, 1840–42, in which he recorded impressions derived on the spot, and pictured each place with its inhabitants—freed, as he says, from the heaviness of the antiquarian rubbish piled upon them. Visiting Heidelberg in 1840, primarily for the education of their children, the Howitts remained in Germany two years, studying their neighbours, and busying their pens in descriptions of their new surroundings. In 1841 Howitt produced *The Student Life of Germany*, under the pseudonym of "Dr Cornelius," including translations of some of the most popular German songs. The next year he published *The Rural and Domestic Life of Germany, with characteristic Sketches of its Cities and Scenery*; in the year following a translation of Chamisso's *Wonderful History of Peter Schlemihl*; and in 1844 *The Life of Jack of the Mill*, a version of Holthaus's *Wanderings of a Journeyman Tailor*, and *German Experiences, addressed to the English*, a satire on the social life of Germany. In 1845 appeared *Life in Dalecarlia*, translated from the Swedish of Miss Bremer, *The Renounced Treasure*, and *Johnny Darbyshire. The Aristocracy of England, a History of the English People*, a political sketch, appeared in 1846, at the beginning of which year Howitt became connected with the management and proprietorship of *The People's Journal*, a weekly paper. A disagreement leading to his withdrawal he started in 1847 a rival called *Howitt's Journal*, but this was continued through three or four volumes only, though *The People's Journal* was merged in it. In 1847 Howitt had translated Ennemoser's *History of Magic*, and written an original work entitled *Homes and Haunts of the most eminent British Poets*, 2 vols., which was succeeded by *The Hall and the Hamlet, or Scenes and Characters of Country Life*, and very speedily by *Stories of English and Foreign Life* (Bohn's Illustrated Library), in which Mrs Howitt assisted. Then appeared *The Year-Book of the Country, or the Field, the Forest, and the Fireside*, and in 1851 a three-volume novel called *Madam Dorrington of the Dene.*

Under the associated names of husband and wife an interesting work was brought out in 1852, *The Literature and Romance of Northern Europe: constituting a complete History of the Literature of Sweden, Denmark, Norway, and Iceland*, in 2 vols. In June of that year Howitt, with two sons and some friends, set sail for Australia, where he spent two of the most trying years of his life, working in the gold diggings, and visiting Melbourne, Sydney, and other towns. Some account of the novel situations in which he was himself placed is given in *A Boy's Adventures in the Wilds of Australia* (1854). Shortly afterwards he returned to the suburbs of London, on this occasion to Highgate, and narrated more elaborately his experiences in *Land, Labour, and Gold; or Two Years in Victoria, with Visits to Sydney and Van Diemen's Land*, 2 vols., 1855, a work which speedily became popular, the condition of the Australian colonies being then almost totally unknown in England. A further account of Australian life was given in 1857 in *Tallangetta, the Squatter's Home*, 3 vols. The year before Howitt had commenced *The Illustrated History of England* for Messrs Cassell, the sixth and last volume of which appeared in 1861. While this work was in progress he wrote in 1859 *A Country Book of Amusements*, and, in connexion with Mrs Hall and others, *The Boy's Birthday Book*, and in 1860 *The Man of the People*, 3 vols. From 1861 to 1864 Mr and Mrs Howitt were occupied on *The Ruined Abbeys and Castles of Great Britain*, issuing, before its completion, *The Wye, its Ruined Abbeys and Castles* (1863); and the same year Howitt printed a series of *Letters on Transportation, and the Cruelties Practised under the Game Laws*, and a work of great research, *The History of the Supernatural in all Ages and Nations, and in all Churches, Christian and Pagan, demonstrating a Universal Faith*, 2 vols. To a man with the mental development of Howitt the miraculous became at all times an absorbing speculation; and he adds to these pages "his own conclusions from a practical examination of the higher phenomena through a course of seven years." "If," he reasons, "you crush the supernatural you must crush the universe." Other works from Howitt's prolific pen were *Sargent's Peculiar* (1864); *The History of Discovery in Australia*, &c., 2 vols., 1865; *The Ruined Abbeys of the Border* (1865), *and of Yorkshire* (1865), jointly with his wife; *Woodburn Grange*, a story of English country life, 3 vols., 1867; *The Northern Heights of London*, an antiquarian and topographical description of Hampstead, Highgate, &c., 1869; *The Mad War-Planet, and other Poems*, 1871; *The Religion of Rome*, 1873. Suffering from bronchitis, Howitt had now made Rome his winter residence, passing the summer in Tyrol. He died at Rome on the 3d of March 1879.

HOWRAH, the largest and most important town in the district of Hooghly, Bengal, and the headquarters of the magisterial district of Howrah, is situated on the right bank of the Hooghly river, opposite Calcutta, and forms a suburb of that city. Since 1785 it has risen from a small village to a town, with a magistrate, subordinate judge, &c., of its own. The total area of Howrah and suburbs within municipal limits is 11·05 square miles; the population in 1872 numbered 97,784, of whom 54,098 were males and 43,686 females (Hindus, 79,335; Mahometans, 16,611; Christians, 1484; others, 354). The municipal income in 1871–72 was £13,994. The town is lighted with gas; it contains several large and important dockyards, and is also the Bengal terminus of the East Indian Railway. Mills and manufactories of various sorts are rapidly developing. Communication with Calcutta is carried on by means of ferry steamers, and by a massive pontoon bridge, which was opened for traffic in 1874. Howrah is a suburban residence for many people who have their places of business in Calcutta. Sibpur, one of the suburbs of Howrah, situated opposite Fort-William, a small village at the commencement of the century, is now a flourishing little town. To the south of Sibpur are the Royal Botanical Gardens and the Bishop's College.

HÖXTER (Latin, *Huxaria*), a town of Prussia, capital of a circle in the government district of Minden, province of Westphalia, is situated on the Weser at its confluence with the Grube and the Schelpe, and on a branch line of the Westphalian Railway, 2½ miles S.W. of Holzminden. It is the seat of a provincial office and of a circle court, and possesses an Evangelical and a Catholic church, a synagogue, a gymnasium, a building-school, and a hospital. The Weser is crossed by a stone bridge about 500 feet in length, erected in 1833. On the Brunsberg adjoining the town there is an old watch-tower said to be the remains of a fortress built by Bruno, brother of Wittekind. Near Höxter is the castle, formerly the Benedictine monastery, of Corvey (see CORVEY). The principal manufactures of the town are linen, cotton, cement, and gum, and there is also a considerable shipping trade. The population in 1875 was 5645.

Höxter in the time of Charlemagne was a *villa regia*, and was the scene of a battle between him and the Saxons. Under the protection of the monastery of Corvey, founded in 816, it gradually increased in prosperity. Ultimately it asserted its independence and joined the Hansa League. It suffered severely during the

Thirty Years' War, being captured four several times. After the peace of Westphalia it was united to Brunswick; in 1802 it was transferred to Orange-Nassau, and in 1807 to Westphalia, after the dismemberment of which in 1814 it came into the possession of Prussia.

HOYLE, EDMUND or EDMOND (1672–1769), the first systematizer of the laws of whist, and author of a book on games, was born in 1672. His parentage and place of birth are unknown, and few details of his life are recorded. For some time he was resident in London, and partially supported himself by giving instruction in the game of whist. For the use of his pupils he drew up a *Short Treatise* on the game, which after circulating for some time in manuscript was printed by him and entered at Stationers' Hall in November 1742. The laws of Hoyle continued to be regarded as authoritative until 1864, since which time they have been gradually superseded by the new rules adopted by the Arlington and Portland clubs in that year. He also published rules for various other games, and his book on games, which includes the *Short Treatise*, has passed into many editions. The weight of his authority is indicated by the phrase "according to Hoyle," which, doubtless first applied with reference to whist, has gained currency as a general proverb. Hoyle died at Cavendish Square, London, August 29, 1769.

HRABANUS MAURUS MAGNENTIUS (776–856), archbishop of Mainz, and one of the most prominent teachers and writers of the Carolingian age, was born of noble parents at Mainz about the year 776. Less correct forms of his name are Rabanus and Rhabanus. At a very early age he was sent to Fulda, where he continued until, on attaining the canonical age, he received deacon's orders (801); in the following year, at the instance of Ratgar his superior, he went along with Haimon (afterwards of Halberstadt) to complete his studies at Tours under Alcuin, who in recognition of his diligence and purity gave him the surname of Maurus, after St Maur the favourite disciple of Benedict. Returning after the lapse of two years to Fulda, he was entrusted with the principal charge of the school, which under his direction rose into a state of great efficiency for that age, and sent forth such pupils as Walafrid Strabo, Servatus Lupus of Ferrières, and Otfrid of Weissenburg. At this period it is most probable that his *Excerptio* from the grammar of Priscian, long so popular as a textbook during the Middle Ages, was compiled. In 814 he was ordained a priest; but shortly afterwards, apparently on account of disagreement with Ratgar, he was compelled to withdraw for a time from Fulda. This "banishment" is understood to have occasioned the pilgrimage to Palestine to which he alludes in his commentary on Joshua. Returning to Fulda on the election of a new abbot (Eigil) in 817, he himself five years afterwards (822) became superior. The duties of this office he discharged with efficiency and success until 842, when, in order to secure greater leisure for literature and for devotion, he resigned and retired to the neighbouring cloister of St Peter's. In 847 he was again constrained to enter public life by his election to succeed Otgar in the archbishopric of Mainz, which see he occupied for upwards of eight years. The principal incidents of historical interest belonging to this period of his life were those which arose out of his relations to Gottschalk; they may be regarded as thoroughly typical of that cruel intolerance which he shared with all his contemporaries, and also of that ardent zeal which was peculiar to himself; but they hardly do justice to the spirit of kindly benevolence which in less trying circumstances he was ever ready to display. He died at Winkel on the Rhine, February 4, 856. He is frequently referred to as St Rabanus, but incorrectly.

His voluminous works, many of which remain unpublished, comprize commentaries on a considerable number of the books both of canonical and of apocryphal Scripture (Genesis to Judges, Ruth, Kings, Chronicles, Judith, Esther, Canticles, Proverbs, Wisdom, Ecclesiasticus, Jeremiah, Lamentations, Ezekiel, Maccabees, Matthew, the Epistles of St Paul, including Hebrews); and various treatises relating to doctrinal and practical subjects, including more than one series of Homilies. Perhaps the most important is that *De Institutione Clericorum*, in three books, by which he did much to bring into prominence the views of Augustine and Gregory the Great as to the training which was requisite for a right discharge of the clerical function; the most popular has been a comparatively worthless tract *De Laudibus Sanctæ Crucis*. Among the others may be mentioned that *De Universo Libri xxii., sive Etymologiarum Opus*, a kind of dictionary or encyclopædia, designed as a help towards the historical and mystical interpretation of Scripture, the *De Sacris Ordinibus*, the *De Disciplina Ecclesiastica*, and the *Martyrologium*. All of them are characterized by erudition (he knew even some Greek and Hebrew) rather than by originality of thought. The poems are of singularly little interest or value, except as including one form of the "Veni Creator." In the annals of German philology a special interest attaches to the *Glossaria Latino-Theodisca*. A commentary, *Super Porphyrium*, printed by Cousin in 1836 among the *Ouvrages inédits d'Abélard*, and assigned both by that editor and by Hauréau to Hrabanus Maurus is now generally believed to have been the work of a disciple.

The first nominally complete edition of the works of Hrabanus Maurus was that of Colvener (Cologne, 6 vols. fol., 1627). The *Opera Omnia* form vols cvii–cxii. of Migne's *Patrologiæ Cursus Completus*. The *De Universo* is the subject of *Compendium der Naturwissenschaften an der Schule zu Fulda im IX. Jahrhundert* (Berlin, 1880). Maurus is the subject of monographs by Schwarz (*De Rhabano Mauro primo Germaniæ præceptore*, 1811), Kunstmann (*Historische Monographie über Hrabanus Magnentius Maurus*, 1841), Spengler (*Leben des heil. Rhabanus Maurus*, 1856), and Köhler (*Rhabanus Maurus u. die Schule zu Fulda*, 1870). *Lives* by his disciple Rudolphus and by Joannes Trithemius are printed in the Cologne edition of the *Opera*. See also Pertz, *Monum. Germ. Hist.*, vols. i. and ii.; and Bähr, *Gesch. d. römischen Literatur im Karoling. Zeitalter*, 1840.

HROSVITHA (frequently ROSWITHA, and properly HROTSUIT), early mediæval dramatist and chronicler, occupies a very notable position in the history of modern European literature. Her endeavours formed part of the literary activity by which the age of the emperor Otto the Great sought to emulate that of Charles the Great. The famous nun of Gandersheim has occasionally been confounded with her namesake, a learned abbess of the same convent, who must have died at least half a century earlier. The younger Hrosvitha was born in all probability about the year 935; and, if the statement be correct that she sang the praises of the three Ottos, she must have lived to near the close of the century. Some time before the year 959 she entered the Benedictine nunnery of Gandersheim, a foundation which was confined to ladies of German birth, and was highly favoured by the Saxon dynasty. In 959 Gerberga, daughter of Duke Henry of Bavaria, and therefore niece of the emperor Otto I., was consecrated abbess of Gandersheim, and the earlier literary efforts of the youthful Hrosvitha (whose own connexion with the royal family appears to be an unauthenticated tradition) were encouraged by the still more youthful abbess, and by a nun of the name of Richarda.

The literary works of Hrosvitha, all of which were as a matter of course in Latin, divide themselves into three groups. Of these the first and least important comprises eight narrative religious poems, in leonine hexameters or distichs. Their subjects are the Nativity of the Virgin (from the apocryphal gospel of St James, the brother of our Lord), the Ascension, and a series of legends of saints (Gandolph, Pelagius, Theophilus, Basil, Denis, Agnes). Like these narrative poems, the dramas to which above all Hrosvitha owes her fame seem to have been designed for reading aloud or recitation by sisters of the convent. For though there are indications that the idea of their representation was at least present to the mind of the authoress, the fact of such a representation appears to be an unwarrantable assumption. The comedies of Hrosvitha are six in number, being doubtless in this respect also intended to recall their nominal model, the comedies of Terence. They were devised on the simple principle that the world, the flesh, and the devil should not have all the good plays to themselves. The experiment upon which the young Christian dramatist ventured was accordingly, although not absolutely novel, audacious enough. In form the dramas of "the strong voice of Gandersheim," as Hrosvitha (possibly alluding to a supposed etymology of her name) calls herself, are by no means Terentian. They are written in prose, with an element of something like rhythm, and an occasional admixture of rhyme. In their themes, and in the treatment of these, they are what they were intended to be, the direct opposites of the lightsome adapter of Menander. They are founded upon legends of the saints, selected with a view to a glorification of religion in its supremest efforts and most transcendental aspects. The emperor Constantine's daughter, for example, Constantia, gives her hand in marriage to *Gallicanus*, just before he starts on a Scythian campaign, though she has already taken a vow of perpetual maidenhood. In the hour of battle he is himself converted, and, having on his return like his virgin bride chosen the more blessed unmarried state, dies as a Christian martyr in exile. The three holy maidens Agape, Chionia, and Irene are preserved by a humorous miracle from the evil designs of *Dulcitius*, to offer up their pure lives as a sacrifice under Diocletian's persecutions. *Callimachus*, who has Romeo-like carried his earthly passion for the saintly Drusiana into her tomb, and among its horrors has met with his own death, is by the mediation of St John raised with her from the dead to a Christian life. All these themes are treated with both spirit and skill, often with instinctive knowledge of dramatic effect—often with genuine touches of pathos and undeniable felicities of expression. In *Dulcitius* there is also an element of comedy, or rather of farce. How far Hrosvitha's comedies were an isolated phenomenon of their age in Germany must remain undecided; in the general history of the drama they form the visible bridge between the few earlier attempts at utilizing the forms of the classical drama for Christian purposes and the miracle plays. They are in any case the productions of genius; nor has Hrosvitha missed the usual tribute of the supposition that Shakespeare has borrowed from her writings.

The third and last group of the writings of Hrosvitha is that of her versified historical chronicles. At the request of the abbess Gerberga she composed her *Carmen de Gestis Oddonis*, an epic attempting in some degree to follow the great Roman model. It was completed by the year 968, and presented by the authoress to both the old emperor and his son (then already crowned as) Otto II. This poem so closely adheres to the materials supplied to the authoress by members of the imperial family that, notwithstanding its courtly omissions, it is regarded as an historical authority. Unfortunately only half of it remains; the part treating of the period from 953 to 962 is lost with the exception of a few fragments, and the period from 962 to 967 is summarized only. Subsequently, in a poem (of 837 hexameters) *De Primordiis Cœnobii Gandersheimensis*, Hrosvitha narrated the beginnings of her own convent, and its history up to the year 919.

The Munich MS., which contains all the works enumerated above except the *Chronicle of Gandersheim*, was edited by the great Vienna humanist Celtes in 1501, and re-edited by the learned H. L. Schurzfleisch in 1707. The comedies have been translated into German by Bendixen (Lübeck, 1858), and into French by A. Magnin (Paris, 1845), whose introduction gives a full account of the authoress and her works. A copious analysis of these plays will be found in Klein, *Geschichte des Dramas*, iii. 665–754. Gustav Freytag is the author of a treatise *De Rosuitha poetria* (Breslau, 1839); and at the beginning of Cohn's *Shakspeare in Germany*, Shakespearean parallels are suggested to certain passages in Hrosvitha's dramas. Her two historical chronicles were edited by Pertz among the *Monumenta Germaniæ* (vol. iv.); for an appreciation of them see Wattenbach, *Geschichtsquellen*, 214–216, and Giesebrecht, *Deutsche Kaiserzeit*, i. 780, who mentions a German translation by Pfund. There is a complete edition of the works of Hrosvitha by K. A. Barack (Nuremberg, 1858). J. Aschbach (1867) attempted to prove that Celtes had forged the productions which he published under the name of Hrosvitha, but he was refuted by R. Köpke (Berlin, 1869). (A. W. W.)

HUANCAVELICA, or GUANCABELICA, the chief town of a department of same name, Peru, is situated in a deep ravine, of an average width of one mile, at about 12,400 feet above sea level, and 160 miles south-east of Lima. It is well and regularly built, the houses being of stone, while several stone bridges span the stream that flows through the town. Huancavelica was founded in 1572 as a mining town by the viceroy Francisco de Toledo, and mining has continued to be the principal employment of the inhabitants. Close by is the famous quicksilver mine of Santa Barbara, with its subterranean San Rosario church, cut out of the cinnabar. Population in 1876, 3937.

HUANUCO, or GUANUCO, the chief town of the Peruvian department of the same name, is situated on the left bank of the river Huallaga near its junction with the Higueras, in a beautiful valley nearly 6000 feet above sea-level, and 180 miles north-west of Lima. The streets are laid out regularly, but the houses are mean-looking. As nearly every house is surrounded by a garden the limits of the town embrace a large area. Sweetmeats for the Lima market are almost the only manufacture, most of the inhabitants being engaged in mining and farming. Huanuco was founded in 1539 by Gomez Alvarado, and was shortly afterwards raised to a bishopric. In 1812 during an insurrection of the Indians of Panao it was plundered. The population in 1876 was 5263.

HUARAZ, chief town of the Peruvian department of Ancachs, and of a district to which it gives its name, is situated on the left bank of the river Santa, in a fertile valley of the Andes, about 190 miles N.N.W. of Lima. There is some export trade in cattle, wheat, sugar, and fruit; and in the vicinity considerable quantities of gold, silver, and copper are mined. A state railway 172 miles long, of which 82 miles are completed, is designed to connect Huaraz with Chimbote on the coast. Near the town there are ruins in the second or Cyclopean style of Inca architecture, sufficiently like the remains at Tiahuanca to allow us to assign Huaraz as the northern limit of the prehistoric Incarial empire, of which Tiahuanca was the southern boundary. Population in 1876, 4851.

HUBER, FRANÇOIS (1750–1831), an eminent Swiss naturalist, especially distinguished by the originality and reach of his researches into the life history of the honey-bee, was born at Geneva, July 2, 1750. He belonged to a family which had already made its mark in the literary and scientific world; his great-aunt, Marie Huber (1695–1753), was known as a voluminous writer on religious and theological subjects, and as the translator and epitomizer of *The Spectator* (*Redaction du Spectateur Anglais à ce qu'il renferme de meilleur*, Amst., 3 vols. 1753); and his father Jean Huber (1721–1786), who had served for many years as a soldier, was a prominent member of the coterie at Ferney, distinguishing himself both by the rare skill with which he could reproduce the likeness of Voltaire by clipping paper and by other unpromising devices, and by the publication of a valuable series of *Observations sur le vol des oiseaux* (Geneva, 1784). From an early age François Huber displayed a dangerous ardour for study; and he was only fifteen years old when he began, in consequence of his ill-judged assiduity, to suffer from an affection of the eyes which gradually resulted in total blindness. Happily at once for his comfort and his fame he had secured the affection of Marie Aimée Lullin. Having patiently waited till she was legally of age, she married the husband of her choice, and ministered to his wants till her death with such unceasing devotion that it was only, he said, when he lost her that he really felt he was blind. For many years her efforts were seconded by François Burnens, a servant, whom Huber had inspired with something of his own love of nature. The results of the investigations which were conducted by this happily assorted trio, at once surprised and delighted the world. So skilfully did the blind man devise his experiments, and so carefully did his assistants conduct and register their observations, that the work *Nouvelles Observations sur les abeilles* (Geneva, 1792; Paris, 1796; new ed., Paris, 1814; English translation, Edinburgh, 1806 and 1821) laid the foundation of all our scientific knowledge of the subject. Huber assisted Senebier in his *Mém. sur l'influence de l'air, &c., dans la germination* (Geneva, 1800); and we also have from his pen "Mém. sur l'origine de la cire" (*Bibliothèque Britannique*, tome xxv.), a "Lettre à M. Pictet sur certains dangers que courent les abeilles" (*Bib. Brit.*, xxvii.), and "Nouvelles observ. rel. au sphinx *Atropos*" (*Bib. Brit.*, xxvii.). He died at the age of eighty-one, December 22, 1831. De Candolle gave his name to a genus of Brazilian trees—*Huberia laurina*. Pierre Huber (1777–1840) followed in his father's footsteps. His best known work is *Recherches sur les mœurs des fourmis indigènes* (Geneva and Paris, 1810; new ed., Geneva, 1861), but he also contributed papers on various entomological subjects to several scientific periodicals.

See the account of François Huber by De Candolle in *Bibl. Universelle*, 1832; and the notice of Pierre in *Bibl. Univ.*, 1866; also Haag, *La France Protestante*.

HUBER, Johann (1830–1879), a philosophical and theological writer whose name is intimately connected in Germany, and indeed throughout Europe, with the Old Catholic and other recent movements towards freedom and enlightenment, was born in very humble circumstances, on August 18, 1830, at Munich, where, originally destined for the priesthood, he early began the study of theology. By the writings of Spinoza and Oken, however, he was strongly drawn to philosophical pursuits, and it was in philosophy that he "habilitated" (1854), and ultimately became professor (extraordinarius in 1859 and ordinarius in 1864). Along with Döllinger and others he attracted a large amount of public attention in 1869 by the challenge to the Ultramontane promoters of the Vatican council in the treatise *Der Papst u. der Koncil*, which appeared under the pseudonym of "Janus," and also in 1870 by a series of letters ("Römische Briefe"), which were published in the *Allgemeine Zeitung*. The nature of the numerous controversies in which he became involved both before and after this main episode of his life may be gathered from the subjoined list of his published writings. He died suddenly of heart disease at Munich on March 20, 1879.

His treatise *Ueber die Willensfreiheit* (1858) was followed in 1859 by *Die Philosophie der Kirchenväter*, which was promptly placed by the Roman authorities upon the *Index*, and which led to the prohibition of all Catholic students from attending his lectures; *Johannes Scotus Erigena*, 1861; *Idee der Unsterblichkeit*, 1864; *Studien*, 1865; *Der Proletarier: zur Orientirung in der socialen Frage*, 1865; *Der Jesuitenorden nach Verfassung u. Doktrin, Wissenschaft u. Geschichte*, 1873; *Der Pessimismus*, 1876; *Die Forschung nach der Materie*, 1877; *Zur Philosophie der Astronomie*, 1878; *Das Gedächtniss*, 1878. He also published adverse criticisms on Darwin, Strauss, Hartmann, and Haeckel; pamphlets on *Das Papstthum u. der Staat*, 1870, and on *Die Freiheiten der französischen Kirche*, 1871; and a volume of *Kleine Schriften*, 1871.

HUBERT (Hugubert or Hugubrecht, "the Bright-witted"), St, bishop of Liége, was son of Bertrand, duke of Guienne, and held a prominent place in the court of the Frankish king Theodoric, and afterwards in that of Pippin of Heristal. He was passionately fond of the chase, but with the death of his wife Floribane all his taste for mundane enjoyments disappeared, and following the counsels of his friend and teacher, Bishop Lambert of Maestricht, he retired to the monastery of Stavelot, whence he afterwards undertook a pilgrimage to Rome, on occasion of which he was by pope Sergius I. appointed bishop of Tongern. In 708 he succeeded Lambert in the see of Maestricht and Liége, to whose memory he erected a cathedral in the latter city. His death occurred in 727, and in 825 his remains (which, it is alleged, suffered no decay for many years) were removed to a Benedictine cloister in the Ardennes, which thenceforth bore his name, and ultimately became a considerable resort of pilgrims. St Hubert's day is November 3, but the date and circumstances of his canonization are not stated. His conversion, represented as having been brought about, while he was hunting on Good Friday, by a miraculous appearance of a stag bearing between his horns a beaming cross or crucifix, has frequently been made the subject of artistic treatment. He is the patron of hunters, and is also invoked in cases of hydrophobia and demoniac possession. Several orders of knighthood have been under his protection; among these may be mentioned the Bavarian, the Bohemian, and that of the electorate of Cologne.

See Jameson, *Sacred and Legendary Art*; Fétis, *Légende de Saint Hubert, précédée d'une préface bibliographique et d'une introduction historique*, 1846; Des Granges, *Vie de Saint Hubert*, 1872; Heggen, *Des heiligen Hubertus Leben u. Wirken*, 1875.

HUBLI, a town in Dhárwár district, Bombay, 15° 20′ N. lat., 75° 12′ E. long., situated 13 miles south-east of Dhárwár, on the main road from Poona to Harihar; it is 230 miles south-east from Poona, 142 miles from Bellári (Bellary), 90 miles from Kárwár, and 97 miles from Kumpta (Coompta). Population (1872) 37,961. Situated on the main lines of communication to Harihar, Kárwár, and Kumpta, the town has become the centre of the cotton trade of the southern Marhattá country. Besides raw cotton and silk fabrics, a general trade in copper vessels, grain, salt, and other commodities is conducted on a large scale. Hubli was formerly the seat of an English factory, which in 1673, with the rest of the town, was plundered by Sivají, the Marhattá leader.

HUC, Évariste Régis (1813–1860), a celebrated French missionary-traveller, was born at Toulouse, 1st August 1813. In his twenty-fourth year he entered the congregation of the Lazarists at Paris, and shortly after receiving holy orders in 1839 set forth fired by missionary zeal for China. At Macao he spent some eighteen months in the Lazarist seminary preparing himself under the instruction of Perboyre for the regular work of a missionary in the interior. Having at last acquired a sufficient command of the Chinese tongue, and modified his personal appearance in accordance with Chinese taste, he started from Canton clad in the flowing costume of the natives, with his skin dyed yellow, and wearing the inevitable queue. He at first superintended a Christian mission in the southern provinces, and then passing to Peking, where he perfected his knowledge of the language, eventually settled in the Valley of Black Waters or He Shuy, a little to the north of the capital, and just within the borders of Mongolia. There, beyond the Great Wall, a large but scattered population of native Christians had found a refuge from the persecutions of Kia-King, to be united half a century later in a vast but vague apostolic vicariate. The assiduity with which Huc devoted himself to the study of the dialects and customs of the Tartars, for whom at the cost of much labour he translated various religious works, was an admirable preparation for undertaking in 1844, at the instigation of the vicar apostolic of Mongolia, an expedition whose object was to dissipate the obscurity which hung over the country and habits of the Tibetans. September of that year found the missionary at Tolon-noor occupied with the final arrangements for his journey, and shortly afterwards, accompanied by his fellow-Lazarist, Joseph Gabet, and a young Tibetan priest who had embraced Christianity, he set out. To escape attention the little party assumed the dress of lamas or priests. Crossing the Hoang-ho at Shagan-Kooren, they advanced into the terrible sandy tract known as the steppes of the Ortoos. After suffering dreadfully from want of water and fuel they entered Kansu, having recrossed the flooded Hoang-ho, but it was not till January 1845 that they reached Tang-Kiuul on the boundary. Rather than encounter alone the horrors of a four months' journey to Lhassa they resolved to wait for eight months till the arrival of a Tibetan embassy on its return from Peking. Under an intelligent teacher they meanwhile studied the Tibetan language and Buddhist literature, and during three months of their stay they resided in the famous Kounboum Lamasery, which was reported to accommodate 4000 persons. Towards the end of September they joined the returning embassy, which comprised 2000 men and 3700 animals. Crossing the deserts of Koko-nur, they passed the great lake of that name, with its island of contemplative lamas, and, ascending with difficulty and hardship the tortuous snow-covered mountains of Chuga and Baylen-Bharat, they at last entered Lhassa on the 29th January 1846. Favourably received by the regent, they opened a little chapel, and were in a fair way to establish an important mission, when the Chinese ambassador interfered and had the two missionaries conveyed back to Canton, where they arrived in October of the same year. For nearly three years Huc remained at Canton, but M. Gabet, returning to Europe, proceeded thence to Rio de Janeiro, and died there shortly afterwards. Huc returned to Europe in shattered health in 1852, visiting India, Egypt, and Palestine on his way, and, after a prolonged residence in Paris, died 31st March 1860. His writings comprise, besides numerous letters and memoirs in the *Annales de la Propagation de la Foi*, the famous *Souvenirs d'un Voyage dans la Tartarie, le Thibet, et la Chine pendant les années* 1844-46 (2 vols., Par., 1850; Eng. transl. by W. Hazlitt, 1851, abbreviated by M. Jones, Lond., 1867); its supplement, crowned by the Academy, entitled *L'Empire Chinois* (2 vols., Par., 1854; Eng. transl., Lond., 1859); and an elaborate historical work, *Le Christianisme en Chine*, &c. (4 vols., Par., 1857-58; Eng. transl., Lond., 1857-58). These works are written in a lucid, racy, picturesque style, which has secured for them an unusual degree of popularity. The narrative of one of the most remarkable feats of modern travel, the *Souvenirs* contain passages of so singular a character as in the absence of corroborative testimony to stir up a feeling of incredulity. That Huc was suspected unjustly has been amply proved by the later research of Bushnell, David, Prejevalski, Richthofen, and Colonel Montgomerie's "Pundits." But although his credibility has been firmly established, and although in his heroic enterprise he gathered a vast amount of novel and curious information, the fact remains that Huc was by no means a practical geographer, and that the record of his travels loses greatly in value from the want of precise scientific data.

See, for information specially relating to the whole subject, the Abbé Desgodin's *Mission du Thibet de 1855 à 1870*, Verdun, 1872; and "Account of the Pundit's Journey in Great Tibet," in the *Royal Geographical Society's Journal* for 1877.

HUCBALD (also called HUGBALDUS and HUBALDUS) was born in or about 840, if we may believe the statement of his biographers to the effect that he died in 930, aged 90. Of his life little is known; not even the place of his birth can be ascertained, but he was no doubt a Frenchman or a Belgian. It is certain that he studied at the convent of St Amand in French Flanders, where his uncle Milo occupied an important position. Hucbald made rapid progress in the acquirement of various sciences and arts, including that of music, and at an early age composed a hymn in honour of St Andrew, which met with such success as to excite the jealousy of his uncle. It is said that Hucbald in consequence was compelled to leave St Amand, and started an independent school of music and other arts at Nevers. In 860, however, we find him at St Germain d'Auxerre, bent upon completing his studies, and in 872 he is back again at St Amand as the successor in the head-mastership of the convent school of his uncle, to whom he had been reconciled in the meantime. Between 883 and 900 Hucbald went on several missions of reforming and reconstructing various schools of music, including that of Rheims, but in the latter year he returned to St Amand, where he remained to the day of his death (June 25, 930, or, according to other chroniclers, June 20, 932), and where his most important works on music were written. Of the character of these works and of the reforms and improvements advocated by them it is not easy to give a correct idea; not even their number is sufficiently certain, for some treatises have been attributed to Hucbald which are obviously not his, and others of which the authorship is at least doubtful. His largest and most authentic work is the *Enchiridion Musicæ*, published with other writings of minor importance in the first volume of Gerber's *Scriptores ecclesiastici*, and containing a complete system of musical science as well as instructions regarding notation. Hucbald as a musical theorist may be called a precursor of Guido d'Arezzo, to whose hexachord system his tetrachord, that is, the use of four instead of seven letters, forms a kind of basis. His scales are founded on strictly Greek principles, and cannot be said to mark a decided step in advance; neither is his system of notation much superior to the earlier ones, although here also he seems in a manner to foreshadow Guido's use of the lines and spaces of the staff from which the modern method took its rise. Of great importance is the 13th chapter of the *Enchiridion*, which treats of the diaphony or organum,—in other words, of singing in parts. Amongst other prescriptions it is curious to find the rule which recommends the use of parallel fifths and fourths, so strictly prohibited by later theorists, while, on the other hand, consecutive thirds, particularly euphonious to the modern ear, are excluded by Hucbald.

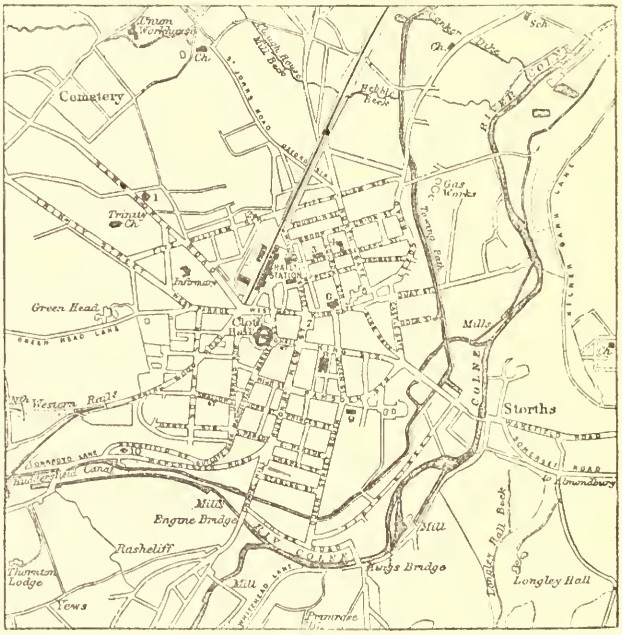
A good account of the monk of St Amand and his system will be found in Coussemaker's *Mémoire sur Hucbald*, Paris, 1841; Hawkins (*History*, vol. i. p. 153) also gives a short notice of Hucbald, and mentions two epitaphs written in his honour by contemporaries.

HUCHTENBURG. Two brothers of this name practised the art of painting in the second half of the 17th century. Both were natives of Haarlem. Jacob, the elder, of whom very little is known, studied under Berghem, and went early to Italy, where he died young about 1667. His pictures are probably confounded with those of his brother. In Copenhagen, where alone they are catalogued, they illustrate the style of a Dutchman who transfers Berghem's cattle and flocks to Italian landscapes and market-places.

John van Huchtenburg (1646-1733), born at Haarlem it is said in 1646, was first taught by Thomas Wyk, and afterwards induced to visit the chief cities of Italy, where, penetrating as far as Rome, he met and dwelt with his brother Jacob. After the death of the latter he wandered homewards, taking Paris on his way, and served under Van der Meulen, then employed in illustrating for Louis XIV. the campaign of 1667-68 in the Low Countries. In 1670 he settled at Haarlem, where he married, practised, and kept a dealer's shop. His style had now merged into an imitation of Philip Wouvermans and Van der Meulen, which could not fail to produce pretty pictures of hunts and robber camps, the faculty of painting horses and men in action and varied dress being the chief point of attraction. Later on Huchtenburg ventured on cavalry skirmishes and engagements of regular troops generally, and these were admired by Prince Eugene and William III., who gave the painter sittings, and commissioned him to throw upon canvas the chief incidents of the battles they fought upon the continent of Europe. When he died at Amsterdam in 1733, Huchtenburg had done much by his pictures and prints to make Prince Eugene, King William, and Marlborough popular. Though clever in depicting a *mêlée* or a skirmish of dragoons, he remained second to Philip Wouvermans in accuracy of drawing, and inferior to Van der Meulen in the production of landscapes. But nevertheless he was a clever and spirited master, with great facility of hand and considerable natural powers of observation.

The earliest date on his pictures is 1674, when he executed the Stag-Hunt in the Museum of Berlin, and the Fight with Robbers in the Lichtenstein collection at Vienna. A Skirmish at Fleurus (1690) in the Brussels gallery seems but the precursor of larger and more powerful works, such as the Siege of Namur (1695) in the Belvedere at Vienna, where William III. is seen in the foreground accompanied by Max Emmanuel, the Bavarian elector. Three years before, Huchtenburg had had sittings from Prince Eugene (Hague museum) and William III. (Amsterdam Trippenhuis). After 1696 he regularly served as court painter to Prince Eugene, and we have at Turin (gallery) a series of eleven canvases all of the same size depicting the various battles of the great hero, commencing with the fight of Zentha against the Turks in 1697, and concluding with the capture of Belgrade in 1717. Had the duke of Marlborough been fond of art he would doubtless have possessed many works of our artist. All that remains at Blenheim, however, is a couple of sketches of battles, which were probably sent to Churchill by his great contemporary. The pictures of Huchtenburg are not very numerous now in public galleries. There is one in the National Gallery, London, another at the Louvre. But Copenhagen has four, Dresden six, Gotha two, and Munich has the well-known composition of Tallart taken Prisoner at Blenheim in 1704.

HUDDERSFIELD, a municipal and parliamentary borough and market-town of England, in the West Riding of Yorkshire, is beautifully situated on the slope of a hill in the valley of the Colne, a tributary of the Calder, 15 miles south of Bradford, and 16½ south-west of Leeds. It is surrounded by a network of railways, and is connected with the extensive canal system of Lancashire and Yorkshire. The town is built principally of stone, and has undergone within late years very extensive improvements, in regard to both its external appearance and its sanitary arrangements. The older portions of the town, where the streets were mean-looking and narrow, have almost disappeared, making way for handsome, spacious, and well-paved thoroughfares, whilst many of the business premises possess considerable architectural merit. Among the churches deserving special mention are St Peter's, the parish church, in the Perpendicular style, rebuilt in 1837 at a cost of £10,000, possessing chancel, nave, aisles, transept, and tower with peal of ten bells; Trinity Church, erected in 1819 at a cost of £12,000, in the Pointed style, with an embattled tower at the west end; St Paul's, built by the parliamentary commissioners in 1831, in the Early English style, with a tower surmounted by a light spire; St Thomas's, in the Transition Early English style, completed in 1859 at a cost of £10,000. Of the numerous Nonconformist places of worship, Ramsden Street (Congregational), Queen Street and Buxton Road (Wesleyan), and Brunswick Street (Free Methodist) chapels are remarkable for their capacity, whilst High Street (New Connexion Methodist), New North Road (Baptist), and Highfield and Hillhouse (Congregational) have considerable architectural beauty. The principal other buildings, in addition to the many fine warehouses, are the Cloth-Hall, erected by Sir Thomas Ramsden in 1768, and extended in 1780,—a circular two-storied brick building, having a diameter of 80 yards, now fallen almost into disuse; the Armoury, erected as a riding-school, but now the headquarters of the rifle volunteers, and also used for concerts and large public meetings; the Victoria Hall, a capacious building recently erected by the Huddersfield Temperance Society; the Philosophical Hall, in the Grecian style, originally used for lectures and public meetings, afterwards converted into a theatre, and burnt almost to the ground February 15, 1880; the Gymnasium Hall, erected in 1847, capable of accommodating 1000 persons, and transformed into public baths in 1879; the Infirmary, erected in 1831, a large and elegant stone edifice of the Doric order with wings and a portico, the latter supported by four fluted columns, a large ward and medicated baths being added later; the General Railway Station, in the Grecian style, erected in 1848, having in front a handsome statue of Sir Robert Peel; the Huddersfield College, in the Baronial style, established in 1838 for sons of gentlemen and tradesmen; the Collegiate School, in the Gothic style, erected in 1839; the Huddersfield Club; the Borough Club; the Masonic Hall (1838); the Corporation offices, in the Classic style (1877); the Town-Hall, also in the Classic style, but much richer (1880); the Guardians' offices (1880); the Ramsden Estate buildings, a handsome and extensive block of the mixed Italian order; the Chamber of Commerce; and a remarkably fine new market-hall, in the Gothic style, with a clock-tower and spire 106 feet in height, founded in 1878, and opened in 1880.



Plan of Huddersfield.

The cost of the building was £28,000, and the sum paid by the corporation to Sir J. W. Ramsden, Bart., for the market-rights and site, was £25,790, in addition to £15,273 for the site and rights of the cattle-market. A public cemetery, off New North Road, the property of the corporation, with mortuary chapels for Churchmen and Nonconformists, was completed in 1855; and the cemetery at Almondbury was taken over by the corporation in 1868. The extensive gas-works are the property of the corporation, as are also the water-works, which afford an ample supply of excellent water, the reservoirs being capable of storing 900,000,000 gallons. The cost has been over £750,000. A public park of 21 acres, called the Beaumont Park, is the gift of Mr H. F. Beaumont; the first sod was cut on May 29, 1880. There are fourteen handsome board schools, erected at a cost of about £120,000, twenty-one national schools, and one Roman Catholic school. The principal public societies are the mechanics' institution, the building for which, a large edifice in the Italian style, was opened in 1861, and the mechanics' institutes at Lindley and Lockwood, each possessing handsome buildings. Huddersfield is a place of considerable antiquity, being mentioned in Domesday, and is supposed by some to derive its name from

Oder or Hudard, a Saxon chief; but its importance dates from the establishment of the woollen manufacture within the last century. It is the principal seat of the fancy woollen trade in England; and it exceeds every other place in the variety of its manufacture of this class of textile fabrics, which includes doeskins, angolas, tweeds, worsted coatings and trouserings, Ulster cloths, mohairs, cashmeres, sealskins, fancy dress skirtings, kerseys, woollen cords, quiltings, a few broad cloths, and a large number of union materials. It also possesses silk and cotton spinning mills, iron foundries, engineering works for steam-engines, steam-engine boilers, and the machinery used in the various manufactures, chemical works, dye-houses, lead-piping and sanitary tube manufactories, and three organ factories. Handloom weaving is carried on in the surrounding villages, but to a much less extent than formerly. A market for woollen goods is held weekly. Coal is abundant in the vicinity. There is a sulphurous spa in the Lockwood ward, with warm, cold, vapour, and shower baths. At Almondbury, 2 miles distant from the centre of the town, there was at one time a Saxon fortress, and by some writers the Roman station *Cambodunum*, mentioned by Antonine, is believed to have been situated there; recent excavations, however, have proved almost conclusively that at Slack, just outside the opposite boundary of the borough, was the real *Cambodunum*. Kirklees park, 3 miles from Huddersfield, is popularly supposed to have been the burial-place of Robin Hood. Since 1832 Huddersfield has returned one member to parliament, and it became a municipal borough in 1868, with 12 wards, and a town council of 56 members. The area of the town was greatly increased at the time of its incorporation. The area of the parliamentary borough is 10,998 acres, and that of the municipal borough 10,498 acres. The population of the parliamentary borough in 1861 was 34,877; and in 1871, owing chiefly to the increased area, it was 74,358. The population of the municipal borough in 1880 was estimated at 81,780.

HUDSON, a city of the United States of America, capital of Columbia county, New York, is situated on the left bank of the Hudson river at the head of navigation, and on the Hudson and Boston and Hudson River Railways, 114 miles north of New York city. It stands on the ridge of a picturesque elevation called Prospect Hill, which after rising abruptly 60 feet from the river, slopes gradually to an elevation of 500 feet. The high river bank projects into the river in the form of a bold promontory, affording a delightful promenade, and having on either side a fine bay with depth of water sufficient for the largest ships. The wharves are situated at the foot of the promontory and along the margin of these bays. The city is for the most part regularly built, with streets crossing each other at right angles, and a public square situated immediately above the wharves. Works to supply the city with water have lately been constructed at a cost of 250,000 dollars. The principal buildings are the court-house, constructed of marble and limestone and surmounted by a dome, the city hall and post-office, and the academy. The city is also well supplied with other schools, and possesses three public libraries. Hudson at one time vied as a trading port with New York, and, although both its West India trade and its whale fishing have now been abandoned, it still carries on an important river trade, and has regular steam communication with New York and Albany. It also possesses large iron smelting works, a stove-foundry, a tannery, a flour-mill, breweries, iron-foundries, and factories for pianos, carriages, paper, car wheels, and steam fire-engines. Hudson was settled in 1784, being then known as Claverack Landing. It became a city in 1785. The population, which in 1870 was 8615, was 8669 in 1880.

HUDSON RIVER, or NORTH RIVER, one of the largest and noblest rivers of the United States, and the principal river of the State of New York, is formed by the confluence of two small streams which rise in the Adirondack mountains in Essex county. About the middle of Warren county the river is joined by another of nearly equal size, the Schroon, which also has its rise in Essex county. After receiving the Sacondaga river 10 miles further south, the Hudson flows irregularly in an easterly direction to Sandy Hill, after which it keeps a very straight course almost due south until it falls into New York Bay. At Troy it receives the Mohawk, whose volume of water is greater than its own, and at Kingston the Wallkill, but its other tributaries, though numerous, are unimportant. Its total length is about 300 miles, and the length of its course from Sandy Hill 190 miles. At Glen's Falls, near Sandy Hill, it makes a precipitous descent of 50 feet, whence there are various rapids of different velocities until it reaches Troy. It is tidal nearly up to Troy, and the fall from Albany, 6 miles below Troy, to the mouth of the river, a distance of 145 miles, is only 5 feet. By means of a lock and dam it is navigable to Waterford, a short distance above Troy, but large steamers do not proceed further up than Hudson, 29 miles below Albany, and 116 from the mouth of the river. A short distance below Albany the navigation has been obstructed by shifting sands, the point at which the difficulties are most formidable being the "overslaugh" at Castleton, but extensive operations have been for some time carried on in order to effect a permanent remedy for the obstructions. The breadth of the river at Albany is about 300 yards, and thence to Haverstraw, distant 34 miles from New York, it varies from 300 yards to 900 yards. From Haverstraw to Piermont it expands into Tappan Bay, with a length of 12 miles and a breadth of from 4 to 5, after which it narrows to a breadth of between 1 and 2 miles. The scenery of the river is for the most part varied and beautiful, generally picturesque, and in many places in the highest degree striking and magnificent. In the upper part the views though not tame are a little monotonous, the gently sloping hills, with the variegated colours of wood and cultivated land and the occasional occurrence of a town or village, repeating one another without any marked feature to break their regularity. Below Troy, for a considerable distance, the number of islands renders much care in navigation necessary. Thirty miles from Troy noble views begin to be obtained of the Catskill mountains, towering up on the west bank, the nearest eminence at the distance of about 7 miles. Forty-six miles below Catskill is the large and flourishing city of Poughkeepsie, and 14 miles further down the prosperous city of Newburgh, a short distance below which, at the favourite summer resort of Cornwall Landing, the river enters the Highlands, passing between a series of hills whose frequently precipitous sides rise often abruptly from the water's edge. The views in this part of the river are of a character in some respects unparalleled, and at several points they have an impressiveness and surprising grandeur rarely equalled. The distance through which the river traverses this mountain scenery is about 16 miles, and about 10 miles after it is entered West Point is reached, a favourite landing place of tourists, the seat of the United States military academy, and historically interesting on account of Fort Putnam, now in ruins, built during the war of American independence, at which time a chain was stretched across the river to prevent the passage of British ships. After passing the pretty town of Peekskill the river widens into Haverstraw Bay, at the extremity of which is the headland of Croton Point. Below is the wider expanse of Tappan Bay, upon which stands Tarrytown, famous both historically and from its connexion with Washington Irving, whose cottage of Sunnyside is in the vicinity. At Piermont, where the bay ends, the range named the Palisades rises picturesquely from the water to the height of between 300 and 500 feet, extending along the west bank for about 20 miles, the left bank being level and dotted with hamlets and villas. At the mouth of the river on the west bank are Hoboken and Jersey city, and on the east bank New York city.

By the Erie canal the river is connected with Lake Erie, by the Champlain canal with Lake Champlain, and by the Delaware canal with the Delaware river; and its commercial importance as a means of traffic is not excelled by that of any other river in the world. It was on the Hudson that Fulton, the inventor of steam navigation, made his first successful experiment. The Hudson River Railway skirts the east bank of the river from New York to Troy, whence it bends eastward on its way to Lake Champlain. On the west bank a railway is to run from Jersey City to Newburg, and branch lines from various centres touch both banks at several points. The Hudson has some valuable fisheries, the principal fish being bass, shad, and sturgeon. The attempts to stock it with salmon have not been very successful. Though Verrazzani in 1524 proceeded up the river Hudson a short distance in a boat, the first to demonstrate its extent and importance was Henry Hudson, from whom it derives its name. He sailed above the mouth of the Mohawk in September 1609.

HUDSON, GEORGE (1800–1871), the "railway king," was born in York in 1800, was a successful linen draper in that city, and subsequently became the leading representative of the railway mania of 1845–46. Elected chairman of the North Midland Company, he was for three years the ruling spirit of speculation and as the arbiter of capital held the key of untold treasures. All classes delighted to honour him, and, as if a colossal fortune were an insufficient reward for his public services, the richest men in England presented him with a tribute of £20,000. Deputy-lieutenant for Durham, and thrice lord mayor of York, he was returned in the Conservative interest for Sunderland in 1845, the event being judged of such public interest that the news was conveyed to London by a special train, which travelled part of the way at the rate of 75 miles an hour. Full of rewards and honours, he was suddenly ruined by the disclosure of the Eastern Railway frauds. Sunderland clung to her generous representative till 1859, but on the bursting of the bubble he had lost influence and fortune at a single stroke. His later life was chiefly spent on the Continent, where he benefited little by a display of unabated energy and enterprise. Some friends gave him a small annuity a short time before his death, which took place in London, 14th December 1871. His name has long been used to point the moral of vaunting ambition and unstable fortune. The "big swollen gambler," as Carlyle calls him in one of the *Latter Day Pamphlets*, was savagely and excessively reprobated by the world which had blindly believed in his golden prophecies. He certainly ruined scrip-holders, and disturbed the great centres of industry; but he had an honest faith in his own schemes, and, while he beggared himself in their promotion, he succeeded in overcoming the powerful landed interest which delayed the adoption of railways in England long after the date of their regular introduction into America.

HUDSON, HENRY, a distinguished English navigator, of whose personal history before April 19, 1607, or after June 21, 1611, absolutely nothing is known, and whose well-earned fame rests entirely on four voyages which were all unsuccessful as regarded their immediate object, the discovery of a commercial passage to China other and shorter than that by the Cape of Good Hope. The first of these, in quest of new trade and the passage to China by the North Pole, was made for the Muscovy Company, with ten men and a boy, in the little "Hopewell" of 60 tons that had so successfully braved the dangers of Frobisher's last voyage twenty-nine years before. Sailing from the Thames on April 19, 1607, Hudson first coasted the east side of Greenland, and thence hugging the Arctic ice-barrier, proceeded to the "north-east of Newland" to near 82° N. lat. He then turned back to seek, according to his chart, the passage round the north of Greenland into Davis Straits to make trial of Lumley's Inlet, or "the furious overfall"; but, having traced the ice-barrier from 78½° to 80°, he on July 27 became convinced that by this way there is no passage, and on August 15 he returned to the Thames. Molineux's chart, published by Hakluyt about 1600, was Hudson's blind guide in this voyage, and the polar map of 1611 by Pontanus illustrates well what he attempted, and the valuable results both negative and positive which he reached. He investigated the trade prospects at Cherrie Island, and recommended his patrons to seek higher game in Newland; hence he may be called the father of the English whale-fisheries at Spitzbergen.

Next year Hudson was a second time sent by the Muscovy Company "to open the passage to China by the north-east between Newland and Nova Zemla;" this voyage lasted from April 22 to August 26, 1608. From June 12 to June 29, he raked the Barrentz Sea between 75° 30′ N.W. and 71° 15′ S.E. on the Goose coast of Nova Zemla, meeting with much ice and no great encouragement for trade, and deleting Willoughby Island from his chart. On July 6, "voide of hope of a north-east passage (except by the Waygats, for which I was not fitted to try or prove), I therefore resolved to use all means I could to sayle to the north-west" (still harping on Lumley's Inlet and "the furious overfall"). The failure of this second attempt satisfied the Muscovy Company, which thenceforward directed all its energies to the profitable Spitzbergen trade.

In the Autumn of 1608 Hudson "had a call" to Amsterdam, where he saw Plancius, who gave him Waymouth's journals, and Hondius, who supplied him with translations of certain Dutch papers. After some vacillating negotiations he finally undertook for the Dutch East India Company his important third voyage to find the passage to China "by the east or the west." With a mixed crew of eighteen or twenty men he left the Texel in the "Half-Moon" on April 5, and by May 5 was in the Barrentz Sea, and soon afterwards among the ice near Costin Sarch in Nova Zemla, where he had been the year before. Some of his men becoming disheartened and mutinous (it is now supposed that he had arrived two or three months too early), he soon lost hope of effecting anything by that route, and submitted to his men, as alternative proposals, either to go to Lumley's Inlet and follow up Waymouth's light, or to make for North Virginia and seek the passage in about 40° lat., according to the letter and map sent him by his friend Captain John Smith. The latter plan was adopted, and on May 14 Hudson set his face towards the Chesapeake and China. He touched at Stromo for water, and on June 15 off Newfoundland in about 48° lat. the "Half-Moon" "spent overboord her foremast." This accident compelled him to put into Sagadahoc (44° 1′ lat.), where on July 18 a mast was procured, some communication with the Indians was had, and an unnecessary battle fought, in which the ship's two "stone murderers" were employed. Sailing again on July 25, he was off Cape Cod on August 6, and on the 9th (38° 39′ lat.) "went with low sail because we were in an unknown sea." On August 18 they made Smith's Islands, 6 or 7 miles north of the entrance to the Chesapeake. On August 28, beginning the survey where Smith left off at 37° 36′ according to his map, he coasted north to Sandy Hook, passing the "overfall" of the Delaware with scarcely any notice, probably because a western inlet there would have taken him in amid Smith's surveys. On September 3, in 40° 30′, he entered the fine bay now known by the name of New York. After having gone 150 miles up what is now the Hudson river, treating with the Indians, surveying the country, and trying the stream above tide-water, he became satisfied that this course did not lead to the South Sea or China, a conclusion in harmony with that of Champlain, who the same summer had been making his way south through Lake Champlain and Lake St Sacrement to the South Sea. The two explorers by opposite routes approached within 20 leagues of each other. On October 4 the "Half-Moon" weighed for the Texel, and on November 7 put in to Dartmouth, where she was seized by the English Government and the crew detained. The voyage had fallen short of Hudson's expectations, but it served many purposes perhaps as important to the world. Among other results it exploded Hakluyt's myth, which from the publication of Lok's map in 1582 to the 3d charter of Virginia in May 1609 he had lost no opportunity of promulgating, that near 40° lat. there was a narrow isthmus, formed by the sea of Verrazano, like that of Tehuantepec or Panama.

Hudson's three failures served only to increase men's confidence in the existence of a passage by the north-west, for the discovery of which a new and strong joint-stock company was accordingly formed. The command was given to Hudson, who on April 10, 1610, sailed in the "Discoverie" of 70 tons, the ship that took Waymouth in 1602 in the same direction. How he penetrated through the long straits, discovered the great bay that bears his name, at once his monument and his grave, how he and his men wintered in its southern extremity, how in coming north in the next summer, near the east coast, half way back to the straits, he, his son, and seven of his men, in a mutiny, were put into a shallop and cut adrift on Midsummer day 1611, is told in many books. The ringleaders and half the crew perished miserably, but the "Discoverie" was finally brought home to London. No more tidings were received of Hudson, but no one doubted the complete success of his voyage. A grander company was incorporated in 1612, under Prince Henry, to complete the exploration of the passage, and to find the lost discoverer and his companions. Sir Thomas Butler was the commander in 1612, and the "Discoverie" was again the chosen ship. In 1613 the voyage was repeated by Gibbons, and once more in 1614 by Baffin; and the bay was thoroughly explored with the results which have long been universally familiar.

See *Henry Hudson, the Navigator* (Hakluyt Society, 1860)

HUDSON'S BAY COMPANY is a joint-stock association formed for the purpose of importing into Great Britain the furs and skins which it obtains, chiefly by barter, from the Indians of British North America. The trading forts of the company are dotted over the immense region (excluding Canada Proper and Alaska) which is bounded E. and W. by the Atlantic and Pacific Oceans, and N. and S. by the Arctic Ocean and the United States. From these forts the furs are despatched by boat or canoe to York Fort on Hudson's Bay, whence they are shipped to England to be sold by auction.

In the year 1670 Charles II. granted a charter to Prince Rupert and seventeen other noblemen and gentlemen, incorporating them as the "Governor and Company of Adventurers of England trading into Hudson's Bay," and securing to them "the sole trade and commerce of all those seas, straits, bays, rivers, lakes, creeks, and sounds, in whatsoever latitude they shall be, that lie within the entrance of the straits commonly called Hudson's Straits, together with all the lands and territories upon the countries, coasts, and confines of the seas, bays, &c., aforesaid, that are not already actually possessed by or granted to any of our subjects, or possessed by the subjects of any other Christian prince or state." Besides the complete lordship and entire legislative, judicial, and executive power within these vague limits (which the company finally agreed to accept as meaning all lands watered by streams flowing into Hudson's Bay), the corporation received also the right to "the whole and entire trade and traffic to and from all havens, bays, creeks, rivers, lakes, and seas into which they shall find entrance or passage by water or land out of the territories, limits, or places aforesaid." The first settlements in the country thus granted, which was to be known as Rupert's Land, were made on James's Bay and at Churchhill and Hayes rivers; but it was long before there was any advance into the interior, for in 1749, when an unsuccessful attempt was made in parliament to deprive the company of its charter on the plea of "non-user," it had only some four or five forts on the coast, with about 120 regular employés. Although the commercial success of the enterprise was from the first immense, great losses, amounting before 1700 to £215,514, were inflicted on the company by the French, who sent several military expeditions against the forts. After the cession of Canada to Great Britain in 1763, numbers of fur-traders spread over that country, and into the north-western parts of the continent, and began even to encroach on the Hudson's Bay Company's territories. These individual speculators finally combined into the North-West Fur Company of Montreal, of which Washington Irving has given an interesting description in his *Astoria*. The fierce competition which at once sprang up between the companies was marked by features which sufficiently demonstrate the advantages of a monopoly in commercial dealings with savages, even although it is the manifest interest of the monopolists to retard the advance of civilization towards their hunting grounds. The Indians were demoralized, body and soul, by the abundance of ardent spirits with which the rival traders sought to attract them to themselves; the supply of furs threatened soon to be exhausted by the indiscriminate slaughter, even during the breeding season, of both male and female animals; the worst passions of both whites and Indians were inflamed to their fiercest, and costly destruction of human life and property was the result (see RED RIVER SETTLEMENT). At last, in 1821, the companies, mutually exhausted, amalgamated, obtaining a licence to hold for 21 years the monopoly of trade in the vast regions lying to the west and north-west of the older company's grant. In 1838 Hudson's Bay Company acquired the sole rights for itself, and obtained a new licence, also for 21 years. On the expiry of this, it was not renewed, and since 1859 the district has been open to all, the Hudson's Bay Company having no special advantages beyond its tried and splendid organization. The licences to trade did not of course affect the original possessions of the company. These it retained till 1869, when they were transferred to the British Government for £300,000; in 1870 they were incorporated with the Dominion of Canada. The company, which now trades entirely as a private corporation, still retains one-twentieth of the entire grant, together with valuable blocks of land round the various forts; and these possessions will doubtless, as the country becomes opened up and colonized, yield a considerable revenue at some future time.

For further information see the *Report* of the Select Parliamentary Committee in 1857; *The Hudson's Bay Territories and Vancouver's Island*, by R. M. Martin, 1849; *An Examination of the Charter and Proceedings of the Hudson's Bay Company, &c.*, by J. E. Fitzgerald, 1849; *Notes of a Twenty-five Years' Service in the Hudson's Bay Territory*, by J. Maclean, 2 vols., 1849; *The Great Lone Land*, 1872, and *The Wild North Land*, 1873, both by Captain W. F. Butler.

HUÉ, or HUE-FOO (variously called QUANG-DUK, PHU-THUA-THIEN, and SAN HUÉ), the capital of the kingdom of Anam, is situated in a province of its own name, on the left bank of the Truòng-Tiên or Hué river, which falls into the Chinese Sea about 8 miles further down in 16° 34′ 28″ N. lat. and 107° 38′ 39″ E. long. The surrounding country is a flat alluvial plain, traversed by streams and canals, and largely occupied by extensive rice-fields; to the south-west, at a distance of about 3 or 4 miles, rise the Ai-van hills, of which Hondun has a height of 1445 feet. The centre of Hué is formed by the citadel, which was built in the reign of Gialong (d. 1820) after the plans of the French colonel Olivier. It is 7323 feet square, has six equal bastions on each side, and is surrounded by ditches about 120 feet in width, but not more than 5 or 6 feet in depth. Within are the royal residence, the houses of the ministers, the treasury, the arsenal, the barracks, &c.,—the royal residence, or Thanh Noi, having a special encincture of its own, measuring about 2290 feet each way. The inner town or citadel has a population of 30,000, inclusive of the garrison, and there are nearly as many in the suburbs and market-villages within a radius of 2½ miles. The suburb of Mang-Sa (*i.e.*, Fish Mouth) at the north-east corner of the citadel is the centre of the local traffic, and the neighbouring part of the river serves as an inner harbour. At the village Thanh Phuoc, about 2 miles below the town, are the winter quarters for the Anamese fleet, and in its vicinity is a ship-building yard and docks. On the landward slope of the sand-dune which lies between the sea and the lagoon at the river mouth stretches the village of Thuân, with about 1400 inhabitants, and serving as a sort of port to the capital. During the rainy season, October to January, the level of the Truòng-Tiên rises about 3 feet, and all the plain is laid under water. No European residents are permitted at Hué, except the members of the French legation, who have been allowed to erect consular buildings on the right bank of the river, there 1180 feet wide, directly opposite the citadel.

See *J. Roy. Geogr. Soc.*, 1849; M. Dutreuil de Rhins, "Notice géog. sur la rivière de Hué," in *Bull. Soc. Géogr. de Paris*, 1878.

HUELVA, one of the eight provinces into which Andalucia has since 1833 been divided, is bounded on the N. by Badajoz, on the E. by Seville, on the S. and S.W. by the Atlantic, and on the W. by Portugal, and has an area of 4122 square miles. With the exception of its south-east angle, where the province merges into the flat waste lands known as Las Marismas of the Guadalquivir, Huelva presents throughout its entire extent an agreeably varied surface, being traversed in a south-westerly direction by the western spurs of the Sierra Morena. The principal streams are the Odiel and the Tinto, which both fall into the Atlantic by navigable rias or estuaries; the Malagon, the Chanza, the Murtiga, which belong to the Guadiana system, and the Huelva, belonging to that of the Guadalquivir, also take their rise in this province. Iron pyrites and manganese occur in the Sierra in considerable quantities; among many important mines, which are at present inactive, may be mentioned Lagunazo, Carpio, Lapilla, San Miguel, Monterubio, Sotiel, Coronada, San Telmo, Cueva de la Mora, and Toya. Those of Rio Tinto, situated to the north-east of Valverde del Camino, and near the source of the river Tinto, are ascertained to have been known to the Phœnicians and Romans. They are at present wrought by an Anglo-German company; in 1876 the output amounted to 329,305 tons; the number of men employed approached 5000. The mines of Tharsis and Calañas, and of Buitron and Poderosa, are of corresponding importance. Saline and other mineral springs are also of frequent occurrence in the province. The soil possesses great fertility, and produces excellent pasturage; among the exports are included, besides corkwood and esparto, oranges, grapes, figs, oil, and wine. The only railways at present in the province are those constructed for mineral traffic between Rio Tinto mines and Huelva (52 miles), between Tharsis and Huelva (30 miles), and between Buitron and Poderosa and San Juan del Puerto at the head of the Tinto estuary (44 miles); but a line from Huelva to Seville is at present in course of construction. The towns of chief interest and importance in the province are, besides Huelva the capital, Ayamonte, Aracena, Valverde, La Palma, Niebla, and Moguer, with Palos its harbour. The population in 1877 was 210,641.

Huelva, the capital of the above province, is situated on the western shore of the triangular peninsula formed by the estuaries of the Odiel and Tinto, 53 miles west by south of Seville. Its streets are wide and well built, and among the public edifices may be mentioned two parish churches, an Academia Onubense, two hospitals, and a theatre. The town has a considerable coasting trade in the produce of the province, and there is a limited manufacture of esparto floor mattings; others of the inhabitants find employment in the sardine, tunny, and bonito fisheries of the neighbourhood. The chief source of the growing prosperity of Huelva, however, is in connexion with the extensive exportation of ore from the Tharsis and Rio Tinto mines. The total quantity of pyrites shipped amounted in 1872 to 261,373 tons, and in 1876 had risen to 442,201 tons (value £552,506). The exportation of manganese, however, which in 1868 amounted to 41,000 tons, did not in 1876 exceed 6972 tons (value £41,813); 7178 tons of precipitate of copper were valued at £279,956. For the accommodation of the Rio Tinto mineral traffic there is a fine pier 2682 feet long, 65½ feet wide, and 43½ feet above the level of the river at high-water, at which vessels of 2000 tons can be moored and loaded with ease. In 1876 the total number of vessels entering the port was 1409, with a tonnage of 278,594; of these 512 were British, with a tonnage of 237,610. The total imports amounted to £315,856; from Great Britain, £149,939. Total exports £918,506; to Great Britain, £833.968. Population 13,174 (1877).

Huelva is usually identified with the Onuba Æstuaria of Ptolemy, the Onoba or Onuba of Strabo, Mela, and the numismatists, described in the *Antonine Itinerary* as situated on the estuary of the river Luxia, on the road from the mouth of the Anas to Augusta Emerita. There still exist vestiges of a Roman aqueduct, which, however, are fast disappearing. The town is alleged to have been founded by the Phœnicians; the name Welba or Wuelba is due to the Moors.

HUESCA, one of the three provinces into which the old northern Spanish kingdom of Aragon was divided in 1833, is bounded on the N. by France, E. by Lerida, S. and S.W. by Saragossa, and W. and N.W. by Navarre. The total area is 7530 square miles. The surface is mountainous, especially in the north, which is occupied by the lofty offshoots of the Pyrenees, which there reach in Monte Perdido (Mont Perdu) the height of 11,430 feet. The chief river is the Cinca; but the want of natural streams has in some measure been made up for by a system of irrigation. Mineral springs are numerous throughout the province. The climate varies much according to the region; in the north cold winds from the snow-capped Pyrenees prevail, while in the south the warm summers are often unhealthy from the humidity of the atmosphere. The leading industry of Huesca is agriculture, although only a limited proportion of the soil is under cultivation. There is good summer pasturage on the mountains, where cattle, sheep, and swine are reared. The mountains are richly clothed with forests of pine, beech, oak, and fir, and the southern regions produce abundant crops of cereals, vines, mulberries, and numerous kinds of fruits and vegetables. The mineral resources include argentiferous lead, copper, iron, and cobalt, with limestone, millstone, gypsum, granite, and slate. The mining industry was formerly much more important, but the difficulties of transport caused by the absence of good roads have much hindered the development of this and other resources of the province. Huesca exports timber, cereals, wine, oil, and some cattle, and imports iron, flax, and colonial and foreign goods. The manufactures, which are unimportant, include brandy, wine, soap, linen, woollens, baize, and common crockery. The population in 1877 was 252,165.

Huesca, chief town of the above province, and the seat of a bishop, is pleasantly situated on an eminence commanding an extensive view over the surrounding fertile plain. It stands near the right bank of the Isuela, 35 miles north-east of Saragossa. The town bears many traces of its antiquity. The streets in the older part are narrow and crooked, though clean, and many of the houses witness by their size and style to the former magnificence, and by their neglected and ruined aspect to the present decay of the place. The newer streets are wide, and the houses have some claims to regularity. There are several squares and plazas, in one of which rises the imposing Gothic cathedral, begun in 1400 and finished in 1515, and enriched with fine carving. In the same plaza is the old palace of the kings of Aragon, formerly given up for the use of the now closed *Sertorio* (the university), so named in memory of a school for the sons of nativo chiefs, founded at Huesca by Sertorius in 77 B.C. (Plut., *Sert.* 15). Among the other prominent buildings are the interesting parish churches (San Pedro, San Martin, and San Juan), the archiepiscopal palace, the town-house, and various benevolent and religious houses. Huesca manufactures cloth, pottery, bricks, and leather. Its chief trade is in exporting fruit and cereals, and in importing linen, cloth, silk, hardware, and colonial produce. The population in 1877 was 7760.

Huesca is a very ancient town. Strabo (iii. 161, where some editors read *Ileosca*) describes it as a town of the Ilergetes, and the scene of Sertorius's death; while Pliny places the Oscenses in *regio Vescitania*. Plutarch (*loc. cit.*) calls it a large city. Julius Cæsar names it *Venecdora*; and the name by which Augustus knew it, *Urbs victrix Osca*, was stamped on its coins, and is still preserved on its arms. It fell under Saracen rule; but in 1096 Pedro I. of Aragon regained it, after winning the decisive battle of Alcoraz, as the termination of the two years' siege.

HUESCAR, chief town of a judicial district in the Spanish province of Almeria, is situated in a plain, surrounded by mountains on three sides, about 91 miles north-east of Granada. The town occupies a large area in proportion to the number of its houses, and although the older streets are narrow and tortuous, the newer quarters have wide and regular streets. Among the chief buildings are the court-house and the adjoining prison, the hospital, the foundling hospital, and three schools. There are two parish churches, dating respectively from 1498 and 1504. About three miles to the east are the ruins of Huescar la Vieja, a Carthaginian foundation. Pottery, woollen and hempen cloth, linen, and baize are manufactured at Huescar. There are also oil and flour mills. The export trade is not extensive. The population in 1870 was 5106.

HUET, PIERRE DANIEL (1630–1721), bishop of Avranches, is the last of those encyclopædic and massive scholars of whom France produced so many. He left no successor to his omnivorous learning, prodigious memory, and indomitable energy. He was born at Caen of a family formerly Huguenot. He lost both father and mother while still a child, and was brought up by his aunt, wife of the mathematician Gilles Macé, to whom he owed his respect for science. He says himself that the ardour of study did not possess him in earnest until in early manhood he was reading the *Géographie Sacrée* of Bochart, and suddenly became intoxicated with the desire of becoming a scholar. It may be remarked that a youth who was not already studious would hardly be reading such a book. However, the statement means that he began about that time to study not in earnest only but with passion and fury. In Hebrew alone so great was his industry that he read through the Old Testament in the original no less than four-and-twenty times during his life. At the age of twenty he had already achieved a reputation as one of the most promising scholars of the time. He went at the age of twenty-one to Paris, where he formed a friendship with Gabriel Naudé, conservator of the Mazarin library. In the following year Bochart, being invited by Queen Christina to her court at Stockholm, took his friend Huet with him. This journey, in which he saw Leyden, Amsterdam, and Copenhagen, as well as Stockholm, resulted chiefly in the discovery of some fragments of Origen's *Commentary on St Matthew*, which gave Huet the idea of editing Origen. On his return to France he assisted at the foundation of the academy of Caen, and shortly afterwards quarrelled with his friend Bochart, who accused him of having suppressed a line in Origen in the Eucharistic controversy. Shortly afterwards he removed to Paris, where he entered into close relations with Chapelain. At this time arose the famous dispute of Ancients and Moderns. Huet took the side of the Ancients against Charles Perrault and Desmarets. Among his friends at this period were Corrart and Pellisson. His taste for mathematics led him to the study of astronomy, and in 1672 he founded the Academy of Science at Caen. He next turned his attention to anatomy, and, being himself shortsighted, devoted his inquiries mainly to the question of vision and the formation of the eye. In this pursuit he made more than 800 dissections. He then learned all that was then to be learned in chemistry, and wrote a Latin poem on salt. All this time he was no mere book-worm or recluse, but was haunting the salons of Mlle. de Scudéry and the studios of painters; nor did his scientific researches interfere with his classical studies, for during this time he was discussing with Bochart the origin of certain medals, and was learning Syriac and Arabic under the Jesuit Parvilliers. Nor did he neglect the lighter walks of letters. He translated the pastorals of Longus, wrote a tale called *Diane de Castro*, and defended in a treatise on the origin of romance the reading of fiction. Then, being appointed assistant tutor to the Dauphin, he edited with the assistance of Anne Lefèvre, afterwards Madame Dacier, the well-known edition of the classics *ad usum Delphini*. He also continued to work upon his edition of Origen, and issued one of his greatest works, the *Demonstration Évangelique*. It was at the age of forty-six that he took orders, a step which he had contemplated for some years. Two years later the king gave him the abbey of Aunay, where he wrote his *Questions d'Aunay, sur l'accord de la Foi et de la Raison*, his *Critique de la Philosophie de Descartes*, his *Memoires pour servir à l'Histoire du Cartésianisme*, his dissertation on the site of the terrestrial paradise, and his discussion with Boileau on the Sublime. In 1685 he was made bishop of Soissons, but after waiting for installation for four years he took the bishopric of Avranches instead. He exchanged the cares of his bishopric for what he thought would be the easier chair of the Abbey of Fontenay, but there he was vexed with continual law suits. At length he retired to the Jesuits' House in the Rue Saint Antoine at Paris, where he ended his days, in 1721, amidst incessant labours maintained to the end, at the age of ninety-one. His great library and manuscripts, after being bequeathed to the Jesuits, were bought by the king for the royal library.

It is impossible here to enter upon an estimate of the place in philosophy, literature, and scholarship now occupied by this remarkable and omnivorous student. It has been disputed whether a writer who could so strenuously advocate the claim of philosophy could have been at the same time an orthodox believer. Perhaps like many other men Huet separated his creed from his philosophy, and while he argued on Descartes forgot that he was a bishop. In the *Huetiana* will be found the most ready materials for arriving at an idea of his prodigious labours, exact memory, and wide scholarship. His own autobiography, found in his *Commentarius de rebus ad eum pertinentibus*, was translated into English by Dr Aiken in 1726. It remains to be said that he owed the preservation of his faculties to extreme old age, and perhaps the prolongation of his life, to the rigid observance of a spare diet which he began at the age of forty, dining moderately, and taking no other supper than a little bouillon.

HUFELAND, CHRISTOPH WILHELM (1762–1836), a distinguished physician and writer on medical subjects, was born at Langensalza, 12th August 1762. His early education was carried on at Weimar, where his father held the office of court physician to the grand duchess. In 1780 he entered the university at Jena, and in the following year proceeded to Göttingen, where in 1783 he graduated in the faculty of medicine. After assisting his father for some years at Weimar, he was called in 1793 to the chair of medicine at Jena, receiving at the same time the dignities of court physician and councillor at Weimar. In 1793 he was placed at the head of the medical college and generally of state medical affairs in Berlin, with the title of privy councillor. He filled the chair of pathology and therapeutics in the university of Berlin, founded in 1809, and in 1810 became councillor of state. He died at Berlin in 1836.

Hufeland is celebrated as the most eminent practical physician of his time in Germany, and as the author of numerous works displaying extensive reading and cultivated and critical faculty. The most widely known of his many writings is the treatise entitled *Makrobiotik, oder die Kunst das menschliche Leben zu verlängern*, 1796. Of his practical works, all of the kind which cannot long retain their place in the literature of special science, the *System of Practical Medicine* ("System der praktischen Heilkunde," 3 vols., 1828) is the most elaborate. By medical writers Hufeland's services in promoting and elevating the study of the art of medicine are highly extolled. His autobiography was published in 1863. Sketches of his life and labours appeared shortly after his death by Augustin and Stourdza, 1837.

HUFELAND, Gottlieb (1760–1817), a distinguished writer on political economy and law, was born at Dantzic on 19th October 1760. He was educated at the gymnasium of his native town, and completed his university studies at Leipsic and Göttingen. He graduated at Jena, and in 1788 was there appointed to an extraordinary professorship. Five years later he was made ordinary professor. His lectures on natural law, in which he developed with great acuteness and skill the formal principles of the Kantian theory of legislation, attracted a large audience, and contributed to raise to its height the fame of the university of Jena, then unusually rich in able teachers. In 1803, after the secession of many of his colleagues from Jena, Hufeland accepted a call to Würzburg, from which, after but a brief tenure of a professorial chair, he proceeded to Landshut. From 1808 to 1812 he acted as burgomaster in his native town of Dantzic. Returning to Landshut, he lived there till 1816, when he was invited to Halle, where he died in February 1817.

Hufeland's works on the theory of legislation—*Essay upon the Fundamental Theorem of Natural Law* ("Versuch über die Grundsatz Naturrechts," 1785), *Handbook of Natural Law* ("Lehrbuch des Naturrechts," 1790), *Institutes of Positive Law* ("Institutionen des gesammten positiven Rechts," 1798), and *History and System of German Positive Law* ("Lehrbuch der Geschichte und Encyclopädie aller in Deutschland geltenden positiven Rechte," 1790)—are distinguished by precision of statement and clearness of deduction. They form on the whole the best commentary upon Kant's *Rechtslehre*, the principles of which they carry out in detail, and apply to the discussion of positive laws. In political economy Hufeland's chief work is the *New Foundation of National Economy* ("Neue Grundlegung der Staatswirthschaftskunst," 2 vols., 1807 and 1813), the second volume of which has the special title, *Theory of Money and Circulation* ("Lehre vom Gelde und Geldumlaufe"). The principles of this work are for the most part those of the *Wealth of Nations*, which were then beginning to be accepted and developed in Germany; but both in his treatment of fundamental notions, such as economic good and value, and in details, such as the theory of money, Hufeland's treatment has a certain originality. Two points in particular seem deserving of notice. Hufeland was the first among German economists to point out the profit of the *entrepreneur* as a distinct species of revenue with laws peculiar to itself. He also tends towards, though he does not explicitly state, the view that rent is a general term applicable to all payments resulting from differences of degree among productive forces of the same order. Thus the superior gain of a specially gifted workman or specially skilled employer is in time assimilated to the payment for a natural agency of more than the minimum efficiency. See Roscher, *Geschichte der Nationalökonomik in Deutschland*, pp. 654–662.

HUG, Johann Leonhard (1765–1846), Roman Catholic theologian and Biblical critic, was born at Constance, where his father was a locksmith, on June 1, 1765. After passing through the gymnasium of his native town, he proceeded in 1783 to the university of Freiburg, where he became a pupil in the seminary for the training of priests, and very early distinguished himself in the departments of classical and Oriental philology as well as of Biblical exegesis and criticism. In 1787 he became superintendent of studies in the seminary, and he continued to hold this appointment until the breaking up of the establishment in 1790. In the following year he was called to the Freiburg chair of Oriental languages and Old Testament exegesis; to the duties of this post were added in 1793 those of the professorship of New Testament exegesis. Steadily declining calls to Breslau, Tübingen, and (repeatedly) to Bonn, Hug continued to labour at his post in Freiburg for upwards of thirty years, varying the monotony of his work only by an occasional literary tour to Munich, Paris, or Italy. In 1827 he resigned some of his professorial work, but continued in active duty until in the autumn of 1845 he was seized with a painful illness, which proved fatal on March 11 of the following year.

Hug's earliest publication was the first instalment or "heft" of his *Einleitung*; in it he argued with much acuteness against Eichhorn in favour of the "borrowing hypothesis" of the origin of the synoptical gospels, maintaining the priority of Matthew, the present Greek text having been the original. His subsequent works were dissertations on the origin of alphabetical writing (*Die Erfindung der Buchstabenschrift*, 1801), on the antiquity of the *Codex Vaticanus* (1810), and on ancient mythology (*Ueber den Mythos der alten Völker*, 1812); a new interpretation of the Song of Solomon (*Das hohe Lied in einer noch unversuchten Deutung*, 1813), to the effect that the lover represents King Hezekiah, while by his beloved is intended the remnant left in Israel after the deportation of the ten tribes; and treatises on the indissoluble character of the matrimonial bond (*De Conjugii Christiani vinculo indissolubili commentatio exegetica*, 1816) and on the Alexandrian version of the Pentateuch (1818). His *Einleitung in die Schriften des Neuen Testaments*, undoubtedly his most important work, was completed in 1808 (fourth German edition, 1847; English translations by Wait, London, 1827; and by Fosdick, New York; French partial translation by Cellerier, Geneva, 1823). It is specially valuable in the portion relating to the history of the text (which up to the middle of the 3d century he holds to have been current only in a κοινὴ ἔκδοσις, of which recensions were afterwards made by Hesychius, an Egyptian bishop, by Lucian of Antioch, and by Origen) and in its discussion of the ancient versions. The author's intelligence and acuteness are more completely hampered by doctrinal presuppositions when he comes to treat questions relating to the history of the individual books of the New Testament canon. From 1839 to his death Hug was a regular and important contributor to the *Freiburger Zeitschrift für Kathol. Theologie*.

HUGH, St, of Avalon (c. 1135–1200), bishop of Lincoln, was born of a noble family at Avalon, near Pontcharra in Burgundy, about 1135. At the age of eight he entered along with his widowed father the neighbouring priory of canons regular at Villarbenoit, where he was ordained deacon at nineteen. Appointed not long after prior of a dependent cell, Hugh was attracted from that position by the holy reputation of the monks of the Grande Chartreuse, whose house he finally entered despite an oath to the contrary which he had given his superior. There he remained about ten years, receiving priest's orders, and rising to the important office of procurator, which brought him into contact with the outer world. The wide reputation for energy and tact which Hugh speedily attained penetrated to the ears of Henry II. of England, and induced that monarch to request the procurator's assistance in establishing at Witham in Somersetshire the first English Carthusian monastery. Hugh reluctantly consented to go to England, where in a short time he succeeded in overcoming every obstacle, and in erecting and organizing the convent, of which he was appointed first prior. He speedily became prime favourite with Henry, who in 1186 procured his election to the see of Lincoln. Forced sorely against his will to accept this responsible post, Hugh nevertheless set himself actively and piously to discharge its important functions, although at least once a year he retired to live for a short period as a simple monk at Witham. He took little to do with political matters, maintaining as one of his chief principles that a churchman should hold no secular office. A sturdy upholder of what he believed to be right, he let neither royal nor ecclesiastical influence interfere with his conduct, but fearlessly resisted whatever seemed to him an infringement of the rights of his church or diocese. But with all his bluff firmness Hugh had a calm judgment and a ready tact, which almost invariably left him a better friend than before of those whom he opposed; and the astute Henry, the impetuous Richard, and the cunning John, so different in other points, agreed in respecting the bishop of Lincoln. St Hugh's manners were a little apt to be boisterous at times, and his early monastic discipline had left him rigid and harsh; but, though an ascetic to himself, "so that his whole life was a continued martyrdom," he was distinguished by a broad kindliness to others, so that even the Jews of Lincoln wept at his funeral. He had great skill in taming birds, and for some years had a pet swan, which occupies a prominent place in all histories and representations of the saint. In 1200 Bishop Hugh revisited his native country and his first convents, and on the return journey was seized with an illness, of which he died at London, on November 16, 1200. Twenty years later he was canonized.

The chief life of St Hugh is the *Magna Vita S. Hugonis* (MS. in the Bodleian Library), written by Adam, the saint's private chaplain, of which a number of abridgments have been made at various dates. A *Metrical Life of St Hugh of Avalon* is preserved in two MSS. in the British Museum and the Bodleian Library. Both these *Lives* have been edited by the Rev. J. E. Dimock. The best modern source for information as to St Hugh and his time is Canon Perry's *Life of St Hugh of Avalon*, &c., 1879.

HUGH OF ST CHER, Hugo (Ugo) de S. Caro or Carensis (*c.* 1200–1263), a learned compiler of the 13th century, was born at St Cher, a suburb of Vienne, Dauphiné, about the year 1200, became a student of theology and canon law in Paris, and in 1224 entered the Dominican cloister of St Jacob there (whence he is sometimes designated as Hugo de S. Jacobo). After having taught theology for upwards of twenty years, in the course of which his learning was frequently appealed to by those in authority for the solution of difficult questions, he was in 1245 created cardinal of St Sabina by Pope Innocent IV. He died at Orvieto in 1263.

His principal works are *Correctorium Bibliæ*, a revised text of the Vulgate, prepared about 1236, hitherto unprinted, but forming the basis of the *Correctorium Bibliæ Sorbonicum*; *Postilla in universa Biblia juxta quadruplicem sensum*, first printed in 1487 (Basel) and often since, as for example at Cologne in 1621 (8 vols. fol.); *Speculum Ecclesiæ*, a manual for the priesthood (ed. prin., Lyons, 1554); and *Sacrorum Bibliorum Concordantiæ*, in the preparation of which he was assisted by the members of the community to which he belonged, hence it is sometimes known as *Concordantiæ S. Jacobi* (Lyons, 1540; Basel, 1543). See *Hist. Litt. de la France*, vol. xix.

HUGH OF ST VICTOR, Hugo a S. Victore, sometimes also known as Hugh of Paris (*c.* 1097–1141), was born, probably in the neighbourhood of Ypres, about 1097, and is known to have received his early education in the cloister of Hamersleben near Halberstadt; in 1115 he removed for the further advancement of his studies to the abbey of St Victor, which had recently been founded by William of Champeaux, the preceptor of Abelard, in the neighbourhood of Paris. There the remainder of his life was spent in teaching or in studious retirement. He died in 1141.

The works of Hugh of St Victor, who was the intimate friend of St Bernard, share all the learning, acuteness, and mysticism of the theological school which then sought to neutralize the opinions and the influence of Abelard. Of chief importance are—*Institutiones Monasticæ*, including the treatises *De arca morali*, *De arca mystica*, and *De vanitate mundi*; *De Sacramentis Fidei*, on the mysteries of the faith, and thus a complete exposition of Catholic theology; and *De Eruditione Didascalica*, in six books, which earned for its compiler the title of magister or didascalus. It forms a sort of encyclopædia of the sciences as then understood, viewed of course merely in their subordination to theology. In his treatment of Biblical introduction, the sharpness with which he separates the apocryphal from the canonical books has been noticed; but in doing so it is important also to recollect that he seems to place on a par with the New Testament the canons, the decretals, and the writings of the fathers. An Augustinian in spirit and in language, so as to deserve the titles Alter Augustinus and Lingua Augustini, by which he is frequently designated, Hugo was still more eminently the disciple of Anselm and Abelard; he, however, had a strongly marked individuality of his own, which appears in his somewhat fully elaborated theory of knowing and being. All the knowable he assigns to one or other of three spheres, that of intelligence, that of science, and that of logic. That of intelligence embraces both theory and practice. Under theory fall to be classed theology, mathematics (arithmetic, music, geometry, astronomy), and physics; practice is equivalent to ethics. Science has to do with the practical arts and industries, while logic embraces grammar, rhetoric, and dialectic. In correspondence to the trichotomous division of man, as made up of body, soul, and spirit, he speaks of a threefold eye, that of the body, that of reason, and that of contemplation. The last of these, by which God is discerned, has been totally destroyed by sin; the second has been much impaired. Faith now takes the place of contemplation; but by oratio and operatio it can attain to real convictions and genuine love. The doctrine of the Trinity he illustrates by the analogy of the human personality as spirit, wisdom, and love. The collected works have been printed at Paris in 1528, at Venice in 1588, at Mainz and Cologne in 1617, and at Rouen in 1648. They occupy three volumes (175–177) in Migne's *Patrologiæ Cursus Completus*. See *Hist. Litt. de la France*, vol. xii.; Liebner, *H. v. S. Victor*, (1832); Görres, *Die christliche Mystik*; and other works bearing on this general subject.

HUGUENOTS, THE. The word Huguenot first appears in France about the middle of the 16th century, and there is historical proof that it was imported from Geneva, where it had existed for some time as a political nickname in a form which connects it directly with the German-Swiss *Eidgenossen*, oath-comrades, confederates. In France it was used as a term of reproach for those who aimed at a reform of religion according to the pattern displayed by Calvin in his famous *Institutio Christianæ Religionis*. The name attached itself to the Reformers when, having shaken off all connexion with Lutheranism, they were beginning to organize themselves both as a church and as a political body. The Lutheran ideas, which had early come into northern France by way of Metz and Meaux, had for a short time seemed likely to prevail at the court of Francis I., where the king's love of culture welcomed whatever came from the land of the learned; the genius of Erasmus, or the sharp satire of Hutten, or Luther's weighty tractates, all seemed to him at first to be so many protests against the darkness of a monkish past; the hymns of Marot, the bright poetry of Margaret of Valois, the king's sister, harmonized not ill with the desire for a humanist reform which prevailed at the French court. But when the destructive enthusiasm of the artisans who embraced the new opinions, breaking out in attacks on the art-treasures of the churches, alienated the royal moderates, the simpler and more marked theology of the "Sacramentarians" of Geneva quietly replaced the Lutheranism of the first Reformers; and by the middle of the 16th century the new Huguenots were an unpopular party, drawing their inspiration from Calvin, and bitterly disliked by the court and the bulk of the people of France. The persecutions, varied by protection, of the reign of Francis I. had given place to a vehement desire to crush the rising heresy; the character of Henry II. and his chief advisers led them towards a thorough persecution.

Influenced by these repressive measures, and taught by Calvin's book and his frequent letters, the French Reformers now began to organize their infant churches. Hitherto they had been content to meet in quiet, to sing Marot's psalms, to listen to earnest prayer and practical discourse in some lowly chamber, deferring questions as to church government; now their ecclesiastical system began to develop itself. In 1555 the first Protestant French church was established at Paris, and almost immediately there sprang up fifteen communities, the largest being at Meaux, Poitiers, and Angers, each having its pastor, elders, and deacons, each ruling itself, and recognizing no common bond of union save that of charity and suffering. These were the heroic days of the Huguenot movement in

France, each little church striving only to fulfil the simplest ideal of Christian faith and practice, happiest when least observed, purest when least developed. Three influences had hitherto acted on French religious feeling:—that of the Lutherans, that of the ancient Vaudois churches of south-eastern France, represented by Faber, and lastly that of Calvin of Noyon, the Picard exile settled at Geneva. Now a fourth element came in: resistance had elicited organization, organization demanded leadership; and, unhappily for France and the Huguenots, the movement fell too much into the hands of secular chiefs, great lords who used it for their own political and selfish purposes.

In 1559 the churches of the Huguenots met in a first synod at Paris, eleven sending representatives. This body drew up a confession of faith, which bears throughout the mark of Calvin's hand, in its scrupulous orthodoxy, strong statements as to God's election of some to eternal life, and careful definitions of the nature and structure of the church; the synod also issued a scheme of discipline to which the churches were all to conform. No church should take lordship over any other (a church being a single community under one pastor). Each "colloque" or synod should have a freely-elected president; every pastor should come to the colloque, bringing each at least one elder or deacon from his church; this body was to meet at least twice a year; new pastors were to be appointed by it to vacant churches, on presentation by the elders and deacons; minute rules were laid down for church discipline; it was ordered that provincial synods should be held in each province, and finally that there should be from time to time a general or national synod of representatives of the whole body.

Two years later the civil war broke out (see FRANCE, vol. ix. pp. 560–564), and lasted over thirty years. At the beginning of this period we have some data as to the Huguenot strength: Beza tells us that in 1558 there were 400,000 of them; a list presented by Condé to Catherine de' Medici is said to have contained the names of 2150 (some say 2500) churches; and it is probable that the number of their open adherents had increased rapidly. John Correro, Venetian envoy in 1569, says that only one-thirtieth of the common folk, but one-third of the nobles, were Huguenots, for the strength of the movement had undoubtedly come to lie in the noblesse. The list of the Huguenot churches given by Haag (*La France Protestante*, vol. i., "Pièces justificatives," No. xviii. p. 52) provides us with data as to their distribution in France. The two centres were Languedoc in the south, and the Orléanais in the middle of the country; and a line drawn north-west to south-east through a point halfway between Paris and Orleans would nearly give the northern limit of Huguenot success. Normandy, thanks to the Châtillon influence, had many churches; in Orleans and Burgundy they were well represented. In Guyenne and throughout western France they had numerous communities. The little independent principality of Béarn, through the influence of Jeanne d'Albret, Henry IV.'s mother, was entirely Huguenot. On the other hand, though there were some churches in the Île de France and Champagne, they had little hold there; and Picardy was from the first profoundly hostile to them, while Paris became the headquarters of the Catholic League. Their churches sprang up with wonderful quickness at this time; thus we see that all the 76 congregations in Languedoc named by Haag were established between 1558 and 1562. All were characterized by a like aptitude for organization; their constitution, simple and popular, is a proof that under better auspices the French people might have well exercised the privileges of constitutional liberty; the Huguenots had a popular representation and frequent deliberative assemblies. Between 1559 and 1598 they held fifteen general church synods, and from 1573 to 1622 many political assemblies, in which all questions bearing on the interests of the "cause" were debated and decided.

The subordination of the religious to the political interests of the Huguenots became inevitable after the massacre of St Bartholomew's day, 1572; while at the same time their organization assumed a more decidedly republican tone. The horror they felt at the violent action of Charles IX. seemed to free them from all allegiance to him; they looked to England and Germany for help, to Switzerland and the United Provinces for encouragement and political example. They at once drew up an independent constitution, democratic and federative, framed chiefly after the Swiss pattern. Like all other attempts at a republican form of government, it had an aristocratic and a democratic side, the latter for the time seeming to be the stronger. For the centre of their power was now passing from the aristocracy to the burghers, from country chateaux to provincial towns. In the towns the only distinction recognized was that of pastor and elders, and these might be, and mostly were, men of the people, chosen by the people. The great nobles who sided with them, the "Politique" princes, like Alençon or Damville-Montmorency, winked for a time at this new "state within the state," the germ of that Huguenot organization which later on hampered Richelieu's path. Their system was based on the towns in their hands. In each an independent government was elected by popular suffrage, and was composed of a mayor, a council of twenty-four, and an elective chamber of seventy-five citizens, making up in all a hundred rulers. This body was a court of justice, with some amount of sovereignty. Thus, the twenty-four with the mayor had control over war, police, and "things of highest importance," though without the seventy-five they could neither pass nor abrogate laws, as to coin, taxation, truces, or terms of peace. The mayors and privy councils of the confederate towns were charged with the election of a general, a kind of Roman dictator, who was to have both a council to advise him and also five lieutenants to help and succeed him, if need were. Lastly, provision was made for a strict moral discipline.

Soon after this the Huguenots established a system of "generalities" or districts, each with its own local estates, and over these provincial councils and a states-general, thus materially strengthening their independent organization. This system continued throughout the League-wars (1574–1589), during which the religious movement was controlled by a knot of selfish political leaders, and in the course of which their point of view completely changed: for, while in the beginning they had passionately called for popular institutions and the convocation of the states-general of France, in the end they became the followers of Henry of Navarre, as heir to the French crown, representative throughout of the anti-popular temper of the Bourbon house. Under him the discontented Huguenots again reorganized themselves into nine great circles, over each of which was a council of from five to seven members, elected by delegates from the churches, and having the duty of laying their independent taxation, of levying, commanding, and paying their own troops. There was also a general assembly for all the circles (after the pattern of the United Provinces) sitting in three estates—pastors, nobles, burghers; the whole polity being representative as an aristocratic republic. This general assembly sat frequently, sent embassies to foreign powers, sometimes acting as an independent body politic.

The discontent of the Huguenots at last extorted from Henry IV. the famous edict of Nantes (2d May 1598), a document which in the main only reproduced the more favourable of the earlier edicts. Its provisions were at least as helpful for Catholics as for Protestants; it was always being so modified as to show less and less favour to the Calvinists, who were little satisfied with it. They had dreamed of dominance, had hoped for equality, and were now put off with tolerance. For whatever Henry IV. might feel about their faith, he was determined, as he once told Sully, "to reduce to nothing the Huguenot faction," to destroy their political independence, and by closing up the civil strife to secure the solid establishment of the central monarchy. The edict allows public exercise of the Huguenot faith in the houses of nobles and gentry, and in a few named towns; it gave the sectaries full civil rights, and made them eligible to all civil offices; in several parliaments mixed chambers were established; the education of their children was left in their own hands.

We find that about 1590 the Huguenots had exercise of their worship in about 3500 chateaux, and in about 200 towns or bourgs, chiefly in the south and west. In most parts of the north, except Paris and round Rouen and Amiens, they had one place for worship in each bailliage or sénéchaussée. In 1598 we have a list of about 150 places granted by Henry IV. to the Huguenots for their safety, the chief groups being in the generalities of Bordeaux and Montpellier, and in Poitou; these were either free towns, like La Rochelle, Nîmes, Montauban, or towns belonging to private gentlemen, or towns belonging to the king, which had fallen into Huguenot hands during the wars.

Throughout the next quarter of a century we trace their history in a series of outbursts, indicating noble impatience and Calvinistic dissatisfaction. The siege and fall of La Rochelle (1627–1628) brought this period to an end. During this time their number seems to have increased; at the accession of Louis XIII. they had about 500 churches; in 1622 and 1628 we have lists of 688; in 1637 no less than 720 are enumerated, though of these 49 were either vacant or suspended. Richelieu and Mazarin treated them with statesman-like prudence; their synods were discouraged, their grumblings ceased; they grew in piety and purity as the political arena was closed to them, and the noble houses one by one deserted them. This was the time of their material prosperity, and of their important contribution to the welfare of France which Louis XIV. so rudely cast away.

As that king got hold of his power, the tranquillity of the Huguenots waned. In 1657 they were forbidden to hold colloquies, lest perchance they should take to politics; in 1659 they were practically told to hold no more synods. Soon the court went further: conversions were undertaken. Wherever a pastor could be bribed, won over, or got rid of, his "temple" was at once torn down; the Huguenot worship became almost impossible in towns, and lingered on in a few castles, whereby it fell still more under the royal displeasure. As his conscience grew morbid, under Madame de Maintenon's direction, Louis XIV. became more eager to expiate his own crimes by punishing the heretics. Between 1657 and 1685 520 churches were rooted up; Anquetil declares that 700 had been destroyed before 1685. All through this period, while thousands yielded to oppression or bribery, thousands also fled the land; the emigration began in 1666 and went on for fifty years. It is probable that in 1660 there were over two millions of Huguenots, the best and thriftiest citizens in the land; it is said, though no figures can be trusted, that in all fully a million of French subjects escaped from their inhospitable fatherland. At last in 1685, thinking that the Huguenots were as good as suppressed, Louis XIV. revoked the edict of Nantes (see FRANCE, vol. ix. p. 579). The revocation was the sentence of civil death on all Huguenots; it crushed more than half the commercial and manufacturing industry of the kingdom. It is said that at the time of it there were 1000 Huguenot pastors; of these over 600 escaped from France, 100 were slain or sent to the galleys, the remainder conformed or disappeared.

The war of 1689 called attention away from the persecuted remnant of the Huguenots, and they had a breathing space in Languedoc, the Cevennes, and Dauphiné; but directly the peace of Ryswick was signed, repression began again, and consequently, when the Spanish succession war commenced, the Huguenots of the "Desert," that is, of the country about Nîmes, broke out after endless provocations into open war, which lasted two years, and for a while defied all the efforts of the court. Marshal Villars was at last sent down, and by mingled gentleness and severity he both secured the submission of the gallant Cavalier, the chief leader of the Huguenots, and the defeat of the more determined of the mountaineers. Throughout the rest of the century the down-trodden Protestantism of France was kept alive chiefly by the exertions of Antoine Court, the apostle of the Desert, who never lost faith in the cause, and who reorganized the dying churches, breathing into them fresh life. Though under the influence of oppression and excitement, the Huguenot story is here and there disfigured by fanatical outbursts of the "prophets" and "prophetesses," still on the whole the account of their endurance is among the most remarkable and heroic records of religious history.

After the interference of Voltaire in behalf of Calas, their sufferings came almost to an end; the general change of opinion, the steady weakening of the Catholics, the indolence or good nature of the sovereign, forbade the scandals of the past, until at last in 1787, under Necker's influence, Louis XVI. signed a memorable edict which restored, after 102 years' deprivation, their civil status to the Huguenots. The Revolution of 1789 carried justice a stage further; among the many titles of the Revolution to the gratitude of posterity none is more marked than the complete restoration of the non-Catholic elements of French society to their rights. From that moment to the present time the descendants of the Huguenots have had peace.

There are now about half a million Calvinists in France; by the census of 1872 they numbered 467,531 souls, of whom about 100,000 were in the north, and the rest mostly in their old quarters in the south; in the Gard, the ancient Desert, nearly a quarter of the whole body still abide. Of late years the Protestant Church in France has shown a tendency to division into two parties, that of the more rigid Calvinistic opinions, and that of a more liberal and less orthodox theology. In either case they form a group of loyal citizens, on whom French politicians now look with favour. The old reproach that "the Huguenots are all republicans" has at last turned to their credit.

The persecutions which checked all wholesome developments at home, whether religious, literary, or commercial, were favourable to their growth abroad; and we consequently find that in literary and artistic excellence the Huguenots have taken their full share. Their first attention was naturally called to theology, in which the names of Calvin and Farel, Beza, Daillé, the Drélincourts, the learned S. Desmarets, Jortin, P. Jurieu, Labadie the mystic, the Leclercs, the great Hebraist Mercier, Mestrezat the preacher, the old hero Duplessis Mornay, Salmasius, J. Saurin, first of Protestant orators, and a crowd of lesser men testify to their activity in this branch. Add to these the dictionary of Bayle, the works of the Basnages, Morin the Orientalist, Pithou, the Daciers, Étienne Dolet, Ramus, Le Févre of Etaples, above all Scaliger, as leaders in learning; in history, Bénoît, Bongars, Palma Cayet, Hubert Languet, Béroalde, and Rapin-Thoyras; and with them the political writer Hotman. Of lawyers they claim Baudouin, Cujas, Coras, Doneau, Hérault, and Godefroy, famed as the most learned of jurisconsults. In science they have the Cuviers, Desmaizeaux, Dubois the chemist, Paré, father of modern surgery, Papin, herald of the steam-engine, the physician Joubert, L'Ecluse the botanist, and the Hubers. In art they lay claim to Crispin, J. Cousin, Pallissy, Simon the engraver, the Picarts, and Goujon the architect. Their poets are Marot and Margaret of Valois. The general effect of this activity is hard to gauge: from Amsterdam and Berlin, Geneva and London, issued sermon, political pamphlet, controversial polemic; but these efforts had no settled audience, they failed to win the ear of France. The same is true of their religious heroism; though it seemed to be exactly what was wanted to strengthen the national character, the confessors were scattered, like the Jews, among the nations, and ceased to affect the progress of their fatherland. In the Revolution we can see traces of their mental and moral activity; it may be that their day of influence is not yet over. For their history is a standing marvel, illustrating the abiding power of strong religious convictions, narrow in theory, pure in practice; they have stood as much ill-usage as has befallen any branch of Christ's church. It remains for their descendants to show to France that their creed goes well with freedom and advance,—that the religious instinct, so deeply implanted in man, is a true friend of orderly and rational national life. Religion which does not abuse its power, a freedom from divided allegiances, an aptitude for constitutional institutions, and an intelligent belief in the sovereignty of the people—these are the elements which the Huguenots of to-day can bring to the service of the republic under which they dwell safely, none making them afraid.

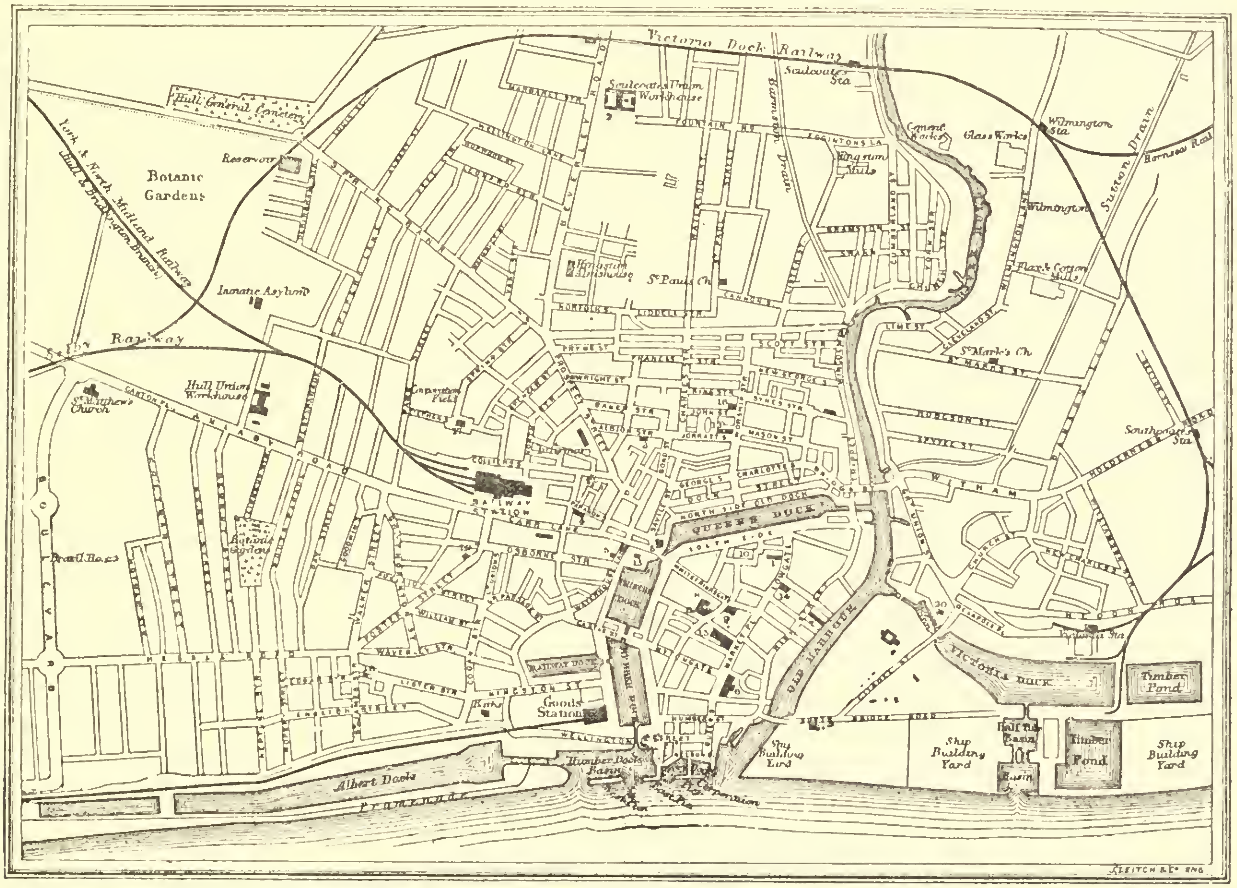
HULL, or KINGSTON-UPON-HULL, a municipal and parliamentary borough, and one of the principal seaport towns of England, is, though a county in itself, locally within the East Riding of Yorkshire, situated in 53° 44′ N. lat. and 0° 10′ W. long., on the west side of the Hull, where it discharges into the estuary of the Humber, 20 miles from the German Ocean at Spurn Head. By rail it is 41½ miles east-south-east of York. Branch lines of the North-Eastern Railway connect it with the principal towns in the East Riding; and by means of the steam ferry across the Humber to New Holland it has communication with the Great Northern and the Manchester, Sheffield, and Lincolnshire Railways. The town stands on a level plain so low as to render embankments necessary to protect it from inundation, and the flatness of the surrounding country as far as the eye can reach is unbroken by anything that can be properly termed an elevation. The older portion of the town, which is completely enclosed between the docks on the north and west and the Hull and Humber on the east and south, was originally very densely inhabited, and its streets were narrow and irregular, but in this respect it has lately undergone great improvements. The streets in the modern quarter are spacious and regular, and the villas of the wealthier classes occupy the suburbs. A pier fronting the Humber affords a pleasant promenade. To the north of the town there is a public park presented in 1860 by Z. C. Pearson, then mayor of Hull. It is 27 acres in extent, is tastefully laid out, and contains full-sized marble statues of her Majesty the Queen and of the late Prince Consort. A botanic garden about 40 acres in extent was opened in 1880. There is a large public cemetery, which possesses separate chapels for churchmen and dissenters. The town is supplied with water from springs about 4 miles distant, two condensing engines of 60 horse power each being employed in pumping it.

The principal public buildings are the town-hall in Lowgate, completed in 1866 in the Italian Renaissance style, having a very richly adorned façade, with a central dome 135 feet in height resting on eight arches, and containing a clock and bell; the exchange in the same street, completed also in 1866, in a less ornate form of the Italian style, containing a hall 70 feet long by 40 feet wide, and the offices of the Hull chamber of commerce and the Hull guardian society for the protection of trade; the corn exchange in High Street, a plain building with a great hall 157 feet long by 36 feet wide; the custom-house in Whitefriargate; Trinity House, a handsome brick building in the Tuscan style, erected in 1753 by the guild of Trinity House, originally established in 1369; Charterhouse, rebuilt in 1645, belonging to a foundation for the support "of the feeble and old," which was established by Sir Michael de la Pole in 1384; the dock offices, an elaborate building in the Italian style; the royal institution, a large and beautiful edifice in the Roman Corinthian style, opened by Prince Albert in 1854, possessing a museum, a library of 40,000 volumes, and accommodation for the meetings of the literary and philosophical society; the new general post-office, in the modern Italian style, opened in 1877; the prison, constructed on the new model principle, opened in 1869; the music-hall, in the Renaissance style; the theatre royal, opened in 1873, a stuccoed structure with a handsome Corinthian front; the public baths and washhouses, in the Tudor style, completed in 1850 at a cost of £12,000. The only church of special interest or architectural merit is that of Holy Trinity, on the west side of the market-place, a cruciform edifice in the floral Gothic style, originally founded at the end of the 13th century, but of various dates, and lately completely restored at a cost of over £30,000, having an extreme length of 272 feet, the breadth of the nave being 72 feet and that of the chancel 70 feet. It possesses a very fine west window, filled with stained glass in 1862 at a cost of £1000, and is surmounted at the intersection of the nave and transept by a noble tower, with finely decorated pinnacles, rising from the point of intersection to the height of 140 feet. St Mary's church in Lowgate, in the Perpendicular style, was originally founded in the beginning of the 14th century, but has been nearly all rebuilt since that period, the tower being erected in 1696, and the whole building restored in 1863–65 at a cost of £10,000. The principal educational establishments are the grammar school, founded in 1486; the Hull and East Riding college, a proprietary school for sons of gentlemen; the Trinity House marine school, founded in 1716; Cogan's charity school for girls, founded in 1763; national, British, Catholic, Wesleyan, and school board schools; a ragged and industrial school; and the Humber industrial school ship "Southampton." Among the other institutions for ministering to the intellectual wants of the community are the school of science and art, the literary and philosophical society, the royal institution, the mechanics' institution, the Hull church institute and library, the young people's Christian and literary institute, the Catholic institute, the Lyceum library and reading-room, and the literary club. The charities and benevolent foundations are numerous, and, in addition to Charterhouse and Trinity House, already mentioned, include the infirmary, founded in 1782, and extended by the addition of two wings in 1840, and of detached fever wards in 1874; the Hull and Sculcoates dispensary, founded in 1814; the hospital for sick children, opened in 1873; the homœopathic dispensary; the blind institute; the borough lunatic asylum, erected in 1849, with accommodation for 160 patients; the Hull workhouse, the Sculcoates union workhouse, the seamen's and general orphan asylum; the sailors' home, opened in 1860; the sailors' orphan home and school, erected in 1863; Gregg's hospital, founded in 1416, Lister's in 1641, and Crowle's in 1661.

Hull ranks as the third port of the United Kingdom, being surpassed in the value of its exports and imports by London and Liverpool only. The original harbour occupied that part of the river Hull which faced the old town, but in 1774 an Act was passed for forming a dock on the site of the old fortifications, having its entrance at the upper end of the old harbour. This dock, known for some time as the Old dock, is 1703 feet long and 254 feet broad, and its area is 10 acres. In 1809 the Humber dock at the south end of the town was opened; it is 914 feet long and 342 feet broad, and its area is 7 acres. These two docks were connected by a third, opened in 1829, at first named the Junction dock, its length being 645 feet and a breadth of 238 feet; its area is 6 acres. After a visit paid to Hull by the Queen and Prince Albert in 1854, the name of the Old dock was changed to the Queen's dock, and that of the Junction dock to the Prince's dock. The Railway dock, opened in 1846, extends to 3 acres. In 1850 the Victoria dock was opened, on the east side of the river Hull, with entrances from it and the



Plan of Hull.

Humber, and occupied an area of about 12½ acres. In 1863 this dock was extended 7½ acres eastward. In connexion with this dock was a timber pond of 9½ acres, subsequently enlarged to 14 acres, and a new one of 11 acres was about the same date constructed near it. The Albert dock, opened by the prince of Wales in July 1869, occupies an area of 24½ acres, and has a length of 3370 feet, with a breadth at the eastern end of 480 feet, and at the western end of 200 feet. To the west of it an additional dock of 6 acres was opened in May 1880. A capacious graving dock, 460 feet long, which is entered from the last-mentioned dock is now (1880) in course of construction. Another dock of 24 acres, to the west of the new West dock, has been commenced. Rails in connexion with the North-Eastern Railway are laid along the quays of the docks. In 1880 an Act was obtained for a railway from Hull to Barnsley, and a dock in connexion with it. The shipping trade of Hull is chiefly with the Baltic ports, Denmark, Norway, Germany, and Holland; but it has also regular steam communication with the other principal ports of Europe, as well as with the United States, the Black Sea, Egypt, &c. In 1878 the number of ships that entered was 4996, with a tonnage of 1,750,977, and the number that cleared 4802, with a tonnage of 1,788,214. For the five years ending 1878 the average number of ships that entered was 4987, with a tonnage of 1,742,120, while 4857 cleared, with a tonnage of 1,726,151.

The value of imports of foreign and colonial merchandise in 1878 was £17,849,197, and the average value for the five years 1874–78 was £18,038,263. The value of exports of produce of the United Kingdom in 1878 was £19,109,797, and the average value for the five years was £21,267,391. Hull is one of the principal shipping ports for the manufactures of Yorkshire and Lancashire, and imports large quantities of grain from Russia, Prussia, America, and the British colonies, and of timber from Norway and Sweden. The import of cattle is very large, and a commodious cattle depôt has been constructed. The deep-sea fishing is extensively prosecuted, and, in addition to several small steamers, employs about 450 boats, with 2500 hands. Whale-fishing, once an important industry, is now discontinued.

The staple industry of Hull is seed-crushing for oil and cake making. It possesses extensive engineering works and foundries, large iron shipbuilding yards, rope-yards, sail-lofts, tanneries, breweries, flax and cotton mills, chemical works, and manufactures of blue and black lead, paints, colours, and varnishes, Portland and Roman cement, phosphate of lime, tobacco, starch, paper, soap, furniture, and organs.

The population of the parliamentary borough, which was 84,690 in 1851, had in 1871 reached 123,408. The population of the municipal borough in 1861 was 97,661, and in 1871 it had increased to 121,892. The area of the municipal borough is 3635 acres, and of the parliamentary 4447 acres.

History.—Hull originated in the two nearly contiguous villages of Myton and Wyke, the latter of which was a considerable port not long after the Norman Conquest. For some period the united village was known as Myton-Wyke, but even before the reign of Edward I. it is also occasionally mentioned as Hull. In 1298 Edward I., on returning from the battle of Dunbar, happened to pay it a visit, when, struck with its advantages as a commercial port, he purchased it from the abbot of Meaux, with the purpose of fortifying it. He created the town a manor of itself, bestowed upon it the name of Kingston-upon-Hull, and issued a proclamation offering to all who settled in it special advantages. In 1299 it received a royal charter constituting it a free borough. About the same time the improvements on its harbour were completed, and from this period its increase in prosperity was rapid and uninterrupted. In 1316 a regular ferry was established between Hull and Barton in Lincolnshire, and a few years later the town was fortified with walls and ditches. Much of the early prosperity of the town was due to the enterprise of the famous merchants, the De la Poles, who were high in favour with successive monarchs, and the head of which house was in 1385 created earl of Suffolk. Such was the importance of the town in the reign of Edward III. that in 1359 it supplied for the armament against France 16 ships and 466 seamen, the quota of London being 25 ships and 662 seamen, and that of Newcastle 17 ships and 314 seamen. In the reign of Richard II. the fortresses were repaired and a strong castle was erected on the east side of the river Hull. By Henry VI. additional charters were granted, erecting the town and liberties into a county in itself, under the designation of "The Town and County of the Town of Kingston-upon-Hull," constituting it a corporate town, and appointing, instead of a mayor and bailiffs, for its government a mayor, sheriff, and aldermen. In the Wars of the Roses it strenuously maintained the cause of Lancaster; and so zealous was it in its loyalty that after the borough funds were exhausted additional money was raised by the sale of the materials of the market cross. In the 15th, 16th, and 17th centuries it suffered greatly from the plague, and in 1527 and 1549 much damage was caused by inundations. During the insurrection in 1536 called the Pilgrimage of Grace, originated by the dissolution of the monasteries, Hull was seized by the insurgents, but, after the dispersion of the main body at Doncaster, the ringleaders in the town were seized by the magistrates and executed. During the second rebellion in Yorkshire in 1537 the town was taken possession of by the insurgents headed by Sir Robert Constable, and held for a month, but the loyal inhabitants, surprising them in the middle of the night, compelled them to surrender; many of them were executed, and the body of Sir Robert Constable was hung in chains over the Beverley gate. In 1540 Hull was visited by Henry VIII., who, after a careful survey of the town and neighbourhood, gave directions for the erection of a castle and other fortifications, for the cutting of a canal from Newland to Hull in order to provide "additions of fresh water," and for the improvement of Suffolk palace, originally erected by the De la Poles, but since then acquired by the crown. During the parliamentary war the possession of Hull was an object of ambition to both parties on account of its importance as a depôt for arms and military stores. In 1642 the governor, Sir John Hotham, refused to admit Charles I. into the town. In 1643 and 1644 it sustained two long sieges and many vigorous attacks by the royalists.

In 1534 Hull was made the see of a suffragan bishop, but the office was abolished on the death of Edward VI. By the 33d of Edward I. the town returned burgesses to parliament. The privilege was afterwards for some time in abeyance till the 12th of Edward II., since which period it has returned two members.

Among the eminent natives of Hull, besides the De la Poles, are Andrew Marvell, William Mason the friend of Gray the poet, William Wilberforce, and Major-General Perronet Thompson.

The principal histories of Hull are those of Gent, 1735, reprinted 1869 Hadley, 1788; Tickell, 1798; Frost, 1827; and Sheahan, 1864. See also Symons's *High-Street, Hull, some years since, and Biographical Sketches interspersed with Historical Accounts of the Town, Ancient and Modern, &c.*, 1862; Wooley's *Statutes relating to Kingston-upon-Hull*, 1830; Symons's *Hullinia, or Selections from Local History*, 1872, and *Sketches of Hull Authors*, 1879.

HULS, a town of Prussia, in the circle of Kempen, and government district of Düsseldorf, is situated at the terminus of a branch railway line to Crefeld and Düsseldorf, 4 miles north of Crefeld and 17 north-west of Düsseldorf. It possesses manufactures of damask and velvet, and in the neighbourhood ironstone is obtained. The population in 1875 was 6096.

HULSE, JOHN (1708-1789), founder of the Hulsean lectureship at the university of Cambridge, was born at Middlewich, in Cheshire, in 1708. Entering St John's College, Cambridge, he graduated in 1728, and on taking holy orders was presented to a small country curacy. His father having died in 1753, Hulse succeeded to his estates in Cheshire, where, owing to feeble health, he lived in retirement till his death in 1789. He bequeathed his estates to Cambridge University for the purpose of maintaining two scholars at St John's College, of founding a prize for a dissertation, and of instituting the offices of Christian advocate and of Christian preacher or Hulsean lecturer. By a statute in 1860 the Hulsean professorship of divinity was substituted for the office of Christian advocate, and the lectureship was considerably modified. The first course of lectures under the benefaction was delivered in 1820. In 1830 the number of annual lectures or sermons was reduced from twenty to eight; subsequently they were restricted to four. The annual value of the Hulse endowment is between £800 and £900, of which eight-tenths go to the professor of divinity and one-tenth to the prize and lectureship respectively.

HUMBLE-BEE, a name applied by phonetic instinct under various inflexions (such as "Bumble-bee" in England provincially, and "Hummel" in Germany) to the large bees of the genus *Bombus* (which, like the French "Bourdon," is probably also suggested by the noise made by these insects). They belong to the social section of the great family *Apidæ*, of which the common hive-bee is the type, and, like that well-known insect, live in colonies composed of the two sexes and neuters. Instead of a single female (or queen), however, many are found in one nest; and the workers do not hibernate. The female also differs from the queen hive-bee in having dense fringes of hairs on the pollen-plates of the hind legs, and a widened base to the hind tarsi, a structure necessitated by her having to work single-handed at the commencement of the season, as the workers and males do not survive the winter. Early in the spring these large hibernated females may be observed on the wing, each becoming the founder of a fresh colony, in which the neuters are first produced. There are two kinds of females, the smaller one only producing male eggs, but not surviving the winter. The number of individuals in a colony varies with the different species, and as a rule is least in those building their nest above ground. In one very common subterranean species, *Bombus terrestris*, as many as 107 males, 56 females, and 180 workers have been found in one nest. There is considerable difference between the males, females, and neuters; the last two differ, however, but little except in size, whereas the males often exhibit a very varying coloration, and have structural peculiarities, such as an additional segment to the abdomen, longer antennæ and tongue, no pollen-basket, &c. They have also no sting, whereas both female and worker are armed like the hive-bee. Great difficulty exists in referring these three constituents to their proper species, owing to individual variation, alteration with age, and the difficulty of seeing all the members of a colony at the same time; so that naturalists are not by any means agreed as to the specific status of many of them, and the synonymy is very complicated. The nests are not constructed after the symmetrical fashion of those of the hive-bee, but consist of a collection of oval brownish cells, at first few in number, but receiving additions and extensions as the brood increases, and accompanied by cells containing pollen and honey. The workers assist in rearing the larvæ, and in disengaging the individuals from their pupal integuments as they reach the perfect state; and it has been noticed that this metamorphosis is accelerated by a kind of incubation. The nests are made under bushes, in banks, &c., sometimes as much as 5 feet from the surface. A well-known one is made by the "Moss-carder" humble-bee, *Bombus muscorum*, which has often been observed collecting the natural material for its dome, working in line. As usual with provident or social animals, these interesting insects are subject to encroachment by parasites of various kinds; most noteworthy among which are some species (there are three or four in England) of the closely allied genus *Apathus* (or *Psithyrus*), superficially resembling exactly the true humble-bees, but with no pollen-collecting apparatus, and no workers. They exist apparently on friendly terms with their hosts, whose stores are at times materially preyed upon by the larvæ of *Volucella*, a genus of *Diptera* or two-winged flies also resembling humble-bees. Various beetles, such as *Antherophagus*, *Cryptophagus*, *Leptinus*, &c., and the larvæ of *Tinea pellionella*, a small moth, also occur in their nests.

As regards distribution, the *Bombi* are found in Europe, America (North and South), Africa, India, China, and Java, but not in Australasia, where, indeed, it has even been attempted to introduce some species for the purpose of fertilizing the introduced clover, for which the structure of the native insects is apparently insufficient. It is, however, in the northern zone that they flourish best, their hardy nature enabling them to exist in the Arctic regions, as far as man has penetrated; and the numerous additions continually being made to the list of known species from the Caucasus, the Amur district, Turkistan, Arizona, &c., point, not only to a wide geographical range, but to a large adaptation to some useful end. The experiments of Darwin, Müller, and others show how important a part is played by humble-bees in the economy of nature as plant fertilizers; and, though perhaps not exhibiting such highly-developed instincts as the hive-bee, they possess sufficient reasoning power to enable them, by perforating the base of the calyx of certain flowers, to obtain otherwise inaccessible honey.

HUMBOLDT, Friedrich Heinrich Alexander, Baron von (1769–1859), a distinguished naturalist and traveller, was born at Berlin, September 14, 1769. His father, who was a major in the Prussian army, belonged to a Pomeranian family of consideration, and was rewarded for his services during the Seven Years' War with the post of royal chamberlain. He married in 1766 Maria Elizabeth von Colomb, widow of Baron von Hollwede, and had by her two sons, of whom the younger is the subject of this notice. The childhood of Alexander von Humboldt was not a promising one, as regards either health or intellect. His characteristic tastes, however, soon displayed themselves; and from his fancy for collecting and labelling plants, shells, and insects he received the playful title of "the little apothecary." The care of his education, on the unexpected death of his father in 1779, devolved upon his mother, who discharged the trust with constancy and judgment. Destined for a political career, he studied finance during six months at the university of Frankfort-on-the-Oder; and a year later, April 25, 1789, he matriculated at Göttingen, then eminent for the lectures of Heyne and Blumenbach. His vast and varied powers were by this time fully developed; and during the vacation of 1789 he gave a fair earnest of his future performances in a scientific excursion up the Rhine, and in the treatise thence issuing, *Mineralogische Beobachtungen über einige Basalte am Rhein* (Brunswick, 1790). His native passion for distant travel was confirmed by the friendship formed by him at Göttingen with George Forster, Heyne's son-in-law, the distinguished companion of Cook's second voyage. Henceforth his studies, which his rare combination of parts enabled him to render at once multifarious, rapid, and profound, were directed with extraordinary insight and perseverance to the purpose of preparing himself for his distinctive calling as a scientific explorer. With this view he studied commerce and foreign languages at Hamburg, geology at Freiberg under Werner, anatomy at Jena under Loder, astronomy and the use of scientific instruments under Zach and Köhler. His researches into the vegetation of the mines of Freiberg led to the publication in 1793 of his *Floræ Fribergensis Specimen*; and the results of a prolonged course of experiments on the phenomena of muscular irritability, then recently discovered by Galvani, were contained in his *Versuche über die gereizte Muskel- und Nervenfaser* (Berlin, 1797), enriched in the French translation with notes by Blumenbach.

In 1794 he was admitted to the intimacy of the famous Weimar coterie, and contributed (June 1795) to Schiller's new periodical, *Die Horen*, a philosophical allegory entitled *Die Lebenskraft, oder der rhodische Genius*. In the summer of 1790 he paid a flying visit to England in company with Forster. In 1792 and 1797 he was in Vienna; in 1795 he made a geological and botanical tour through Switzerland and Italy. He had obtained in the meantime official employment, having been appointed assessor of mines at Berlin, February 29, 1792. Although the service of the state was consistently regarded by him but as an apprenticeship to the service of science, he fulfilled its duties with such conspicuous ability that he not only rapidly rose to the highest post in his department, but was besides entrusted with several important diplomatic missions. The death of his mother, November 19, 1796, set him free to follow the bent of his genius, and, finally severing his official connexions, he waited for an opportunity of executing his long-cherished schemes of travel. On the postponement of Captain Baudin's proposed voyage of circumnavigation, which he had been officially invited to accompany, he left Paris for Marseilles with Bonpland, the designated botanist of the frustrated expedition, hoping to join Bonaparte in Egypt. The means of transport, however, were not forthcoming, and the two travellers eventually found their way to Madrid, where the unexpected patronage of the minister d'Urquijo determined them to make Spanish America the scene of their explorations.

Armed with powerful recommendations, they sailed in the "Pizarro" from Corunna, June 5, 1799, stopped six days at Teneriffe for the ascent of the Peak, and landed, July 16, at Cumana. There Humboldt observed, on the night of the 12–13th of November, that remarkable meteor-shower which forms the starting-point of our acquaintance with the periodicity of the phenomenon; thence he proceeded with Bonpland to Caracas; and in February 1800 he left the coast for the purpose of exploring the course of the Orinoco. This trip, which lasted four months, and covered 1725 miles of wild and uninhabited country, had the important result of establishing the existence of a communication between the water-systems of the Orinoco and Amazon, and of determining the exact position of the bifurcation. On the 24th of November the two friends set sail for Cuba, and after a stay of some months regained the mainland at Cartagena. Ascending the swollen stream of the Magdalena, and crossing the frozen ridges of the Cordilleras, they reached

Quito after a tedious and difficult journey, January 6, 1802. Their stay there was signalized by the ascent of Pichincha and Chimborazo, and terminated in an expedition to the sources of the Amazon *en route* for Lima. At Callao Humboldt observed the transit of Mercury on November 9, and studied the fertilizing properties of guano, the introduction of which into Europe was mainly due to his writings. A tempestuous sea-voyage brought them to the shores of Mexico, and after a year's residence in that province, followed by a short visit to the United States, they set sail for Europe from the mouth of the Delaware, and landed at Bordeaux, August 3, 1804.

Humboldt may justly be regarded as having in this memorable expedition laid the foundation of the sciences of physical geography and meteorology in their larger bearings. By his delineation (in 1817) of "isothermal lines," he at once suggested the idea and devised the means of comparing the climatic conditions of various countries. He first investigated the rate of decrease in mean temperature with increase of elevation above the sea-level, and afforded, by his investigations into the origin of tropical storms, the earliest clue to the detection of the more complicated law governing atmospheric disturbances in higher latitudes; while his essay on the geography of plants was based on the then novel idea of studying the distribution of organic life as affected by varying physical conditions. His discovery of the decrease in intensity of the earth's magnetic force from the poles to the equator was communicated to the Paris Institute in a memoir read by him, December 7, 1804, and its importance was attested by the speedy emergence of rival claims. His services to geology were mainly based on his attentive study of the volcanoes of the New World. He showed that they fell naturally into linear groups, presumably corresponding with vast subterranean fissures; and by his demonstration of the igneous origin of rocks hitherto held to be of aqueous formation, he contributed largely to the spread of juster views than those then prevailing.

The reduction into form and publication of the encyclopædic mass of materials—scientific, political, and archæological—collected by him during his absence from Europe was now Humboldt's most urgent desire. After a short trip to Italy with Gay-Lussac for the purpose of investigating the law of magnetic declination, and a sojourn of two years and a half in his native city, he finally, in the spring of 1808, settled in Paris with the view of securing the scientific co-operation required for bringing his great work through the press. This colossal task, which he at first hoped would have occupied but two years, eventually cost him twenty-one, and even then remained incomplete. With the exception of Napoleon Bonaparte, he was now the most famous man in Europe. A chorus of applause greeted him from every side. Academies, both native and foreign, were eager to enrol him among their members. Frederick William III. of Prussia conferred upon him the honour, without exacting the duties, attached to the post of royal chamberlain, together with a pension of 2500 thalers, afterwards doubled. He refused the appointment of Prussian minister of public instruction in 1810. In 1814 he accompanied the allied sovereigns to London. Three years later he was summoned by the king of Prussia to attend him at the congress of Aix-la-Chapelle. Again in the autumn of 1822 he accompanied the same monarch to the congress of Verona, proceeded thence with the royal party to Rome and Naples, and returned to Paris in the spring of 1823.

The French capital he had long regarded as his true home. There he found, not only scientific sympathy, but the social stimulus which his vigorous and healthy mind eagerly craved. He was equally in his element as the lion of the *salons* and as the *savant* of the institute and the observatory. Thus, when at last he received from his sovereign a summons to join his court at Berlin, he obeyed indeed, but with deep and lasting regret. The provincialism of his native city was odious to him. He never ceased to rail against the bigotry without religion, æstheticism without culture, and philosophy without common sense, which he found dominant on the banks of the Spree. The unremitting benefits and sincere attachment of two well-meaning princes secured indeed his gratitude, but could not appease his discontent. At first he sought relief from the "nebulous atmosphere" of his new abode by frequent visits to Paris; but as years advanced his excursions were reduced to accompanying the monotonous "oscillations" of the court between Potsdam and Berlin. On the 12th of May 1827 he settled permanently in the Prussian capital, where his first efforts were directed towards the furtherance of the science of terrestrial magnetism. For many years it had been one of his favourite schemes to secure, by means of simultaneous observations at distant points, a thorough investigation of the nature and law of "magnetic storms"—a term invented by him to designate abnormal disturbances of the earth's magnetism. The meeting at Berlin, September 18, 1828, of a newly-formed scientific association, of which he was elected president, gave him the opportunity of setting on foot an extensive system of research in combination with his diligent personal observations. His appeal to the Russian Government in 1829 led to the establishment of a line of magnetic and meteorological stations across northern Asia; while his letter to the duke of Sussex, then (April 1836) president of the Royal Society, secured for the undertaking the wide basis of the British dominions. Thus that scientific conspiracy of nations which is one of the noblest fruits of modern civilization was by his exertions first successfully organized.

In 1811, and again in 1818, projects of Asiatic exploration were proposed to Humboldt, first by the Russian, and afterwards by the Prussian Government; but on each occasion untoward circumstances interposed, and it was not until he had entered upon his sixtieth year that he resumed his early *rôle* of a traveller in the interests of science. Between May and November 1829 he, together with his chosen associates Gustav Rose and Ehrenberg, traversed the wide expanse of the Russian empire from the Neva to the Yenesei, accomplishing in twenty-five weeks a distance of 9614 miles. The journey, however, though carried out with all the advantages afforded by the immediate patronage of the Russian Government, was too rapid to be profitable. Its most important fruits were the correction of the prevalent exaggerated estimate of the height of the Central-Asian plateau, and the discovery of diamonds in the gold-washings of the Ural—a result which Humboldt's Brazilian experiences enabled him to predict, and by predicting to secure.

Between 1830 and 1848 Humboldt was frequently employed in diplomatic missions to the court of Louis Philippe, with whom he always maintained the most cordial personal relations. The death of his brother, Wilhelm von Humboldt, who expired in his arms, April 8, 1836, saddened the later years of his life. In losing him, Alexander lamented that he had "lost half himself." The accession of the crown prince as Frederick William IV., on the death of his father, in June 1840, added to rather than detracted from his court favour. Indeed, the new king's craving for his society became at times so importunate as to leave him only some hours snatched from sleep for the prosecution of his literary labours.

It is not often that a man postpones to his seventy-sixth year, and then successfully executes, the crowning task of his life. Yet this was Humboldt's case. The first two volumes of the *Kosmos* were published, and in the main composed, between the years 1845 and 1847. The idea of a work which should convey, not only a graphic description, but an imaginative conception of the physical world—which should support generalization by details, and dignify details by generalization, had floated before his mind for upwards of half a century. It first took definite shape in a set of lectures delivered by him before the university of Berlin in the winter of 1827–28. These lectures formed, as his latest biographer expresses it, "the cartoon for the great fresco of the *Kosmos*." The scope of this remarkable work may be briefly described as the representation of the unity amid the complexity of nature. In it the large and vague ideals of the 18th are sought to be combined with the exact scientific requirements of the 19th century. And, in spite of inevitable shortcomings, the attempt was in an eminent degree successful. Nevertheless, the general effect of the book is rendered to some extent unsatisfactory by its tendency to substitute the indefinite for the infinite, and thus to ignore, while it does not deny, the existence of a power outside and beyond those of nature. A certain heaviness of style, too, and laborious picturesqueness of treatment make it more imposing than attractive to the general reader. Its supreme and abiding value, however, consists in its faithful reflexion of the mind of a great man. No higher eulogium can be passed on Alexander von Humboldt than that, in attempting, and not unworthily attempting, to portray the universe, he succeeded still more perfectly in portraying his own comprehensive intelligence.

The last decade of his long life—his "improbable" years, as he was accustomed to call them—was devoted to the continuation of this work, of which the third and fourth volumes were published in 1850–58, and a fragment of a fifth appeared posthumously in 1862. In these he sought to fill up what was wanting of detail as to individual branches of science in the sweeping survey contained in the first volume. Notwithstanding their high separate value, it must be admitted that, from an artistic point of view, these additions were deformities. The characteristic idea of the work, so far as such a gigantic idea admitted of literary incorporation, was completely developed in its opening portions, and the attempt to convert it into a scientific encyclopædia was in truth to nullify its generating motive. Humboldt's remarkable industry and accuracy were never more conspicuous than in the erection of this latest trophy to his genius. Nor did he rely entirely on his own labours. He owed much of what he accomplished to his rare power of assimilating the thoughts and availing himself of the co-operation of others. He was not more ready to incur than to acknowledge obligations. The notes to *Kosmos* overflow with laudatory citations, which were, indeed, the current coin in which he discharged his intellectual debts.

On the 24th of February 1857 Humboldt was attacked with a slight apoplectic stroke, which, however, passed away without leaving any perceptible trace. It was not until the winter of 1858–59 that his strength began to decline, and on the ensuing 6th of May he tranquilly expired, wanting but six months of completing his ninetieth year. The honours which had been showered on him during life followed him after death. His remains, previously to being interred in the family resting-place at Tegel, were conveyed in state through the streets of Berlin, and received by the prince-regent with uncovered head at the door of the cathedral. The first centenary of his birth was celebrated September 14, 1869, with equal enthusiasm in the New as in the Old World; and the numerous monuments erected in his honour, and newly-explored regions called by his name, bear witness to the universal diffusion of his fame and popularity.

Humboldt was never married, and seems to have been at all times more social than domestic in his tastes. To his brother's family he was, however, much attached; and in his later years the somewhat arbitrary sway of an old and faithful servant held him in more than matrimonial bondage. By a singular example of weakness, he executed, four years before his death, a deed of gift transferring to this man Seifert the absolute possession of his entire property. It is right to add that no undue advantage appears to have been taken of this extraordinary concession. Of the qualities of his heart it is less easy to speak than of those of his head. The clue to his inner life might probably be found in a certain egotism of self-culture which influenced his affections as well as regulated his studies. His attachments, however, once formed, were sincere and lasting. He made innumerable friends; and it does not stand on record that he ever lost one. His benevolence was throughout his life active and disinterested. His early zeal for the improvement of the condition of the miners in Galicia and Franconia, his consistent detestation of slavery, his earnest patronage of rising men of science, bear witness to the large humanity which formed the ground-work of his character. The faults of his old age have been brought into undue prominence by the injudicious publication of his letters to Varnhagen von Ense. The chief of these was his habit of smooth speaking, almost amounting to flattery, which formed a painful contrast with the caustic sarcasm of his confidential utterances. His vanity, at all times conspicuous, was tempered by his sense of humour, and was so frankly avowed as to invite sympathy rather than provoke ridicule. After every deduction has been made, he yet stands before us as a colossal figure, not unworthy to take his place beside Goethe as the representative of the scientific side of the culture of his country.

The best biography of Humboldt is that of Professor Karl Bruhns (3 vols., 8vo, Leipsic, 1872), excellently translated into English by the Misses Lassell, with the omission, however, of the exhaustive bibliographical notice and scientific summary contained in the original. The *Voyage aux régions équinoxiales du Nouveau Continent, fait* 1799–1804, *par Alexandre de Humboldt et Aimé Bonpland*, (Paris, 1807, &c.), consisted of thirty folio and quarto volumes, and comprised a considerable number of subordinate but important works. Among these may be enumerated *Vue des Cordillères et monuments des peuples indigènes de l'Amérique*, 2 vols., folio, 1810; *Examen critique de l'histoire de la géographie du Nouveau Continent*, 1814–34; *Atlas géographique et physique du royaume de la Nouvelle Espagne*, 1811; *Essai politique sur le royaume de la Nouvelle Espagne*, 1811; *Essai sur la géographie des plantes*, 1805 (now very rare); and *Relation historique*, 1814–25, an unfinished narrative of his travels, including the *Essai politique sur l'île de Cuba*. The *Nova genera et species plantarum* (7 vols. folio, 1815–25), containing descriptions of above 4500 species of plants collected by Humboldt and Bonpland, was mainly compiled by C. S. Kunth; Oltmanns assisted in preparing the *Recueil d'observations astronomiques*, 1808; Cuvier, Latreille, Valenciennes, and Gay-Lussac co-operated in the *Recueil d'observations de zoologie et d'anatomie comparée*, 1805–33. Humboldt's *Ansichten der Natur* (Stuttgart and Tübingen, 1808) went through three editions in his lifetime, and was translated into nearly every European language. The results of his Asiatic journey were published in *Fragments de géologie et de climatologie asiatiques*, (2 vols. 8vo, 1831), and in *Asie centrale* (3 vols. 8vo, 1843)—an enlargement of the earlier work. The memoirs and papers read by him before scientific societies, or contributed by him to scientific periodicals, are too numerous for specification.

Since his death considerable portions of his correspondence have been made public. The first of these, in order both of time and of importance, is his *Briefe an Varnhagen von Ense*, Leipsic, 1860. This was followed in rapid succession by *Briefwechsel mit einem jungen Freunde* (Friedrich Althaus), Berlin, 1861; *Briefwechsel mit Heinrich Berghaus*, 3 vols., Jena, 1863; *Correspondance scientifique et littéraire*, 2 vols., Paris, 1865–69; *Lettres à Marc-Aug. Pictet*, published in *Le Globe*, tome vii., Geneva, 1868; *Briefe an Bunsen*, Leipsic, 1869; *Briefe an seinen Bruder Wilhelm*, Stuttgart, 1880; besides some other collections of less note. An octavo edition of Humboldt's principal works was published in Paris by Th. Morgand, 1864–66. (A. M. C.)

HUMBOLDT, KARL WILHELM VON (1767–1835), the elder brother of the more celebrated Alexander von Humboldt, was born at Potsdam, on the 22d of June 1767. After being educated at Berlin, Göttingen, and Jena, in the last of which places he formed a close and lifelong friendship with Schiller, he married Fräulein von Dacherode, a lady of birth and fortune, and in 1802 was appointed by the Prussian Government first resident and then minister plenipotentiary at Rome. While there he published a poem entitled *Rom*, which was reprinted in 1824. This was not, however, the first of his literary productions; his critical essay on Goethe's *Hermann and Dorothea*, published in 1800, had already placed him in the first rank of authorities on æsthetics, and, together with his family connexions, had much to do with his appointment at Rome; while in the years 1795 and 1797 he had brought out translations of several of the odes of Pindar, which were held in high esteem. On quitting his post at Rome he was made councillor of state and minister of public instruction. He soon, however, retired to his estate at Tegel, near Berlin, but was recalled and sent as ambassador to Vienna in 1812 during the exciting period which witnessed the closing struggles of the French empire. In the following year, as Prussian plenipotentiary at the congress of Prague, he was mainly instrumental in inducing Austria to unite with Prussia and Russia against France; in 1815 he was one of the signatories of the capitulation of Paris, and the same year was occupied in drawing up the treaty between Prussia and Saxony, by which the territory of the former was largely increased at the expense of the latter. The next year he was at Frankfort settling the future condition of Germany, but was summoned to London in the midst of his work, and in 1818 had to attend the congress at Aix-la-Chapelle. The reactionary policy of the Prussian Government made him resign his office of privy councillor and give up political life in 1819; and from that time forward he devoted himself solely to literature and study.

During the busiest portion of his political career, however, he had found time for literary work. Thus in 1816 he had published a translation of the *Agamemnon* of Æschylus, and in 1817 corrections and additions to Adelung's *Mithridates*, that famous collection of specimens of the various languages and dialects of the world. Among these additions that on the Basque language is the longest and most important, Basque having for some time specially attracted his attention. In fact, Wilhelm von Humboldt may be said to have been the first who brought Basque before the notice of European philologists, and made a scientific study of it possible. In order to gain a practical knowledge of the language and complete his investigations into it, he visited the Basque country itself, the result of his visit being the valuable "Researches into the Early Inhabitants of Spain by the help of the Basque language" (*Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelst der vaskischen Sprache*), published in 1821. In this work he endeavoured to show, by an examination of geographical names, that a race or races speaking dialects allied to modern Basque once extended through the whole of Spain, the southern coast of France, and the Balearic Islands, and suggested that these people, whom he identified with the Iberians of classical writers, had come from Northern Africa, where the name of Berber still perhaps perpetuates their old designation. Another work on what has sometimes been termed the metaphysics of language appeared from his pen in 1828, under the title of *Ueber den Dualis*; but the great work of his life, on the ancient Kawi language of Java, was unfortunately interrupted by his death on the 8th of April 1835. The imperfect fragment was edited by his brother and Dr Buschmann in 1836, and contains the remarkable introduction on "The Heterogeneity of Language and its Influence on the Intellectual Development of Mankind" (*Ueber die Verschiedenheit des menschlichen Sprachbaues und ihren Einfluss auf die geistige Entwickelung des Menschengeschlechts*), which has been since edited and defended against Steinthal's criticisms by Professor Pott (2 vols., 1876). This essay, which has been called the text-book of the philosophy of speech, first clearly laid down that the character and structure of a language expresses the inner life and knowledge of its speakers, and that languages must differ from one another in the same way and to the same degree as those who use them. Sounds do not become words until a meaning has been put into them, and this meaning embodies the thought of a community. What Humboldt terms the inner form of a language is just that mode of denoting the relations between the parts of a sentence which reflects the manner in which a particular body of men regards the world about them. It is the task of the morphology of speech to distinguish the various ways in which languages differ from each other as regards their inner form, and to classify and arrange them accordingly. Other linguistic publications of Humboldt, which had appeared in the *Transactions* of the Berlin Academy, the *Journal* of the Royal Asiatic Society, or elsewhere, were republished by his brother in the seven volumes of Wilhelm von Humboldt's *Gesammelte Werke* (1841–52). These volumes also contain poems, essays on æsthetical subjects, and other creations of his prolific mind. Perhaps, however, the most generally interesting of his works, outside those which deal with language, is his correspondence with Schiller, published in 1830. Both poet and philosopher come before us in it in their most genial mood. For, though Humboldt was primarily a philosopher, he was a philosopher rendered practical by his knowledge of statesmanship and wide experience of life, and endowed with keen sympathies, warm imagination, and active interest in the method of scientific inquiry. (A. H. S.)

HUME, DAVID (1711–1776), the most subtle metaphysician and one of the greatest historians and political economists of Great Britain, was born at Edinburgh, on the 26th April (O.S.) 1711. His father, Joseph Hume or Home, a scion of the noble house of Home of Douglas, was owner of a small estate in Berwickshire, on the banks of the Whitadder, called, from the spring rising in front of the dwelling-house, Ninewells. David was the youngest of a family of three, two sons and a daughter, who after the early death of the father were brought up with great care and devotion by their mother, the daughter of Sir David Falconer, president of the college of justice. She survived till 1749, long enough to see securely established the foundations of the literary fame of the younger son, for whose powers she seems at one time to have entertained no great respect. "Our Davie," she is reported to have said, perhaps with reference to what seemed his folly in rejecting more lucrative professions than that of literature, "Our Davie 's a fine good-natured crater, but uncommon wake-minded."

Of Hume's early education little is known beyond what he has himself stated in his *Life*. He appears to have entered the Greek classes of the university of Edinburgh in 1723, and, he tells us, "passed through the ordinary course of education with success." It is uncertain how long he remained at the university, though a passage in the remarkable letter first printed by Mr Burton fixes this with comparative definiteness.[1] "As our college education in Scotland, extending little further than the languages, ends commonly when we are about fourteen or fifteen, I

[1] Burton's *Life*, i. 30–39.

was after that left to my own choice in my reading." We may conclude, then, that about the year 1726 Hume returned to Ninewells with a fair knowledge of Latin, slight acquaintance with Greek, and literary tastes decidedly inclining to "books of reasoning and philosophy, and to poetry and the polite authors." He has nowhere given any indications of an explicit character with regard to his reading, or to the works which contributed most in forming his own opinions; and in his writings, save where the subject is of an historical kind, literary references are conspicuous by their rarity. Yet it seems possible from what we know of the sources open to him, of his own preferences, of the problems with which he first busied himself, and of the general current of his speculations regarding them, to infer with some exactness the course of his studies. It is to be noted that at a very early period of his life the dominant passion had declared itself. The love of literature for its own sake was combined with the keen overmastering desire for a literary reputation. At an unusually early age he had determined for himself his future course, and no inducement was strong enough to make him swerve from it. His temperament, on the whole placid and even phlegmatic, readily inclined him to seek as his mode of life the golden mean, equally removed from such external influences as could distract or disturb contemplative repose. He practised what he taught and learned of the Stoic rules, and was concerned only to obtain such external fortune as would place him above the necessity of wasting his powers on temporary and transient objects. His prudence was as remarkable as his moderation; and his life, on the whole, may be regarded as one of the most perfect and successful instances of constant devotion to literary aims. While he was thus fortunate in choosing early and maturely the object towards which all his industry was to be directed, he was no less fortunate in the selection of the special form of literary work to which he was to devote himself. It is clear that his inclinations at a very early age led him towards the analysis of human nature, from which all his later writings take their origin. Speculation upon the nature and certainty of knowledge, whether in its abstract form, that of mere psychology, or in its more concrete applications, as in theology, seems to have been the earliest occupation of his thought; and in this speculation we cannot doubt he was directed largely by the writings of Cicero and Seneca, though the main factor was unquestionably the great English works which had begun to exert their influence at the time. While we trace the matter of Hume's later reflexions to Locke, Berkeley, and Butler, we must not overlook the great part in his mental development which is due to the sceptical or academical writings of the earlier thinkers. The philosophical treatises of Cicero were familiar to Hume, whose writings have a colouring undeniably due to this source. The form in which he cast some of the most important of his speculations is an imitation, more or less conscious, of these ancient models.

We see Hume, then, in the years during which the influences that mould a man's character and career are most actively at work, resolutely devoting himself to a life of literature, possessed by the most intense ambition for literary fame, and busying himself with reflexion upon those problems of "philosophy and critics" in which, as he found, "nothing was yet established." His means were slender, and it was necessary for him, even in view of his primary object, to endeavour after independence. The first choice of a profession, that of law, made for him by his relatives, who thought it suited to his "studious habits, sobriety, and industry," proved unsuccessful. Although his intellect was acute and practical, yet at this period he was so entirely devoted to the more subtle and speculative problems that law could present nothing beyond a barren waste of technical jargon. While his friends thought "he was poring over Voet and Vinnius, Cicero and Virgil were the authors he was secretly devouring." The intensity of his studies, the agitation due to the novelty of the ideas which began to crowd upon him as he tried to carry out systematically the first principles of human knowledge which he learned from Locke and Berkeley, combined to throw him for a time into a state of physical exhaustion and lassitude. His health was gradually restored by more careful regimen; but, as we learn from the curious diagnosis he made of his own state, the vigour requisite for protracted and connected speculation seemed to have vanished. "I have collected," he writes, the "rude materials for many volumes; but in reducing these to words, when one must bring the idea he comprehended in gross nearer to him, so as to contemplate its minutest parts, and keep it steadily in his eye, so as to copy these parts in order, this I found impracticable for me, nor were my spirits equal to so severe an employment." In these circumstances he determined to try the effect of complete change of scene and occupation. "I resolved to seek out a more active life, and, though I could not quit my pretensions to learning but with my last breath, to lay them aside for some time, in order the more effectually to resume them." The effectual remedy which commended itself to him was the trial of a mercantile life, and early in 1734 he set out for Bristol, armed with recommendations to some eminent merchants. A residence of a few months was sufficient to convince him that in this attempt at least he had not hit the mark. He found "the scene wholly unsuitable" to him, and about the middle of the year 1734 set out for France, resolved to spend some years in quiet study and retirement. He visited Paris, resided for a time at Rheims, and then settled at La Flèche, famous in the history of philosophy as the school of Descartes. His health seems to have been perfectly restored, and during the three years of his stay in France his speculations were worked into systematic form in the *Treatise of Human Nature.* In the autumn of 1737 he was in London negotiating with publishers and printers regarding the appearance of his great work, and carefully pruning and polishing it in preparation for the judgments of the learned. In January 1739 there appeared the first and second volumes of the *Treatise of Human Nature, being an Attempt to Introduce the Experimental Method of Reasoning into Moral Subjects*, containing book i., *Of the Understanding*, and book ii., *Of the Passions.* The third volume, containing book iii., *Of Morals*, was published in the following year. Few phrases are better known than the laconic sentence in which Hume, looking back on his own life, tells the tale of his first venture. "Never literary attempt was more unfortunate; it fell *dead-born from the press*, without reaching such distinction as even to excite a murmur among the zealots." "But," he adds, "being naturally of a cheerful and sanguine temper, I very soon recovered the blow, and prosecuted with great ardour my studies in the country." This brief notice, however, is not sufficient to explain the full significance of the event for Hume's own life. The work undoubtedly failed to do what its author expected from it; even the notice, otherwise not unsatisfactory, which it obtained in the *History of the Works of the Learned*, then the principal critical journal, did not in the least appreciate the true bearing of the *Treatise* on the current philosophical and theological discussions. Hume, who had been living in abstractions, to whom the disputes of the time had presented themselves in their real nature as fundamental differences of philosophical analysis, naturally expected that the world would see with as great clearness as he did the connexion between the concrete problems agitating contemporary thought and the abstract principles on which their solution depended. Accordingly he looked for the intensest opposition, and expected that, if his principles were received, the greatest of revolutions, a change in general conceptions of things, would ensue. Apart from all considerations of personal reputation, which undoubtedly had no small influence on him, he was, therefore, on the eve of the publication of his work, with justice perturbed "at the nearness and greatness of the event." It is true that in the *Treatise* there is little or no direct reference to the theological questions which were then prolific in the production of literature, and probably this omission contributed towards the first failure of the work; but Hume, as before said, is invariably chary of his references, and one cannot doubt that he was himself fully alive to the fact that in his philosophic analysis the matters in debate in the theological world had been reduced to their purest essence, had been brought back to first principles. Overlooking, then, the obvious fact that nothing is less common than systematic thinking, that the greater portion of opinion rests on the accidents of training and surroundings rather than on clearly perceived and rationally tested grounds, he anticipated an immediate and vehement onslaught on his work. His disappointment was great in proportion to the height of his expectations; and though he never entirely relinquished his metaphysical speculations, though all that is of value in his later writings depends on the acute analysis of human nature to which he was from the first attracted, one cannot but regret that his high powers were henceforth withdrawn for the most part from the consideration of the foundations of belief, and expended on its practical applications. In later years he was accustomed to explain his want of success as due to the immature style of his early thoughts and exposition, to the rashness of a young innovator in an old and well-established province of literature. "So vast an undertaking, planned before I was one-and-twenty, and composed before twenty-five, must necessarily be very defective." The disclaimer of the *Treatise* in the preface to the *Inquiry concerning Human Understanding* is well known. But all this has little foundation beyond the personal irritation of an author at his own failure to attract such attention as he deems his due. None of the principles of the *Treatise* are given up in the later writings, and no addition was made to them. Nor can the superior polish of the more mature productions overbalance the freshness and concentrated vigour of the more youthful work. Hume is at his best in the *Treatise*; and it is curious to think what might have been the position of British philosophy at the close of the 18th century had the success of his first attempt encouraged him to continue with equal zeal and undivided attention his early metaphysical speculations.

After the publication of the *Treatise* Hume retired to his brother's house at Ninewells and carried on his studies, mainly in the direction of politics and political economy, adding to this, however, a wide if not exact reading in classical literature. In 1741 he published the first volume of his *Essays*, which had a considerable and immediate success. A second edition was called for in the following year, in which also a second volume was published. It is interesting to learn from one of Hume's letters that Butler, to whom he had sent a copy of his *Treatise*, but with whom he had failed to make personal acquaintance, warmly commended the *Essays* to all his friends. The philosophical relation between Butler and Hume is one of the curious points in history. So far as analysis of knowledge is concerned both are in thorough harmony, and Hume's sceptical conclusions regarding belief in matters of fact are the foundations on which Butler's defence of religion rests. Butler, however, appears to retain, alongside of his destructive theory of knowledge, confidence in the rational proofs for the existence of God, and certainly maintains what may be vaguely described as an *a priori* view of conscience. It is probable that, though Butler never worked out the system of his belief, his theological principles will be found to rest ultimately on ethical grounds. Hume had the greatest respect for the author of the *Analogy*, ranks him with Locke and Berkeley as the originators of the experimental method in moral science, and in his specially theological essays, such as that on *Particular Providence and a Future State*, has Butler's views specifically in mind. See BUTLER.

The success of the *Essays*, though hardly great enough to satisfy the author's somewhat exorbitant cravings, was a great encouragement to Hume. He began to hope that his earlier and heavier work, if recast and lightened, might share the fortunes of its successor; and at intervals throughout the next four years he occupied himself in reducing its fundamental principles into a more succinct form, and in giving to them all the literary grace at his command. Meantime he continued to look about for some post which might secure him the modest independence he desired. In 1744 we find him, in anticipation of a vacancy in the chair of moral philosophy at Edinburgh university, moving his friends to do him good offices with the electors; and though, as he tell us, "the accusation of heresy, deism, scepticism, or theism, &c., &c., was started" against him, it had no effect, "being bore down by the contrary authority of all the good people in town." To his great mortification, however, he thought he could discover that Hutcheson and Leechman, with whom he had been on terms of friendly correspondence, were giving the weight of their opinion against the propriety of electing him to such a post. The after history of these negotiations is obscure. Hume in all probability perceived that fortune was against him, and accepted in 1745 a very anomalous post, that of tutor or guardian or keeper to the marquis of Annandale, a harmless literary lunatic. Although the salary paid during the year Hume spent in this capacity "made a considerable accession" to his fortune, the position was unmistakably false and painful. The letters relating to this episode of his life, first printed by Dr Thomas Murray, 1841 (see Burton's *Life*, i. ch. v.), are not pleasant reading; and the close of the connexion between Hume and his pupil left the philosopher under the necessity of instituting an action for recovery of arrears due to him. The details of the affair are not sufficiently clear to enable a modern judge to assign either admiration or blame to Hume's tenacity in the matter of his rights.

In 1746 Hume accepted the office of secretary to General St Clair, and was a spectator of the ill-fated expedition to France in the autumn of that year. His admirable account of the transaction has been printed by Mr Burton. After a brief sojourn at Ninewells, doubtless occupied in preparing for publication his *Philosophical Essays* (afterwards entitled *An Inquiry concerning Human Understanding*), Hume was again associated with General St Clair, and in 1748 accompanied him as secretary in the embassy to Vienna and Turin. The notes of this journey are written in a light and amusing style, showing Hume's usual keenness of sight in some directions and his almost equal blindness in others. During his absence from England, early in the year 1748, the *Philosophical Essays* were published; but, to his great disappointment, the first reception of the work was little more favourable than that accorded to the unfortunate *Treatise*. "On my return from Italy," he writes, "I had the mortification to find all England in a ferment on account of Dr Middleton's *Free Inquiry*, while my performance was entirely overlooked and neglected." To the later editions of the work Hume prepared an "Advertisement" referring to the *Treatise*, and desiring that the *Essays* "may alone be regarded as containing his philosophical sentiments and principles." Not a few modern critics have accepted this disclaimer as of real value, but in fact it has no significance; and Hume has himself in a striking letter to Gilbert Elliott indicated the true relation of the two works. "I believe the *Philosophical Essays* contain everything of consequence relating to the understanding which you would meet with in the *Treatise*, and I give you my advice against reading the latter. By shortening and simplifying the questions, I really render them much more complete. *Addo dum minuo.* The philosophical principles are the same in both." The *Essays* are undoubtedly written with more maturity and skill than the *Treatise*; they contain in more detail application of the principles to concrete problems, such as miracles, providence, immortality; but the entire omission of the discussion forming part ii. of the first book of the *Treatise*, and the great compression of part iv., are real defects which must always render the *Treatise* the more important work in the history of philosophy.

In 1749 Hume returned to England, enriched with "near a thousand pounds." Two years he spent at Ninewells, and then in 1751 removed to Edinburgh, where for the most part he resided during the next twelve years of his life. These years are the richest so far as literary production is concerned. In 1751 he published his *Political Discourses*, which had a great and well-deserved success. In the same year appeared the recast of the third book of the *Treatise*, called *Inquiry concerning the Principles of Morals*, of which he says that "of all his writings, philosophical, literary, or historical, it is incomparably the best." At this time also we hear of the *Dialogues concerning Natural Religion*, a work which Hume was prevailed on not to publish, but which he touched and retouched with the greatest care, and evidently regarded with the greatest favour. The work itself, left by Hume with instructions that it should be published, did not appear till 1779.

In 1751 Hume was again unsuccessful in the attempt to gain a professor's chair. A candidate unknown to fame then or afterwards was appointed to the chair of logic at Glasgow. In the following year he received the first public preferment that had ever fallen to his lot, the librarianship of the Advocates' Library in Edinburgh, small in emoluments, but rich in opportunity for literary work. His delight was great. In his playful style he writes to Dr Clephane, "I have been ready to burst with vanity and self-conceit this week past, and, being obliged from decorum to keep a strict watch over myself and check all emphasis of that kind, I really begin to find my health injured by it." The usual objections had been raised to his election without avail; but, "what is more extraordinary, the cry of religion could not hinder the ladies from being violently my partisans, and I owe my success in a great measure to their solicitations. One has broke off all commerce with her lover because he voted against me; and W. Lockhart, in a speech to the faculty, said that there was no walking the streets, nor even enjoying one's own fireside, on account of their importunate zeal. The town says that even his bed was not safe for him, though his wife was cousin-german to my antagonist."

The only work published at this time which requires somewhat special notice is the set of essays called *Political Discourses*. In these Hume shows greater aptitude for economical inquiries, and makes greater advances in political economy, than any previous writer. Although only a few of the many subjects of discussion are touched upon, the general principles of the science are firmly expressed and illustrated with clearness that leaves nothing to be desired. The fundamental theorem, "everything in the world is purchased by labour, and our passions are the only causes of labour," on which Smith afterwards constructed his more elaborate system, is used as the key to resolve the difficulties regarding the advantages of foreign trade, the causes of the efflux and influx of bullion, the general range of prices in a country, the influence of credit on prices and on trade, the connexion of interest, profits, and the general conditions of industry, and the most economical modes of levying taxes. In many respects the analysis of the complex phenomena of commerce is more sound and thorough than that given in the *Wealth of Nations*, for Hume never forgets that the ultimate causes of our economic movements are the "customs and manners" of the people, and always finds his solution by referring to the elementary factors of industry. It is curious that on the publication of the *Wealth of Nations* Hume indicated to Smith that he differed from him regarding the influence of rent on prices, the point from which the later advances of English political economy have taken their start. It is also remarkable that Hume had formed a much sounder judgment than Smith on the merits of the French Economists. In short, the main errors of the *Wealth of Nations* are to be found in the deviations from the principles of the *Political Discourses.*

In 1753 Hume was fairly settled in Edinburgh, enjoying the dignity and delights of householding, and preparing for his new attempt in literature, the *History of England.*[1] He had decided to begin the *History*, not with Henry VII., as Adam Smith recommended, but with James I., considering that the political differences and parties of his time took their origin from that period, and that then, as he thought, "the misrepresentations of faction began chiefly to take place." On the whole his attitude in respect to disputed political principles seems not to have been at first consciously unfair. "I am sensible," he writes to Clephane, "that the history of the two first Stuarts will be most agreeable to the Tories, that of the two last to the Whigs; but we must endeavour to be above any regard either to Whigs or Tories." As for the qualities necessary to secure success as a *writer* on history, he felt that he possessed them in a high degree; and, though neither his ideal of an historian nor his equipment for the task of historical research would now appear adequate, in both he was much in advance of his contemporaries and predecessors. Naturally, then, he was "sanguine in his expectations of the success of his work." "But," he writes in the well-known passage of his *Life*, "miserable was my disappointment. I was assailed by one cry of reproach, disapprobation, and even detestation; . . . what was still more mortifying, the book seemed to sink into oblivion. Mr Millar told me that in

---

[1] "About seven months ago," he writes to Dr Clephane, "I got a house of my own, and completed a regular family, consisting of a head, viz., myself, and two inferior members, a maid and a cat. My sister has since joined me, and keeps me company. With frugality I can reach, I find, cleanliness, warmth, light, plenty, and contentment. What would you have more? Independence? I have it in a supreme degree. Honour? That is not altogether wanting. Grace? That will come in time. A wife? That is none of the indispensable requisites of life. Books? That is one of them; and I have more than I can use. In short, I cannot find any blessing of consequence which I am not possessed of in a greater or less degree; and without any great effort of philosophy, I may be easy and satisfied. As there is no happiness without occupation, I have begun a work which will employ me several years, and which yields me much satisfaction. 'Tis a history of Great Britain, from the Union of the Crowns to the present time. I have already finished the reign of King James I. My friends flatter me (by which I mean that they don't flatter me) that I have succeeded. You know that there is no post of honour in the English Parnassus more vacant than that of history. Style, judgment, impartiality, care—everything is wanting in our historians; and even Rapin, during this latter period, is extremely deficient. I make my work very concise, after the manner of the ancients. It divides into three very moderate volumes: one to end with the death of Charles the First; the second at the Revolution; the third at the Accession, for I dare come no nearer the present times. The work will neither please the duke of Bedford nor James Fraser; but I hope it will please you and posterity. Κτῆμα εἰς ἀεί."

a twelvemonth he sold only forty-five copies of it." This account must be accepted with great qualification. It expresses Hume's feelings rather than the real facts. In Edinburgh, as we learn from one of his letters, the book succeeded well, no fewer than 450 copies being disposed of in five weeks. Nor is there anything in Hume's correspondence to show that the failure of the book was so complete as he declared it to have been. Within a very few years the sale of the *History* was sufficient to gain for the author a larger revenue than had ever before been known in his country to flow from literature, and to place him in comparative affluence. At the same time the bitterness of Hume's feelings and their effect are of importance in his life. It is from the publication of the *History* that we date the extraordinary virulence of his hatred towards everything English, towards society in London, Whig principles, Whig ministers, and the public generally.[1] He was convinced that to be a Scotchman and a Tory was to be an object of contempt and hatred to all Englishmen; and that on the whole there was a conspiracy to suppress and destroy everything that was Scotch.[2] As a consequence of these strong feelings, the remainder of the *History* became little better than a party pamphlet, written with a definite bias and a definite aim. The second volume, published in 1756, carrying on the narrative to the Revolution, was better received than the first; but Hume then resolved to work backwards, and to show from a survey of the Tudor period that his Tory notions were grounded upon the history of the constitution. In 1759 this portion of the work appeared, and in 1761 the work was completed by the history of the pre-Tudor periods. The numerous editions of the various portions,—for, despite Hume's wrath and grumblings, the book was a great literary success,—gave him an opportunity of careful revision, which he employed to remove from it all the "villainous seditious Whig strokes," and "plaguy prejudices of Whiggism" that he could detect lurking in it. In other words, he bent all his efforts towards making his *History* more of a party work than it had originally been, and in his effort he was entirely successful. It has been the business of subsequent historians to correct his misrepresentations so far as they referred to the period of which he had fair knowledge, and to supersede his accounts of those periods which his insufficient knowledge disabled him from treating in a manner worthy of him. The early portion of his *History* may be regarded as now of little or no value. The sources at Hume's command were few, and he did not even use them all. None the less, the *History* has a distinct place in the literature of England. It was the first attempt at a really comprehensive and thoughtful treatment of historic facts, the first to introduce the social and literary aspects of a nation's life as of importance only second to its political fortunes, and the first historical writing in an animated yet refined and polished style. It has received from later writers its due meed of praise and blame.[3]

While the *History* was in process of publication, Hume did not entirely neglect his other lines of activity. In 1757 appeared *Four Dissertations: The Natural History of Religion, Of the Passions, Of Tragedy, Of the Standard of Taste.* Of these the dissertation on the passions is a very subtle piece of psychology, containing the essence of the second book of the *Treatise*. It is remarkable that Hume does not appear to have been acquainted with Spinoza's analysis of the affections. The last two essays are contributions of no great importance to æsthetics, a department of philosophy in which Hume was not strong. The *Natural History of Religion* is a powerful contribution to the deistic controversy; but, as in the case of Hume's earlier work, its significance was at the time overlooked. It is an attempt to carry the war directly into a province hitherto allowed to remain at peace, the theory of the general development of religious ideas. Deists, though raising doubts regarding the historic narratives of the Christian faith, had never disputed the general fact that belief in one God was natural and primitive. Hume endeavours to show that polytheism was the earliest as well as the most natural form of religious belief, and that theism or deism is the product of reflexion upon experience, thus reducing the validity of the historical argument to that of the theoretical proofs.

In 1763 he accompanied Lord Hertford to Paris, doing the duties of secretary to the embassy, with the prospect of the appointment to that post. He was everywhere received "with the most extraordinary honours"; in fact, he was "lionized." The society of Paris was peculiarly ready to receive a great philosopher and historian, especially if he were known to be an avowed antagonist of religion. Hume basked in the sunshine of his popularity; but at the same time he made some valuable friendships, especially with D'Alembert and Turgot, the latter of whom admired sincerely and profited much by Hume's economical essays. In 1766 he left Paris and returned to Edinburgh; but in the following year (1767) he accepted the post of under-secretary to General Conway, and spent two years in London. He settled finally in Edinburgh in 1769, having now through his pension and otherwise the handsome fortune of £1000 a year. The solitary incident of note in this period of his life is the ridiculous quarrel with Rousseau, an episode still amusing, and throwing much light upon the strange character of the great sentimentalist. Hume certainly did his utmost to secure for Rousseau a comfortable retreat in England, but his usually sound judgment seems at first to have been quite at fault with regard to his protégé. That is surely an amusing likeness which Hume discovered between Rousseau and Socrates; and it is interesting to note the conflict between his preconceived opinion

[1] "If a man have the misfortune, in the former place (*i.e.*, London), to attach himself to letters, even if he succeeds, I know not with whom he is to live nor how he is to pass his time in a suitable society. The little company there that is worth conversing with are cold and unsociable, or are warmed only by faction and cabal; so that a man who plays no part in public affairs becomes altogether insignificant; and, if he is not rich, he becomes even contemptible. Hence that nation are fast relapsing into the deepest stupidity and ignorance."—Burton, ii. 268. "There are fine doings in America. O! how I long to see America and the East Indies revolted, totally and finally—the revenue reduced to half—public credit fully discredited by bankruptcy,—the third of London in ruins, and the rascally mob subdued."—*Ib.*, ii. 417. "Our government has become a chimera, and is too perfect, in point of liberty, for so rude a beast as an Englishman, who is a man, a bad animal too, corrupted by above a century of licentiousness."—*Ib.*, ii. 434.

[2] "The rage and prejudice of parties frighten me; and above all, this rage against the Scots, which is so dishonourable and indeed so infamous to the English nation. We hear that it increases every day without the least appearance of provocation on our part. It has frequently made me resolve never in my life to set foot on English ground." —Burton, ii. 265; *cf.* ii. 148, 238. Perhaps our knowledge of Johnson's sentiments regarding the Scotch in general, and of his expressions regarding Hume and Smith in particular, may lessen our surprise at this vehemence.

[3] We append the judgment of Macaulay on Hume's characteristic fault as an historian:—"Hume is an accomplished advocate. Without positively asserting much more than he can prove, he gives prominence to all the circumstances which support his case; he glides lightly over those which are unfavourable to it; his own witnesses are applauded and encouraged; the statements which seem to throw discredit on them are controverted; the contradictions into which they fall are explained away; a clear and connected abstract of their evidence is given. Everything that is offered on the other side is scrutinized with the utmost severity; every suspicious circumstance is a ground for argument and invective; what cannot be denied is extenuated, or passed by without notice; concessions even are sometimes made; but this insidious candour only increases the effect of the vast mass of sophistry."—*Miscell. Writings*, "History." With this may be compared the more favourable verdict by the late Prof. Brewer, in the preface to his edition of the *Student's Hume*.

and that which detached circumstances gave him occasion to form. He finds "Rousseau a very modest, mild, well-bred, gentle-spirited, and warm hearted man as ever I knew in my life," and thinks he "could live with him all his life in mutual friendship and esteem." At the same time he cannot avoid remarking that Rousseau "is a great humorist" (*i.e.*, full of caprices); that though "he intends seriously to draw his own picture in its true colours . . . nobody knows himself less;" that he would be unhappy in solitude, "as he has, indeed, been always in all situations." The quarrel which all the acquaintances of the two philosophers had predicted soon came, and no language had expressions strong enough for Rousseau's hatred and distrust of his protector. Hume, it must be admitted, came well out of the business, and had the sagacity to conclude that, after all, his admired friend was little better than a madman.

In 1769 Hume settled in Edinburgh, and in one of his most delightful letters he gives an animated description of the domestic economy of his later years.[1] The house alluded to as that to which he was about to remove was built under his own directions at the corner of what is now called St David Street; and we may picture it to ourselves as being, during the closing period of Hume's life, the centre of the most lively and cultivated society of Edinburgh. The gay and cheerful temper of the philosopher, his unfailing equanimity, and the solid goodness of his heart had made him many friends, even among those who dissented most from his religious views. The resolute strength with which he pushed speculation to its limits was combined with a perfect gentleness of disposition and an amiability that endeared him to all who had the pleasure of knowing him. He was singularly free from jealousy, and no feature of his character is more attractive than the unfailing cordiality with which he welcomed the literary successes of those who might have been thought his rivals. To Robertson and Smith, his personal friends, he is open and unrestrained in his praise and commendation; and his good services were ever exerted in their cause. To opponents of whose merits he was convinced, to Campbell and Reid, he was cordial and generous. His respect for his own profession led him always to encourage those who had engaged their fortunes in the perilous hazard of literary success, and to extend to them his good offices. For Blackwell and for Smollett, in their misfortunes, he exerted himself to the utmost. Nor was he without his recompense. During the closing decade of his life he was the acknowledged patriarch of literature; the veneration and respect of his friends, for his character no less than for his abilities, were unbounded. The "gaiety of his temper," says Adam Smith, "so agreeable in society, and which is so often accompanied with frivolous and superficial qualities, was in him certainly attended with the most severe application, the most extensive learning, the greatest depth of thought, and a capacity in every respect the most comprehensive. Upon the whole, I have always considered him, both in his lifetime and since his death, as approaching as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit."

In the spring of 1775 Hume was struck with a tedious and harassing though not painful illness. A visit to Bath seemed at first to have produced good effects, but on the return journey northwards more alarming symptoms developed themselves, his strength rapidly sank, and, little more than a month after he had reached Edinburgh, he died (25th August 1776).

No notice of Hume would be complete without the sketch of his character drawn by his own hand:—"To conclude historically with my own character, I am, or rather was (for that is the style I must now use in speaking of myself, which emboldens me the more to speak my sentiments),—I was, I say, a man of mild dispositions, of command of temper, of an open, social, and cheerful humour, capable of attachment, but little susceptible of enmity, and of great moderation in all my passions. Even my love of literary fame, my ruling passion, never soured my temper, notwithstanding my frequent disappointments. My company was not unacceptable to the young and careless, as well as to the studious and literary; and as I took a particular pleasure in the company of modest women, I had no reason to be displeased with the reception I met with from them. In a word, though most men anywise eminent have found reason to complain of calumny, I never was touched, or even attacked, by her baleful tooth; and, though I wantonly exposed myself to the rage of both civil and religious factions, they seem to be disarmed on my behalf of their wonted fury. My friends never had occasion to vindicate any one circumstance of my character and conduct; not but that the zealots, we may well suppose, would have been glad to invent and propagate any story to my disadvantage, but they could never find any which they thought would wear the face of probability. I cannot say there is no vanity in making this funeral oration of myself, but I hope it is not a misplaced one; and this is a matter of fact which is easily cleansed and ascertained." The more his life has become known, the more confidence we place in this admirable estimate.

The philosophical writings of Hume, which mark a distinct epoch in the development of modern thought, can here be considered in two only of the many aspects in which they present themselves as of the highest interest to the historian of philosophy. In the *Treatise of Human Nature*, which is in every respect the most complete exposition of Hume's philosophical conception, we have the first thorough-going attempt to apply the fundamental principles of Locke's empirical psychology to the construction of a theory of knowledge, and, as a natural consequence, the first systematic criticism of the chief metaphysical notions from this point of view. Hume, in that work, holds the same relation to Locke and Berkeley as the late J. S. Mill held with his *System of Logic* to Hartley and James Mill. In certain of the later writings, pre-eminently in the *Dialogues on Natural Religion*, Hume brings the results of his speculative criticism to bear upon the problems of current theological discussion, and gives in their regard as previously with respect to general philosophy the final word of the empirical theory in its earlier form. The interesting parallel between Hume and J. S. Mill in this second feature will not be overlooked.

In the first instance, then, Hume's philosophical work is to be regarded as the attempt to supply for empiricism in psychology a consistent, that is, a logically developed theory of knowledge. In Locke, indeed, such theory is not wanting, but, of all the many inconsistencies in the *Essay on the Human Understanding*, none is more apparent or more significant than the complete want of harmony between the view of knowledge developed in the fourth book and the psychological principles laid down in the earlier part of the work. Though Locke, doubtless, drew no distinction between the problems of psychology and of theory of knowledge, yet the discussion of the various forms of cognition given in the fourth book of the *Essay* seems to be based on grounds quite distinct from and in many respects inconsistent with the fundamental psychological principle of his work. The perception of relations, which, according to him, is the essence of cognition, the demonstrative character which he thinks attaches to our inference of God's existence, the intuitive knowledge of self, are doctrines incapable of being brought into harmony with the view of mind and its development which is the keynote of his general theory. To some extent Berkeley removed this radical inconsistency, but in his philosophical work it may be said with safety there are two distinct aspects, and while it holds of Locke on the one hand, it stretches forward to Kantianism on the other. Nor in Berkeley are these divergent features ever united into one harmonious whole. It was left for Hume to approach the theory of knowledge with full consciousness from the psychological point of view, and to work out the final consequences of that view so far as cognition is concerned. The terms which he employs in describing the aim and scope of his work are not those which we should now employ, but the declaration, in the introduction to the *Treatise*, that the science of human nature must be treated according to the

[1] "I live still, and must for a twelvemonth, in my old house in James' Court, which is very cheerful, and even elegant, but too small to display my great talent for cookery, the science to which I intend to addict the remaining years of my life! I have just now lying on the table before me a receipt for making *soupe à la reine*, copied with my own hand; for beef and cabbage (a charming dish), and old mutton, and old claret, nobody excels me. I make also sheep-head broth, in a manner that Mr Keith speaks of it for eight days after; and the Duc de Nivernois would bind himself apprentice to my lass to learn it. I have already sent a challenge to David Moncrief; you will see that in a twelvemonth he will take to the writing of history, the field I have deserted; for, as to the giving of dinners, he can now have no further pretensions. I should have made a very bad use of my abode in Paris, if I could not get the better of a mere provincial like him. All my friends encourage me in this ambition, as thinking it will redound very much to my honour."

experimental method, is in fact equivalent to the statement of the principle implied in Locke's *Essay*, that the problems of psychology and of theory of knowledge are identical. And this view is the characteristic of what we may call the English school of philosophy.

In order to make perfectly clear the full significance of the principle which Hume applied to the solution of the chief philosophical questions, it is necessary to render somewhat more precise and complete the statement of the psychological view which lies at the foundation of the empirical theory, and to distinguish from it the problem of the theory of knowledge upon which it was brought to bear. Without entering into details, which it is the less necessary to do because the subject has been recently discussed with great fulness in works readily accessible, it may be said that for Locke as for Hume the problem of psychology was the exact description of the contents of the individual mind, and the determination of the conditions of the origin and development of conscious experience in the individual mind. And the answer to the problem which was furnished by Locke is in effect that with which Hume started. The conscious experience of the individual is the result of interaction between the individual mind and the universe of things. It is evident that this solution presupposes a peculiar conception of the general relation between the mind and things which in itself requires justification, and which, so far at least as the empirical theory was developed by Locke and his successors, could not be obtained from psychological analysis. Either we have a right to the assumption contained in the conception of the individual mind as standing in relation to things, in which case the grounds of the assumption must be sought elsewhere than in the results of this reciprocal relation, or we have no right to the assumption, in which case reference to the reciprocal relation can hardly be accepted as yielding any solution of the psychological problem. But in any case,—and, as we shall see, Hume endeavours so to state his psychological premises as to conceal the assumption made openly by Locke,—it is apparent that this psychological solution does not contain the answer to the wider and radically distinct problem of the theory of knowledge. For here we have to consider how the individual intelligence comes to know any fact whatsoever, and what is meant by the cognition of a fact. With Locke, Hume professes to regard this problem as virtually covered or answered by the fundamental psychological theorem; but the superior clearness of his reply enables us to mark with perfect precision the nature of the difficulty inherent in the attempt to regard the two as identical. For purposes of psychological analysis the conscious experience of the individual mind is taken as given fact, to be known, *i.e.*, observed, discriminated, classified, and explained in the same way in which any one special portion of experience is treated. Now if this mode of treatment be accepted as the only possible method, and its results assumed to be conclusive as regards the problem of knowledge, the fundamental peculiarity of cognition is overlooked. In all cognition, strictly so-called, there is involved a certain synthesis or relation of parts of a characteristic nature, and if we attempt to discuss this synthesis as though it were in itself but one of the facts forming the *matter* of knowledge, we are driven to regard this relation as being of the quite external kind discovered by observation among matters of knowledge. The difficulty of reconciling the two views is that which gives rise to much of the obscurity in Locke's treatment of the theory of knowledge; in Hume the effort to identify them, and to explain the synthesis which is essential to cognition as merely the accidental result of external relations among the elements of conscious experience, appears with the utmost clearness, and gives the keynote of all his philosophical work. The final perplexity, concealed by various forms of expression, comes forward at the close of the *Treatise* as absolutely unsolved, and leads Hume, as will be pointed out, to a truly remarkable confession of the weakness of his own system.

While, then, the general idea of a theory of knowledge as based upon psychological analysis is the groundwork of the *Treatise*, it is a particular consequence of this idea that furnishes to Hume the characteristic criterion applied by him to all philosophical questions. If the relations involved in the fact of cognition are only those discoverable by observation of any particular portion of known experience, then such relations are quite external and contingent. The only necessary relation which can be discovered in a given fact of experience is that of non-contradiction; the thing must be what it is, and cannot be conceived as having qualities contradictory of its nature. The universal test, therefore, of any supposed philosophical principle, seeing that such principles are but expressions of relations among facts, is the possibility or impossibility of imagining its contradictory. All our knowledge is but the sum of our conscious experience, and is consequently material for imagination. "Let us fix our attention out of ourselves as much as possible; let us chase our imagination to the heavens or to the utmost limits of the universe; we never really advance a step beyond ourselves, nor can conceive any kind of existence, but those perceptions which have appeared in that narrow compass. This is the universe of the imagination, nor have we any idea but what is there produced" (*Works*, ed. of 1854, i. 93, *cf.* i. 107).

The course of Hume's work follows immediately from his fundamental principle, and the several divisions of the treatise, so far as the theoretical portions are concerned, are but its logical consequences. The first part of the first book contains a brief statement of the contents of mind, a description of all that observation can discover in conscious experience. The second part deals with those judgments which rest upon the formal elements of experience, space and time. The third part discusses the principle of real connexion among the elements of experience, the relation of cause and effect. The fourth part is virtually a consideration of the ultimate significance of this conscious experience, of the place it is supposed to occupy in the universe of existence, in other words, of the relations between the conscious experience of an individual mind as disclosed to observation and the supposed realities of self and external things.

In the first part Hume gives his own statement of the psychological foundations of his theory. Viewing the contents of mind as matter of experience, he can discover among them only one distinction, a distinction expressed by the terms *impressions* and *ideas*. Ideas are secondary in nature, copies of data supplied we know not whence. All that appears in conscious experience as primary, as arising from some unknown cause, and therefore relatively as original, Hume designates by the term *impression*, and claims to imply by such term no theory whatsoever as to the origin of this portion of experience. There is simply the fact of conscious experience, arising we know not how. Moreover, if we remain faithful to the fundamental conception of the contents of mind as being merely matters of experience, it is evident in the first place that as impressions are strictly individual, ideas also must be strictly particular, and in the second place that the faculties of combining, discriminating, abstracting, and judging, which Locke had admitted, are merely expressions for particular modes of having mental experience, *i.e.*, are modifications of *conceiving* (*cf.* i. 128 n., 137, 192). Thus at a single stroke Hume removes all the philosophical discussions that had centred round the problem of abstract ideas and the nature of judgment. It is merely by accidental concomitance, which on the subjective side is custom, that one fact, a word, sign, symbol, or type comes to stand for a series of resembling facts, while the comparison of perceptions, with resulting consciousness of their resemblance or difference, is in itself a single, isolated perception (see i. 37, 38, 100).

Such, in substance, is Hume's restatement of Locke's empirical view. Conscious experience consists of isolated states, each of which is as a fact and is related to others in a quite external fashion. It remains to be seen how knowledge can be explained from such a basis; but, before proceeding to sketch Hume's answer to this question, it is necessary to draw attention, first, to the peculiar device invariably resorted to by him when any exception to his general principle that ideas are secondary copies of impressions presents itself, and, secondly, to the nature of the substitute offered by him for that perception of relations or synthesis which even in Locke's confused statements had appeared as the essence of cognition. Whenever Hume finds it impossible to recognize in an idea the mere copy of a particular impression, he introduces the phrase "manner of conceiving." Thus general or abstract ideas are merely copies of a particular impression conceived in a particular manner. The ideas of space and time, as will presently be pointed out, are copies of impressions conceived in a particular manner. The idea of necessary connexion is merely the reproduction of an impression which the mind *feels* itself compelled to conceive in a particular manner. Such a fashion of disguising difficulties points, not only to an inconsistency in Hume's theory as stated by himself, but to the initial error upon which it proceeds; for these perplexities are but the consequences of the doctrine that cognition is to be explained from what can be discovered by observation among the facts of experience, and observation can discover none but external relations. These external relations are, in fact, what Hume describes as the natural bonds of connexion among ideas, and, regarded subjectively as principles of association among facts of mental experience, they form the substitute he offers for the synthesis implied in knowledge. These principles of association determine the imagination to combine ideas in various modes, and by this mechanical combination Hume, for a time, endeavoured to explain what are otherwise called judgments of relation. It was impossible, however, for him to carry out this view consistently. The only combination which, even in appearance, could be explained satisfactorily by its means was the formation of a complex idea out of simpler parts, but it is absurd to describe the idea of a relation among facts as a complex idea; and, as such relations have no basis in impressions, Hume is finally driven to a confession of the absolute impossibility of explaining them. Such confession, however, is only reached after a vigorous effort had been made to render some account of knowledge by the experimental method.

The psychological conception, then, on the basis of which Hume proceeds to discuss the theory of knowledge, is that of conscious experience as containing merely the succession of isolated impressions and their fainter copies, ideas, and as bound together by merely natural or external links of connexion, the principles of association among ideas. The foundations of cognition must be discovered by observation or analysis of experience so conceived. Hume wavers somewhat in his division of the various kinds of cognition, laying stress now upon one now upon another of the points in which mainly they differ from one another. Nor is it of the first importance, save with the view of criticizing his own consistency, that we should adopt any of the divisions implied in his exposition. For practical purposes we may regard the most important discussions in the *Treatise* as falling under two heads. In the first place there are certain principles of cognition which appear to rest upon and to express relations of the universal elements in conscious experience, viz., space and time. The propositions of mathematics seem to be independent of this or that special fact of experience, and to remain unchanged even when the concrete matter of experience varies. They are formal. In the second place, cognition, in any real sense of that term, implies connexion for the individual mind between the present fact of experience and other facts, whether past or future. It appears to involve, therefore, some real relation among the portions of experience, on the basis of which relation judgments and inferences as to matters of fact can be shown to rest. The theoretical question is consequently that of the nature of the supposed relation, and of the certainty of judgments and inferences resting on it.

Hume's well-known distinction between relations of ideas and matters of fact corresponds fairly to this separation of the formal and real problems in the theory of cognition, although that distinction is in itself inadequate and not fully representative of Hume's own conclusions.

With regard, then, to the first problem, the formal element in knowledge, Hume has to consider several questions, distinct in nature and hardly discriminated by him with sufficient precision. For a complete treatment of this portion of the theory of knowledge, there require to be taken into consideration at least the following points : (*a*) the exact nature and significance of the space and time relations in our experience, (*b*) the mode in which the primary data, facts or principles, of mathematical cognition are obtained, (*c*) the nature, extent, and certainty of such data, in themselves and with reference to the concrete material of experience, (*d*) the principle of inference from the data, however obtained. Not all of these points are discussed by Hume with the same fulness, and with regard to some of them it is difficult to state his conclusions. It will be of service, however, to attempt a summary of his treatment under these several heads,—the more so as almost all expositions of his philosophy are entirely defective in the account given of this essential portion. The brief statement in the *Inquiry*, § iv., is of no value, and indeed is almost unintelligible unless taken in reference to the full discussion contained in part ii. of the *Treatise*.

The nature of space and time as elements in conscious experience is considered by Hume in relation to a special problem, that of their supposed infinite divisibility. Evidently upon his view of conscious experience, of the world of imagination, such infinite divisibility must be a fiction. The ultimate elements of experience must be real units, capable of being represented or imagined in isolation. Whence then do these units arise ? or, if we put the problem as it was necessary Hume should put it to himself, in what orders or classes of impressions do we find the elements of space and time ? Beyond all question Hume, in endeavouring to answer this problem, is brought face to face with one of the difficulties inherent in his conception of conscious experience. For he has to give some explanation of the nature of space and time which shall identify these with impressions, and at the same time is compelled to recognize the fact that they are not identical with any single impression or set of impressions. Putting aside, then, the various obscurities of terminology, such as the distinction between the objects known, viz., "points" or several mental states, and the impressions themselves, which disguise the full significance of his conclusion, we find Hume reduced to the following as his theory of space and time. Certain impressions, the sensations of sight and touch, have in themselves the element of space, for these impressions (Hume skilfully transfers his statement to the *points*) have a certain order or mode of arrangement. This mode of arrangement or manner of disposition is common to coloured points and tangible points, and, considered separately, is the impression from which our idea of space is taken. All impressions and all ideas are received, or form parts of a mental experience only when received, in a certain order, the order of succession. This manner of presenting themselves is the impression from which the idea of time takes its rise.

It is almost superfluous to remark, first, that Hume here deliberately gives up his fundamental principle that ideas are but the fainter copies of impressions, for it can never be maintained that order of disposition is an impression, and, secondly, that he fails to offer any explanation of the mode in which *coexistence* and *succession* are possible elements of cognition in a conscious experience made up of isolated presentations and representations. For the consistency of his theory, however, it was indispensable that he should insist upon the real, *i.e.*, presentative character of the ultimate units of space and time.

How then are the primary data of mathematical cognition to be derived from an experience containing space and time relations in the manner just stated ? It is important to notice that Hume, in regard to this problem, distinctly separates geometry from algebra and arithmetic, *i.e.*, he views extensive quantity as being cognized differently from number. With regard to geometry, he holds emphatically that it is an empirical doctrine, a science founded on observation of concrete facts. The rough appearances of physical facts, their outlines, surfaces, and so on, are the data of observation, and only by a method of approximation do we gradually come near to such propositions as are laid down in pure geometry. He definitely repudiates a view often ascribed to him, and certainly advanced by many later empiricists, that the data of geometry are hypothetical. The ideas of perfect lines, figures, and surfaces have not, according to him, any existence. (See *Works*, i. 66, 69, 73, 97, and iv. 180.) It is impossible to give any consistent account of his doctrine regarding number. He holds, apparently, that the foundation of all the science of number is the fact that each element of conscious experience is presented as a unit, and adds that we are capable of considering any fact or collection of facts as a unit. This *manner of conceiving* is absolutely general and distinct, and accordingly affords the possibility of an all-comprehensive and perfect science, the science of discrete quantity. (See *Works*, i. 97.)

In respect to the third point, the nature, extent, and certainty of the elementary propositions of mathematical science, Hume's utterances are far from clear. The principle with which he starts and from which follows his well known distinction between relations of ideas and matters of fact, a distinction which Kant appears to have thought identical with his distinction between analytical and synthetical judgments, is comparatively simple. The *ideas* of the quantitative aspects of phenomena are exact representations of these aspects or quantitative impressions ; consequently, whatever is found true by consideration of the ideas may be asserted regarding the real impressions. No question arises regarding the *existence* of the fact represented by the idea, and in so far, at least, mathematical judgments may be described as hypothetical. For they simply assert what will be found true in any conscious experience containing coexisting impressions of sense (specifically, of sight and touch), and in its nature successive. That the propositions are hypothetical in this fashion does not imply any distinction between the abstract truth of the ideal judgments and the imperfect correspondence of concrete material with these abstract relations. Such distinction is quite foreign to Hume, and can only be ascribed to him from an entire misconception of his view regarding the ideas of space and time. (For an example of such misconception, which is almost universal, see Riehl, *Der philosophische Kriticismus*, i. 96, 97.)

From this point onwards Hume's treatment becomes exceedingly confused. The identical relation between the ideas of space and time and the impressions corresponding to them apparently leads him to regard judgments of continuous and discrete quantity as standing on the same footing, while the ideal character of the data gives a certain colour to his inexact statements regarding the extent and truth of the judgments founded on them. The emphatic utterances in the *Inquiry* (iv. 30, 186), and even at the beginning of the relative section in the *Treatise* (i. 95), may be cited in illustration. But in both works these utterances are qualified in such a manner as to enable us to perceive the real bearings of his doctrine, and to pronounce at once that it differs widely from that commonly ascribed to him. "It is from the idea of a triangle that we discover the relation of equality which its three angles bear to two right ones ; and this relation is invariable, so long as our idea remains the same" (i. 95). If taken in isolation this passage might appear sufficient justification for Kant's view that, according to Hume, geometrical judgments are analytical and therefore perfect. But it is to be recollected that, according to Hume, an idea is actually a *representation* or individual picture, not a notion or even a *schema*, and that he never claims to be able to extract the predicate of a geometrical judgment by analysis of the subject. The properties of this individual subject, the idea of the triangle, are, according to him, discovered by observation, and as observation, whether actual or ideal, never presents us with more than the rough or general appearances of geometrical quantities, the relations so discovered have only approximate exactness. "Ask a mathematician what he means when he pronounces two quantities to be equal, and he must say that the idea of *equality* is one of those which cannot be defined, and that it is sufficient to place two equal qualities before any one in order to suggest it. Now this is an appeal to the general appearances of objects to the imagination or senses" (iv. 180). "Though it (*i.e.*, geometry) much excels, both in universality and exactness, the loose judgments of the senses and imagination, yet [it] never attains a perfect precision and exactness" (i. 97). Any exactitude attaching to the conclusions of geometrical reasoning arises from the comparative simplicity of the data for the primary judgments.

So far, then, as geometry is concerned, Hume's opinion is perfectly definite. It is an experimental or observational science, founded on primary or immediate judgments (in his phraseology, *perceptions*), of relation between facts of intuition; its conclusions are hypothetical only in so far as they do not imply the existence at the moment of corresponding real experience; and its propositions have no exact truth. With respect to arithmetic and algebra, the science of numbers, he expresses an equally definite opinion, but unfortunately it is quite impossible to state in any satisfactory fashion the grounds for it or even its full bearing. He nowhere explains the origin of the notions of unity and number, but merely asserts that through their means we can have absolutely exact arithmetical propositions (*Works*, i. 97, 98). Upon the nature of the reasoning by which in mathematical science we pass from data to conclusions, Hume gives no explicit statement. If we were to say that on his view the essential step must be the establishment of identities or equivalences, we should probably be doing justice to his doctrine of numerical reasoning, but should have some difficulty in showing the application of the method to geometrical reasoning. For in the latter case we possess, according to Hume, no standard of equivalence other than that supplied by immediate observation, and consequently transition from one premise to another by way of reasoning must be, in geometrical matters, a purely verbal process.

Taken as a whole, the theory is perhaps the only consistent development from the psychological principle with which Hume had started, and its incompleteness, even incoherence, points to the gravest defects of that principle. Hume has not offered even a plausible explanation of the mode by which it becomes possible for a consciousness made up of isolated momentary impressions and ideas to be aware of coexistence and number, or succession. The relations of ideas are accepted as facts of immediate observation, as being themselves perceptions or individual elements of conscious experience, and to all appearance they are regarded by Hume as being in a sense analytical, because the formal criterion of identity is applicable to them. It is applicable, however, not because the predicate is contained in the subject, but because, such judgments of relation being thought as immediate facts of conscious experience, the supposition of their non-existence is a contradiction in terms. The ambiguity in his criterion, however, seems entirely to have escaped Hume's attention.

A somewhat detailed consideration of Hume's doctrine with regard to mathematical science has been given for the reason that this portion of his theory has been very generally overlooked or misinterpreted. It does not seem necessary to endeavour to follow his minute examination of the principle of real cognition with the same fulness. It will probably be sufficient to indicate the problem as conceived by Hume, and the relation of the method he adopts for solving it to the fundamental doctrine of his theory of knowledge.

Real cognition, as Hume points out, implies transition from the present impression or feeling to something connected with it. As this thing can only be an impression or perception, and is not itself present, it is represented by its copy or idea. Now the supreme, all-comprehensive link of connexion between present feeling or impression and either past or future experience is that of causation. The idea in question is, therefore, the idea of something connected with the present impression as its cause or effect. But this is explicitly the idea of the said thing as having had or as about to have existence,—in other words, belief in the existence of some matter of fact. What, for a conscious experience so constituted as Hume will admit, is the precise significance of such belief in real existence?

Clearly the real existence of a fact is not demonstrable. For whatever is may be conceived not to be. "No negation of a fact can involve a contradiction." Existence of any fact, not present as a perception, can only be proved by arguments from cause or effect. But as each perception is in consciousness only as a contingent fact, which might not be or might be other than it is, we must admit that the mind can conceive no necessary relations or connexions among the several portions of its experience.

If, therefore, a present perception leads us to assert the existence of some other, this can only be interpreted as meaning that in some natural, *i.e.*, psychological, manner the idea of this other perception is excited, and that the idea is viewed by the mind in some peculiar fashion. The natural link of connexion Hume finds in the similarities presented by experience. One fact or perception is discovered by experience to be uniformly or generally accompanied by another, and its occurrence therefore naturally excites the idea of that other. But when an idea is so roused up by a present impression, and when this idea, being a consequence of memory, has in itself a certain vivacity or liveliness, we regard it with a peculiar indefinable feeling, and in this feeling consists the immense difference between mere imagination and belief. The mind is led easily and rapidly from the present impression to the ideas of impressions found by experience to be the usual accompaniments of the present fact. The ease and rapidity of the mental transition is the sole ground for the supposed necessity of the causal connexion between portions of experience. We mistake the subjective transition resting upon custom or past experience for an objective connexion independent of special feelings. All reasoning about matters of fact is therefore a species of feeling, and belongs to the sensitive rather than to the cogitative side of our nature.

While it is evident that some such conclusion must follow from the attempt to regard the cognitive consciousness as made up of disconnected feelings, it is equally clear, not only that the result is self-contradictory, but that it involves certain assumptions not in any way deducible from the fundamental view with which Hume starts. For in the problem of real cognition he is brought face to face with the characteristic feature of knowledge, distinction of self from matters known, and reference of transitory states to permanent objects or relations. Deferring his criticism of the significance of self and object, Hume yet makes use of both to aid his explanation of the belief attaching to reality. The reference of an idea to past experience has no meaning, unless we assume an identity in the object referred to. For a past impression is purely transitory, and, as Hume occasionally points out, can have no connexion of fact with the present consciousness. His exposition has thus a certain plausibility, which would not belong to it had the final view of the permanent object been already given.

The final problem of Hume's theory of knowledge, the discussion of the real significance of the two factors of cognition, self and external things, is handled in the *Treatise* with great fulness and dialectical subtlety.

As in the case of the previous problem, it is unnecessary to follow the steps of his analysis, which are, for the most part, attempts to substitute qualities of feeling for the relations of thought which appear to be involved. The results follow with the utmost ease from his original postulate. If there is nothing in conscious experience save what observation can disclose, while each act of observation is itself an isolated feeling (an impression or idea), it is manifest that a permanent identical thing can never be an object of experience. Whatever permanence or identity is ascribed to an impression or idea is the result of association, is one of those "propensities to feign" which are due to natural connexions among ideas. We regard as successive presentations of one thing the resembling feelings which are experienced in succession. Identity, then, whether of self or object, there is none, and the supposition of *objects*, distinct from impressions, is but a further consequence of our "propensity to feign." Hume's explanation of the belief in external things by reference to association is well deserving of careful study and of comparison with the more recent analysis of the same problem by J. S. Mill.

At the close of his presentation of the empirical theory of cognition, Hume gives one of those comprehensive reviews of its significance and its difficulties which mark the rare acuteness of his intellect. He has done what was possible to manufacture cognition out of the isolated, disconnected states of mental experience. He has endeavoured to contemplate conscious experience *ab extra*, as itself an object of experience, and to admit nothing which was not capable of being presented in the fashion of an immediate fact of experience. And as the result of the whole he has to confess that his laboriously constructed theory of cognition is but a rope of sand, that no ingenuity can conjure coherence into elements assumed from the outset as incoherent, that the attempt to regard cognition of a fact as being merely one isolated state leads to hopeless confusion. The passage in which, with the utmost frankness, he expresses his opinion on the sum total of his speculative analysis is so remarkable, both in reference to his own work and in reference to later developments of philosophy, that it is well to quote it in full. In the *Appendix* to the *Treatise* he gives a brief *résumé* of what he clearly recognized to be the *crux* in his theory, the explanation of belief, a cognition which involves the relation among themselves of the parts of experience, and then goes on to say:—

"If perceptions are distinct existences, they form a whole only by being connected together. But no connexions among distinct existences are ever discoverable by human understanding. We only *feel* a connexion or determination of the thought to pass from one object to another. It follows, therefore, that the thought alone feels personal identity, when, reflecting on the train of past perceptions that compose a mind, the ideas of them are felt to be connected together and naturally introduce each other.

"However extraordinary this conclusion may seem, it need not surprise us. Modern philosophers seem inclined to think that personal identity *arises* from consciousness, and consciousness is nothing but a reflected thought or perception. The present philosophy, therefore, has a promising aspect. But all my hopes vanish when I come to explain the principles that unite our successive perceptions in our thought or consciousness. I cannot discover any theory which gives me satisfaction on this head. . . . .

"In short, there are two principles which I cannot render consistent, nor is it in my power to renounce either of them; viz., *that all our distinct perceptions are distinct existences*, and *that the mind never perceives any real connexion among distinct existences.* Did our perceptions either inhere in something simple or individual, or did the mind perceive some real connexion among them, there would be no difficulty in the case" (ii. p. 551).

The closing sentences of this passage may be regarded as pointing to the very essence of the Kantian attempt at solution of the problem of knowledge. Hume sees distinctly that if conscious experience be taken as containing only isolated states, no progress in explanation of cognition is possible, and that the only hope of further development is to be looked for in a radical change in our mode of conceiving experience. The work of the critical philosophy is the introduction of this new mode of regarding experience, a mode which, in the technical language of philosophers, has received the title of *transcendental* as opposed to the psychological method followed by Locke and Hume. It is because Kant alone perceived the full significance of the change required in order to meet the difficulties of the empirical theory that we regard his system as the only sequel to that of Hume. The writers of the Scottish school, Reid in particular, did undoubtedly indicate some of the weaknesses in Hume's fundamental conception, and their attempts to show that the isolated feeling cannot be taken as the ultimate and primary unit of cognitive experience are efforts in the right direction. But the question of knowledge was never generalized by them, and their reply to Hume, therefore, remains partial and inadequate, while its effect is weakened by the uncritical assumption of principles which is a characteristic feature of their writings.

The results of Hume's theoretical analysis are applied by him to the problems of practical philosophy and religion. For the first of these the reader is referred to the article ETHICS, where Hume's views are placed in relation to those of his predecessors in the same field of inquiry. His position, as regards the second, is very noteworthy. As before said, his metaphysic contains *in abstracto* the principles which were at that time being employed, uncritically, alike by the deists and by their antagonists. There can be no doubt that Hume has continually in mind the theological questions then current, and that he was fully aware of the mode in which his analysis of knowledge might be applied to them. A few of the less important of his criticisms, such as the argument on miracles, became then and have since remained public property and matter of general discussion. But the full significance of his work on the theological side was not at the time perceived, and justice has barely been done to the admirable manner in which he has reduced the theological disputes of the century to their ultimate elements. The importance of the *Dialogues on Natural Religion*, as a contribution to the criticism of theological ideas and methods, can hardly be overestimated. A brief survey of its contents will be sufficient to show its general nature and its relations to such works as Clarke's *Demonstration* and Butler's *Analogy*. The *Dialogues* introduce three interlocutors, Demea, Cleanthes, and Philo, who represent three distinct orders of theological opinion. The first is the type of a certain *a priori* view, then regarded as the safest bulwark against infidelity, of which the main tenets were that the being of God was capable of *a priori* proof, and that, owing to the finitude of our faculties, the attributes and modes of operation of deity were absolutely incomprehensible. The second is the typical deist of Locke's school, improved as regards his philosophy, and holding that the only possible proof of God's existence was *a posteriori*, from design, and that such proof was, on the whole, sufficient. The third is the type of completed empiricism or scepticism, holding that no argument, either from reason or experience, can transcend experience, and consequently that no proof of God's existence is at all possible. The views of the first and second are played off against one another, and criticized by the third with great literary skill and effect. Cleanthes, who maintains that the doctrine of the incomprehensibility of God is hardly distinguishable from atheism, is compelled by the arguments of Philo to reduce to a minimum the conclusion capable of being inferred from experience as regards the existence of God. For Philo lays stress upon the weakness of the analogical argument, points out that the demand for an ultimate cause is no more satisfied by thought than by nature itself, shows that the argument from design cannot warrant the inference of a perfect or infinite or even of a single deity, and finally, carrying out his principles to the full extent, maintains that, as we have no experience of the origin of the world, no argument from experience can carry us to its origin, and that the apparent marks of design in the structure of animals are only results from the conditions of their actual existence. So far as argument from nature is concerned, a total suspension of judgment is our only reasonable resource. Nor does the *a priori* argument in any of its forms fare better, for reason can never demonstrate a matter of fact, and, unless we know that the world had a beginning in time, we cannot insist that it must have had a cause. Demea, who is willing to give up his abstract proof, brings forward the ordinary theological topic, man's consciousness of his own imperfection, misery, and dependent condition. Nature is throughout corrupt and polluted, but "the present evil phenomena are rectified in other regions and in some future period of existence." Such a view satisfies neither of his interlocutors. Cleanthes, pointing out that from a nature thoroughly evil we can never prove the existence of an infinitely powerful and benevolent Creator, hazards the conjecture that the deity, though all-benevolent, is not all-powerful. Philo, however, pushing his principles to their full consequences, shows that unless we assumed (or knew) beforehand that the system of nature was the work of a benevolent but limited deity, we certainly could not, from the facts of nature, infer the benevolence of its creator. Cleanthes's view is, therefore, an hypothesis, and in no sense an inference.

The *Dialogues* ought here to conclude. There is, however, appended one of those perplexing statements of personal opinion (for Hume declares Cleanthes to be his mouthpiece) not uncommon among writers of this period. Cleanthes and Philo come to an agreement, in admitting a certain illogical force in the *a posteriori* argument, or, at least, in expressing a conviction as to God's existence, which may not perhaps be altogether devoid of foundation. The precise value of such a declaration must be matter of conjecture. Probably the true statement of Hume's attitude regarding the problem is the somewhat melancholy utterance with which the *Dialogues* close.

It is apparent, even from the brief summary just given, that the importance of Hume in the history of philosophy consists in the vigour and logical exactness with which he develops a particular metaphysical view. Inconsistencies, no doubt, are to be detected in his system, but they arise from the limitations of the view itself, and not, as in the case of Locke and Berkeley, from imperfect grasp of the principle, and endeavour to unite with it others radically incompatible. In Hume's theory of knowledge we have the final expression of what may be called psychological individualism or atomism, while his ethics and doctrine of religion are but the logical consequences of this theory. So far as metaphysic is concerned, Hume has given the final word of the empirical school, and all additions, whether from the specifically psychological side or from the general history of human culture, are subordinate in character, and affect in no way the nature of his results. It is no exaggeration to say that the more recent English school of philosophy, represented by J. S. Mill, has made in theory no advance beyond Hume. In the *logic* of Mill, *e.g.*, we find much of a special character that has no counterpart in Hume, much that is introduced *ab extra*, from general considerations of scientific procedure, but, so far as the groundwork is concerned, the *System of Logic* is a mere reproduction of Hume's doctrine of knowledge. Such a statement does not detract from the merits of the *Logic* or even from its originality, for it is remarkable how slight seems to have been the acquaintance of Mill with the works of his greatest predecessor, but it does imply that, so far as solution of the philosophical problem is concerned, no advance has been made beyond the position of Hume. The same remark, indeed, may be applied to the few efforts of the later empirical writers in the region of metaphysics or theology. It is impossible for any reader of Mill's remarkable posthumous essay on theism to avoid the reflexion that in substance the treatment is identical with that of the *Dialogues on Natural Religion*, while on the whole the superiority in critical force must be assigned to the earlier work. All this merely shows how fully the conclusion one would naturally draw from Hume's writings has been borne out by the history of later thought. From his position, and on his lines, no further advance was possible. For a new treatment of philosophical problems a thorough revision of those premises, the adoption of new ground, was requisite. So far as one can see, the only systems of thought which have endeavoured or are endeavouring in a comprehensive fashion to take up anew the work of philosophy are, on the one hand, the Kantian, with its extensive developments, and, on the other, that of scientific naturalism, which latter, though weak in its metaphysic, is yet penetrated with a truly philosophical spirit.

The chief work for Hume's life is that of Mr J. H. Burton, *Life and Correspondence of David Hume*, 2 vols., 1846. Of his collected writings, the standard edition has been till recently that of 1826 (reprinted 1854), in 4 vols. The best edition, containing, in addition to philosophical introductions, much bibliographical matter, is that of 1874, in 4 vols., by T. H. Green and T. H. Grose. Of works upon Hume, the numerous sketches and essays being omitted, the following are the most important:—Jodl, *Leben und Philosophie David Hume's*, 1872; E. Pfleiderer, *Empirismus und Skepsis in David Hume's Philosophie*, 1874 (containing good matter, but too much spun out); T. H. Green, "Introduction to the *Treatise*," in vol. i. of *Hume's Works*, 1874 (by far the most elaborate and minute analysis of Hume in his philosophical relation to Locke and Berkeley); Spicker, *Kant, Hume, und Berkeley*, 1875; Compayré, *La Philosophie de David Hume*, 1873, A. Meinong, *Hume-Studien*, i., 1877 (a very careful study of Hume's nominalism); V. Gizycki, *Die Ethik David Hume's in ihrer geschichtlichen Stellung*, 1878 (the most thorough exposition of Hume's utilitarianism); T. H. Huxley, *Hume*, 1879 (a clear reproduction of the more popular results of Hume's philosophy, without criticism or historical treatment). Mr Leslie Stephen's *English Thought in the Eighteenth Century*, vol. i., 1876, contains the best account of Hume's theological position. Most works on the Kantian philosophy contain sections specially on Hume. The treatments in the general histories of philosophy cannot be pronounced satisfactory. (R. AD.)

HUME, JOSEPH (1777-1855), an eminent political reformer, was born in January 1777, of humble parents, at Montrose, Scotland. After completing his course of medical study at the university of Edinburgh he sailed in 1797 for India, where he was attached as surgeon to a regiment; and his knowledge of the native tongues and his capacity for business threw open to him the lucrative offices of interpreter and commissary-general. On the eve of Lord Lake's Mahratta war in 1803 his chemical knowledge enabled him to render a signal service to the administration by making available a large quantity of gunpowder which damp had spoiled. In 1808, on the restoration of peace, he resigned all his civil appointments, and returned home in the prime of life, and in the possession of a well-earned fortune. His first care on arriving in England was to study thoroughly the country and its resources, for which purpose he made various journeys, to see the actual state of the people and the practical operation of the laws. In 1812 he took his seat for the borough of Weymouth and Melcombe-Regis; but he was soon obliged to resign it, when it was discovered by his Tory patron that he had had the audacity to talk of reform. Six years elapsed before he again entered the House, and during that interval he had made the acquaintance and imbibed the doctrines of James Mill and the philosophical reformers of the school of Bentham. He had joined his efforts to those of Mr Place, of Westminister, and other philanthropists, to relieve and improve the condition of the working classes, labouring especially to establish schools for them on the Lancasterian system, and promoting the formation of savings banks. In 1818, soon after his marriage with Miss Burnley, the daughter of an East India director, he was returned to parliament as member for the Aberdeen burghs. He was afterwards successively elected for Middlesex (1830), Kilkenny (1837), and for the Montrose burghs (1842), in the service of which constituency he died. From the date of his re-entering the House Hume began, unaided and alone, that course of reform in which he persevered to his death. He became the self-elected guardian of the public purse, withstanding every abuse of the public money, by challenging and bringing to a direct vote every single item of public expenditure. The difficulties Hume encountered in the course of his efforts to reduce the enormous burden of taxation under which the country groaned were aggravated by the confused state of the public accounts. But no obstacle daunted or discouraged him in his enlightened efforts as the pioneer of commercial, financial, and parliamentary reform. Other labours with which his name is connected deserve to be recorded. He unravelled the Orange Lodge conspiracy, the ramifications of which spread over England, Scotland, and the colonies, and the object of which was to make the duke of Cumberland king in place of William IV. He carried on a successful warfare against the old combination laws that hampered workmen and favoured masters; he brought about the repeal of the laws prohibiting the export of machinery and of the Act preventing workmen from going abroad. He constantly protested against flogging in the army, the impressment of sailors, and imprisonment for debt. He took up the question of lighthouses and harbours; in the former he secured greater efficiency, in the latter he prevented useless expenditure. At first despised and ridiculed, afterwards dreaded for his tenacity of purpose, he ended by gaining the respect of friends and of foes, and the confidence of the whole nation. The breadth of his action, his singleness of aim, his perfect independence of all party or personal considerations, and an almost heroic earnestness and self-denial in carrying out his views, were the secrets of his influence. Himself as incorruptible as Aristides, he made it a special duty to hunt out and expose political corruption under whatever guise it lurked, and the whole army of place-hunters and jobbers found in him their most indefatigable and inexorable foe. There were many abler, but there was no more useful member in the House during the greater portion of his parliamentary career. He died February 20, 1855.

HUMERUS, Lars Johansson (*c.* 1642–1674), Swedish poet, more commonly known as Lucidor the Unfortunate, was born in Stockholm about the year 1642. His father, Captain Johan Erichsson, and his mother died in his infancy; in 1656 he was entered as a student of the university of Upsala, at the expense of his patron, Admiral Wrangel, whose sons he afterwards conducted through Germany, Italy, France, England, and Holland, and back to Sweden in the autumn of 1668. He returned to Upsala, received a professorship, and took the pseudonym of Lucidor, which he employed until his death. He stayed but one year at Upsala, and in the winter of 1669 settled again in Stockholm. There one of his poems gave offence to the Government, and he was banished from the city for a year and a day. After his return he lived by his pen, writing odes and epithalamia for the rich burghers. He boasted that he would "live like a poet," that is to say, with but slight regard for the conventions of society. He was murdered on the night of August 13, 1674, in a cellar at Stockholm, by a drunken soldier, Lieutenant Arvid Storm, with whom he was quarrelling. The body of the poet was carried out into the street; but he only said, "I am stabbed," and died. Storm was condemned to death for the murder, but was helped by his mother to escape. The stories, so long repeated, of Lucidor's romantic intrigue with a lady of high rank, and his assassination in her arms, must be relegated to the domain of fable.

Lucidor's poems were not collected until after his death, when they were published in a volume called *Flowers of Helicon.* He wrote verses, not merely in Swedish, but also in Latin, French, German, English, Italian, and Dutch. His style is deeply tinged with the prevalent fashion for conceit and tasteless ingenuity, but he possesses force and passion; and he is certainly the most important Swedish writer between Stjernhjelm and Dahlstjerna. The best edition of his works is that published in 1876 by J. Linck, who has dedicated a great deal of time and care to the investigation of the life of Humerus.

HUMILIATI, a religious order founded at Milan early in the 12th century by certain noblemen of Lombardy, who, having been carried captive into Germany, had regained their freedom by their "humility," did not, according to Helyot in his *Ordres Monastiques,* take the monastic vows till 1134, when they were induced to do so by St Bernard. In 1164 their ranks were recruited by other Milanese noblemen who had been similarly carried into Germany by Frederick Barbarossa. About 1151 the order was brought under the rule of St Benedict, and in 1200 it was approved by Innocent III. Confirmed and privileged by succeeding popes, the Humiliati began to be corrupted by their popularity and prosperity, until, after a futile attempt to reform the order, Pius V. finally suppressed it in 1571. At that date they had ninety-four houses under their jurisdiction. The wives of the original founders instituted a female order of *Humiliatæ,* also called, from a prominent early member, the *Nuns of Blassoni,* which, exempted from Pius's bull of suppression, still has representatives in Italy.

HUMMEL, Johann Nepomuk (1778–1837), a celebrated composer and pianist, was born November 14, 1778, at Pressburg, in Hungary, and received his first artistic training from his father, himself a musician in a humble way. In 1785 the latter received an appointment as conductor of the orchestra at the theatre of Schikaneder, the friend of Mozart and the librettist of the *Magic Flute.* It was in this way that young Hummel became acquainted with the great composer, who took a great fancy to him, and even invited him to his house for a considerable period. During two years Hummel received the invaluable instructions of Mozart, after which he set out with his father on an artistic tour through Germany, England, and other countries, his clever playing winning for the boy the admiration of amateurs. After his return to Vienna he completed his studies under Albrechtsberger, the celebrated contrapuntist, and Haydn, and for a number of years devoted himself exclusively to composition. For eight years (1803–1811) he held the appointment of orchestral conductor to Prince Eszterhazy, previously occupied by Haydn. It was not till 1816 that he again appeared in public as a pianist, his success being quite extraordinary. His gift of improvisation at the piano was especially admired, but his larger compositions also were highly appreciated, and for a time Hummel was considered one of the leading musicians of an age in which Beethoven was in the zenith of his power. In Prussia, which he visited in 1822, the ovations offered to him were unprecedented, and other countries—France in 1825 and 1829, Belgium in 1826, and England in 1830 and 1833—added further laurels to his crown. He died in 1837 at Weimar, where for a long time he had been the musical conductor of the court theatre. His compositions are very numerous, and comprise almost every branch of music. He wrote amongst other things several operas, both tragic and comic, and two grand masses (*Op.* 80 and 111). Infinitely more important are his compositions for the pianoforte (his two concerti in A minor and B minor, and the sonata in F sharp minor), and his chamber music (the celebrated septet, and several trios, &c.). His experience as a player and teacher of the pianoforte was embodied in his *Great Pianoforte School* (Vienna), and the excellence of his method is further proved by such pupils as Henselt and Ferdinand Hiller. Both as a composer and as a pianist Hummel continued the traditions of the earlier Viennese school of Mozart and Haydn; his style in both capacities was marked by purity and correctness rather than by passion and imagination. In his compositions there is much that is now antiquated; but to deny him all merit would be as uncritical as were his contemporaries in the opposite direction when they mentioned him in the same breath with Beethoven.

HUMMING-BIRD, a name in use for more than two centuries, and possibly ever since English explorers first knew of the beautiful little animals to which, from the sound occasionally made by the rapid vibrations of their wings, it is applied. Among books that are ordinarily in naturalists' hands, the name seems to be first found in the *Musæum Tradescantianum*, published in 1656, but it therein occurs (p. 3) so as to suggest its having already been accepted and commonly understood; and its earliest use, as yet discovered, is said to be by Thomas Morton in the *New English Canaan*, printed in 1632—a rare work reproduced by Peter Force in his *Historical Tracts* (vol. ii., Washington, 1838). Thevet, in his *Singularitez de la France antarctique* (Antwerp, 1558, fol. 92), has been more than once cited as the earliest author to mention Humming-birds, which he did under the name of *Gouambuch*; but it is quite certain that Oviedo, whose *Hystoria general de las Indias* was published at Toledo in 1525, preceded him by more than thirty years, with an account of the "*paxaro mosquito*" of Hispaniola, of which island "the first chronicler of the Indics" was governor.[1] This name, though now apparently disused in Spanish, must have been current about that time, for we find Gesner in 1555 (*De avium natura*, iii. p. 629) translating it literally into Latin as *Passer muscatus*, owing, as he says, his knowledge of the bird to Cardan, the celebrated mathematician, astrologer, and physician, from whom we learn (*Comment. in Ptolem. de astr. judiciis*, Basel, 1554, p. 472) that, on his return to Milan from professionally attending Archbishop Hamilton at Edinburgh, he visited Gesner at Zurich, about the end of the year 1552.[2] The name still survives in the French *Oiseau-mouche*; but the ordinary Spanish appellation is, and long has been, *Tominejo*, from *tomin*, signifying a weight equal to the third part of an *adarme* or drachm, and used metaphorically for anything very small. Humming-birds, however, are called by a variety of other names, many of them derived from American languages, such as *Guainumbi*, *Ourissia*, and *Colibri*, to say nothing of others bestowed upon them (chiefly from some peculiarity of habit) by Europeans, like *Picaflores*, *Chuparosa*, and *Froufrou*. Barrere, in 1745, conceiving that Humming-birds were allied to the Wren, the *Trochilus*,[3] in part, of Pliny, applied that name in a generic sense (*Ornith. Spec. novum*, pp. 47, 48) to both. Taking the hint thus afforded, Linnæus very soon after went further, and, excluding the Wrens, founded his genus *Trochilus* for the reception of such Humming-birds as were known to him. The unfortunate act of the great nomenclator cannot be set aside; and, since his time, ornithologists with but few exceptions have followed his example, so that now-a-days Humming-birds are universally recognized as forming the Family *Trochilidæ*.

The relations of the *Trochilidæ* to other birds were for a long while very imperfectly understood. Nitzsch first drew attention to their agreement in many essential characters with the Swifts, *Cypselidæ*, and placed the two Families in one group, which he called *Macrochires*, from the great length of their manual bones, or those forming the extremity of the wing. The name was perhaps not very happily chosen, for it is not the distal portion that is so much out of ordinary proportion to the size of the bird, but the proximal and median portions, that in both Families are curiously dwarfed. Still the *manus*, in comparison with the other parts of the wing, is so long that the term *Macrochires* is not wholly inaccurate. The affinity of the *Trochilidæ* and *Cypselidæ*, once pointed out, became obvious to every careful and unprejudiced investigator, and there are probably few systematists now living who refuse to admit its validity. More than this, it is confirmed by an examination of other osteological characters. The "lines," as a boat-builder would say, upon which the skeleton of each form is constructed are precisely similar, only that whereas the bill is very short and the head wide in the Swifts, in the Humming-birds the head is narrow and the bill long—the latter developed to an extraordinary degree in some of the *Trochilidæ*, rendering them the longest-billed birds known.[4] Professor Huxley considers these two Families,

[1] In the edition of Oviedo's work, published at Salamanca in 1547, the earliest the present writer has been able to see, the account (lib. xiv. cap. 4) runs thus:—"Ay assi mismo enesta ysla vnos paxaricos tan negros como vn terciopelo negro muy bueno & son tan pequeños que ningunos he yo visto en Indias menores/ excepto el que aca se llama paxaro mosquito. El qual es tan pequeño que el bulto del es menor harto o assaz que le cabeça del dedo pulgar de la mano. Este no le he visto enesta Ysla pero dizen me que aqui los ay: & por esso dexo de hablar enel pa lo' dezir dõde los he visto que es en la tierra firme quãdo della se trate." A modern Spanish version of this passage will be found in the beautiful edition of Oviedo's works published by the Academy of Madrid in 1851 (i. p. 444).

[2] See also Prof. Morley's *Life of Girolamo Cardano* (ii. pp. 152,153).

[3] Under this name Pliny perpetuated (*Hist. Naturalis*, viii. 25) the confusion that had doubtless arisen before his time of two very distinct birds. As Sundevall remarks (*Tentamen*, p. 87, note), *τροχίλος* was evidently the name commonly given by the ancient Greeks to the smaller Plovers, and was not improperly applied by Herodotus (ii. 68) to the species that feeds in the open mouth of the Crocodile—the *Pluvianus ægyptius* of modern ornithologists—in which sense Aristotle (*Hist. Animalium*, ix. 6) also uses it. But the received text of Aristotle has two other passages (ix. 1 and 11) wherein the word appears in a wholly different connexion, and can there be only taken to mean the Wren—the usual Greek name of which would seem to be *ὄρχιλος* (Sundevall, *Om Aristotl. Djurarter*, No. 54). Though none of his editors or commentators have suggested the possibility of such a thing, one can hardly help suspecting that in these passages some early copyist has substituted *τροχίλος* for *ὄρχιλος*, and so laid the foundation of a curious error. It may be here remarked that the Crocodile of St Domingo is said to have the like office done for it by some kind of bird, which is called by Descourtilz (*Voyage*, iii. p. 26), a "*Todier*," but, as Geoffr. St Hilaire observes (*Descr. de l'Égypte*, ed. 2, xxiv. p. 440), is more probably a Plover. Unfortunately the fauna of Hispaniola is not much better known now than in Oviedo's days.

[4] Thus *Docimastes ensifer*, in which the bill is longer than both head and body together.

together with the Goatsuckers (*Caprimulgidæ*), to form the division *Cypselomorphæ*—one of the two into which he has separated his larger group *Ægithognathæ*. However, the most noticeable portion of the Humming-bird's skeleton is the *sternum*, which in proportion to the size of the bird is enormously developed both longitudinally and vertically, its deep keel and posterior protraction affording abundant space for the powerful muscles which drive the wings in their rapid vibrations as the little creature poises itself over the flowers where it finds its food.[1]

So far as is known, all Humming-birds possess a protrusible tongue, in conformation peculiar among the class *Aves*, though to some extent similar to that member in the Woodpeckers (*Picidæ*)[2]—the "horns" of the hyoid apparatus upon which it is seated being greatly elongated, passing round and over the back part of the head, near the top of which they meet, and thence proceed forward, lodged in a broad and deep groove, till they terminate in front of the eyes. But, unlike the tongue of the Woodpeckers, that of the Humming-birds consists of two cylindrical tubes, tapering towards the point, and forming two sheaths which contain the extensile portion, and are capable of separation, thereby facilitating the extraction of honey from the nectaries of flowers, and with it, what is of far greater importance for the bird's sustenance, the small insects that have been attracted to feed upon the honey.[3] These, on the tongue being withdrawn into the bill, are caught by the mandibles (furnished in the males of many species with fine, horny, saw-like teeth[4]), and swallowed in the usual way. The stomach is small, moderately muscular, and with the inner coat slightly hardened. There seem to be no cæca. The trachea is remarkably short, the bronchi beginning high up on the throat, and song-muscles are wholly wanting, as in all other *Cypselomorphæ*.[5]

Humming-birds, as is well known, comprehend the smallest members of the class *Aves*. The largest among them measures no more than 8 inches and a half,[6] and the least 2 inches and three-eighths in length, for it is now admitted generally that Sloane must have been in error when he described (*Voyage*, ii. p. 308) the "Least Humming-bird of Jamaica" as "about $1\frac{1}{4}$ inch long from the end of the bill to that of the tail"—unless, indeed, he meant the proximal end of each, an interpretation, however, that will not save Edwards and Latham from the charge of careless misstatement, when they declare that they had received such a bird from that island. Next to their generally small size, the best known characteristic of the *Trochilidæ* is the wonderful brilliancy of the plumage of nearly all their forms, in which respect they are surpassed by no other birds, and are only equalled by a few, as, for instance, by the *Nectariniidæ*, or Sun-birds of the tropical parts of the Old World, in popular estimation so often confounded with them, and even by some mistaken naturalists thought to be their allies.

The number of species of Humming-birds now known to exist considerably exceeds 400; and, though none depart very widely from what a morphologist would deem the typical structure of the Family, the amount of modification, within certain limits, presented by the various forms is surprising and even bewildering to the uninitiated. But the features that are ordinarily chosen by systematic ornithologists in drawing up their schemes of classification are found by the "trochilidists," or special students of the *Trochilidæ*, insufficient for the purpose of arranging these birds in groups, and characters on which genera can be founded have to be sought in the style and coloration of plumage, as well as in the form and proportions of those parts which are most generally deemed sufficient to furnish them. Looking to the large number of species to be taken into account, convenience has demanded what science would withhold, and the genera established by the ornithologists of a preceding generation have been broken up by their successors into multitudinous sections—the more adventurous making from 150 to 180 of such groups, the modest being content with 120 or thereabouts, but the last dignifying each of them by the title of genus. It is of course obvious that these small divisions cannot be here considered in detail, nor would much advantage accrue by giving statistics from the works of the latest trochilidists, Messrs Gould,[7] Mulsant,[8] and Elliot.[9] It would be as unprofitable here to trace the successive steps by which the original genus *Trochilus* of Linnæus, or the two genera *Polytmus* and *Mellisuga* of Brisson, have been split into others, or have been added to, by modern writers, for not one of these professes to have arrived at any final, but only a provisional, arrangement; it seems, however, expedient to notice the fact that some of the authors of the last century[10] supposed themselves to have seen the way to dividing what we now know as the Family *Trochilidæ* into two groups, the distinction between which was that in the one the bill was arched and in the other straight, since that difference has been insisted on in many works. This was especially the view taken by Brisson and Buffon, who termed the birds having the arched bill "*Colibris*," and those having it straight "*Oiseaux-mouches*." The distinction wholly breaks down, not merely because there are *Trochilidæ* which possess almost every gradation of decurvation of the bill, but some which have the bill upturned after the manner of that strange bird the Avocet,[11] while it may be remarked that several of the species placed by those authorities among the "*Colibris*" are not Humming-birds at all.

The extraordinarily brilliant plumage which most of the *Trochilidæ* exhibit has been already mentioned, and in describing it ornithologists have been compelled to adopt the vocabulary of the jeweller in order to give an idea of the indescribable radiance that so often breaks forth from some part or other of the investments of these feathered gems. In all save a few of other birds, the most imaginative writer sees gleams which he may adequately designate metallic, from their resemblance to burnished gold, bronze, copper, or steel, but such similitudes wholly fail when he has to do with the *Trochilidæ*, and there is hardly a precious stone—ruby, amethyst, sapphire, emerald, or topaz—the name of which may not fitly, and without any exaggeration, be employed in regard to Humming-birds. In some cases this radiance beams from the brow, in some it glows from the throat, in others it shines from the tail-coverts, in others it sparkles from the tip only of elongated feathers that crest the head or surround the neck as with a frill, while again in others it may appear as a luminous streak across the cheek or auriculars. The feathers that cover the upper parts of the body very frequently have a metallic lustre of golden-green, which in other birds would be thought sufficiently beautiful, but in the *Trochilidæ* its sheen is overpowered by the almost dazzling splendour that radiates from the spots where Nature's lapidary has set her jewels. The flight feathers are almost invariably dusky—the rapidity of their movement would, perhaps, render any display of colour ineffective; while, on the contrary, the feathers of the tail, which, as the bird hovers over its food-bearing flowers, is almost always expanded, and is therefore comparatively motionless, often exhibit a rich translucency, as of stained glass, but iridescent in a manner that no stained glass ever is—cinnamon merging into crimson, crimson changing to purple, purple to violet,

---

[1] This is especially the case with the smaller species of the group, for the larger, though shooting with equal celerity from place to place, seem to flap their wings with comparatively slow but not less powerful strokes. The difference was especially observed with respect to the largest of all Humming-birds, *Patagona gigas*, by Mr Darwin.

[2] The resemblance, so far as it exists, must be merely the result of analogical function, and certainly indicates no affinity between the families.

[3] It is probable that in various members of the *Trochilidæ* the structure of the tongue, and other parts correlated therewith, will be found subject to several and perhaps considerable modifications, as is the case in various members of the *Picidæ*. At present there are scarcely half a dozen species of Humming-birds of which it can be said that any part of their anatomy is known.

[4] These are especially observable in *Rhamphodon nævius* and *Androdon æquatorialis*.

[5] Mr Gosse (*Birds of Jamaica*, p. 130) says that *Mellisuga minima*, the smallest species of the Family, has "a real song"—but the like is not recorded of any other.

[6] There are several species in which the tail is very much elongated, such as the well-known *Aithurus polytmus* of Jamaica, and the remarkable *Loddigesia mirabilis* of Chachapoyas in Peru, which last was until lately only known from a unique specimen (*Ibis*, 1880, p. 152); but "trochilidists" in giving their measurements do not take these extraordinary developments into account.

[10] Salerne must be excepted, especially as he was rebuked by Buffon for doing what we now deem right.

[11] For example *Avocettula recurvirostris* of Guiana and *A. euryptera* of Colombia.

and so to indigo and bottle-green. But this part of the Humming-bird is subject to quite as much modification in form as in colour, though always consisting of ten *rectrices*. It may be nearly square, or at least but slightly rounded, or wedge-shaped with the middle quills prolonged beyond the rest; or, again, it may be deeply forked, sometimes by the overgrowth of one or more of the intermediate pairs, but most generally by the development of the outer pair. In the last case the lateral feathers may be either broadly webbed to their tip, or acuminate, or again, in some forms, may lessen to the filiform shaft, and suddenly enlarge into a terminal spatulation as in the forms known as "Racquet-tails." The wings do not offer so much variation; still there are a few groups in which diversities occur that require notice. The primaries are invariably ten in number, the outermost being the longest, except in the single instance of *Aithurus*, where it is shorter than the next. The group known as "Sabre-wings," comprising the genera *Campylopterus*, *Eupetomena*, and *Sphenoproctus*, present a most curious sexual peculiarity, for while the female has nothing remarkable in the form of the wing, in the male the shaft of two or three of the outer primaries is dilated proximally, and bowed near the middle in a manner almost unique among birds. The feet again, diminutive as they are, are very diversified in form. In most the tarsus is bare, but in some groups, as *Eriocnemis*, it is clothed with tufts of the most delicate down, sometimes black, sometimes buff, but more often of a snowy whiteness. In some the toes are weak, nearly equal in length, and furnished with small rounded nails; in others they are largely developed, and armed with long and sharp claws.

Apart from the well-known brilliancy of plumage, of which enough has been here said, many Humming-birds display a large amount of ornamentation in the addition to their attire of crests of various shape and size, elongated ear-tufts, projecting neck-frills, and pendant beards—forked or forming a single point. But it would be impossible here to dwell on a tenth of these beautiful modifications, each of which as it comes to our knowledge excites fresh surprise and exemplifies the ancient adage—*maxime miranda in minimis Natura*. It must be remarked, however, that there are certain forms which possess little or no brilliant colouring at all, but, as most tropical birds go, are very soberly clad. These are known to trochilidists as "Hermits," and by Mr Gould have been separated as a Subfamily under the name of *Phaethornithinæ*, though Mr Elliot says he cannot find any characters to distinguish it from the *Trochilidæ* proper. But sight is not the only sense that is affected by Humming-birds. The large species known as *Pterophanes temmincki* has a strong musky odour, very similar to that given off by the Petrels, though, so far as appears to be known, that is the only one of them that possesses this property.[1]

All well-informed people are aware that the *Trochilidæ* are a Family peculiar to America and its islands, but one of the commonest of common errors is the belief that Humming-birds are found in Africa and India—to say nothing even of England. In the first two cases the mistake arises from confounding them with some of the brightly-coloured Sun-birds (*Nectariniidæ*), to which British colonists or residents are apt to apply the better-known name; but in the last it can be only due to the want of perception which disables the observer from distinguishing between a bird and an insect—the object seen being a Hawk-Moth (*Macroglossa*), whose mode of feeding and rapid flight certainly bears some resemblance to that of the *Trochilidæ*, and hence one of the species (*M. stellarum*) is very generally called the "Humming-bird Hawk-Moth." But though confined to the New World the *Trochilidæ* pervade almost every part of it. In the south *Eustephanus galeritus* has been seen flitting about the fuchsias of Tierra del Fuego in a snow-storm, and in the north-west *Selatophorus rufus* in summer visits the ribes-blossoms of Sitka, while in the north-east *Trochilus colubris* charms the vision of Canadians as it poises itself over the althæa-bushes in their gardens, and extends its range at least so far as lat. 57° N. Nor is the distribution of Humming-birds limited to a horizontal direction only, it rises also vertically. *Oreotrochilus chimborazo* and *O. pichincha* live on the lofty mountains whence each takes its trivial name, but just beneath the line of perpetual snow, at an elevation of some 16,000 feet, dwelling in a world of almost constant hail, sleet, and rain, and feeding on the insects which resort to the indigenous flowering plants, while other peaks, only inferior to these in height, are no less frequented by one or more species. Peru and Bolivia produce some of the most splendid of the Family—the genera *Cometes*, *Diphlogæna*, and *Thaumastura*, whose very names indicate the glories of their bearers. The comparatively gigantic *Patagona* inhabits the west coast of South America, while the isolated rocks of Juan Fernandez not only afford a home to the *Eustephanus* before mentioned, but also to two other species of the same genus which are not found elsewhere (see BIRDS, vol. iii. p. 745). The slopes of the Northern Andes and the hill country of Colombia furnish perhaps the greatest number of forms, and some of the most beautiful, but leaving that great range, we part company with the largest and most gorgeously arrayed species, and their number dwindles as we approach the eastern coast. Still there are many brilliant Humming-birds common enough in the Brazils, Guiana, and Venezuela. The *Chrysolampis mosquitus* is perhaps the most plentiful. Thousands of its skins are annually sent to Europe to be used in the manufacture of ornaments, its rich ruby-and-topaz glow rendering it one of the most beautiful objects imaginable. In the darkest depths of the Brazilian forests dwell the russet-clothed brotherhood of the genus *Phaethornis*—the "Hermits"; but the great wooded basin of the Amazons seems to be particularly unfavourable to the *Trochilidæ*, and from Pará to Ega there are scarcely a dozen species to be met with. There is no island of the Antilles but is inhabited by one or more Humming-birds, and there are some very remarkable singularities of geographical distribution to be found (see BIRDS, vol. iii. p. 749). Northwards from Panama, the highlands present many genera, whose names it would be useless here to insert, few or none of which are found in South America—though that must unquestionably be deemed the metropolis of the Family, and advancing towards Mexico the numbers gradually fall off. Eleven species have been enrolled among the fauna of the United States, but some on slender evidence, while others only just cross the frontier line.

FIG. 1.—*Mellisuga minima* on nest, natural size. (After Gosse.)

But little room is left to speak of the habits of Humming-birds, which is perhaps of the less consequence since the subject, as regards most of the species which in life have come under the observation of ornithologists, has been so ably treated by writers like Waterton, Wilson, and Audubon, to say nothing of Mr Gosse, Mr Wallace, Mr Bates, and some others, while, whatever novelty further investigation may supply, it is certain that at present we lack information that will explain the origin or the function of the many modifications of external structure of which mention has been made. But there is no one appreciative of the beauties of nature who will not recall to memory with delight the time when a live Humming-bird first met his gaze. The suddenness of the apparition, even when expected, and its brief duration, are alone enough to fix the fluttering vision on the mind's eye. The wings of the bird, if flying, are only visible as a thin grey film, bounded above and below by fine black threads, in form of a St Andrew's cross,—the effect on the observer's retina of the instantaneous reversal of the motion of the wing at each beat—the strokes being so rapid as to leave no more distinct image. Consequently an adequate representation of the bird on the wing cannot be produced by the draughtsman. Humming-birds show to the greatest advantage when engaged in contest with another, for rival cocks fight fiercely, and, as may be expected, it is then that their plumage flashes with the most glowing tints. But these are quite invisible to the ordinary spectator except when very near at hand, though doubtless efficient enough for their object, whether that be to inflame their mate or to irritate or daunt their opponent, or something that we cannot compass. Humming-birds, however, will also often sit still for a while, chiefly in an exposed position, on a dead twig, occasionally darting into the air, either to catch a passing insect or to encounter an adversary; and so pugnacious are

[1] The specific name of a species of *Chrysolampis*, commonly written by many writers *moschitus*, would lead to the belief that it was a mistake for *moschatus*, *i.e.*, "musky," but in truth it originates with their carelessness, for though they quote Linnæus as their authority they can never have referred to his works, or they would have found the word to be *mosquitus*, the "mosquito" of Oviedo, awkwardly, it is true, Latinized. If emendation be needed, *muscatus*, after Gesner's example, is undoubtedly preferable.

they that they will frequently attack birds many times bigger than themselves, without, as would seem, any provocation.

The food of Humming-birds consists mainly of insects, mostly gathered in the manner already described from the flowers they visit; but, according to Mr Wallace, there are many species which he has never seen so occupied, and the "Hermits" especially seem to live almost entirely upon the insects which are found on the lower surface of leaves, over which they will closely pass their bill, balancing themselves the while vertically in the air. The same excellent observer also remarks that even among the common flower-frequenting species he has found the alimentary canal entirely filled with insects, and very rarely a trace of honey. It is this fact doubtless that has hindered almost all attempts at keeping them in confinement for any length of time—nearly every one making the experiment having fed his captives only with syrup, which is wholly insufficient as sustenance, and seeing therefore the wretched creatures gradually sink into inanition and die of hunger.

The beautiful nests of Humming-birds, than which the work of fairies could not be conceived more delicate, are to be seen in most museums, and will be found on examination to be very solidly and tenaciously built, though the materials are generally of the slightest—cotton-wool or some vegetable down and spiders' webs. They vary greatly in form and ornamentation—for it would seem that the portions of lichen which frequently bestud them are affixed to their exterior with that object, though probably concealment was the

Fig. 2.—*Phaethornis eurynome*, and nest. (After Gould.)

original intention. They are mostly cup-shaped, and the singular fact is on record (*Zool. Journal*, v. p. 1) that in one instance as the young grew in size the walls were heightened by the parents, until at last the nest was more than twice as big as when the eggs were laid and hatched. Some species, however, suspend their nests from the stem or tendril of a climbing plant, and more than one case has been known in which it has been attached to a hanging rope. These pensile nests are said to have been found loaded on one side with a small stone or bits of earth to ensure their safe balance, though how the compensatory process is applied no one can say. Other species, and especially those belonging to the "Hermit" group, weave a frail structure round the side of a drooping palm-leaf. The eggs are never more than two in number, quite white, and having both ends nearly equal. The solicitude for her offspring displayed by the mother is not exceeded by that of any other birds, but it seems doubtful whether the male takes any interest in the brood. (A. N.)

HUNDRED, in England, is an ancient territorial division intermediate between the parish or township and the county. Such subordinate districts were also known in different parts of the county as *wapentakes*, *wards*, and sometimes *shires*. The name *wapentake*, which seems to have a distinct reference to the military side of the organization, is generally connected with the Danish occupation, and is said to be found only in the Anglian districts,—Yorkshire, Lincolnshire, Nottinghamshire, Derbyshire, Rutlandshire, and Leicestershire. In some parts of England a further intermediate division is to be found between the hundred and the county. Thus in Yorkshire we have the trithing, or as it is now called the riding, in Lincolnshire the soke, the lathe in Kent, and the rape in Sussex. The origin of these divisions is generally ascribed to the creative genius of Alfred, who, according to the popular theory, divided the country into counties, the county into hundreds, and the hundreds into tithings or towns. The exact opposite would appear to have been the real process, the larger division being formed by the aggregation of the smaller groups. The significance of the name hundred is a question of some difficulty. The simplest theory is the old one that the hundred denoted first the group of a hundred families into which the community was divided, and then the district occupied by the group, just as the tithing represents ten families and the district which the ten families occupy. Another view is that the hundred is a term of measurement only, denoting a hundred hides of land. Or again, it has been supposed to be the district from which the complement of one hundred warriors was furnished to the host. The hundred as a group of persons is a well-known feature of the constitution of the German tribes, *e.g.*, as described by Tacitus, the *centeni ex singulis pagis* who formed the army, and the *centeni ex plebe comites* who acted as assessors to the chiefs. The hundred as a territorial division in later times is equally common. The real connexion between them is a matter of conjecture. "It is very probable that the colonists of Britain arranged themselves in hundreds of warriors; it is not probable that the country was carved into equal districts. The only conclusion that seems reasonable is that under the name of geographical hundreds we have the variously-sized *pagi* or districts in which the hundred warriors settled, the boundaries of these being determined by other causes" (Stubbs's *Constitutional History*, vol. i.). As a territorial division, the hundred like the shire and the parish had its appropriate moot or court, of which the lords, the priest, and four representatives of the parish were members, and in which a specially selected body of twelve appears to have been charged with active judicial functions. The two leading features of the English constitution—representation and trial by jury—thus appear in germ at least in the old constitution of the hundred.

The hundred is now for most of its ancient purposes an obsolete division. The hundred courts were for the most part extinguished by a section in the County Courts Act, 1867, which enacts that no action which can be brought in a county court shall thenceforth be brought in a hundred court, or other inferior court, not being a court of record. The court of record for the hundred of Salford is an example of the survival of this ancient jurisdiction.

Perhaps the most important of the surviving duties of the hundred is its liability to make good damages occasioned by rioters. The 7 and 8 Geo. IV. c. 31 consolidates and amends the laws relating to remedy against the hundred. The principal section enacts that, if any church, house, or other building or section shall be feloniously pulled down or destroyed, the hundred or other district in the nature of a hundred by whatever name it shall be denominated shall be liable to yield full compensation to the persons damnified, provided such person, or his servant having charge of the property, appear before a justice of the peace within seven days after the commission of the offence, to give information. Actions of this kind must be commenced within three months after the offence. The 17 and 18 Vict. c. 104 (Merchant Shipping Act) gives the same remedy in the case of a wrecked ship if plundered by a riotous assemblage, the hundred in or nearest to which the offence was committed being made liable.

HUNGARY

I. Geography and Statistics.

Plate II. Position and extent. HUNGARY (Hung., *Magyarország*; Ger., *Ungarn*; Fr., *Hongrie*; It., *Ongaria*), the second factor of the dual Austrian-Hungarian monarchy, is an extensive country in the south-eastern portion of Central Europe, lying between 44° 10′ and 49° 35′ N. lat. and between 14° 25′ and 26° 25′ E. long. It thus covers about 5 degrees of latitude and 12 of longitude, and contains an area of 124,234 square miles, or more than half of the whole Austrian-Hungarian realm, being larger than the United Kingdom of Great Britain and Ireland by about 3000 square miles.

General divisions. The kingdom of Hungary in its widest extent, or the "Realm of the Crown of St Stephen," comprises Hungary Proper, with the former grand principality of Transylvania, the town and district of Fiume, Croatia and Slavonia, and the Military Frontier. Dalmatia, which both from its geographical position and from historical associations ought also to form part of Hungary, sends its representatives to the Austrian Reichsrath.

	Area in Eng. Miles
Hungary Proper and Transylvania	108,263
Fiume	8
Croatia and Slavonia	8,665
Military Frontier	7,298
Total	124,234

In the article AUSTRIA (vol. iii. pp. 115–141) the Austrian-Hungarian monarchy has already been treated of as a whole, and under the heading CROATIA AND SLAVONIA (vol. vi. pp. 591–592) will be found further special information with reference to that province (see also FIUME, vol. ix. p. 273). In the present article we shall therefore treat generally of the lands belonging to the Hungarian crown, and more particularly of the "mother country," or Hungary Proper and Transylvania.

Hungary Proper and Transylvania. The province of Hungary Proper and Transylvania, now united under one administration, and sometimes officially styled simply "Hungary," lies between 44° 30′ and 49° 35′ N. lat. and between 16° and 26° 25′ E. long., and comprises an area of 108,263 English square miles. It is bounded on the N. by Moravia, Silesia, and Galicia; on the E. by Bukowina and Moldavia; on the S. by Wallachia, Servia, and Croatia and Slavonia; and on the W. by Styria, Lower Austria, and Moravia. The narrow strip of country known as the Military Frontier, which stretches as a border line between Bosnia and Servia and the south of Croatia and Slavonia, prior to 1873 extended beyond the limits of that province, through Hungary Proper to Transylvania. The whole Military Frontier thus constituted formerly a joint crown land, consisting of the present Croatian-Slavonian frontier, and the so-called Servian-Bánát frontier, now incorporated into the province of Hungary Proper and Transylvania. The political changes introduced between 1868 and 1876 will be considered below.

Natural boundaries. With the exception of the short extent of seaboard on the Adriatic belonging to the Hungarian Littorale, the Hungarian monarchy is entirely surrounded by other countries. Its natural boundaries are for the most part well defined: on the N.W. and N. it is separated from Moravia, Silesia, and Galicia by the Carpathian mountains; on the E. and S.E. the Eastern Carpathians form a natural barrier between Transylvania and Moldavia and Wallachia; on the S. it is bounded by the Danube, Save, and Unna, which separate it from Servia and Bosnia; on the S.W. by Dalmatia and the Adriatic; and on the W., where its natural boundaries are not so clearly marked, by Carniola, Styria, and Lower Austria. From the river Lajta or Leitha, which, like the March, forms a portion of the boundary of the last-mentioned province, originate the terms Cisleithan and Transleithan, sometimes applied to the collective provinces of Austria and of Hungary respectively.

The mountains of Hungary belong to the two great European systems, the Carpathians and the Alps. The former extend in a semicircular form over the north and east of the monarchy, enclosing the whole of the left basin of the Danube from Dévény near Pozsony (Pressburg) to Orsova, while spurs of the Styrian Alps traverse the country in the west; to these latter belong also the Bakony and Vértes ranges. The Central Carpathians consist of several groups, among which the Tátra mountains form the most imposing mass, having an average elevation of about 6000 feet, and attaining at some points an altitude of over 8000 feet. To the south of these are the various ranges of the Hungarian Ore-Mountains or Erzgebirge (Liptó, Zólyom, Bars, Hont), and the midland chains which connect the Carpathians with the Styrian Alps. The Eastern Carpathians and Transylvanian highlands cover the greater part of Transylvania, and the eastern portion of the old Servian-Bánát; the Fogaras is the highest group, some crests of which, as, for instance, the Négoj, Bucsesd, and Vurfu Ourla, attain an elevation of between 8000 and 9000 feet. The low western mountains of Hungary which traverse Croatia and Slavonia belong to the Julian Alps. Taking a general survey, it will be observed that the greatest elevations are in the north of Hungary Proper, in the east and south of Transylvania, and in the eastern portion of the Bánát. In the Northern Carpathians large plateaus are not unfrequent, but in Transylvania the Alpine character predominates. The sides of the Carpathians are generally covered with forests to a considerable height, and on some favourable slopes barley, oats, wheat, and rye are cultivated. The mountainous lands in the south-west of the Hungarian monarchy are in elevation much inferior to those in the north and east, but their greater proximity to the sea and their frequently bare and rugged character cause them to have a considerable influence both on the climate and commercial relations of the country. Mountains.

The great Carpathian and Alpine mountain systems enclose two extensive plains, the smaller of which, called the "Little Hungarian Alföld" or "Pressburg Basin," covers an area of about 6000 square miles, and lies to the west of the Bakony and Mátra ranges, which separate it from the "Pest Basin" or "Great Hungarian Alföld." This is the largest plain in Europe, and comprises an area of about 37,000 square miles, with an average elevation of from 300 to 350 feet above the level of the sea. The Pest Basin extends over the greater portion of central and southern Hungary, and is traversed by the Theiss and its numerous tributaries. This immense tract of low land, though in some parts covered with barren wastes of sand, alternating with marshes, presents in general a very rich and productive soil. The monotonous aspect of the Alföld is in summer time varied by the *déli-báb*, or *Fata Morgana*. Plains.

The geological constitution of the mountains of Hungary is on the whole similar to that of the Alps.[1] The central axis is in some places composed of granite, on which crystalline schists are superposed; in other places the rocks are of Mesozoic age, and associated with Tertiary beds. Whilst Geology.

[1] *Cf.* Dr Max Hantken, in Keleti's *Skizze der Landeskunde Ungarns*, p. 13, Budapest, 1874.

the Palæozoic formations are of comparatively rare occurrence, the Mesozoic attain a very considerable development. These latter in part crop out at the base of the granite and schistose mountain masses, or themselves are the nucleus of more extensive ranges. In some neighbourhoods independent mountain groups are formed by Tertiary strata. Alluvial formations constitute the general external crust out of which the mountains arise. Recent formations on the banks of rivers, more especially in the south at the junction of the Danube, Theiss, Temes, Drave, and Save, are mainly confined to the tracts subject to the inundations of the same, but are here and there, as in the neighbourhood of Pest, Totis, Esztergom (Gran), and some parts of the Great Alföld, represented by accumulations of drift-sand; and in other places, as for instance on the left bank of the lake of Totis, and at Szomod in Komárom county, there are deposits of calcareous tufa.

Caverns. The numerous caverns deserve a passing notice. One of them, the Aggtelek cave, in the county of Gömör, is about 50 feet in breadth by 16 in height, and extends in its recesses for a length of several thousand feet. In it various fossil mammalian remains have been found. The Fonácza cave, in the county of Bihar, has also yielded fossils. No less remarkable are the Okno, Vodi, and Deményfalva caverns in the county of Liptó, the Veterani in the Bánát, and the ice cave at Dobsina in Gömör county. Of the many interesting caverns in Transylvania the most remarkable are the sulphureous Büdös in the county of Háromszék, the Almás to the south of Udvarhely, and the brook-traversed rocky caverns of Csetate-Boli, Pestere, and Ponor in the southern mountains of Hunyad county.

Rivers. Nature has amply provided the greater part of Hungary with both rivers and springs, but some trachytic and limestone mountainous districts show a marked deficiency in this respect. The Mátra group, *e.g.*, is poorly supplied, while the outliers of the Vértes mountains towards the Danube are almost entirely wanting in streams, and have but few water sources. A relative scarcity in running waters prevails in the whole region between the Danube and the Drave. The greatest proportionate deficiency, however, is observable in the arenaceous region between the Danube and Theiss, where for the most part only periodical floods occur. This, however, is far from being the case in the north and east of the kingdom, where the rivers and streams are numerous. The misfortune is that the rivers of Hungary nearly all flow either mediately or immediately to the Danube, and are therefore not available in any other direction as a means of external communication, and even within the country can only serve to a limited extent as water-ways. Thus the Theiss, the greatest wholly native river, is at the present time serviceable for regular steam navigation only as far as Szolnok, while the Maros cannot be navigated except at certain seasons and for a portion of its course; the Drave and the Save, in like manner, are only partly available for steam vessels. But although the length of permanent water-way in Hungary might be much increased by means of canals and other improvements, the Danube must still remain the only river communication with foreign countries, either by way of Austria or the Black Sea, on account of the insurmountable obstacles to connecting the small extent of Hungarian seaboard with the regions through which the Danube flows. This river, which is navigable during the whole of its course through Hungary, enters the monarchy at Dévény near Pressburg, and leaves it at Orsova on the Turkish frontier, receiving numerous tributaries in its course, among which are, on the right, the Raab, Drave, and Save, and, on the left, Waag, Neutra, Gran, Eipel, Theiss, Temes, and Czerna. The breadth of the Danube is about 900 feet near its entrance, 1400 at Budapest, 1800 at Földvár, and 3500 near Pétervárad (Peterwardein). Among the extensive islands formed by branches of the Danube are the Great Schütt and the Csepel in its upper course. The Theiss, the greatest tributary of the Danube, rises in the north-east, in the county of Máramaros, and flowing first in a north-westerly and afterwards in a southerly direction ultimately joins the main river near Tittel, draining in its course the Great Hungarian Plain. Amongst the many affluents of the Theiss are (*r.*) the Bodrog, Sajó, and Zagyva, and (*l.*) the Szamos, Körös, and the Maros, which last, after traversing Transylvania and eastern Hungary, joins the Theiss at Szeged. The Save, rising in Carniola, winds through Croatia, is fed by the Unna and Kulpa, and falls into the Danube at Belgrade. It will be observed that the whole river system of Hungary belongs to the Danube or the Theiss,—the Poprád, which runs through the county of Szepes (Zips), alone having a northerly course, and flowing to the Dunajec, an affluent of the Vistula. The south-western or Trans-Danubian division of Hungary Proper, although comparatively meagre in water-courses, includes the two principal lakes.

Lakes and marshes. The Balaton or Platten-See, the largest lake, not only in Hungary, but in the whole of the Austrian-Hungarian dominions, lies between the counties of Veszprém, Somogy, and Zala, is about 47 miles in length by 3 to 9 in breadth, and with the surrounding marshes occupies an area of about 400 square miles. It is supplied by the river Zala, 31 small streams, and 9 springs, while its surplus waters are carried off by the Sió. Phenomena peculiar to the Balaton lake are, that it sometimes becomes violently agitated without any apparent cause, and that in seasons of severe cold the ice on its surface occasionally bursts with a loud report. It is navigable for steamers, and abounds in fish. The Fertö or Neusiedler See lies in the counties of Moson and Sopron, and with the Hanság marsh covers an area of some 130 square miles; it is about 23 miles in length by 6 to 8 in breadth, is very shallow, and its waters are strongly impregnated with salt and soda. In 1865 the bed became almost dry, but since 1870 it has filled again. The other lowland lakes, as, for instance, the Palics near Szabadka (Maria-Theresiopel) and the Velencze in the county of Fehér, are much smaller. Morasses and pools are generally frequent in the vicinity of the Danube and Theiss. The most extensive marshy region is the Sárrét, which covers a considerable portion of the counties of Jász-Kun-Szolnok, Békés, and Bihar. The Ecsedi Láp in the county of Szatmár is now for the most part drained; and the Alibunár and Illancsa marshes in the county of Torontál will also be soon laid dry. Many thousands of acres of marsh land have already been reclaimed in Hungary, and hydraulic operations bid fair to still further reduce the extent of the marshy districts. In the deep hollows between the peaks of the Carpathians are to be found the curious mountain lakes called "eyes of the sea;" of these there are at least thirty-eight in the Tátra alone.

Canals. The canals of Hungary are still far from sufficient for the wants of the country, although lately many improvements have been introduced, and enormous cuttings made in certain places to relieve the rivers from periodical overflow. The most important canal is the Ferencz or "Francis," which traverses the county of Bács. It is some 70 miles in length, and shortens very considerably the passage between the Theiss and the Danube. A branch of this canal called Uj Csatorna, or "New Channel," extends from Kis-Sztapár, a few miles below Zombor, to Ujvidék opposite Peterwardein. The Béga canal runs from Nagy-Becskerek, in the county of Torontál, to beyond Temesvár, but is not navigable throughout. Among other canals are the Versecz in the county of Temes; the Berzava in the county of Torontál; the Sió, which connects the Balaton with the Danube; the Kapos or Zichy in the counties of Somogy, Baranya, and Tolna; and the Sárviz or Nádor, which runs through the counties of Fehér and Tolna.

Sea-ports. On the Adriatic, at the northern extremity of the short line of sea-coast known as the "Hungarian Littorale," lies the port of FIUME (*q.v.*), which is the only direct outlet by sea for the produce of Hungary. Its commanding position at the head of the Gulf of Quarnero, and spacious new harbour works, as also its immediate connexions with both the Austrian and Hungarian railway systems, render it specially advantageous as a commercial port. As shipping stations, Buccari, Portoré, Selce, Novi, Zengg, Cirquenizza, San Giorgio, Stinizza, Jablanac, and Carlopago are of comparative insignificance. The whole of the short Hungarian seaboard is mountainous, and subject to violent winds.

Climate. The climate of Hungary, owing to the physical configuration of the country, varies considerably. If we except Transylvania, three separate zones are roughly distinguishable:—the "highland," comprising the counties in the vicinity of the Northern and Eastern Carpathians, where the winters are very severe and continue for half the year; the "intermediate" zone, embracing the tract of country stretching northwards from the Drave and Mur, with the Little Hungarian Plain, and the region of the Upper Alföld, extending from Budapest to Nyiregyháza and Sárospatak; and the "great lowland" zone, including the main portion of the Great Hungarian Plain, and the region of the lower Danube, where the heat during the summer months is almost tropical. In Transylvania the climate bears the extreme characteristics peculiar to mountainous countries interspersed with valleys; whilst that of the south-western Croatian and Frontier districts bordering on the Adriatic is modified by the neighbourhood of the sea. The minimum of the temperature is attained in January and the maximum in July. At Buda, which, if we exclude Transylvania, is near the centre of the kingdom, the mean average temperature (1862–77) in January is 31° 0' and in July 71° 7'; at Kolozsvár (Klausenburg) in the same months it is 32° 7' and 68° 9' respectively. The rainfall in Hungary is small in comparison with that of Austria. At Buda, where the number of rainy days is 122,[1] the rainfall is about 21½ inches, whilst in the two Hungarian plains generally the rainy days are estimated not to exceed 96 annually. In the vicinity of the Carpathians, however, rain is very prevalent, amounting to between 30 and 40 inches. In these regions the greatest fall is during the summer, though in some years the autumn showers are heavier. Hail storms are of frequent occurrence in the Carpathians. On the plains rain rarely falls during the heats of summer; and, generally speaking, the showers though violent are of but short duration, whilst the moisture is quickly evaporated owing to the aridity of the atmosphere. The vast sandy wastes mainly contribute to the dryness of the winds on the Great Hungarian Alföld. Occasionally, as in the year 1863, the whole country suffers much from drought; but, on the other hand, disastrous floods not unfrequently occur, particularly in the spring, when the beds of the rivers and streams are inadequate to contain the increased volume of water caused by the rapid melting of the snows on the Carpathians. The low-lying arable and pasture lands in the vicinity of the Theiss and Maros are thus sometimes submerged for weeks, and in March 1879 the town of Szeged, situated at the point of junction of these two rivers, was almost completely destroyed. In December of the same year the counties of Arad and Bihar were extensively inundated by the Maros and the Körös. In 1838 the city of Pest, and in February 1876 several localities on the Danube, suffered disastrously from the sudden rising of that river. The average annual number of snow showers is estimated at 23 for the two Hungarian plains, 44 for Transylvania, 50 for the northern, and 30 to 35 for the western and south-western portions of the monarchy. In 1866–67, and again in 1872–73, cholera was very rife; of the 447,571 persons who were attacked by the epidemic in the latter case, 189,017, or over 42 per cent., died. Nevertheless Hungary cannot, on the whole, be regarded as an unhealthy country, excepting in the marshy tracts, where intermittent fever and diphtheria sometimes exhibit great virulence.

Flora. The whole of Hungary, but more especially Hungary Proper, can boast of the great variety and number of its natural productions. This is attributable partly to its geographical position, but chiefly to the varied nature of its surface and climate. The fertility of the soil, if we except the mountainous and sandy regions, is remarkable. The vegetable products include almost every description of grain, especially wheat and maize, besides Turkish pepper, rapeseed, hemp and flax, beans, potatoes, and root crops. Fruits of various descriptions, and more particularly melons and stone fruits, are abundant. In the southern districts almonds, figs, rice, and olives are grown. Amongst the forest and other trees are the oak, which yields large quantities of galls, the beech, fir, pine, ash, and alder, also the chestnut, walnut, and filbert. The vine is cultivated over the greater part of Hungary, the chief grape-growing districts being those of the Hegyalja (Tokay), Sopron, and Ruszt, Ménes, Szerémség, Szekszárd, Somlyó (Schomlau), Béllye and Villány,[1] Balaton, Neszmély, Visonta, Eger (Erlau), and Buda. Next to France, Hungary is the greatest wine-producing country in Europe, and the quality of some of the vintages, especially that of Tokay, is unsurpassed. A great quantity of tobacco is also grown, but it is wholly monopolized by the crown. In Hungary Proper and in Croatia and Slavonia there are many species of indigenous plants, which are unrepresented in Transylvania. Besides 12 species peculiar to the former grand-principality, 14 occur only there and in Siberia.

Fauna. The fauna of Hungary includes about 14,000 species. The horned cattle are amongst the finest in Europe, and large herds of swine are reared in the oak forests. In 1870 the total number of cattle (including 73,243 buffaloes) was estimated at 5,279,193, and of swine at 4,443,279. Of sheep, the breed of which is now greatly improved, the number amounted to 15,076,997; of horses there were 2,158,819, asses 30,480, mules 3,266, and goats 572,951. The wild animals are bears, wolves, foxes, lynxes, wild cats, badgers, otters, martens, stoats, and weasels. Among the rodents there are hares, marmots, beavers, squirrels, rats, and mice,—the last in enormous swarms. Of the larger game the chamois and deer are specially noticeable. Among the birds are the vulture, eagle, falcon, buzzard, kite, lark, nightingale, heron, stork, and bustard. Domestic and wild fowl are generally abundant. The rivers and lakes yield enormous quantities of fish, and leeches also are plentiful. The Theiss, once better supplied with fish than any other river in Europe, has for many years fallen off in its productiveness. The culture of the silkworm is chiefly carried on in the south—in the Military Frontier, and in Croatia and Slavonia. The principal bee-rearing localities are in the counties of Gömör, Szepes, and Mosony, the Military Frontier, and the former Saxon districts of Transylvania. In 1870 the number of bee-hives was estimated at 617,407.

Minerals. The chief mineral products are coal, nitre, sulphur, alum, soda, saltpetre, gypsum, porcelain-earth, pipe-clay, asphalt, petroleum, marble, and ores of gold, silver, mercury, copper, iron, lead, zinc, antimony, cobalt, and arsenic. The opals of Sáros are famous, and precious stones of various descriptions (calcedony, garnet, jacinth, amethyst, carnelian, agate, rock-crystals, &c.) are met with in several localities. Amber occurs at Magura in Szepes county. Gold and silver are found chiefly in the districts of Selmecz (Schemnitz), Körmöcz (Kremnitz), Nagybánya, Szomolnok, Oravicza, Abrudbánya, and Zalatna. The average yearly yield of gold is equal in value to about £219,000, and that of silver to some £178,600. The sand of some of the rivers, as for instance the Maros, Szamos, Körös, and Aranyos, is auriferous. Iron is extensively produced in the counties of Gömör, Zólyom, Liptó, Szepes, Sáros, Borsod, Torna, Abaúj, Szatmár, Bihar, and Krassó; coal in the neighbourhood of Pécsvárad, Oravicza, Salgó-Tarján, and of

[1] Strictly 122·7, the average, for the 16 years 1862–77 inclusive, being 35·3 for winter, 30·7 for spring, 29·2 for summer, and 27·5 for autumn.—*Budapest Meteorologiai Viszonyai*, issued (1879) by the Royal Hungarian Central Meteorological Institute.

[2] The quantity of (Riesling grape) wines produced on the archduke Albrecht's estates near Béllye and Villány is said to exceed 1,000,000 bottles annually.

the river Sil. There are fine marble quarries at Piszke and the neighbouring Almás in the counties of Esztergom and Komárom, as also at various places in the counties of Baranya, Veszprém, Abaúj, Szepes, and Liptó. The largest salt-mines are at Rónaszék, Sugatag, and Szlatina in the county of Máramaros, in Hungary Proper, and at Vizakna, Parajd, Torda, Decsakna, and Marosujvár in Transylvania. In 1877 the value of the salt produced was 12,369,599 florins, of other minerals 18,787,757 florins. The yearly worth of the whole mining produce of the Hungarian realm is estimated at over £3,000,000, of which, however, the amount attributable to Croatia and Slavonia is comparatively small. There are several hundred cold and 64 warm mineral springs in Hungary Proper and in Croatia and Slavonia, whilst a relatively greater number are met with in Transylvania. Of warm springs the most famous are those of Buda, Mehádia, Eger (Erlau), Nagyvárad (Grosswardein), Sztubnya, Szliács, Harkány, Pöstény, Krapina, and Teplitz. Among the cold mineral springs the more worthy of note are those of Suliguly, Borszék, Bártfa, Czigelka, Szulin, Parád, Koritnicza, and Szalatnya; the Buda *keserü viz* (bitter water) is also much prized, and largely exported.

Agriculture.

The general agricultural division of the soil is shown approximately in the following table, adapted from Keleti's *Magyarország Statistikája*:—

	Hungary Proper and Transylvania.	Fiume.	Croatia and Slavonia.	Military Frontier.	Total for the Hungarian Realm.
	Eng. Acres.	E. A.	E. Acres.	E. Acres.	Eng. Acres.
Arable	23,865,703	116	1,868,609	1,213,464	26,947,892
Meadows	9,147,793	956	607,933	465,012	10,221,694
Vineyards[1]	837,676	1077	128,558	32,112	999,423
Pastures	10,157,418	1813	500,244	936,357	11,595,832
Forests	19,449,689	635	2,210,736	1,373,347	23,034,407
Reedy tracts	381,783	...	8,200	...	389,983
Total of productive soil	63,840,062	4597	5,324,280	4,020,292	73,189,231
Barren lands	5,021,384	259	472,449	922,950	6,417,042
Total	68,861,446	4856	5,796,729	4,943,242	79,606,273

Administrative and political divisions.

Since the year 1867 the administrative and political divisions of the lands belonging to the Hungarian crown have been in great measure remodelled. In 1868 Transylvania was definitively reunited to Hungary Proper, and the town and district of Fiume declared autonomous. In 1873 the Servian-Bánát or Eastern Military Frontier was incorporated with Hungary Proper. In 1876 the whole administrative subdivision of Hungary into counties, districts, and sees was revised, and for the sake of uniformity one general system of counties was introduced, except for the Croatian-Slavonian Military Frontier, which is divided into border districts. The total number of subdivisions amounts to 80, of which 65 appertain to Hungary Proper and Transylvania, 1 to Fiume and district, 8 to Croatia and Slavonia, and 6 to the Croatian-Slavonian Military Frontier. Hungary Proper, according to ancient usage, is generally divided into four great divisions or circles, and Transylvania has since 1876 been regarded as the fifth. Neither numerically nor according to territorial extent are the present 65 counties distributed equally among their respective circles, which must be regarded as geographical rather than political divisions, for they are not recognized in the judicial, fiscal, military, postal, and administrative relations of the country.[2] The circles are—

Cis-Danubia (north and east of the Danube), containing 13 counties: Pest-Pilis-Solt-Kis-Kun, Bács-Bodrog, Nógrád, Hont, Esztergom, Bars, Zólyom, Liptó, Árva, Thurócz, Trencsén, Nyitra, Pozsony.

Trans-Danubia (south and west of the Danube), 11 counties: Moson, Sopron, Györ, Komárom, Fehér, Veszprém, Vas, Zala, Somogy, Baranya, Tolna.

Cis-Tisia[3] (north and west of the Theiss), 11 counties: Szepes, Gömör and Kis-Hont, Heves, Jász-Nagy-Kun-Szolnok, Borsod, Torna, Abaúj, Sáros, Zemplén, Ung, Bereg.

Trans-Tisia (south and east of the Theiss), 15 counties: Máramaros, Ugocsa, Szatmár, Szilágy, Szabolcs, Hajdú, Bihar, Békés, Csanád, Csongrád, Arad, Torontál, Temes, Krassó, Szörény.

Trans-Királyhágó, or *Transylvania*, 15 counties: Alsó-Fehér, Beszterczе-Naszód, Brassó, Csik, Fogaras, Háromszék, Hunyad, Kis-Küküllö, Kolozs, Maros-Torda, Nagy-Küküllö, Szeben, Szolnok-Doboka, Torda-Aranyos, Udvarhely.

In the following list of divisions the foreign forms of the names of towns are given which are most frequently met with in the German and English press. Not being recognized officially, these are falling into disuse in Hungary.

Political and Administrative Divisions.

No.	County.	County Town. Official Name.	County Town. Foreign Equivalent.
		Hungary and Transylvania.	
1	Pozsony	Pozsony	Pressburg
2	Nyitra	Nyitra	Neutra
3	Trencsén	Trencsén	Trencsin
4	Árva	Alsó-Kubin	
5	Liptó	Liptó-Szent-Miklós	
6	Thurócz	Thurócz-Szent-Márton	
7	Zólyom	Beszterczebánya	Neusohl
8	Bars	Aranyosmarót	
9	Hont	Ipolyság	
10	Nógrád	Balassa-Gyarmat	
11	Esztergom	Esztergom	Gran
12	Komárom	Komárom	Komorn
13	Györ	Györ	Raab
14	Moson	Magyar-Óvár	Ungrisch-Altenburg
15	Sopron	Sopron	Oedenburg
16	Vas	Szombathely	Stein-am-Anger
17	Zala	Zala-Egerszeg	
18	Veszprém	Veszprém	Veszprim
19	Fehér	Székesfehérvár	Stuhlweissenburg
20	Somogy	Kaposvár	
21	Tolna	Szegszárd	
22	Baranya	Pécs	Fünfkirchen
23	Bács-Bodrog	Zombor	
24	Pest-Pilis-Solt-Kis-Kun	Budapest	Pest or Pesth and Ofen or Buda (prior to 1873)
25	Csongrád	Szeged	Szegedin
26	Jász-Nagy-Kun-Szolnok	Szolnok	
27	Heves	Eger	Erlau
28	Borsod	Miskolcz	
29	Gömör and Kis-Hont	Rima-Szombat	Gross-Steffelsdorf
30	Szepes	Löcse	Leutschau
31	Torna	Torna	
32	Abaúj	Kassa	Kaschau
33	Sáros	Eperjes	Eperies
34	Zemplén	Sátoralja-Ujhely	
35	Ung	Ungvár	
36	Bereg	Beregszász	
37	Máramaros	Sziget	
38	Ugocsa	Nagy-Szöllös	
39	Szatmár	Nagy-Károly	
40	Szilágy	Zilah	
41	Bihar	Nagy-Várad	Grosswardein
42	Szabolcs	Nyiregyháza	
43	Hajdú	Debreczen	Debreczin
44	Békés	Gyula	
45	Csanád	Makó	
46	Arad	Arad	
47	Torontál	Nagy-Becskerek	
48	Temes	Temesvár	
49	Krassó	Lugos	
50	Szörény	Karánsebes	
51	Hunyad	Déva	Diemrich
52	Alsó-Fehér	Nagy-Enyed	
53	Torda-Aranyos	Torda	
54	Kolozs	Kolozsvár	Klausenburg
55	Szolnok-Doboka	Deés	
56	Beszterczе-Naszód	Beszterczе	Bistritz
57	Maros-Torda	Maros-Vásárhely	
58	Csik	Csik-Szereda	
59	Udvarhely	Székely-Udvarhely	
60	Kis-Küküllö	Erzsébetváros	Elizabethstadt
61	Nagy-Küküllö	Segesvár	Schässburg
62	Szeben	Nagy-Szeben	Hermannstadt
63	Fogaras	Fogaras	
64	Brassó	Brassó	Kronstadt
65	Háromszék	Sepsi-Szent-György	
66	Fiume (town and district)	Fiume	
		Croatia and Slavonia.	
67	Fiume	Fiume	
68	Zágráb	Zágráb	Agram
69	Varasd	Varasd	Warasdin
70	Körös	Körös	Kreuz
71	Belovár	Belovár	
72	Pozsega	Pozsega	
73	Veröcze	Eszék	Esseg
74	Szerém	Vukovár	
		Croatian-Slavonian Frontier Districts.	
75	Mitrovicz	Mitrovicz	
76	Vinkovcze	Vinkovcze	
77	Gradiska	Uj-Gradiska	Neu-Gradiska
78	Petrinja	Petrinja	
79	Ogulin	Ogulin	
80	Goszpics	Goszpics	

Population.

The population of Hungary comprises a great variety of races, differing in language and religion, although united under one common sovereignty. At the census of 1870 the whole population, civil and military (exclusive of children under the age of six), amounted to 15,509,455, while the total civil population was 15,417,327; of these 7,653,560 were males and 7,763,767 females, the ages of 185 males and 196 females being given as over 100 years.

On the occasion of the new political divisions that took place in 1873, a fresh census was taken of Croatia and Slavonia and the

[1] In good years the total produce of the vines for the whole of Hungary may be estimated at 390 million gallons, in ordinary years at 227, and in bad years at 91 million gallons.

[2] The four circles of Hungary Proper had formerly their special political significance, owing to the so-called "circular sittings," where the deputies of each of the four circles met for the preliminary discussion of parliamentary questions.

[3] Formerly, but incorrectly Cis-Tibisca.

Military Frontier. This accounts for a slight discrepancy with the above number of the civil population in the total of the following table (from MM. Ballagi and Király), in which the population is arranged according to the new administrative divisions:—

	Population.
Hungary Proper and Transylvania	13,561,245[1]
Fiume and district	17,884
Croatia and Slavonia	1,156,025
Military Frontier	691,095
	15,426,249

According to the *Magyar Statistikai Evkönyv* (Budapest, 1879), the number of births in Hungary Proper and Transylvania during the year 1876 was 623,849, viz., 320,470 boys and 303,379 girls; of these 23,060 boys and 21,889 girls were illegitimate. The number of deaths in that year was 478,684, of whom 250,698 were males and 227,986 females. The number of marriages was 135,011. At the census of 1870 there were in the whole Hungarian monarchy 180 cities and large towns, 769 rural towns, 16,376 villages, and 2,450,213 houses. Budapest,[2] the capital, contained 270,476 inhabitants, Szeged 70,179, and Szabadka (Maria-Theresiopel) 56,323. Four towns contained between 40,000 and 50,000 inhabitants, 3 between 30,000 and 40,000, and 21 between 20,000 and 30,000. Zágráb (Agram), the capital of Croatia and Slavonia, had 19,857 inhabitants.

ices. As regards nationality the Magyar or pure Hungarian race is the most numerously represented in the kingdom, amounting, according to Dr Konek (see Schwicker, *Statistik des Königreiches Ungarn*, 1877), to 6,176,612, or 40 per cent. of the whole civil population. The Magyar element is chiefly confined to Hungary Proper and Transylvania, only about 15,000 Magyars residing in Croatia and Slavonia. The German population amounts to 1,898,202 (12·3 per cent.), for the most part settled in the western and north-western counties of Hungary Proper, bordering on Austria, also in the county of Szepes in the north, in the former Bánát, and in the Saxon counties of Transylvania. The Roumanians, estimated at 2,608,120 (16·9 per cent.), are mostly resident in Transylvania and the counties immediately abutting on it. The Slovaks amount to 1,835,334 (11·9 per cent.), and the Ruthens to 469,420 (3 per cent.), the former chiefly located in the north and north-west and the latter in the north-east of Hungary Proper. The aggregate number of Croats and Serbs is 2,380,985 (15·5 per cent.), chiefly confined to Croatia and Slavonia and the Military Frontier, where they form 97 per cent. of the population, to the former Servian-Bánát, and the southern counties of Hungary Proper. The other nationalities, comprising Armenians, Greeks, Bulgarians, Macedo-Wallachians, Albanians, French, and Italians, are not largely represented, their total number being estimated at only 48,654 (about 0·3 per cent.); the Italians are, however, to be met with in considerable numbers at Fiume and in its vicinity. In the above statistics the Jews scattered over the country, and amounting altogether to rather more than half a million, have been reckoned with the various nationalities where they happen to be settled.[3] The Gipsies, classed partly as Magyars partly as Roumanians, and roughly estimated at 145,000, have their colonies in various parts of the monarchy, but more particularly in Transylvania, and in the county of Gömör in Hungary Proper. On the whole the Magyar element may be said to predominate in 27 of the 65 (new) counties appertaining to the mother country, the German or Magyar-German in 6, the Roumanian in 13, the Slovakian in 9, the Servian in 1, and the Ruthenian in 3. In 6 counties of Hungary Proper no one special nationality can be said to have the absolute majority.

l gion. The total number of the various confessions for the whole population (civil and military) has been computed thus:—

Roman Catholics	7,558,558
Greek Catholics	1,599,628
Armenian Catholics	5,133
Greek (Eastern) Church	2,589,319
Armenians	646
Lutherans	1,113,508
Calvinists	2,031,243
Unitarians	54,822
Other Christian sects	2,733
Jews	553,641
Other non-Christians	224
	15,509,455

The Roman Catholics are in overwhelming majority in 32 counties, the adherents of the Greek (Eastern) Church in 11, the Greek Catholics in 10, and the Lutherans in 5. Further the Greek Orientalists have a majority in 6 counties, the Calvinists in 5, the Roman Catholics in 4, the Lutherans in 2, and the Greek Catholics in 1 county. The Roman Catholic Church has 4 archbishops: Esztergom (Gran), Kalocsa, Eger (Erlau), and Zágráb (Agram), and 17 real diocesan bishops; to the latter must be added, moreover, the chief abbot of Pannonhalma, who likewise enjoys episcopal rights. The primate is the archbishop of Esztergom, who also bears the title of prince, and whose special privilege it is to crown the sovereigns of Hungary. The Greek Catholic Church, which is in connexion with the Romish communion, owns besides the archbishop of Esztergom the archbishop of Gyulafehérvár (Carlsburg), or rather Balásfalva (*i.e.*, "Blasiusville"), and 6 bishops. The Armenian Catholic Church is partly under the jurisdiction of the Roman Catholic bishop of Transylvania, and partly under that of the Roman Catholic archbishop of Kalocsa. The Greek (Eastern) Church in Hungary is subject to the authority of the metropolitan of Carlowitz and the archbishop of Nagyszeben (Hermannstadt); under the former are the bishops of Bács, Buda, Temesvár, Versecz, and Pakrácz, and under the latter the bishops of Arad and Karánsebes. The two great Protestant communities are divided into ecclesiastical districts, five for each; the heads of these districts bear the title of superintendents. The Unitarians, chiefly resident in Transylvania, are under the authority of a bishop, whose see is Klausenburg. The Jewish communities are comprised in ecclesiastical districts, the head direction being at Budapest. At the commencement of 1870 there were 19,858 clerics of various creeds in Hungary.

Since the year 1867 great improvements have been effected in the educational system of Hungary, especially in Hungary Proper and Transylvania. Before that year public instruction was in the hands of the ecclesiastics of the various confessions, and the public schools had in consequence more or less of a denominational character. One of the first cares of the new responsible ministry of 1867 was to provide for the education of all children not attending the then existing scholastic establishments, by the introduction of supplementary non-denominational schools. By a law passed in 1868 the Government made it compulsory on children of both sexes between the ages of 6 and 12 to attend school, and it moreover required that children from 12 to 15 should attend the "repetition schools." The educational system of Croatia and Slavonia is autonomous, being under the independent direction of the Croatian-Slavonian provincial government. Education.

The various educational establishments may be divided into four classes:—common, middle, high, and special schools. In 1877 Hungary Proper and Transylvania had 15,486 belonging to the first-mentioned class; of these 13,755 were private or denominational, and 1731 communal and state schools. These figures show a total increase of 2341 since the year 1865, when the number was only 13,145. It is estimated that at the end of 1877 there was one school for every 870 inhabitants. In that year the number of children between the ages of six and fifteen who came under the education act amounted to 2,127,950, and of these 1,559,636 or 73 per cent. attended; whereas in 1869 the percentage of day scholars barely reached 48, showing an increase of 25 per cent. in the course of eight years. In 1874 there was already an attendance of 1,497,144, or nearly 70 per cent. The number of children who attended school in Croatia and Slavonia, with the Military Frontier, at that date was 73,635, making a general total for the whole of Hungary for the year 1874 of 1,570,779. On account of the variety of languages and races prevailing in many parts of Hungary, the education in numerous schools has to be conducted in two, and in several instances even in three languages. Out of 15,486 schools[4] in Hungary Proper and Transylvania in 1877 Hungarian was used in 7024, German in 1141, Roumanian in 2773, Slovakian in 1901, Servian in 259, Croatian in 70, Ruthenian in 491, two languages in 1692, and three in 135. The aggregate number of teachers in the above schools was 20,717.

The middle schools consist of the gymnasia, real-schools, and similar institutions. In 1874 there were in Hungary Proper and Transylvania 146 gymnasia, with 1734 teachers and 26,273 pupils; in 1877 the gymnasia had increased to 149, the teachers to 1814, and the pupils to 31,455. In 1874 there were 32 real-schools, with 387 teachers and 7743 pupils; in 1877 there were 26[5] such schools, with 383 teachers and 6647 pupils. The above results added together give an aggregate, for the year 1877, of 175 schools, 2197 teachers, and 38,102 pupils. With the omission of a few of a specially sectarian, technical, or private character, the total number of middle schools at that time in the whole Hungarian monarchy (including Croatia and Slavonia and the Military Frontier) was, as nearly as can be computed, about 205, with some 2450 teachers, and 42,000 pupils. In the mother country there were also 51 training seminaries[6] for masters (2853 scholars), and 14 for mistresses (1138 scholars); of these 65 establishments, 16 of the former and 6 of the latter kind were state, and the remaining 43 confessional, viz., 26 Roman Catholic, 3 Greek Eastern Church, 4 Lutheran, 9 Calvinist,

[1] The civil population of Hungary Proper and Transylvania at the end of 1876 was 13,670,624.
[2] In 1876 the population of Budapest, including military, was 309,208.
[3] *Cf.* Dr Jos. Bergl, *Geschichte der ungarischen Juden*, Leipsic, 1879.

[4] Of the children who left these schools in 1877, the percentage of those who could both read and write was 85, of those who could only read 15.
[5] These figures refer to upper and lower real-schools fairly complete in their formation. The total number of real-schools, perfect and imperfect, in the mother country, including also Fiume, was 36 (viz., 24 upper and 12 lower).
[6] Chiefly for the lower or common school teachers.

and 1 Jewish. The number of commercial schools was 24, with 129 masters and 1114 pupils.

The high schools comprise the universities of Budapest, Kolozsvár (Klausenburg), and Zágráb (Agram), the Joseph-Polytechnic, the theological institutes, the law academies, &c. The Budapest university (founded at Tyrnau in 1635) has four faculties,—theology, jurisprudence, medicine, and philosophy. In the year 1877 the number of professors amounted to 166, and that of students to 2929 (in 1878 to 180 and 3117 respectively). The university of Kolozsvár was founded in 1872, and is similar in its organization to that of Budapest, excepting that it has a faculty for mathematics and natural science, but none for theology. The number of professors in 1877 was 64, and that of students 391. Zágráb university was founded in 1869, but was not in active operation till 1874, and was even then incomplete in its formation. It has three faculties,—jurisprudence, theology, and philosophy. The Joseph-Polytechnic, ranking as a high school at Budapest since 1871, had in 1877 as many as 56 professors with 800 students. The number of theological institutions in Hungary Proper and Transylvania at that date was 45,[1] with 284 professors and 1534 novices; 25 of these institutions were Roman Catholic, 4 Greek Catholic, 3 Greek Eastern Church, 7 Lutheran, 5 Calvinistic, and 1 Unitarian. There were, moreover, 12 law academies, with 115 professors and 1067 students. In 1878 there were 125 professors and 1043 pupils. In Croatia and Slavonia there were 5 theological institutes (4 Roman Catholic and 1 Greek Eastern Church), with about 30 professors and some 200 students. The special schools are for particular branches of science and art. Among these are the school of design at Budapest; the music academy (founded 1875); several establishments for teaching mining, at Selmecz (Schemnitz), Nagyág, Felsö-Bánya; farming and agriculture, at Magyar-Óvár (Altenburg), Keszthely, Kolozsvár, Debreczen; and the management of forests, at Selmecz; also institutes for the blind, deaf, and dumb, and for lunatics at Vácz (Waitzen), Budapest, and Pozsony; and schools for veterinary surgery, obstetrics, &c. There are, moreover, military seminaries at Budapest, Kassa (Kaschau), Déva, Köszeg (Güns), Fehértemplom, and Zágráb, and a naval school at Fiume.

The Hungarian academy of sciences is the supreme representative of the national culture. First constituted with royal sanction in 1830, the academy in 1879 consisted of 321 (224 home and 97 foreign) members, arranged in 3 classes. Next follow the Kisfaludy (comprising in 1879 only 50 home and 15 foreign members) and Petöfi societies of Budapest, the royal meteorological institute, and the medical and physical (natural science), historical, archæological, geological, geographical (founded 1872), and philological (1875) societies. To these must be added the Roman Catholic "St Stephen's union," the "Protestant union," the Zágráb "South Slavonian Academy" (founded 1861), and the various Transylvanian and provincial learned societies.

Industries. As the industrial products and commerce of Hungary have been already described in the article AUSTRIA (vol. iii. p. 119–121), we need only add here a few remarks as to the chief localities of certain trades and manufactures.

Manufactures. The principal machine factories, foundries, bell and type works, and works for iron and other metallic wares are at Pest, Buda, Temesvár, Resicza, Diósgyör, and Sopron (Oedenburg). Boat-building is carried on at the chief towns on the great rivers, especially at Szeged, Arad, Buda, Komárom (Komorn), and Györ (Raab); steam-vessels are constructed at Buda and Fiume. The glass manufacture, mostly carried on in the hilly districts, is not yet fully developed, and the articles are of an inferior quality. The best manufactories of stoneware and earthenware are those of Csákvár, Pécs (Fünfkirchen), Rimaszombat, Murány, Pápa, Köszeg (Güns), Igló, Körmöczbánya, Zágráb, and Krapina; of porcelain the most important is that of Herend. Debreczen, Pápa, Selmeczbanya, and Szigetvár are famed for their clay pipes. The preparation of chemical stuffs is carried on chiefly at Pest, Nagyszombat (Tyrnau), Pozsony (Pressburg), Nagyszeben (Hermannstadt), and Ujmoldova; whilst Debreczen and Szeged are noted for their soap and candles. Oil factories are numerous, especially in Hungary Proper and Transylvania; the chief oil mills and refining houses are at Pest, New Pest, Rákospalota, Székesfehérvár (Stuhlweissenburg), Györ, Pozsony, Kassa (Kaschau), Temesvár, Brassó, (Kronstadt), and Cservenka, which last has forty mills. The manufacture of silk stuffs is still undeveloped, but there are spinneries at Nagyczenk, Hidja, Sopron, and Féltorony, also in the Bánát, and in various parts of Transylvania and of the Frontier districts. Flax is mostly homespun, and confined to the commoner kinds of linen. There are factories for woollen yarn at Brassó, Nagyszeben, and Gurano, and for woollen stuffs at Losoncz and Szakolcza. Coarse cloth is made in many parts of the kingdom. Leather is prepared at Kassa, Pozsony, Rozsnyó (Rosenau), Körmend, Temesvár, Késmárk, and Budapest. Paper is made at Diósgyör, Nezsider (Neusiedl), Hermanecz, Szlabos, and Fiume. Breweries are chiefly to be found in the neighbourhood of the large towns, which contain a mixed population, as the Magyars are drinkers of wine and spirits rather than of beer; the breweries of Köbánya near Pest are the most extensive. The taste for beer is said to be increasing, although the total number of breweries in Hungary has since 1860 been steadily falling, and many of the smaller establishments no longer exist, or have been absorbed. A considerable quantity of beer is, moreover, imported from Bohemia and the neighbourhood of Vienna. The largest sugar-works are those of Surány, Moson (Wieselburg), Szent-Miklós, and Edelény. The most important tobacco factories are those of Pest, Kassa, Debreczen, and Fiume.

As regards the number of factories exact data are not forthcoming. It appears, however, that in 1874 there were in the whole kingdom altogether 82,570 spirit distilleries, of which 991 were substantial factories and 81,579 rural stills. The breweries in activity at that date amounted to 247, of which 211 were in the mother country, and 36 in Croatia and Slavonia. There were, besides, 20 sugar refineries, and about 30,000 flour-mills of various descriptions, of which nearly 25,000 were in Hungary Proper and Transylvania. In fact the preparation of flour, which is, moreover, largely exported to Germany and Switzerland, is one of the most important industries of Hungary.

According to a report of M. de Hieronimy, under secretary of state in the Hungarian ministry of public works, the length of Hungarian railways in operation in the year 1867 was only 1375 English miles. The length of railways constructed from that date to the year 1876 amounted to 2675 miles, and thus at the beginning of 1877 there were 4050 miles of railway in operation in Hungary. By the early part of 1879 the total length was about 7000 kilometres or 4400 miles. There are also some 18,000 miles of highways (good and bad), and more than 2500 miles of navigable river and canal communication. The imports (including those from Austria) may be roughly estimated at £45,000,000, and the exports at £35,000,000. There is also a considerable transit trade carried on between Austria and the western states and the regions of the lower Danube, estimated at £8,500,000 yearly. The number of freighted vessels that arrived at the ports of the Hungarian Littorale in 1876 was 3524, the number that left 3362; of the former 909, and of the latter 926 were steamers. Commu- nication.

Besides the several branches of the "Austrian-Hungarian Bank" at Budapest, Kassa (Kaschau), Debreczen, and Temesvár, Hungary possesses about 120 industrial, commercial, and credit banks. There are, moreover, 12 chambers of commerce and industry at Budapest, Pozsony (Pressburg), Kassa, Sopron (Oedenburg), Debreczen, Temesvár, Arad, Kolozsvár (Klausenburg), Brassó (Kronstadt), Fiume, Zágráb (Agram), and Eszék. The number of savings banks is about 310; of other associations, such as loan societies, popular, mutual, and alliance banks, &c., the aggregate is over 200. In the year 1876 the number of post-office orders issued amounted to 1,832,757. The total number of telegraphic messages sent, received, or transmitted was 6,462,335. The aggregate of postal missives was 112,851,516; of these 46,617,106 were prepaid and 1,452,233 not prepaid letters; 4,581,027 were registered, and 13,954,354 official letters; 9,016,232 were post-cards; 28,876,062 were articles per newspaper, 1,364,490 per pattern, and 6,990,012 per book post. Banks. Post-office.

The form of government in Hungary is that of a constitutional monarchy. The sovereign power is at present vested in the house of Hapsburg-Lorraine, whose descendants succeed by right of primogeniture in the male line. By virtue of the Pragmatic Sanction, females may also reign in the event of there being no male successor. The king is the guardian of the laws, and the head of the army and of the executive. His power is limited by parliament, which consists of an upper and a lower house, and must be summoned yearly and elected triennially. The upper house comprises 407 members, viz., 3 princes of the reigning house, 31 Roman and Greek Catholic prelates, 11 standard-bearers, 57 lord-lieutenants of counties, 3 dukes, 219 counts, 81 barons, and 2 deputies for Croatia and Slavonia. The lower house, elected by the eligible tax-payers, consists of 446 members, of whom 403 represent Hungary Proper and Transylvania (including also Fiume), and 43 Croatia and Slavonia and the Military Frontier. The language used in the house is the Magyar, but the representatives of Croatia and Slavonia may use their native language. The executive is vested in a president of the cabinet and the following ministries:—court; finance; interior; religion and education; justice; public works; agriculture, industry, and commerce; *honvéd* (home-defence); and a ministry for Croatia and Slavonia. For matters relating to its special provincial administration, Croatia and Slavonia has at Zágráb (Agram) its own government, at the head of which is the ban, who is nominated by the king. The departments are three,—interior and finance, religion and education, and justice. (For the relations of the kingdom of Hungary to the joint Austrian-Hungarian monarchy, and for the delegations, comparative revenue and expenditure, joint army, &c., see AUSTRIA, vol. iii. pp. 122, 123.) Government.

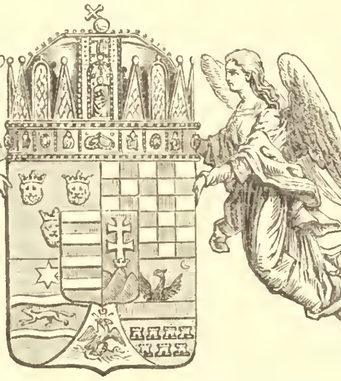
The judicial power is independent of the administrative, the functions of the minister of justice being to see that the laws are properly applied. The supreme courts of justice, as also those of second instance for Hungary Proper and Transylvania and Fiume, are at Budapest. There is also a secondary court of appeal at Maros- Justi

[1] To the above must be now added the "Rabbinerschule," opened October 4, 1877, and numbering (in 1878–79) 31 pupils.

Vásárhely in Transylvania. The number of royal courts of justice in the mother country (including also Fiume) in 1877 was 66, and there were 375 circuit courts. Of the 23,033 criminals condemned in 1877, 13,237 or 57·47 per cent. were completely illiterate, 1193 or 5·18 per cent. were able to read, 8314 or 36·10 per cent. could both read and write, and 289 or 1·25 per cent. were persons of superior education. As to the punishments awarded, 34 persons were condemned to death (of whom only 3 were executed), 13 were sentenced to prison with hard labour for life, 124 to from 10 to 20 years' imprisonment, 272 to from 5 to 10 years, 3537 to from 1 to 5 years, and 19,053 to less than a year's imprisonment.

ce. As regards the financial position of the kingdom, owing to the vast sums spent on state railways, the Fiume harbour works, and other large undertakings, the annual deficit rapidly increased until 1874, but from that date until 1878 it fell from about 33 to 21 million florins, the budget for the latter year giving a revenue of 219,846,016 and an expenditure of 240,967,435 florins.

The national colours are red, white, and green. The only order is that of St Stephen.



Crown and Arms of the Realm of St Stephen.

The shield contains four quarters:—1. azure, three leopards' heads crowned, or, for *Dalmatia*; 2, chequy, argent and gules, for *Croatia*; 3, azure, on a fess wavy gules, cotised argent, a marten courant proper, in chief an estoile of six points or (Mars), for *Slavonia*; 4. coupé: the chief azure, a demi-eagle issuant sable (*Hungarian nation*), in chief [a sun or, and] moon argent (*Szekler nation*); the base or, seven towers (Siebenbürgen) embattled four and three gules, over all a fesse gules, for *Transylvania*. In base enté, a double-headed eagle rising, contourné, for *Fiume*. On an escutcheon of pretence, barry of eight, argent and gules, impaling, gules, on a triple mount vert, out of a crown or, a patriarchal cross argent, for *Hungary Proper*; the bars argent representing emblematically the Danube, Theiss, Drave, and Save; the triple mount, the Tátra, Fátra, and Mátra. The whole is surmounted in chief by the Hungarian crown, with two genii or angel supporters. The lower part of the crown is a circlet inlaid with jewels and enamelled portraits, and heightened in the centre by a figure of Christ in majesty forming the middle portion of the arch or upper part of the crown, which is surmounted by a slanting cross.

A good native map for the new administrative divisions of 1876 is that of J. Hátsek, *A Magyar korona országainak ...közigazgatási beosztása* (Budapest, 1877). For the physical features the *Uebersichts-Karte von Oesterreich-Ungarn* (1:2,500,000) of A. Steinhauser (Vienna, 1879) leaves little to be desired. For bibliography of geographical and statistical works and maps published previous to 1871, see F. Grassauer, *Landeskunde von Oesterreich-Ungarn* (Vienna, 1875).

II. History.

The south-western portion of Hungary, as formed by the Danube, belonged to the Roman province of Pannonia; the south-eastern portion, as formed by the Theiss (Ptol. iii. 8, § 4), to that of Dacia; the tract of country lying between these two rivers was inhabited by the Jazyges. As early as 274 A.D. Dacia was abandoned by the Romans to the Goths. In 376 the Huns crossed the Don, and, having overrun the intervening country, about 380 established themselves in Pannonia, where under Attila their power was so vastly extended that in 432 the authority of the Romans entirely ceased. After the death of Attila (453) the greater part of the country fell into the hands of the Ostrogoths and Gepidæ. These yielded in their turn to the Longobardi, who in 526–548 gained possession of the whole of Pannonia. When the latter removed to Italy in 568, the Avars entered, but they were reduced to subjection by Charlemagne in 791–796.

The history of Hungary really begins with the appearance of the Magyars in Europe about the year 884. It is generally admitted that they were a branch of the Turanian stock, and descendants of the ancient Scythians; certain affinities of language show them to be related to the Lapps, Esths, and Finns. They are believed to have wandered from the Ural mountains to the region of the middle Volga, and thence to have migrated westward over the Dnieper and the Bug. At the time of their crossing the Carpathians about 889, under the lead of Álmos, they were divided into seven tribes, united by a compact which guaranteed justice and equality among their members. At the death of Álmos in 889, the chiefs of the tribes elected his son Arpád successor. His followers overran the whole of Hungary and Transylvania, extending their conquests beyond the ancient province of Pannonia. From the time of the conquest to the year 1000, Hungary was ruled by dukes, the regal title being first assumed by Vaik (Stephen). The following table gives the dates of accession of the Árpád dynasty, which ruled over Hungary for upwards of four centuries:—

Dukes.		Ladislaus I., the Saint	1077
Árpád the Conqueror	889	Coloman the Learned	1095
Zoltán	907	Stephen II.	1114
Taksony	947	Béla II.	1131
Geyza	972	Geyza II.	1141
Vaik (afterwards Stephen I.)	997	Stephen III.	1161
Kings.		Ladislaus II. and Stephen IV. (usurpers)	1162
		Stephen III. (again)	1162
Stephen I., the Saint	1000	Béla III.	1173
Peter	1038	Emeric	1196
Aba Samú	1041	Ladislaus III.	1204
Peter (again)	1044	Andrew II.	1205
Andrew I.	1047	Béla IV.	1235
Béla I.	1061	Stephen V.	1270
Solomon	1063	Ladislaus IV.	1272
Geyza I.	1074	Andrew III.	1290

The following ruled from the extinction of the native dynasty to the commencement of the Hapsburg period:—

Wenceslaus (usurper)	1301	Uladislaus I.	1442
Otho (usurper)	1305	John Hunyady (Gubernator)	1446
Charles Robert (of Anjou)	1308		
Louis I., the Great	1342	Ladislaus V. (Posthumus)	1453
Maria	1382		
Charles II.	1385	Matthias Hunyady (Corvinus)	1458
Maria and Sigismond	1386		
Albert of Austria	1437	Uladislaus II.	1490
Elizabeth	1439	Louis II.	1516

Under Zoltán and Taksony the Hungarians made various expeditions beyond the limits of their own country, spreading terror and devastation through Europe. They were ultimately checked, however, by the emperor Henry I., near Merseburg, in 933, and afterwards by Otho the Great at the Lech (955). These defeats caused the Hungarians to turn their attention to the consolidation of their power within their own territory. Geyza, who succeeded Taksony in 972, married a Christian princess, and also furthered the introduction of Christianity by entrusting the education of his son Vaik to Adalbert, bishop of Prague. On succeeding his father, Vaik applied for and received the title of "apostolic king" from the hands of Pope Sylvester II., and was crowned in the year 1000 under the name of Stephen. This monarch, known as "St Stephen of Hungary," laid the foundation of many existing institutions. He subdivided the land into counties, and provided it with an ecclesiastical organization, establishing bishoprics, and founding churches, chapels, convents, and schools. Having elevated the bishops to the highest posts of trust and power in the state, he forced the people to pay tithes to the clergy. He also created a national council, consisting of the lords temporal and spiritual, and of the knights or lower nobility, from which assembly the subsequent diets originated. Stephen dying in 1038, and leaving no heir, the queen Gisela contrived to gain the throne for her nephew Peter, but a portion of the nobles declared for Aba, who was of Arpadian blood. In the wars which ensued both princes perished, when Andrew I., who was nearly related to Stephen I., succeeded to the throne in 1047, but he was ultimately forced to yield it to his brother Béla I. The next monarch's reign that offers anything worthy of notice is that of Ladislaus I., whose religious zeal gained him the appellation of "Saint," and who was distinguished on account of his conquest of Croatia (1089) and part of Galicia (1093), and for his victories over the Cumans (1086–89), the invaders of Transylvania and the neighbouring districts. His nephew Coloman, a brave and talented monarch, guarded the country against the depredations of the hosts of crusaders who passed through it during his reign. He also wrested Dalmatia from the Venetians (1102), and annexed it to the Hungarian kingdom. Coloman died in 1114, leaving the throne to his youthful son Stephen II., who soon entangled himself in warfare with neighbouring princes. The reign of his successor Béla II. (1131–41), like that of the other kings of the 12th century, presents few features of interest. That of Andrew II. (1205–35) is celebrated on account of the "Golden Bull," or Hungarian Magna Charta, extorted from the king by the nobles in the year 1222, after his return from a crusade forced upon him by the pope. The Golden Bull guaranteed that the states should be convoked annually, that no noble was to be arrested without being first tried and legally condemned, that the property of the nobility should be exempt from dues, that foreign service was to be rewarded, that appointments to the highest offices should be under the control of the diet. It also contained numerous other clauses granting certain freedoms, privileges, and exemptions to the nobility and the clergy, and included a proviso of the right of armed resistance to tyrannical measures on the part of the crown. This charter was duly sworn to by subsequent kings of Hungary, but the article relating to the right of appeal to arms was abrogated in 1687. A few years after the accession of Béla IV., son of Andrew II., the Mongols invaded and devastated the whole country, massacring great numbers of the population (1241–42). Béla did all in his power, by the introduction of German colonists, to retrieve the disasters inflicted by the invasion; but his wars with Austria and Styria, and the revolts of his son Stephen, were prejudicial to the restoration of order. He, however, successfully repelled a second Mongol invasion in 1261. The reigns of the next two monarchs, Stephen V. (1270–72) and Ladislaus IV. (1272–90), are noticeable chiefly for the wars on behalf of Rudolf of Austria against Ottokar of Bohemia. Ladislaus is said to have been murdered in 1290 amidst violent commotions caused by his Cumanian amours. His successor Andrew III., the last king of the Árpád dynasty, after a short but disturbed reign, died in 1301, leaving no issue.

On the death of Andrew III. the royal dignity became an object of competition. One party elected Wenceslaus, son of the king of Bohemia and Poland (1301–5), and after him Otho of Bavaria (1305–8), both connected with the Arpadian house. Pope Boniface VIII. and the bishops successfully espoused the cause of Charles Robert of Anjou, nephew of the king of Naples, and related to the extinct dynasty through his mother, a daughter of Stephen V. Under Charles and his son Louis, which latter in 1370 succeeded Casimir III. on the throne of Poland, Hungary made great progress both at home and abroad. During the reign of Louis it became the most formidable state in Europe. Among many other territories he conquered Moldavia (1352) and Bulgaria (1365); he also greatly extended and developed the royal prerogatives in his own kingdom. Upon the death of Louis (1382), the states raised to the throne his daughter Maria, who, after the assassination of the pretender Charles II. (1386), reigned conjointly with her consort Sigismond of Brandenburg, son of the emperor Charles IV. In the early part of this reign the Turks under the sultan Bajazet infested some of the Hungarian provinces, and at length in 1396 utterly defeated Sigismond at Nicopolis, obliging him to fly the kingdom. During his absence a party headed by the palatine Gara raised the standard of rebellion, and upon his return deprived him of his liberty. Scarcely was he released when he met with a rival in Uladislaus, king of Poland, who had married Hedwig, second daughter of Louis. Elected emperor (1411), and afterwards king of Bohemia (1419), Sigismond, instead of providing for the safety of the country, employed his time in persecuting the Hussites. He ended his long and troublous reign 9th December 1437, and was succeeded by his son-in-law Albert, archduke of Austria.

The year 1439 witnessed the sudden death of Albert; his widow, however, was soon delivered of a son, Ladislaus Posthumus. The states invited Uladislaus of Poland to the throne, and thus considerable dissensions existed until the death of the queen in 1442, when the party of Uladislaus secured his accession. At the commencement of his reign the Turks were several times defeated by John Hunyady (Corvinus), and they were at length forced to conclude a truce for ten years. The Hungarians, having almost immediately broken faith with the Turks, and taken the field against them, were completely routed at Varna on the 10th November 1444. In this battle Uladislaus met his end, whilst Hunyady escaped with a few followers. Amid the troubles which ensued the states proclaimed Hunyady "governor of Hungary" pending the absence of Ladislaus Posthumus, whom the emperor Frederick III. refused to deliver to the Hungarians to be acknowledged king. After the release and recognition[1] of Ladislaus in 1452, Hunyady resigned the office of governor, and was nominated generalissimo by the king.

After the fall of Constantinople in 1453, Mohammed II. made preparations for the conquest of Hungary, and in 1456 appeared before Belgrade with an army of 150,000 men. This force was, however, utterly routed on July 21, 1456, by the combined Hungarian, Italian, and Spanish troops, in all about 70,000 men, under the command of John Hunyady and the monk John Capistran. Soon after this victory, which resulted in the Turks raising the siege, Hunyady succumbed to dysentery aggravated by excessive fatigue, leaving behind him two sons, Ladislaus and Matthias. The former was executed by order of Ladislaus Posthumus, while the latter, after that monarch's death in November 1457, being supported by a strong party under the leadership of his uncle Michael Szilágyi, was elevated to the royal dignity on the 24th January 1458, under the title of Matthias I. The emperor Frederick, having disputed his right to the throne, and assumed the regal title himself, was forced by Matthias to surrender all claims to the Hungarian dominions, and to conclude a peace in July 1463. During the next few years Matthias was employed in reorganizing the military system and repelling the Turks. He after this turned his arms against Podiebrad, king of Bohemia (1468), ostensibly for the purpose of defending the Catholics against the Hussites. Being victorious in these campaigns, Matthias in May 1469 caused himself to be proclaimed king of Bohemia and Moravia at Olmütz. Meanwhile the Turks, taking advan-

[1] He took the oath in 1453, but Frederick withheld the crown.

tage of the absence of the king, made incursions into the southern provinces of Hungary. This misfortune created a party against Matthias, who, having returned to Hungary and restored order, marched against the Ottoman forces, and totally defeated them in a sanguinary battle on the plains of Kenyérmezö in Transylvania (13th November 1479). After the death of Mohammed II. in 1481, Matthias renewed hostilities with the emperor Frederick, and having taken Vienna (1485), made it the seat of his government. Matthias was not only an able and warlike monarch, but a patron of letters,[1] and administered his kingdom with impartiality, subduing the rebellious nobles, and restoring order, law, and prosperity.

At the death of Matthias, 6th April 1490, there were several pretenders to the throne, among them John Corvinus, a natural son of the late king, the emperor Frederick, and his son Maximilian. But the states disallowed their claims, and declared for Uladislaus of Bohemia, whose weak reign is marked chiefly by the insurrection of the peasantry in Transylvania, under Dózsa, which was suppressed with great bloodshed in 1514, as also for the collection made by Verböczy of the common laws of the realm, entitled "Tripartitum Opus Juris Consuetudinarii Inclyti Regni Hungariæ," which code was sanctioned by the king and the diet in 1514. Under this monarch and his son Louis II., who succeeded him, the power of Hungary rapidly declined, and it was at length utterly overthrown by the Turks under Soliman the Magnificent. This powerful ruler, having captured Belgrade and Peterwardein, advanced at the head of 200,000 men into the interior of the country, and annihilated the Hungarian army at the battle of Mohács, 29th August 1526. In the carnage several prelates and the flower of the Hungarian nobility were destroyed, and Louis himself perished in his flight. The Ottomans, after pillaging Buda and spreading devastation over the whole country, took their departure with many thousands of captives.

After the catastrophe at Mohács and death of Louis in 1526, a portion of the nobles declared for John Zápolya, waywode of Transylvania, who was accordingly crowned at Székesfehérvár (Stuhlweissenburg). Maria, the widow of Louis, immediately summoned a diet of the nobility of the western counties at Pozsony (Pressburg), who pronounced the election of Zápolya illegal, and proclaimed the queen's brother, Ferdinand of Austria, king of Hungary (16th December 1526). In the following August Ferdinand, having proceeded to Hungary, was again proclaimed king at Buda; he was afterwards crowned at Székesfehérvár, 5th November 1527. With this monarch the Hapsburg period commences, the sovereign rulers of Austria after him succeeding to the title of the Hungarian crown. The following is a list of the kings of Hungary, and of the more prominent of the princes who ruled over Transylvania to the end of the 17th century:—

Hungary.	
Ferdinand I. (rival John Zápolya)	1526
Maximilian (rival Sigismond Zápolya)	1564
Rudolph I.	1577
Matthias II.	1608
Ferdinand II.	1619
Ferdinand III.	1637
Leopold I.	1657
Joseph I.	1705
Charles III.	1711
Maria Theresa	1740
Joseph II.	1780
Leopold II.	1790
Francis I.	1792
Ferdinand V.	1835
Francis Joseph (crowned 1867)	1848

Transylvania.	
Stephen Báthori	1571
Stephen Bocskay	1605
Gabriel Báthori	1608
Gabriel Bethlen	1613
George Rákóczy I.	1631
George Rákóczy II.	1648
John Kemény	1661
Michael Apaffi I.	1661
Michael Apaffi II.	1690

Hapsburg dynasty.

John Zápolya, being compelled to retire before the superior forces of Ferdinand, took refuge for a time in Poland, whence he sought the assistance of Soliman II. The sultan listened to his request, and in 1529 conducted a large army into Hungary, took Buda by storm (3d September), reinstated Zápolya, and drove the Austrians before him to Vienna. Failing to take that city, Soliman in October retraced his steps, and after garrisoning Buda with Turkish troops returned in triumph to Constantinople. After several years of desultory warfare between John and Ferdinand, their rival claims were ultimately settled by a treaty concluded at Nagyvárad (Grosswardein) on the 25th February 1538. By this treaty it was stipulated that John was to retain the title of king, together with Transylvania and the eastern portion of Hungary then in his possession, whilst Ferdinand was to hold the remainder, with the proviso that John's male descendants were to surrender all claims to the regal dignity. John having died on the 21st July 1540, his infant son Sigismond was crowned by the adherents of his father, and he was subsequently confirmed in his title to Transylvania by Soliman. This sultan, however, retained a great portion of Hungary in his own possession, and even placed a pasha as regent at Buda; he, moreover, compelled Ferdinand to pay him an annual tribute of 30,000 ducats. Ferdinand, having caused his son Maximilian to be crowned as his successor in 1563, died on the 25th July of the following year. When Maximilian succeeded to the throne, he found himself obliged to continue the war with the young Zápolya, whose cause was espoused by Soliman. In 1566 the sultan, advancing at the head of a large force, was arrested at the small fortress of Sziget by Nicholas Zrinyi, who with a garrison of 3000 men for four weeks heroically defied the whole power of the besiegers.[2] Soliman himself died shortly before the final assault on the citadel, which was overpowered only after the destruction of a large part of his army. In the year 1570 Zápolya concluded peace with Maximilian, and on his death in the following year Stephen Báthori, with the consent of the sultan Selim, was elected prince of Transylvania. Maximilian, having in 1573 secured the succession of his son Rudolph to the throne of Hungary, died on the 12th October 1576.

By this time the Reformation had made considerable progress in Hungary, more especially among the higher classes, but with Rudolph the persecution of the Protestants commenced. In Transylvania, however, they met with a protector in Stephen Báthori, from 1576 to 1586 distinguished as king of Poland. In 1604 the Protestants of Hungary, having raised the standard of freedom under Stephen Bocskay, defeated the generals of Rudolph in several engagements, and on the 23d June 1606 they forced him to conclude peace at Vienna, thus securing to themselves for a time their religious liberties. In 1608 Rudolph resigned the kingdom to his brother Matthias, who during his short reign showed great toleration towards the adherents of the Reformed creeds. He died 20th March 1619, leaving the crown to his cousin Ferdinand II., the hero of the "Thirty Years' War." The accession of this monarch was signalized by the insurrection of the Protestants of Bohemia, and the renewal of persecutions in Hungary, fomented by the Jesuit prelate Peter Pázmán. But the victories of the Transylvanian prince Bethlen Gábor (Gabriel Bethlen) over the imperialist troops forced Ferdinand to conclude the treaty of Nikolsburg, 31st December 1621. By this compact the privileges of the Protestants were declared inviolate,

[1] The world-famed Bibliotheca Corvina is variously estimated to have contained from 5000 to 10,000 volumes, chiefly manuscripts, many of which were bought from Greek scholars who had fled from Constantinople, or had been copied in different parts of Italy.

[2] In the Map Department of the British Museum there is a curious old print by H. van Schoel (1602), taken from an engraving by A. Lafrery (1566), which represents one of the Turkish attacks upon this fortress.

and Bethlen's claim to the principality of Transylvania and seven counties of Hungary Proper was established. The infringement of this treaty on the part of Ferdinand brought about a renewal of hostilities, which resulted in a second peace, concluded at Pozsony (Pressburg) in 1626. After the death of Bethlen in 1629, the Jesuits succeeded in gaining over several powerful families to the Roman Church, and the religious persecutions were renewed by Ferdinand III., who succeeded his father in 1637. The Transylvanians had elected George Rákóczy as their prince, who proclaimed himself the protector of Protestantism and of Hungarian liberty. Having drawn up a statement of grievances—those of the Protestants in particular—he laid the document before Ferdinand, who, however, paid no attention to it. Rákóczy thereupon collected troops and gained several successes over the imperialists (1644), and in the next year formed a league with the Swedes. This coalition brought Ferdinand into desperate straits, and he therefore soon entered into a treaty of peace with Rákóczy at Linz (16th December 1645). By this treaty, confirmed at the diet held in 1647, Rákóczy was formally recognized as the legitimate prince of Transylvania. He died the year afterwards (1648), and was succeeded by his son George II. Rákóczy. The year 1657 witnessed the death of Ferdinand III., who was succeeded by his second son Leopold I.[1]

During the long reign of this monarch, so injurious to the cause of Hungarian liberty, Hungary was the theatre of intestine wars, insurrections, and the most tragic events. Shortly after his accession, Leopold became involved in war with the Turks, who had created Michael Apaffi prince of Transylvania in the place of his own partisan John Kemény. The Turks, although at first successful, were ultimately defeated by the imperialists at St Gotthard, 1st August 1664. This victory enabled Leopold to conclude a hasty and disadvantageous peace at Vasvár (10th August) with the infidels, and to direct his whole energies against the Protestants. The irritation consequent upon this harsh treatment resulted in a conspiracy,[2] which was organized by the Croatian ban Peter Zrinyi, Count Frangepan, Francis Rákóczy, and the chief justice Nádasdi, and had for its object the separation of Hungary from the house of Hapsburg. The plot having been discovered, the leaders were surprised, conveyed to Vienna, and, with the exception of Rákóczy, executed (30th April 1671). Although an amnesty was proclaimed on the 6th of June of the same year, Leopold in February 1673 appointed a bigoted Catholic, John Caspar Ambringen, governor-general of the kingdom, and made every effort to extirpate the Protestant religion. The oppression becoming at last intolerable, the Protestants again rose in arms under Michael Teleki and Emeric Tökölyi (1678), and were subsequently supported by the grand vizier Kara Mustapha, who in 1683 marched straight to Vienna with a large force. The valour of Sobieski, king of Poland, delivered the city (12th September 1683), and saved Austria from the threatened destruction. In 1686 Buda was taken from the Turks by Charles of Lorraine, and these troublesome foes were at length driven out of most of the provinces and towns of Hungary where they had been settled for about a century and a half. The glory of these achievements was, however, tarnished by the emperor's revengeful treatment of the Hungarians, hundreds of whom, on suspicion of complicity with the enemy, were put to death upon the scaffold erected in the market-place of Eperies by order of General Caraffa, which remained standing from March 1687 till the end of the year. Leopold at length granted a general amnesty, but obliged the diet to declare the throne hereditary in the house of Austria, and to abrogate the clause of the Golden Bull which allowed the right of armed resistance to tyranny (31st October 1687). The victories of Prince Eugene, which completed the conquests over the Turks, resulted in the peace of Carlowitz, January 26, 1699, by which the Porte abandoned Hungary and Transylvania to the emperor. On the 5th May 1705 Leopold died, and was succeeded by his eldest son Joseph I. In the year 1703 Francis Rákóczy II. headed a new revolution, which lasted till May 1711, when peace was concluded at Szatmár by Károly, the chief of the Hungarian generals. The emperor Joseph I. died on the 17th April of the same year, and was succeeded by his brother the archduke Charles. From this time until 1848 no open rupture occurred between Hungary and her Hapsburg rulers.

By the treaty of Passarowitz, concluded 21st July 1718, Temesvár, the last of the Turkish possessions, reverted to Hungary. In 1722 Charles received the adhesion of the diet to the Pragmatic Sanction, which secured the right of succession to the throne in the female line. At the instigation of Russia hostilities were renewed against the Turks, but Prince Eugene being now dead, and no other leader of equal ability appearing in his place, the Austrians were subjected to a series of disgraceful defeats. These misfortunes were consummated by the humiliating treaty of Belgrade (18th September 1739), in accordance with which the emperor was forced to cede the fortress of Belgrade, with Servia and Austrian Wallachia. On the 20th October of the following year Charles died, leaving the throne to his daughter Maria Theresa. Her claims to the imperial dignity were almost immediately called in question by Prussia, Saxony, France, and Bavaria, and her hereditary dominions were invaded by hostile troops. Maria in despair fled to Pozsony (Pressburg), and summoned the Hungarian diet. Appearing before that assembly on the 11th September 1741, with her infant son Joseph in her arms, she appealed in Latin to the magnanimity and loyal spirit of the nobles. The result of her address was the unanimous declaration on their part: "Moriamur pro 'rege nostro' Maria Theresa." Nor was this an empty burst of enthusiasm, for the "insurrectio" or general rise of the nation was proclaimed, and a large army collected, and Hungarian blood was profusely shed in support of her cause. Maria repaid the devotion of her subjects by the zeal which she showed for their welfare, and the salutary changes which she effected in the country. Transylvania was raised into a grand principality (1765), and the town and district of Fiume declared a *corpus separatum* of the Hungarian crown (23d April 1779). Maria Theresa also created an Hungarian guard, established several schools, and enlarged the university at Nagyszombat (Tyrnau), which in 1777 was transferred to Buda, and seven years later to Pest. But her efforts to ameliorate the condition of the peasantry, and the reforms which she introduced under the name of the *Urbarium* (1765), which determined the rights of the tenant serfs in relation to the landowners, are among the chief merits of her reign. She died on the 29th November 1780, and was succeeded by her son Joseph II.

This philosophic monarch was wholly carried away by his zeal for reforms, which were both subversive of the constitution and opposed to the will of the nation. He refused to be crowned in Hungary, and thus avoided the obligations of the usual coronation oath. In defiance of ancient custom he carried the crown of St Stephen to Vienna, dispensed altogether with the use of diets, and governed the country autocratically by decrees. He issued

[1] The elder son of Ferdinand III., who in 1647 had been designated Ferdinand IV., died in 1654.

[2] Known as "Palatine Wesselényi's Plot." The palatine, however, died in 1667, prior to the failure of the movement.

a general edict of toleration in religious matters (October 1781), but forced upon the people heavy taxes and foreign officials; he moreover enjoined the exclusive use of the German language in the schools, courts of justice, and public administration. The general discontent at these measures was heightened by the unfavourable issue of the war against Turkey; and Joseph, shortly before his death (1790), found himself compelled to revoke nearly all his edicts, and promise redress to his irritated subjects. His brother and successor, Leopold II., appeased the Hungarians by more definitely confirming the rights and liberties of the nation than any of his predecessors. After a reign of only two years Leopold died, and was succeeded by his eldest son Francis I. (1792). This monarch duly swore to maintain the laws and constitution of Hungary, but his efforts were eventually directed wholly against them. During the continuance of his war with France he repeatedly convoked the states, only, however, for the purpose of obtaining supplies of men and money to carry on the struggle. Through the whole of this crisis the Hungarians faithfully supported the Austrian cause, and disdainfully rejected the offers of Napoleon in his proclamation of the 15th May 1809, calling upon them to rise for national independence. But at the end of the great war the Hungarian nation received little gratitude for its devotion. Francis for several years discontinued the holding of the diet, and acted in direct violation of the constitution by levying troops and increasing the taxation to more than double. The opposition which these arbitrary measures provoked in the counties at length obliged him in 1825 to convene the states, and thus appease the widespread dissatisfaction.

To the holding of this diet, in which Count Stephen Széchenyi initiated the use of the Magyar instead of the accustomed Latin tongue, may be traced not only a reaction in favour of the native language, but also the commencement of the reform movement. The spirit of nationality was fully aroused, and liberal sentiments were diffused over the whole kingdom, notwithstanding the active opposition of the Viennese court influenced by Metternich, in the reigns of both Francis and his successor Ferdinand (1835). The diets of 1832, 1839, and 1843 passed several measures of reform, amongst which the most important were those demanding the official use of the Magyar language, the equality of the various Christian confessions, and the rights of the peasantry and of the non-ennobled citizens. Amongst the leaders of the liberal party the magnates were Count Louis Batthyányi and Barons Nicholas Wesselényi and Joseph Eötvös, and the deputies Deák, Klauzál, Fáy, Beöthy, Balogh, Szemere, and Louis Kossuth. In the hope of intimidating the advanced liberals, the Viennese court in 1839 imprisoned Wesselényi and Kossuth, but they were released in 1840 owing to the amnesty then proclaimed for political offenders. The publication of the *Pesti Hirlap* (Pest Gazette) was commenced in 1841 by Kossuth as the organ of the liberal party. This paper, the leading articles of which were written in a spirit directly opposed to the policy of the Government, gained an immense circulation, and considerably influenced the public mind. A pamphlet styled *A Kelet Népe* (The People of the East), written by Széchenyi in order to counteract the schemes of Kossuth, only served to add to the importance of the *Pesti Hirlap*. The conservative journal *Világ* (Light) was conducted by Count Aurél Dessewffy, who from 1833 until his death in 1842 was the leader of the conservative party.

Meanwhile intellectual and material improvement made rapid progress, especially in the Hungarian capital. Numerous works, literary and political, were published, the former due to the encouragement offered by the Hungarian academy and the Kisfaludy society, the latter the outcome of the great political excitement prevailing throughout the country. Clubs really if not avowedly political were established in most of the principal towns. Steam navigation of the Danube, the Budapest suspension bridge (commenced May 1840), and other improvements of the means of internal communication, which had received their first impulse from Count Széchenyi, were rapidly proceeded with. In order to encourage native trade and industry, long obstructed by toll and custom duties, Kossuth called into existence the *Védegylet* (Protection Union), the members of which pledged themselves to abstain from the use of Austrian manufactures until the tariff should be reformed. This association soon overspread the country, and affected Austrian trade so seriously that some manufacturers had to transport their factories into Hungary in order to save themselves from ruin. The establishment of this association, the liberal measures of the late diets, and the unanimity of national feeling in Hungary Proper and Transylvania embarrassed the Government of Vienna, which could reckon only on the support of the Conservatives, whose numbers and moral influence were comparatively small. Metternich therefore determined to annihilate the municipal independence of the counties, in whose assemblies lay the real strength of the Liberals, by the appointment of "administrators" paid by the court to fill the places of all absent lord-lieutenants. This measure raised the political excitement of the nation to the highest pitch. The Liberals were soon divided into two parties, the so-called "municipalists," with Kossuth at their head, who urged the reaffirmation of the county institutions, and the "centralists," led by Szalay and Eötvös, who insisted upon the nomination of a responsible ministry. On the approach of the elections for the diet of 1847 these two parties agreed upon a common course of action. In November the diet was summoned, when Kossuth appeared as a candidate for the county of Pest, and after a warm contest was elected. On the 12th November the diet was opened at Pozsony (Pressburg) by Ferdinand V. in person, who by addressing the assembled states in the Magyar language instead of Latin produced a very favourable impression. The first act of the diet was the unanimous election of a successor to the late palatine Joseph in the person of his son the archduke Stephen. Thus far all was well, but the address to the throne containing clauses, inserted by Kossuth's party, deprecatory of unconstitutional measures by the Government, after passing the lower was rejected by the upper house, by which means the royal speech was practically ignored. At the commencement of the year 1848 an Act was carried through both houses, ordaining the exclusive use of the Magyar language in all branches of the administration, in legal documents, and in the schools and colleges. Certain provisions were, however, made respecting Croatia and Slavonia.

Upon the news of the French revolution the diet was powerfully impressed, and the Liberals assumed a more determined attitude. On the proposal of Kossuth it was unanimously resolved to send a deputation to Vienna demanding from the Government a responsible ministry, the abolition of all feudal burdens, the equalization of taxes, the extension of the franchise, freedom of the press, complete religious toleration, and several other measures of reform. On the 16th of March the address was presented to Ferdinand, who, by reason of the troubled state of his Italian provinces and the revolutionary aspect of Vienna, was compelled to yield his assent. The palatine archduke Stephen was nominated viceroy in Hungary, and Count Louis Batthyányi entrusted with the formation of a ministry. The irritation of the Viennese Government at this enforced compliance with the Hungarian demands was increased by the choice of Kossuth as minister of finance. On the 11th April Ferdinand repaired to Pozsony (Pressburg), and the diet was closed with a Magyar speech from the throne.

Events of 1848.

But the Austrian Government, although compelled to abandon for the present its position of open and direct hostility to the national will of the Hungarians, was determined by other means to prevent the new reforms from being carried out. The plan adopted was that of secretly encouraging the southern non-Magyar nationalities to assert their independence, and oppose by force of arms the consolidation of the new constitution. Croatia and Slavonia and the Bánát refused to submit to the Hungarian rule, and demanded separate rights and autonomous administration; while in Transylvania, the diet of which had proclaimed its reunion with Hungary Proper, the Wallachs and Saxons rose in arms against the Magyars. The whole of the south and south-west of the country was soon in a state of revolt, and a war of races was carried on with indescribable fury. Representations to the court of Vienna remained virtually unheeded, the emperor contenting himself with hypocritical proclamations against the rebels, and with placing at the disposal of the Hungarian ministry a few regiments of soldiers, whose officers were disaffected to the Hungarian cause.

It now became evident that the Hungarians, in order to retain their national existence, must rely entirely upon their own resources, and make an immediate and vigorous effort, more especially as Jellachich, the newly-appointed ban of Croatia, was making preparations to march upon Pest. Ferdinand, who still professed his determination to defend the integrity of the Hungarian monarchy, convoked the diet for the 5th of July, when it was opened by the palatine Stephen, as viceroy. At the suggestion of Kossuth a levy of 200,000 men and ample supplies for the purposes of national defence were unanimously voted; but to these measures Ferdinand withheld his assent. On the 6th of September a deputation of a hundred members arrived at Vienna in order to urge upon the emperor the necessity of taking immediate and decisive steps to oppose the Croatian invasion. On the 9th of September they were admitted to an audience, but, receiving only an evasive answer, they straightway returned to Pest. The abortive result of the deputation, and an official report that Jellachich had crossed the Drave, were announced to the diet on the 11th September, and brought matters to a crisis. A few days later the palatine archduke Stephen, who at the demand of the diet had set out for the camp, but failed in his efforts at mediation, fled to Austria. The emperor thereupon nominated Count Lamberg royal commissioner and commander-in-chief of all the military forces in Hungary (September 25), but the diet pronounced his appointment illegal and invalid, and he was murdered on the Budapest bridge of boats by the infuriated populace (September 28). The Batthyányi ministry now resigned, and a committee of national defence was formed under the presidency of Kossuth. On the 29th September, Jellachich, who had advanced to within 25 miles of Buda, was defeated at Velencze, whence he fled towards Vienna during a three days' armistice that was granted to him by General Móga. Ferdinand now declared openly against the Hungarians, annulled the decrees of the diet, and nominated Jellachich generalissimo of the forces to be employed for the reduction of Hungary. While the Austrian Government, still further exasperated at the march of a Hungarian force to Schwechat (30th October), was preparing for a general invasion, the Hungarian diet hastily equipped a large army to resist it. In the meantime a new Austrian ministry was formed at Vienna, and on the 2d December Ferdinand was induced to resign the imperial throne. He was succeeded by his nephew archduke Francis Joseph, son of Francis Charles, the heir-apparent, who refused to accept the crown. The Hungarian diet, however, protested against this dynastic change as unconstitutional.

Revolution.

Revolutionary war (1848–49).

On the 15th of December the main body of the Austrian army under Prince Windischgrätz began to cross the western frontier of Hungary near Bruck on the Leitha, while the Hungarian army of the Upper Danube, commanded by Görgei, who had succeeded Móga, retreated in the direction of Moson (Wieselburg). On the 18th December the second Austrian army corps occupied Pozsony (Pressburg), which the Hungarian troops had evacuated, and upon the same day Jellachich, who commanded the first army corps, occupied Moson, compelling Görgei to withdraw towards Györ (Raab). Upon the occupation of this town by the Austrians, on the 27th December, Görgei removed to Bábolna, where he hoped to effect a junction with Perczel, who had been ordered to reinforce him. But Perczel being overtaken and defeated at Móor on the 29th December by the troops of the ban, was obliged to beat a hasty retreat towards Székesfehérvár (Stuhlweissenburg). These reverses having rendered Budapest insecure, the diet and the committee of national defence on the 1st January 1849 transferred their seat to Debreczen, and on the night of the 4th and 5th the Hungarian troops marched out of the capital, which on the following day was taken possession of by Windischgrätz. Perczel, who had gathered together the remains of his corps at Budapest, followed the Government by way of Szolnok, while Görgei made a flank movement to the north, and led his corps by a circuitous route through the Carpathians to join the army on the Theiss. Windischgrätz, mindful of Schwechat, and, regarding the Hungarians as rebels, had refused to listen to a deputation headed by Count Batthyányi making proposals of peace, and Batthyányi himself was arrested. While the Austrian generals were making this rapid progress in Hungary Proper, the Polish general Bem had succeeded in organizing a large force in Transylvania, by means of which he reduced the refractory Wallachs to subjection, and drove the Austrians out of the principality, which had been forced to submit to General Puchner.

In the diet now held at Debreczen Kossuth declared that the nation was on the verge of destruction, and could only be saved by extraordinary measures. But the inactivity of Windischgrätz, who, instead of hastening onwards to the Theiss, remained for several weeks at Pest, gave the committee of national defence time to concentrate its forces, procure war material, and make other provisions for a determined resistance. On the 12th of February Görgei arrived at Kassa (Kaschau), and the two Hungarian armies could now act in concert. Meanwhile the national cause made little progress in the south, a great portion of which was in the hands of the enemy. On the 14th February the fortress of Eszék in Slavonia was lost to the Hungarians; that of Lipótvár (Leopoldstadt) in the north had already fallen on the 2d of the same month.

At length the main body of the Austrians under Windischgrätz advanced, and attacked the Hungarians under the Polish general Dembinski on the 26th and 27th February at Kápolna. The battle, though obstinately contested, proved indecisive, and the Hungarians were obliged to retire beyond the Theiss in order to recruit their forces. A few days later, however, an Hungarian corps, withdrawn from the lower Danube, and commanded by Damjanics, routed the Austrians under Grammont at Szolnok (5th March). Meanwhile the Russians, coming to the aid of the Austrians, had penetrated into Transylvania and occupied Nagyszeben (Hermannstadt) and Brassó (Kronstadt), but the Hungarians under Bem regained these fortresses on the 11th and 20th March, and drove the Russians into Wallachia.

By the middle of March an army of 120,000 men, provided with excellent generals and ample artillery, was concentrated on the Theiss. Towards the end of the month the Hungarians crossed the river at various points, and advanced on the road to Pest, under the command of Görgei, Damjanics, Aulich, Klapka, and others,—Guyon having been nominated to the commandership of Komárom (Komorn), the relief of which was the ultimate object of the campaign. The leadership of the Hungarian forces had meanwhile passed from Dembinski to Vetter, on account of whose ill-health it was provisionally transferred on the 31st March to Görgei. From this time the Austrians had to endure a rapid succession of defeats,—at Hatvan (April 2), Tápió-Bieske (April 4), Isaszeg (April 6), Gödöllö (April 7), and Vácz or Waitzen (April 10). In consequence of these reverses Windischgrätz was recalled, and the chief command of the Austrian troops was given to Baron Welden (April 12). In order to prevent the relief of Komárom, Welden opposed the advance of Görgei with a force under Wohlgemuth, which was, however, defeated by Damjanics on the 19th April at Nagy-Sarló, so that on the 22d the relief of the fortress of Komárom was effected upon the left bank of the Danube, Guyon having previously succeeded in passing through the hostile lines. The subsequent rout of the besieging forces at Uj-Szöny on the 26th April completed the discomfiture of the Austrians, and forced them to fly to the frontier. The ban Jellachich meanwhile retreated to Croatia, and nearly the whole country was once more in the hands of the Hungarians.

In the midst of these victories Kossuth proposed in the diet at Debreczen the dethronement of the Hapsburg dynasty, and upon the 14th April an act to that effect was almost unanimously passed, although afterwards unfavourably received by Görgei and a large portion of the army. The chief provocation to the passing of this extreme and, as it eventually proved, unfortunate measure was the promulgation of the new constitution on the 4th March by the emperor Francis Joseph, which made a *tabula rasa* of all the time-honoured laws, rights, and privileges of Hungary. The substance of the declaration of independence was as follows: "That the house of Hapsburg, having violated the integrity of the kingdom, treacherously levied war against the nation, and called in the aid of a foreign power to accomplish its aims, has trampled under foot all the treaties that united it to Hungary, and is therefore declared for ever excluded from the Hungarian throne." The form of government was to be settled afterwards by the diet, but in the meantime Kossuth was nominated governor, the committee of national defence was dissolved, and a new responsible ministry formed under the presidency of Szemere.

It is generally admitted that, had the Hungarians followed up their victories by an immediate march upon Vienna, they would have been able to force the Austrian Government to terms, and thus have warded off the Russian invasion, the preparations for which were now being conducted upon an enormous scale. Instead, however, of acting on the offensive across the Austrian frontier, the Hungarian commander-in-chief, Görgei, after a few days delay at Komárom, made a retrograde movement towards the Hungarian capital. On the 4th May he arrived before Buda, which was still in the possession of the Austrians, but it was in vain that he summoned the commander Hentzi to surrender. On the 15th began the regular bombardment of the fortress, and on the 21st it was taken by assault. On the 5th of June Kossuth made his entry into Pest, and the diet having adjourned its sittings at Debreczen, the Government returned to the capital. Every preparation was now set on foot for a desperate defence against the combined armies of Russia and Austria, which by the middle of the month had completed their arrangements, and had begun to invade the country at various points. Prince Paskewitch advanced from Galicia at the head of the main body of the Russian army, consisting of over 100,000 men, while Haynau crossed the western frontier with an Austrian force of 60,000, supported by a Russian division of 12,000 under Paniutin. On the Drave and the Styrian frontier Nugent commanded 12,000, and near Eszék was Jellachich with 25,000 men. In Transylvania the combined Austrian and Russian forces under Puchner and Lüders amounted to 60,000; so that, including the garrisons of the fortresses in their hands, the allied forces were in all not less than 275,000 men with 600 guns. The whole available forces of Hungary did not amount to more than half this number, the army of the Upper Danube under Görgei being 50,000, that of Perczel and Vécsey in the south 30,000, the army of the north under Dembinski 12,000; while there were about 32,000 men under

Bem in Transylvania, and a few thousands under Kazinczy in the county of Máramaros. On the 19th of June the Russian corps under Lüders burst through the Red Tower Pass into Transylvania, and, having defeated the Hungarians, took the fortress of Nagy-Szeben, whilst in the following month Brassó in like manner surrendered to the Austrians. Jellachich was, however, defeated on the 14th July at Hegyes, and forced to retire from the Bácska. In the meantime Haynau's operations on the Danube met with general success, while the Russian main army advanced over Eperies and Kassa into the interior of the country. These disasters to the Hungarian cause were aggravated by the want of unanimity between the Hungarian commander-in-chief and the Government, which, being again obliged to leave Pest, transferred its seat to Szeged (July 11). After various sanguinary engagements with the invading forces in the vicinity of Komárom, Görgei on the night of the 12th July left the fortress under the charge of Klapka. On the 15th and 17th Görgei encountered the Russians at Vácz, and proceeded thence over Vadkert, Losoncz, and Rimaszombat, where on the 21st the Russian offers of truce were refused. Görgei, closely followed, finally crossed the Theiss on the 28th July near Tokay, whence he proceeded in the direction of Nagyvárad (Grosswardein) by routes to the east of Debreczen. There on the 2d August his first army corps under Nagy Sándor was defeated by the troops of Paskewitch. The Government had meanwhile removed to Arad, which fortress, having previously surrendered to the Hungarians, was made the last point of general concentration. In Transylvania the army of Bem had been overpowered on the 31st July at Segesvár (Schässburg); and in Hungary Proper Dembinski retreated first to Szeged and Szöreg, whence he was repulsed on the 5th August by Haynau, and afterwards to Temesvár. There on the 9th he suffered an overwhelming defeat. Upon the news of this catastrophe reaching Arad on the night of the 10th to 11th, Görgei, who had already arrived there on the 9th by forced marches from Nagyvárad, induced Kossuth and the few ministers who were with him to lay down their authority, and upon the 11th received from them the supreme civil and military command. On the evening of the same day, after the departure of Kossuth for Lugos, the new dictator, believing further resistance hopeless, communicated with the Russian general Rüdiger, offering to surrender at discretion. The sally of Klapka from Komárom, and his signal victory over the besieging Austrian army (August 3), were unknown at Arad. On August 13 Görgei surrendered his army, consisting of some 24,000 men with 140 guns, to Rüdiger at Szöllös near Világos; on the 16th Kazinczy followed with his troops, and on the 17th Damjanics gave up the fortress of Arad, and on the 5th September a similar fate befell Peterwardein.

A few thousand men followed Bem and Guyon to Turkey, whither Kossuth and the late ministers Szemere, Casimir Batthyányi, and Mészáros, and the military leaders Dembinski, Vetter, Perczel, Kmetty, and Wysocki also escaped. On the 2d to 5th October Komárom capitulated on honourable terms, General Klapka having refused to surrender until an amnesty and free passports had been granted by the Austrians. On the 6th October Aulich, Damjanics, Dessewffy, Kiss, Knézich, Lahner, Lázár, Leiningen, Nagy-Sándor, Pöltenberg, Schweidel, Török, and Vécsey met their end at Arad. On the same day Count Louis Batthyányi, and subsequently Prince Woronieczki, Baron Jeszenak, Csányi, Perényi, and others suffered at Pest. By a decree of Haynau, to whom the Russians had delivered up the prisoners of war, all officers below the rank of a general, if not consigned to prison, were pressed as privates into the Austrian service. The Hungarian commander-in-chief Görgei, however, was pardoned, and interned at Klagenfurt in Carinthia.

Hungary now lay entirely prostrate, and was treated as a conquered country. The Russians retreated to the north and east, leaving the Austrians with their commander Haynau, who availed himself of the summary powers conferred on him by the state of siege to inflict the greatest cruelties on the vanquished people. Many of the Hungarian nobility were condemned to long terms of imprisonment; the estates of the richer patriots were confiscated; and numerous Austrian and Bohemian officials were thrust upon the exhausted country. A rigorous censorship of the press was at the same time enforced. At length, in July 1850, Haynau was removed from the chief authority. A milder régime was inaugurated by the archduke Albrecht, who arrived at Pest on the 14th October 1851 as the new civil and military governor. But it was only after the visit of the emperor to Hungary (5th June to 14th August 1852) that the military courts were closed. The whole country, now reduced to a province of the Austrian empire, was placed under the direct control of the central Government at Vienna. On the 1st May 1853 the new organization was carried into effect, and the Austrian civil code made applicable to Hungary. On the 8th September the Hungarian insignia of royalty, which had disappeared from Arad at the time of Kossuth's flight, were discovered in the neighbourhood of Orsova; they were conveyed on the 19th to Vienna, but were afterwards transferred to Buda. On the 17th April 1854 the state of siege was abolished, and on the 12th July 1856 an amnesty was proclaimed. On the 4th May of the following year the emperor visited Hungary, and on the 9th of the same month granted the restoration of their confiscated estates to late political offenders. In August he commenced a second progress through his Hungarian dominions, and availed himself of the opportunity to express his sentiments of consideration for the people.

Indeed, from this time (1857) both the emperor and the Government of Vienna seemed desirous of making the Hungarians forget the troubles of 1848 and 1849 by concessions to the national will, whilst the encouragement given to improvements in the means of communication, and to the new projects for the regulation of the Theiss, as also the schemes for the colonization of sparsely populated districts, are well worthy of notice. During the year the railways from Szeged to Temesvár and from Szolnok to Debreczen were opened. By an imperial decree issued at the end of 1858 agricultural colonists, if of one nationality and creed, were allowed to settle in various parts of Hungary, with special exemptions from taxation. By a ministerial order of the 8th August 1859 the language used in the higher schools was for the future to be regulated according to circumstances of nationality, the predominance of German being thereby abolished. On the 21st of the same month the absolutist minister Bach was dismissed, in consequence of the ill-success of the Italian war, which was attributed to his ill-advised policy against the various nationalities of the realm. The so-called "Protestant patent" of September 1st, which ostensibly granted the communes the free administration of their own educational and religious matters, was, however, the cause of much dissatisfaction, and more than 2,800,000 Protestants petitioned for its withdrawal. In April 1860 the archduke Albrecht was at his own desire removed from the civil and military governorship of Hungary, and the master of the ordnance, Benedek, a native Magyar, was appointed in his stead. The Hungarian members in the Reichsrath, specially summoned for the purpose of finding a definite form of settlement for the whole empire, now put forward claims for the autonomy of their country, and by an imperial diploma of the 20th October their wishes were partly met. Benedek was removed from the general governorship of the kingdom, whilst the Hungarian court chancellery was restored, and Baron Vay nominated chancellor. At the same time the *curia regia* (supreme court of judicature) and the county assemblies were reinstituted, and the Magyar recognized as the official language. Furthermore, the emperor on the 27th December granted the reannexation of the Temesvár Bánát to Hungary Proper. In the following February it was decreed that their former constitutions should be restored to Hungary, Transylvania, and Croatia and Slavonia, and on the 6th of April the diet met at Buda, afterwards removing to Pest. But as the address sent to Vienna in June demanded the fullest autonomy for Hungary, and the Hungarians refused to yield their claims, in spite of the emperor's declared inability to accede, the diet was dissolved by imperial decree on the 22d August. Meanwhile a new Hungarian court chancellor had been appointed in the person of Count Forgách. Stringent measures were taken by the Government of Vienna to counteract the organized passive resistance of the counties, and in many places the payment of the taxes was enforced by military aid. On the 27th October the holding of all public county meetings was forbidden, and administrators or coadjutors were in many counties thrust upon the lord-lieutenants, who were forced to submit to the authority of the newly-appointed Government superintendent Count Pálffy de Erdöd. On the 18th November 1862 a general amnesty was granted to those who were implicated by their hostility to the late Government measures. In the summer of 1863 Hungary suffered from a severe famine, but the Reichsrath voted 20 million florins to alleviate the distress. On the 22d April 1864 Count Forgách was replaced by Count Arminius Zichy, who, on account of his unpopularity, was on the 26th June 1865 removed for Count George Majláth, a Conservative. In a visit to Budapest on the 6th to 9th June 1865, the emperor declared his willingness to do justice to the constitutional demands of the Hungarians, as far as was consistent with the integrity of the empire. On the 18th July Count Pálffy de Erdöd was replaced by Baron Sennyey, one of the leaders of the old Conservative party. On the 14th December the diet was opened by the emperor in person, who assented to the principle of self-government for Hungary, and agreed to recognize the Pragmatic Sanction as the basis of a settlement of the questions involved. The diet, however, demanded also an acknowledgment of the continuity of the constitutional rights of 1848. After the outbreak of the war between Austria and Prussia the diet was prorogued (26th June 1866). Upon its reopening on the 19th November an imperial rescript was read in which the emperor acquiesced in the Hungarian demands for constitutional self-government, and promised to appoint a responsible ministry. The result of the "compromise" effected by Baron Beust between the Austrian Government and the committee, headed by Deák, empowered by the Hungarian diet, was the dualistic system of the Austrian-Hungarian monarchy, as finally sanctioned on the 18th February 1867. This arrangement secured to Hungary the restoration of the constitutional, legal, and administrative autonomy of 1848, while the supreme command

and direction of the army were assigned to the emperor-king. A responsible ministry, including Barons Wenckheim and Eötvös, Count Mikó, Melchior Lónyay, and others, was formed on the 20th February 1867, under the presidency of Count Andrássy. On the 8th of the following June the emperor and empress were crowned king and queen of Hungary at Budapest, and a complete pardon was proclaimed to all political offenders both at home and abroad.

The reconciliation of the Magyars with the Hapsburg dynasty being thus complete, both parties sought to throw a veil over the past by mutual concessions. Transylvania was incorporated with Hungary Proper, and a joint commercial contract was entered upon between Hungary and Austria. In like manner foreign affairs and joint finance were assigned to "common ministries." On the 8th of August 1868 the Hungarian house of representatives accepted the dual Government military scheme, by which the standing army remained under the direction of the imperial ministry of war. The *Honvéd* (home defence) army obtained its own special organization and commander-in-chief. The long-existing misunderstanding between Hungary and Croatia was at length settled by the agreement concluded in September, which placed the relations of Croatia to the Hungarian crown on a more equable footing than hitherto. After the passing of various other measures of reform, including the emancipation of the Jews, a compulsory education act, and a special act (November 29) for the consolidation of all nationalities under the crown of St Stephen, the session of the Hungarian diet was closed on the 10th December 1868. In the elections for the next session (1869–72) the Deák party, which had taken the lead in the previous diet, were returned by a large majority, and in the new diet, opened April 23, 1869, the policy of conciliation still prevailed. The ministry from time to time underwent certain modifications, owing to the death of Baron Eötvös, the minister of education (February 1871), the appointment of Count Lónyay (May 1870) to the imperial ministry of finance, and his subsequent nomination to the presidency of the Hungarian council in the place of Count Andrássy, who in November 1871 succeeded Beust as foreign minister of Austria-Hungary. Meanwhile the finances of Hungary were becoming rapidly embarrassed owing to the repeated contraction since 1867 of enormous loans for state railways and costly public works. The elections of 1872 were, however, again favourable to the Deák faction. At the end of November Lónyay retired from the presidency of the ministry, and on the 1st December was succeeded by Szlávy, who in March 1873 obtained the consent of the diet to some additional taxes. In August the Military Frontier districts were placed under civil jurisdiction, the eastern portion or the Servian-Bánát frontier being incorporated with Hungary Proper. The new cabinet was not more fortunate than that which had preceded it in a solution of the financial question, and in March 1874 made room for a coalition ministry under Bittó, with Ghyczy as finance minister. Upon its resignation in February 1875, in consequence of the refusal of the house to grant further taxation, a strong liberal combination was formed by Tisza from members of the left and of the former Deák party. The new ministry, under the presidency of Wenckheim (3d March), was supported by an overwhelming majority in the elections for the new session (1875–78). On the 16th October Tisza, minister of the interior, was nominated president, and the financial difficulty was met by an advance in the income tax, and a fresh loan. The death of Deák on the 29th January 1876 cast a gloom over the whole country. For some time previously he had withdrawn from the field of politics, where less moderate but more distinctly Magyarizing tendencies now prevailed. By its resolutions of the 24th and 27th March 1876 the diet deprived of their former privileges the so-called "Saxon" sees and districts in Transylvania. From these new counties were formed on the system adopted for the rest of Hungary, and were placed under the general administration. The number of royal free towns in Hungary was, moreover, much reduced, especially in the Transylvanian circle. The insurrectionary state of the Slavic provinces of Turkey excited the apprehensions of the Magyars with regard to the Slav races of southern Hungary, and aroused a strong feeling of sympathy for the Porte. This was still further increased by the attitude of Russia, and the cordiality towards the Magyars evinced by the sultan Abdul Hamid II., who in 1877 presented the university of Budapest with a portion of the remains of the library of Matthias Corvinus. During the course of the war between Turkey and Russia the Magyars were with difficulty restrained from open manifestations in favour of the former and against the latter power. Nevertheless, after the conclusion of peace, Hungary had, in conformity with the requirements of Art. XXV. of the Berlin Treaty (July 1878), to furnish her quota of troops for the occupation of Bosnia and the Herzegovina, a task effected only with a considerable loss of men, and an additional burden on the state finances. The diet having been closed by the king on the 30th June, the new elections were held at the time the struggle for the occupation of Bosnia was progressing. The popular excitement in Hungary Proper was very great, both on account of the losses suffered by the Hungarian troops and the destruction by a violent thunderstorm of the town of Miskolcz. On the 3d October Széll, minister of finance, resigned office; other ministers also tendered their resignations, but were induced to retain their posts for a time. In the elections the majority of votes had fallen to the Liberal or Government party. On the 20th October the Hungarian parliament was opened, and at the beginning of December the reconstruction of the ministry was completed, the only new members being, for finance Count Szapáry, and for commerce Baron Kemény. On the 14th a sum of 20,000,000 florins was granted for the occupation expenses of the following year.

Early in the spring of 1879 the attention of all parties was for a time distracted from political matters by the disastrous inundation of Szeged. At the beginning of May the friendly relations of the non-Magyar nationalities of Hungary, and more particularly of the Roumanians of Transylvania, towards the Magyars seemed to be endangered by the passing of the amended education bill ordering the state language to be taught in all the non-Magyar primary schools. The new law, as affecting many nationalities, is likely to have an important bearing on the future of Hungary. The urgent necessity for more extended river embankments and a better system of dykes and dredging in the water-coursed levels of the midland Trans-Tisian counties became more than ever apparent in December, when inundations of the triple Körös and the Maros submerged many villages, farms, and pasturages, devastated large portions of Nagyvárad (Grosswardein), Arad, and other low-lying communes, and rendered thousands of persons homeless. In March 1880 a loan of 40,000,000 florins was raised for the purposes of regulating the Theiss and the Maros, and of rebuilding and securing the town of Szeged.

Bibliography.—Besides the great historical works in the native language, by Szalay, Jászay, Szilágyi, Count Teleki, and Michael Horváth, noticed under LITERATURE below, and the useful summary by Gideon Ladányi, *Magyarország Törtenelme* (Debreczen, 1867), we mention for those who are unacquainted with Hungarian—Engel, *Geschichte des ungrischen Reichs* (Vienna, 1813-14, 5 vols.); Fessler, *Geschichte der Ungarn und ihrer Landsassen* (3d ed., Leipsic, 1867-68, 5 vols.); Mailáth, *Geschichte der Magyaren* (2d ed., Ratisbon, 1852-53, 5 vols); the German edition of Szalay, by Wögerer (Pest, 1870-75, 3 vols.); Horváth, *Kurzgefasste Geschichte Ungarns* (Pest, 1863, 2 vols.), and *Fünfundzwanzig Jahre aus der Geschichte Ungarns*, 1823-48 (Leipsic, 1867, 2 vols.), both translated from the Hungarian; and Rogge, *Oesterreich von Világos bis zur Gegenwart* (Leipsic, 1872-73, 3 vols.). To these may be added—E. Szabad, *Hungary Past and Present* (Edinburgh, 1854); E. L. Godkin, *History of Hungary and the Magyars* (London, 1853); Sayous, *Histoire Générale des Hongrois* (Paris, 1876, 2 vols.), and *Histoire des Hongrois et de leur littérature politique de 1790 à 1815* (Paris, 1872). For the revolutionary period see Genl. Görgei, *My Life and Acts in Hungary* (London, 1852, 2 vols.), and Genl Klapka, *Memoirs* (London, 1850, 2 vols.), both translated from the German; and Szemere, *Hungary from 1848 to 1860* (London, 1860). See also A. J. Patterson, *The Magyars, their Country and Institutions* (London, 1869, 2 vols.), and the anonymous *Francis Deák, a Memoir* (London, 1880).

III. Language.

The Magyar or native Hungarian language is of Asiatic origin, belonging to the northern or Ural-Altaic (Finnic-Tataric) division of the Turanian Family, and forming along with the Ugro-Ostiakian and Vogul dialects the Ugric branch of that family. The affinity existing between the Magyar and the Finnic languages, first noticed by John Amos Comenius (Komensky) in the middle of the 17th century,[1] and later by Olav Rudbeck[2], Leibnitz[3], Strahlenberg,[4] Eccard, Sajnovics[5], and others, has been proved "grammatically" by Samuel Gyarmathi, in his work entitled *Affinitas linguæ Hungaricæ cum linguis Finnicæ originis grammatice demonstrata* (Göttingen, 1799). The Uralian travels of Anthony Reguly (1843–45), and the philological labours of Paul Hunfalvy and Joseph Budenz, may be said to have established it as an almost incontrovertible fact. The chief points of resemblance to Turco-Tataric and Mongolic dialects have been specially treated by Arminius Vámbéry (1870) and Gabriel Bálint (1877), the well-known recent travellers in Central Asia. Körösi-Csoma for many years zealously but unsuccessfully sought after traces of the origin of the nation and the language in Tibet. His grammar and dictionary of Tibetan, published by the Asiatic Society in 1834, have, however, earned for him a lasting name. The theory of Paul Beregszászi that the Magyar is related to many of the so-called "Oriental" languages[6] has now few supporters.

Although for nearly a thousand years established in Europe and subjected to Aryan influences, the Magyar language has yet retained its essential Turanian features, and the etymology and syntax still preserve these as their chief characteristics. The grammatical forms are expressed, as in Turkish, by means of affixes modulated according to the high or low vowel power of the root or chief syllables of the word with which they are connected,—the former being represented

[6] *Ueber die Aehnlichkeit der hungarischen Sprache mit den Morgenländischen*, Leipsic, 1796.

by *e*, *ö*, *ő*, *ü*, *ű*, the latter by *a*, *á*, *o*, *ó*, *u*, *ú*; the sounds *é*, *i*, *í* are regarded as neutral. Since the number of consonants exceeds that of the Latin alphabet which represents them, the following combinations, forming single articulations, and inseparable as consonants, are used to make up the deficiency:—*cs*, *cz*, *gy*, *ly*, *ny*, *sz*, *ty*, *zs*, and in a few words *dzs*. Among the striking peculiarities of the language are the definite and indefinite forms of the active verb, *e.g.*, *látom*, "I see" (definite, viz., "him," "her," "the man," &c.), *látok*, "I see" (indefinite); the insertion of the causative, frequentative, diminutive, and potential syllables after the root of the verb, *e.g.*, *ver*, "he beats"; *veret*, "he causes to beat"; *veroget*, "he beats repeatedly"; *verint*, "he beats a little"; *verhet*, "he can beat"; the mode of expressing possession by the tenses of the irregular verb *lenni*, "to be" (viz., *van*, "is"; *vannak*, "are"; *volt*, "was"; *lesz*, "will be," &c.), with the object and its possessive affixes, *e.g.*, *nekem vannak könyveim*, literally, "to me are books—my" = "I have books"; *neki volt könyve*, "to him was book—his" = "he had a book." Other characteristic features are the use of the singular substantive after numerals, and adjectives of quantity, *e.g.*, *két ember*, literally, "two man"; *sok szó*, "many word," &c.; the position of the Christian name and title after the family name, *e.g.*, *Ólmosy Károly tanár ur*, "Mr Professor Charles Ólmosy"; and the possessive forms of the nouns, which are varied according to the number and person of the possessor and the number of the object in the following way: *tollam*, "my pen"; *tollaim*, "my pens"; *tollad*, "thy pen"; *tollaid*, "thy pens"; *tollunk*, "our pen"; *tollaink*, "our pens," &c. But, although presenting no auxiliary verb "to have," no primitive possessive pronouns, no gender nor even separate pronominal forms and terminations for the distinction of the sexes, and (suffixed syllables or postpositions being used instead) hardly any true declension for objective terms, the Magyar far surpasses every Teutonic, Slavonic, Italic, and other Indo-European or Aryan language in the wealth of its verbal formations, as also in the power of harmonizing and assimilating the determinatives to the roots. Logical in its derivatives and in its grammatical structure, the Magyar language is, moreover, copious in idiomatic expressions, rich in its store of words, and almost musical in its harmonious intonation. It is, therefore, admirably adapted for both literary and rhetorical purposes.

The first Hungarian grammar known is the *Grammatica Hungaro-Latina* of John Erdösi *alias* Sylvester Pannonius, printed at Sárvár-Ujsziget in 1539. Among the grammatical works of recent date are the posthumous treatises of Nicholas Révai (Pest, 1809); the *Magyar nyelvmester* of Samuel Gyarmathi, published at Klausenburg in 1794; and the various grammars for the use of Germans, by J. Farkas (9th ed., Vienna, 1816), Mailáth (2d ed., Pest, 1832), Kis (Vienna, 1834), Márton (8th ed., Vienna, 1836), Maurice Ballagi or (in German) Bloch (5th ed., Pest, 1869), Töpler (Pest, 1854), Riedl (Vienna, 1858), Schuster (Pest, 1866), Charles Ballagi (Pest, 1868), Remélc (Pest and Vienna, 1869), Roder (Budapest, 1875), Führer (Budapest, 1878), and Ney (20th ed., Budapest, 1879). One of the best modern grammars for the French is that of C. E. De Ujfalvy (Paris, 1876). Two Hungarian grammars have also appeared in English by S. Wékey (London, 1852), and J. Csink (London, 1853).

The earliest lexicon is that of Gabriel (Mizsér) Pesti *alias* Pestinus Pannonius, *Nomenclatura sex linguarum, Latinæ, Italicæ, Gallicæ, Bohemicæ, Ungaricæ, et Germanicæ* (Vienna, 1538), which was several times reprinted. The *Vocabula Hungarica* of Bernardino Baldi (1583), the original MS. of which is in the Biblioteca Nazionale at Naples, contains 2899 Hungarian words with renderings in Latin or Italian.[1] In the *Dictionarium undecim linguarum* of Calepinus (Basel, 1590) are found also Polish, Hungarian, and English words and phrases. This work continued to be reissued until 1682. The *Lexicon Latino-Hungaricum* of Albert Molnár first appeared at Nuremberg in 1604, and with the addition of Greek was reprinted till 1708. Of modern Hungarian dictionaries the best is that of the Academy of Sciences, containing 110,784 articles in 6 vols., by Czuczor and Fogarasi (Pest, 1862–74). The next best native dictionary is that of Maurice Ballagi, *A Magyar nyelv teljes szótára*, (Pest, 1868–73). In addition to the above may be mentioned the work of Kresznerics, where the words are arranged according to the roots (Buda, 1831–32); the *Etymologisches Wörterbuch...aus chinesischen Wurzeln*, of Podhorszky (Paris, 1877); the *Magyar-ugor összehasonlító szótár* (Magyar-Ugrian Comparative Dictionary) of Budenz (Budapest, 1872, &c.); and that of new words, with German and Latin equivalents, by Kunoss (Pest, 1843). Other and more general dictionaries for German scholars are those of Márton (*Lexicon trilingue Latino-Hungarico-Germanicum*, Vienna, 1818–23), A. F. Richter (Vienna, 1836), E. Farkas (Pest, 1848–51), Fogarasi (4th ed., Pest, 1860), Loos (Pest, 1869), and M. Ballagi (Budapest, 3d ed. 1872–74). There are, moreover, Hungarian-French dictionaries by Kiss and Karády (Pest and Leipsic, 1844–48) and Babos and Molé (Pest, 1865), and English-Hungarian dictionaries by Dallos (Pest, 1860) and Bizonfy (Budapest, 1878).

IV. Literature.

The comparatively restricted and unobtrusive character of the Magyar or native Hungarian literature is partly owing to the fact that there are so many other languages current in Hungary, but it is chiefly to be attributed to the almost exclusive recognition, through many centuries, of Latin as the vehicle of cultured thought. The Romish ecclesiastics who settled in Hungary during the 11th century, and who found their way into the chief offices of the state, were mainly instrumental in establishing Latin as the predominant language of the court, the higher schools, and public worship, and of eventually introducing it into the administration. Having thus become the tongue of the educated and privileged classes, Latin continued to monopolize the chief fields of literature until the revival of the native language at the close of the 18th century.

Early Latin chronicles.

Amongst the earliest Latin works that claim attention are the "Chronicle" (*Gesta Hungarorum*), by the "anonymous notary" of King Béla, probably Béla II. (see Podhradczky,[2] *Béla király névtelen jegyzője*, Buda, 1861, p. 48), which describes the early ages of Hungarian history, and may be assigned to the middle of the 12th century; the *Carmen Miserabile* of Rogerius; the *Liber Cronicorum* of Simon Kézai, belonging to the end of the 13th century, the so-called "Chronicon Budense," *Cronica Hungarorum*, printed at Buda in 1473 (Eichhorn, *Geschichte der Litteratur*, ii. 319); and the *Chronicon Rerum Hungaricarum* of John Thuróczi.[3] An extraordinary stimulus was given to literary enterprise by king Matthias Corvinus, who attracted both foreign and native scholars to his court. Foremost amongst the Italians was Antonio Bonfini, whose work, *Rerum Hungaricarum Decades IV.*, comprising Hungarian history from the earliest times to the death of King Matthias, was published with a continuation by Sambucus (Basel, 1568).[4] Marzio Galeotti, the king's chief librarian, wrote an historical account of his reign. The most distinguished of the native scholars was John Cesinge *alias* Janus Pannonius, who composed Latin epigrams, panegyrics, and epic poems. The best edition of his works was published by Count S. Teleki at Utrecht in 1784.

Magyar literature. Earliest relics.

As there are no traces of literary productions in the native or Magyar dialect before the 12th century, the early condition of the language is concealed from the philologist. It is, however, known that the Hungarians had their own martial songs, and that their princes kept lyre and lute players who sang festal odes in praise of the national heroes. In the 11th century Christian teachers introduced the use of the Roman letters, but the employment of the Latin language was not formally decreed until 1114 (see Bowring, *Poetry of the Magyars*, Introd. xix.). It appears, moreover, that up to that date public business was transacted in Hungarian, for the decrees of King Coloman the Learned (1095–1114) were translated from that language into Latin. Among the literary relics of the 12th century are the "Latiatuc" or *Halotti Beszéd* funeral discourse and prayer in Hungarian, to which Döbrentei in his *Régi Magyar Nyelvemlékek* assigns as a probable date the year 1171 (others, however, 1182 or 1183). From the *Margit-Legenda*, or "Legend of St Margaret," composed in the early part of the 14th century,[5] it is evident that from time to time the native language continued to be employed as a means of religious edification.

Arpadian period (1000–1301).

Anjou-Sigismond period (1301–1437).

Under the kings of the house of Anjou, the Magyar became the language of the court. That it was used also in official documents and ordinances is shown by copies of formularies of oaths, the import of which proves beyond a doubt that the originals belonged to the reigns of Louis I. and Sigismond; by a statute of the town of Sajó-St-Peter (1403) relating to the wine trade; by the testament of Kazzai-Karácson (1413); and by other relics of this period published by Döbrentei in vol. ii. of the *R. M. Nyelvemlékek*. To the early part of the 15th century may be assigned also the legends of "St Francis" and of "St Ursula," and possibly the original of the *Ének Pannónia megvételéről*, an historical "Song about the Conquest of Pannonia." But not until the dawn of the Reformation did Magyar begin in any sense to replace Latin for literary purposes. The period placed by Hungarian authors between 1437 and 1530 marks the first development of Magyar literature.

Matthias or pre-Reformation period (1437–1530).

About the year 1437 two Hussite monks named Tamás and Bálint (*i.e.*, Thomas and Valentine) adapted from older sources a large portion of the Bible for the use of the Hungarian refugees in Moldavia. To these monks the first extant Magyar version of part of the Scriptures (the *Vienna* or *Révai Codex*[6]) is directly assigned

---

[1] See Count Géza Kuun's "Lettere Ungheresi," *La Rivista Europea*, anno vi., vol. ii. fasc. 3, pp. 561–62, Florence, 1875.

[2] So also Jámbor (*A Magyar Irod. Tört.*, Pest, 1864, p. 104). Környel, Imre, and others incline to the belief that it was Béla I., and that consequently the "anonymous notary" belongs rather to the 11th than to the 12th century.

[3] An example of this work, printed on vellum in Gothic letter (Augsburg, 1488), and formerly belonging to the library of Matthias Corvinus, king of Hungary, may be seen in the British Museum. Of the three first-mentioned chronicles Hungarian translations by Charles Szabó appeared at Budapest in 1860, 1861, and 1862.

[4] Both this and the later editions of Frankfort (1581), Cologne (1690), and Pressburg (1744) are represented in the British Museum.

[5] The only copy existing at the present time appears to have been transcribed at the beginning of the 16th century. Both this and the *Halotti Beszéd* (Pray Codex) are preserved in the National Museum at Budapest.

[6] This codex contains Ruth, the lesser prophets, and part of the Apocrypha. According to Toldy, it is copied from an earlier one of the 14th century.

by Döbrentei, but the exact date either of this copy or of the original translation cannot now be ascertained. With approximate certainty may be ascribed also to Tamás and Bálint the original of the still extant transcript, by George Németi, of the Four Gospels, the *Jászay* or *Munich Codex* (finished at Tátros in Moldavia in 1466). Amongst other important codices are the *Jordánszky Codex* (1516–19), an incomplete copy of the translation of the Bible made by Ladislaus Bátori, who died about 1456; and the *Döbrentei* or *Gyulafehérvár Codex* (1508), containing a version of the Psalter, Song of Solomon, and the liturgical epistles and gospels, copied by Bartholomew Halabori from an earlier translation (Környei, *A Magyar nemzeti irodalomtörténet vázlata*, 1861, p. 30). Other relics belonging to this period are the oath which John Hunyady took when elected governor of Hungary (1446); a few verses sung by the children of Pest at the coronation of his son Matthias (1458); the *Siralomének Both János veszedelmén* (Elegy upon John Both), written by a certain "Gregori," as the initial letters of the verses show, and during the reign of the above-mentioned monarch; and the *Emlékdal Mátyás király halálára* (Memorial Song on the Death of King Matthias, 1490). To these may be added the rhapsody[1] on the taking of "Szabács" (1476); the *Katalin-Legenda*, a metrical "Legend of St Catherine of Alexandria," extending to over 4000 lines; and the *Feddöének* (Upbraiding Song), by Francis Apáthi.

Reformation period (1530–1606).

In the next literary period (1530–1606) several translations of the Scriptures are recorded. Among these there are—versions of the Epistles of St Paul, by Benedict Komjáti (Cracow, 1533); of the Four Gospels, by Gabriel (Mizsér) Pesti (Vienna, 1536); of the New Testament, by John Erdösi (Ujsziget, 1541; 2d ed., Vienna, 1574[2]), and by Thomas Félegyházi (1586); and the translations of the Bible, by Caspar Heltai (Klausenburg, 1551–65), and by Caspar Károli (Vizsoly, near Göncz, 1589–90). The last, considered the best, was corrected and re-edited by Albert Molnár at Hanau in 1608.[3] Heltai published also (1571) a translation, improved from that by Blasius Veres (1565), of the *Tripartitum* of Verböczy, and *Chronika* (1575) adapted from the *Decades* of Bonfini. Karádi in 1569 brought to light the earliest national drama, *Balassi Menyhért*. Among the native poets, mostly mere rhyming chroniclers of the 16th century, were Csanádi, Tinódi, Nagy-Báczai, Bogáti, Ilósvay, Istvánfi, Görgei, Temesvári, and Valkai. Of these the best and most prolific writer was Tinódi. Székely wrote in prose, with verse introduction, a "Chronicle of the World" under the title of *Cronica ez világnac yeles dolgairól* (Cracow, 1559). Csáktornya and Kákony imitated the ancient classical poets, and Erdösi introduced the hexameter. Andrew Farkas and the homilist Peter Melius (Juhász) attempted didactic verse; and Batizi busied himself with sacred song and Biblical history. During the latter part of the 16th century and the beginning of the 17th two poets of a higher order appeared in Valentine Balassa, the earliest Magyar lyrical writer, and his contemporary John Rimay, whose poems are of a contemplative and pleasing character.

17th century period (1606–1711)

The melancholy state of the country consequent upon the persecutions of Rudolph I., Ferdinand II., and Leopold I., as also the continual encroachment of Germanizing influences under the Hapsburgs, were unfavourable to the development of the national literature during the next literary period, dating from the Peace of Vienna (1606) to that of Szatmár (1711). A few names were, however, distinguished in theology, philology, and poetry. In 1626 a Hungarian version of the Vulgate was published at Vienna by the Jesuit George Káldi,[4] and another complete translation of the Scriptures, the so-called *Komáromi Biblia* (Komorn Bible) was made in 1685 by the Protestant George Csipkés, though it was not published till 1717 at Leyden, twenty-nine years after his death.[5] On behalf of the Catholics the Jesuit Peter Pázmán, eventually primate, Nicholas Eszterházy, Sámbár, Balásfi, and others were the authors of various works of a polemical nature. Especially famous was the *Hodægus, kalauz* of Pázmán, which first appeared at Pozsony (Pressburg) in 1613. Among the Protestants who exerted themselves in theological and controversial writings were Németi, Alvinczy, Alexander Felvinczy, Mártonfalvi, and Melotai, who was attached to the court of Bethlen Gábor. Telkibányai wrote on "English Puritanism" (1654). The Calvinist Albert Molnár, already mentioned, was more especially remarkable for his philological than for his theological labours. Párispápai compiled an Hungarian-Latin Dictionary, *Dictionarium magyar és deák nyelven* (Löcse, 1708), and Apáczai-Csere, a *Magyar Encyclopædia* (Utrecht, 1653). John Szalárdi, Paul Lisznyai, Gregory Pethö, John Kemény, and Benjamin Szilágyi, which last, however, wrote in Latin, were the authors of various historical works. In polite literature the heroic poem *Zrinyiász* (1651), descriptive of the fall of Sziget, by Nicholas Zrinyi, grandson of the defender of that fortress, marks a new era in Hungarian poetry. Of a far inferior character was the monotonous *Mohácsi veszedelem* (Disaster of Mohács), in 13 cantos, produced two years afterwards at Vienna by Baron Liszti. The lyric and epic poems of Stephen Gyöngyösi, who sang the deeds of Maria Széchy, the heroine of Murány, *Murányi Venus* (Kassa, 1664), are samples rather of a general improvement in the style than of the purity of the language. As a didactic and elegiac poet Stephen Kohári is much esteemed, though his poems are of a very serious and contemplative turn. More fluent but not less gloomy are the sacred lyrics of Nyéki-Veres first published in 1636 under the Latin title of *Tintinnabulum Tripudiantium*. The songs and proverbs of Peter Beniczky, who lived in the early part of the 17th century, are not without merit, and have been several times reprinted. We may here mention that, from the appearance of the first extant printed Magyar work[6] at Cracow in 1531 to the end of the period we have just been treating of, more than 1800 publications in the native language are known.[7]

Period of decline (1711–1772).

The period comprised between the peace of Szatmár (1711) and the year 1772 is far more barren in literary results than even that which preceded it. The exhaustion of the nation from its protracted civil and foreign wars, the extinction of the court of the Transylvanian princes where the native language had been cherished, and the prevalent use of Latin in the schools, public transactions, and county courts, all combined to bring about a complete neglect of the Magyar language and literature. Among the few prose writers of distinction were Andrew Spangár, whose "Hungarian Bookstore," *Magyar Könyvtár* (Kassa, 1738), is said to be the earliest work of the kind in the Magyar dialect; George Bárányi, who translated the New Testament (Lauba, 1754); the historians Michael Cserei and Matthew Bél, which last, however, wrote chiefly in Latin; and Peter Bod, who besides his theological treatises compiled a history of Hungarian literature under the title *Magyar Athénás* (Szeben, 1766). But the most celebrated writer of this period was the Jesuit Francis Faludi, the translator, through the Italian, of William Darrell's works. On account of the classic purity of his style in prose Faludi was known as the "Magyar Cicero." Not only as a philosophic and didactic writer, but also as a lyric and dramatic poet he surpassed all his contemporaries. Another pleasing lyric poet of this period was Ladislaus Amade, the naturalness and genuine sentiment of whose lightly running verses are suggestive of the love songs of Italian authors. Of considerable merit are also the sacred lyrical melodies of Paul Rádai in his *Lelki hódolás* (Spiritual Homage), published at Debreczen in 1715. Among the didactic poets may be mentioned Lewis Nagy, George Kálmár, John Illey, and Paul Bertalanfi, especially noted for his rhymed "Life of St Stephen, first Hungarian king," *Dicsöséges Sz. István elsö magyar királynak élete* (Vienna, 1751).

The remaining three literary periods stand in special relationship to one another, and are sometimes regarded as the same. The first two, marking respectively the progress of the "Regeneration of the Native Literature" (1772–1807) and the "Revival of the Language" (1807–1830), were introductory to and preparatory for the third or "Academy" period, which dates from the year 1830, and comprises the results of the native language and literature in the highest state of cultivation.

Regeneration of the literature (1772–1807).

In consequence of the general neglect of the Magyar language during the reigns of Maria Theresa and her successor Joseph II., the more important prose productions of the latter part of the 18th century, as for instance the historical works of George Pray, Stephen Katona, John Engel, and Ignatius Fessler, were written either in Latin or in German. The reaction in favour of the native literature manifested itself at first chiefly in the creation of various schools of poetry. Foremost among these stood the so-called "French" school, founded by George Bessenyei, the author of several dramatic pieces, and of an imitation of Pope's "Essay on Man," under the title of *Az embernek próbája* (Vienna, 1772). Bessenyei introduced the use of rhymed alexandrines in place of the monotonous Zrinian measure. Other writers of the same school were Laurence Orczy and Abraham Barcsay, whose works have a striking resemblance to each other, and were published together by Révai (1789). The songs and elegies of the short-lived Paul Ányos, edited by Bacsányi in 1798, show great depth of feeling. Versifiers and adapters from the French appeared also in Counts Adam and Joseph Teleki, Alexander Báróczi, and Joseph Péczeli, known also as the translator of Young's "Night Thoughts." The chief representatives of the strictly "classical" school, which adopted the ancient Greek and Latin authors as its models, were David Baróti Szabó, Nicholas Révai, Joseph Rájnis, and Benedict Virág. Among the most noteworthy works of Baróti are the *Uj mértékre vett külömb versek* (Kassa, 1777), comprising hexameter verses, Horatian odes, distiches, epistles, and epigrams; the *Paraszti Majorság* (Kassa, 1779–80), an hexameter version of Vanière's *Prædium rusticum*; and an abridged version of "Paradise Lost," contained in the *Költeményes munkaji* (Komárom, 1802). Baróti, moreover, published (1810–13) a translation of Virgil's *Æneid* and *Eclogues*. Of Baróti's

[1] First made known by Coloman Thaly (1871) from a discovery by MM. E. Nagy and D. Véghelyi in the archives of the Csicsery family, in the county of Ung.

[2] One of the only seven perfect copies extant of the Vienna (1574) edition is in the British Museum library.

[3] A copy, with the autograph of the editor, is in the British Museum.

[4] A copy is in the British Museum library.

[5] There are two copies of this edition in the British Museum library.

[6] The earliest, styled "Song on the Discovery of the right hand of the Holy King Stephen," and printed at Nuremberg by Anton Koburger in 1484. is lost.

[7] See Chas. Szabó's *Régi Magyar Könyvtár*, Budapest, 1879. *Cf.* also *Lit. Ber. aus Ungarn* for 1879, Bd. iii. Heft 2, p. 433–434.

purely linguistic works the best known are his *Ortographia és Prosodia* (Komárom, 1800); and the *Kisded Szótár* (Kassa, 1784 and 1792) or "Small Lexicon" of rare Hungarian words. As a philologist Baróti was far surpassed by Révai, whose linguistic labours have already been alluded to (see above, LANGUAGE); but as a poet he may be considered superior to Rájnis, translator of Virgil's *Bucolics* and *Georgics*, and author of the *Magyar Helikonra vezetö kalauz* (Guide to the Magyar Helicon, 1781). The "classical" school reached its highest state of culture under Virág, whose poetical works, consisting chiefly of Horatian odes and epistles, on account of the perfection of their style, obtained for him the name of the "Magyar Horace." The *Poetai Munkai* (Poetical Works) of Virág were published at Pest in 1799, and again in 1822. Of his prose works the most important is the *Magyar Századok* or "Pragmatic History of Hungary" (Buda, 1808 and 1816). Vályi-Nagy, the first Magyar translator of Homer, belongs rather to the "popular" than the "classical" school. His translation of the *Iliad* appeared at Sárospatak in 1821. The establishment of the "national" or "popular" school is attributable chiefly to Andrew Dugonics, though his earliest works, *Troja veszedelme* (1774) and *Ulysses* (1780), indicate a classical bias. His national romances, however, and especially *Etelka* (Pozsony, 1787) and *Az arany pereczek* (Pest and Pozsony, 1790), attracted public attention, and were soon adapted for the stage. The most valuable of his productions is his collection of "Hungarian Proverbs and Famous Sayings," which appeared in 1820 at Szeged, under the title of *Magyar példabeszédek és jeles mondások*. The most noteworthy follower of Dugonics was Adam Horváth, author of the epic poems *Hunniász* (Györ, 1787) and *Rudolphiász* (Vienna, 1817). Joseph Gvadányi's tripartite work *Falusi notárius* (Village Notary), published between 1790 and 1796, as also his *Rontó Pál és gr. Benyowszky történetcik* (Adventures of Paul Rontó and Count Benyowski), are humorous and readable, but careless in style. As writers of didactic poetry may be mentioned John Endrödy, Caspar Göböl, Joseph Takács, and Barbara Molnár, the earliest distinguished Magyar poetess.

Of a more general character, and combining the merits of the above schools, are the works of the authors who constituted the so-called "Debreczen Class," which boasts the names of the naturalist and philologist John Földi, compiler of a considerable part of the *Debreczeni magyar grammatica*; Michael Fazekas, author of *Ludas Matyi* (Vienna, 1817), an epic poem, in 4 cantos; and Joseph Kovács. Other precursors of the modern school were the poet and philologist Francis Verseghy, whose works extend to nearly forty volumes; the gifted didactic prose writer, Joseph Kármán; the metrical rhymster, Gideon Ráday; the lyric poets, Szentjóbi Szabó, John Bacsányi, and the short-lived Gabriel Dayka, whose posthumous "Verses" were published in 1813 by Kazinczy. Still more celebrated were Michael Csokonai and Alexander Kisfaludy. The former is one of the most original and genial of poets, his style somewhat resembling that of Petöfi. The best edition of Csokonai's works was published by Toldy (Pest, 1844). The first volume of Alexander Kisfaludy's *Himfy*, a series of short lyrics of a descriptive and reflective nature, appeared at Buda in 1801, under the title of *Kesergö szerelem* (Unhappy Love), and was received with such applause as but few books have ever met with; nor was the success of the second volume *Boldog szerelem* (Happy Love), which appeared in 1807, inferior. The *Regék*, or "Tales of the Past," were published at Buda from 1807 to 1808, and still further increased Kisfaludy's fame; but in his dramatic works he was not equally successful. Journalistic literature in the native language begins with the *Magyar Hirmondó* (Harbinger) started by Matthias Ráth at Pozsony in 1780. Among the magazines the most important was the *Magyar Muzeum*, established at Kassa (Kaschau) in 1788 by Baróti, Kazinczy, and Bacsányi. The *Orpheus* (1790) was the special work of Kazinczy, and the *Urania* (1794) of Kármán and of Pajor.

[Rev]ival [of th]e [Lang]uage (1807–1830).

Closely connected with the preceding period is that of the "Revival of the Language" (1807–1830), with which the name of Francis Kazinczy is especially associated. To him it was left to perfect that work of restoration begun by Baróti and amplified by Révai. Poetry and belles lettres still continued to occupy the chief place in the native literature, but under Kazinczy and his immediate followers Berzsenyi, Kölcsey, Fáy, and others, a correctness of style and excellence of taste hitherto unknown soon became apparent. Kazinczy, in his efforts to accommodate the national language to the demands of an improved civilization, availed himself of the treasures of European literature, but thereby incurred the opposition of those who were prejudiced by a too biased feeling of nationality. The opinions of his enemies were ventilated in a lampoon styled *Mondolat*. His belletristic works, or *Szép Literatura* (Pest, 1814–16), extend to 9 vols., consisting in great part of translations. His *Eredeti Mukái* (Original Works), in 5 vols., appeared at Pest in 1836–45, under the joint editorship of Bajza and Toldy. Daniel Berzsenyi, whose odes are among the finest in the Hungarian language, was the correspondent of Kazinczy, and like him a victim of the attacks of the *Mondolat*. But the fervent patriotism, elevated style, and glowing diction of Berzsenyi soon caused him to be recognized as a truly national bard. A too frequent allusion to Greek mythological names is a defect sometimes observable in his writings. His collective works were published at Buda by Döbrentei in 1842. Those of John Kis, the friend of Berzsenyi, cover a wide range of subjects, and comprise, besides original poetry, many translations from the Greek, Latin, French, German, and English, among which last may be mentioned renderings from Blair, Pope, and Thomson, and notably his translation, published at Vienna in 1791, of Lowth's "Choice of Hercules." The style of Kis is unaffected and easy. As a sonnet writer none stands higher than Paul Szemere, known also for his rendering of Körner's drama *Zrinyi* (1818), and his contributions to the *Elet és Literatura* (Life and Literature). The articles of Francis Kölcsey in the same periodical are among the finest specimens of Hungarian æsthetical criticism. The lyric poems of Kölcsey can hardly be surpassed, whilst his orations, and markedly the *Emlék beszéd Kazinczy felett* (Commemorative Speech on Kazinczy), exhibit not only his own powers, but the singular excellence of the Magyar language as an oratorical medium. Andrew Fáy, sometimes styled the "Hungarian Æsop," was an industrious writer in almost every branch of literature during both this and the following period, but is now chiefly remembered for his *Eredeti Mesék* (Original Fables). The dramatic works of Charles Kisfaludy, brother of Alexander, won him enthusiastic recognition as a regenerator of the drama. His plays, moreover, bear a distinctive national character, the subjects of most of them referring to the golden era of the country. His genuine simplicity as a lyrical writer is shown by the fact that several of his shorter pieces have passed into popular song. As the earliest Magyarizer of Servian folk-song, Michael Vitkovics did valuable service. Not without interest to Englishmen is the name of Gabriel Döbrentei, the translator of Shakespeare's "Macbeth," represented at Pozsony in 1825, and of Sterne's "Letters from Yorick to Eliza," *Yorick és Eliza levelei* (Pest, 1828). But his chief merit in the eyes of his fellow-countrymen were his editorship of the Kolozsvár *Erdélyi Muzeum* (1814–18, vol. x.), and his laborious compilation of the *Régi Magyar Nyelvemlékek* (Memorials of the Magyar Language), which works are among the most important contributions to the literary history of the nation. An historical poem of a somewhat philosophical nature was produced in 1814 by Andreas Horváth under the title of *Zircz emlékezete* (Reminiscence of Zirez); but his *Árpád*, in 12 books, finished in 1830, and published at Pest in the following year, is a great national epic. Among other poets of this period were Alois Szentmiklóssy, George Gaal, Emil Buczy, Joseph Szász, Ladislaus Tóth, and Joseph Katona, author of the much-extolled historical drama *Bánk Bán*.[1] Izidore Guzmics, the translator of Theocritus into Magyar hexameters, is chiefly noted for his prose writings on ecclesiastical and philosophical subjects. As authors of special works on philosophy, we find Samuel Köteles, John Imre, Joseph Ruszek, Daniel Eresei, and Paul Sárvári; as a theologian and Hebraist John Somossy; as an historian and philologist Stephen Horváth, who endeavoured to trace the Magyar descent from the earliest historic times; as writers on jurisprudence Alexander Kövy and Paul Szlemenics. (For an account of the historian George Fejér, the laborious compiler of the *Codex Diplomaticus*, see FEJÉR, vol. ix. pp. 64, 65.)

Academy period (commencing 1830).

The establishment of the Hungarian Academy of Sciences[2] (17th November 1830) marks the commencement of a new period, in the first eighteen years of which gigantic exertions were made as regards the literary and intellectual life of the nation. The language, nursed by the academy, developed rapidly, and showed its capacity for giving expression to almost every form of scientific knowledge.[3] By offering rewards for the best original dramatic productions, the academy provided that the national theatre should not suffer from a lack of classical dramas. During the earlier part of its existence the Hungarian academy devoted itself mainly to the scientific development of the language and philological research. Since its reorganization in 1869 the academy has, however, paid equal attention to the various departments of history, archæology, national economy, and the physical sciences. The encouragement of polite literature was more especially the object of the Kisfaludy Society, founded in 1836.[4]

[1] The subject is similar to that of Grillparzer's tragedy, *Ein treuer Diener seines Herrn*.

[2] It was founded in 1825 through the generosity of Count Széchenyi, who devoted his whole income for one year (60,000 florins) to the purpose. It was soon supported by contributions from all quarters except from the Government.

[3] Among the earlier publications of the academy were the *Tudománytár* (Treasury of Sciences, 1834–44), with its supplement *Literatura*; the *Külföldi játékszin* (Foreign Theatres); the *Magyar nyelv rendszere* (System of the Hungarian language, 1846; 2d ed., 1847); various dictionaries of scientific, mathematical, philosophical, and legal terms; an Hungarian-German dictionary (1835–38); and a Glossary of Provincialisms (1838). The *Nagy-Szótár* (Great Dictionary), begun by Czuczor and Fogarasi in 1845, was not issued till 1862–74. Among the regular organs of the academy are the "Transactions" (from 1840), in some 60 vols., and the "Annuals."

[4] Among its earlier productions were the *Nemzeti könyvtár* (National Library), published 1843–47, and continued in 1852 under the title *Ujabb Nemzeti könyvtár*, a repository of works by celebrated authors; the *Külföldi Regénytár* (Treasury of Foreign Romances), consisting of translations; and some valuable collections of proverbs, folk-songs, traditions, and fables. Of the many later publications of the Kisfaludy society the most important as regards English literature is the *Shakspere Minden Munkái* (Complete Works of Shakespeare), in 19 vols. (1864–78)

Polite literature had received a great impulse in the preceding period (1807–30), but after the formation of the academy and the Kisfaludy society it advanced with accelerated speed towards the point attained by other nations. Foremost among epic poets, though not equally successful as a dramatist, was Michael Vörösmarty, who, belonging also to the close of the last period, combines great power of imagination with elegance of language. His historical tragedy *Salamon Király* (King Solomon, 1821), though deficient in dramatic force, attracted considerable attention. As fine specimens of epic poetry the *Zalán futása* (Flight of Zalán, 1824) and *Cserhalom* (1826) are unrivalled. His lyrical poems are exquisite both in taste and style; his *Szózat* (Appeal) is the Magyar national anthem. Vörösmarty is also celebrated as the translator of Shakespeare's "Julius Cæsar" and "King Lear." Generally less varied and romantic, though easier in style, are the heroic poems *Augsburgi ütközet* (Battle of Augsburg) and *Aradi gyülés* (Diet of Arad) of Gregory Czuczor, who was, moreover, very felicitous as an epigrammatist. Martin Debreczeni was chiefly famed for his *Kiövi csata* (Battle of Kieff), published at Pest in 1854 after his death by Count Emeric Mikó. The laborious John Garay in his *Szent László* shows considerable ability as an epic poet, but his greatest merit was rather as a romancist and ballad writer, as shown by the "Pen Sketches" or *Tollrajzok* (1845), and his legendary series *Árpádok* (1847). Joseph Bajza was a lyricist of a somewhat melancholy cast, but his *Borének* (Wine Song), *Sohajtás* (Sigh), *Ébresztö* (Awakening), and *Apotheosis* are much admired. He is known further as the translator of F. C. Dahlmann's *Geschichte der englischen Revolution.* As generally able writers of lyrical poetry during the earlier part of this period may be mentioned among others Francis Császár, Joseph Székács, and Andrew Kunoss,—also Lewis Szakál and Alexander Vachott, whose songs and romances are of an artless and simple character, and the sacred lyricist Béla Tárkányi. As an original but rather heavy lyric and didactic poet we may mention Peter Vajda, who was, moreover, the translator of Bulwer's "Night and Morning." Of a more distinctly national tendency are the lyrics of John Kriza[1] and John Erdélyi, but the reputation of the latter was more especially due to his collections of folk-lore made on behalf of the Kisfaludy society. More popular than any of the preceding, and well-known in England through Sir John Bowring's translation, are the charming lyrics of Alexander Petöfi, the "Burns" of Hungary. His poems, embodying as they do the national genius, have passed into the very life of the people; particularly is he happy in the pieces descriptive of rural life. In his verse "Folk-tales," *Népregék* (1846), and "Ballads," *Regék* (1852), may Michael Tompa, another popular poet, be regarded as sometimes hardly less felicitous. The most diversely gifted Magyar singer, however, is John Arany, whose talents have been displayed, not only in ballads and lyrical effusions, but in almost every branch of poetry except the dramatic. Especially famous is the Toldi trilogy, of which the first part *Toldi*, in 12 cantos, relating to the youth of the hero, was published at Pest in 1847; the third part, *Toldi Estéje* (Toldi's Eve), describing his fall and death, in 1854; and the middle part, *Toldi Szerelme* (Toldi's Love), in 1879. The *Nagyidai czigányok* (Eida Gipsies), a fine humorous epic poem in 4 cantos, appeared in 1852. A collective edition of Arany's poetical works was published at Pest and Vienna in 1867.

Among recent lyricists who have attracted attention are the following:—Coloman Tóth, who is also the author of several epic and dramatic pieces; John Vajda, whose *Kisebb Költemények* (Minor Poems), published by the Kisfaludy society in 1872, are partly written in the mode of Heine, and are of a pleasing but melancholy character; Joseph Lévay, known also as the translator of Shakespeare's *Titus Andronicus, Taming of the Shrew*, and *Henry IV.*; and Paul Gyulai, who, not only as a faultless lyric and epic poet, but as an impartial critical writer, is highly esteemed, and whose *Romhányi* is justly prized as one of the best Magyar poems that has appeared in modern times. To the above may be added the names of Charles Berecz, Joseph Zalár, Samuel Nyilas, Joseph Vida, Lewis Tolnai, the sentimental Ladislaus Szelestey, and the talented painter Zoltán Balogh, whose romantic poem *Alpári* was published in 1871 by the Kisfaludy society. The lyrics of Anthony Várady (1875, 1877) are somewhat dull and unequal in tone; both he and Baron Ivor Kaas, author of *Az itélet napja* (Day of Judgment, 1876), have shown skill rather in the art of dramatic verse. The poems of Count Géza Zichy and Victor Dalmady, those of the latter published at Budapest in 1876, are mostly written on subjects of a domestic nature, but are conceived in a patriotic spirit. Emil Ábrányi adopts a rather romantic style, but his *Nagypéntek* (Good Friday) is an excellent descriptive sketch. Alexander Endrödy, author of *Tücsök dalok* (Cricket Songs, 1876), is a glowing writer, with great power of conception, but his metaphors, following rapidly one upon the other, become often confused. Joseph Kiss in 1876 brought out a few lyric and epic poems of considerable merit. The *Mesék* of Augustus Greguss (1878), a collection of verse "Fables," belonging to the school of Gay, partake more of a didactic than lyrical nature. This feature is noticeable also in the *Költemények* (1873) of Ladislaus Torkos, and the *Modern Mesék* (1874) of Ladislaus Névy. An energetic satirical poet has recently appeared in Lewis Bartók.

As one of the latest remarkable productions of Magyar poetry, we must not omit to draw attention to the *Salamon* (1878) of Charles Szász, which poem was rewarded with the prize of the academy. The subject, taken from the age of Hungarian chivalry, is artistically worked out from mediæval legends, and gives an excellent description of the times of St Ladislaus of Hungary. Charles Szász is generally better known as a metrical translator than as an original poet. He is the Magyarizer of Shakespeare's *Anthony and Cleopatra, Othello, Macbeth, Henry VIII., Winter's Tale, Romeo and Juliet*, and *Tempest*, as also of some of the best pieces of Burns, Moore, Byron, Shelley, Milton, Béranger, Lamartine, Victor Hugo, Goethe, and others. A translator from Byron and Pope appeared also in Maurice Lukács.[2]

Meanwhile dramatic literature has found many champions, of whom the most energetic is the late Edward Szigligeti, *proprie* Joseph Szathmáry, who has enriched the Hungarian stage with more than a hundred pieces. Of these the most popular are comedies and serio-comic national dramas. His recently produced tragedy *Béla IV.* is also much admired. A less prolific but more classical writer appeared in Charles Obernyik, whose *George Brankovics* is, next to Katona's *Bánk Bán*, one of the best historical tragedies in the language. Several of the already mentioned lyric and epic poets were, as we have shown in the case of Vörösmarty, occasional writers also for the drama. To these we may add the gifted but unfortunate Sigismund Czakó, Lewis Dobsa, Joseph Szigeti, Ignatius Nagy, Joseph Szenvey (a translator from Schiller), Joseph Gaal, Charles Hugo, Lawrence Tóth (the Magyarizer of the *School for Scandal*), Emeric Vahot, Alois Degré (equally famous as a novelist), Stephen Toldy, and Lewis Dóczi, author of the popular prize drama *Csók* (The Kiss). *Az ember tragoediája* (The Tragedy of Man), by Emeric Madách (1861), is a dramatic poem of a philosophical and contemplative character, and is not intended for the stage. Among the latest most successful dramatic pieces may be mentioned the *Falu rossza* (Village Scamp) of the late Edward Tóth (1875), which represents the life of the Hungarian peasantry, and shows both poetic sentiment and dramatic skill; *A szerelem harcza* (Combat of Love), by Count Géza Zichy; *Iskáriot* (1876) and the prize tragedy *Tamora* (1879), by Anthony Várady; *Jánus* (1877), by Gregory Csiky; and the dramatized romance *Szép Mikhal* (Handsome Michal), by Maurice Jókai (1877). The principal merit of this author's drama *Milton* (1876) consists in its brilliance of language. The *Szerelem iskolája* (School of Love), by Eugene Rákosy, although in some parts exquisitely worded, did not meet with the applause accorded to his *Ripacsos Pista Dolmánya* (1874). The *Gróf Dormándi Kálmán* (Count Coloman Dormándi) of Béla Bercsényi (1877) is a social tragedy of the French school. Among the most recent writers of comedy we single out Árpád Berczik for his *A házasitók* (The Matchmakers); Ignatius Súlyovsky for his *Nöi diplomatia* (Female Diplomacy); and the above-mentioned Gregory Csiky for his *Ellenállhatatlan* (The Irresistible), produced on the stage in 1878. As popular plays the *Sárga csikó* (Bay Foal) and *A piros bugyelláris* (The Red Purse) by Francis Csepreghy, have their own special merit, and were often represented in 1878 and 1879 at Budapest and elsewhere.

Original romance writing, which may be said to have commenced with Dugonics and Kármán at the close of the 18th, and to have

---

to which a supplementary vol., *Shakspere Pályája* (1880), containing a critical account of the life and writings of Shakespeare, has been added by Professor A. Greguss. Translations from Molière, Racine, Corneille, Calderon, and Moreto have also been issued by the Kisfaludy society. The *Évlapok új folyama*, or "New Series of Annuals," from 1860 (Budapest, 1868, &c.), is a chrestomathy of prize orations, and translations and original pieces, both in poetry and prose.

[1] Late Unitarian bishop of Transylvania, author of *Vadrózsák*, or "Wild-Roses" (1863), a collection of Szekler folk-songs, ballads, and sayings.

[2] Besides the various translators from the English, as for instance William Györi, Augustus Greguss, Ladislaus Arany, Sigismond Ács, Stephen Fejes, and Eugene Rákosy, who, like those already incidentally mentioned, have assisted in the Kisfaludy society's version of Shakespeare's complete works, metrical translations from foreign languages have, during the last few years, been successfully made by Emil Ábrányi, Dr Ignatius Barna, Anthony Várady, Andrew Szabó, Charles Bérczy, Julius Greguss, Lewis Dóczi, Béla Erödi, Emeric Gáspár, and many others. A Magyar version, by Ferdinand Barna, of the *Kalewala* was published at Pest in 1871. Faithful renderings by Lewis Szeberényi, Theodore Lehoczky, and Michael Fincicky of the popular poetry of the Slavic nationalities appeared in vols. i and ii. of the *Hazai nép költészet tára* (Treasury of the Country's Popular Song), commenced in 1866, under the auspices of the Kisfaludy society. In vol. iii. Roumanian folk-songs have been Magyarized by George Ember, Julian Grozescu, and Joseph Vulcanu, under the title *Román népdalok* (Budapest, 1877). The *Rózsák* (Zombor, 1875) is a translation by Eugene Pavlovits from the Servian of Jovan Jovanovits. Both the last-mentioned works are interesting from an ethnographical point of view. Versions from the English appear from time to time in the *Budapesti Szemle* (Budapest Review), conducted by Paul Gyulai. We may here note that for foreigners unacquainted with Hungarian there are, besides several special versions of Petöfi and of Arany, 21 anthologies of Magyar poetry in German, by Count Majláth (1825), J. Fenyéry and F. Toldy (1828), G. Steinacker (1840, 1875), G. Stier (1850), K. M Kertbeny (1854, 1860), A. Dux (1854), Count Pongrácz (1859–61), A. M. Riedl (1860), J. Nordheim (1872), G. M. Henning (1874), A. von der Heide (1879), and others. Selections have also been published in English by Sir John Bowring (1830), S Wékey in his grammar (1852), and E. D. Butler (1877), and in French by H. Desbordes-Valmore and C. E. De Ujfalvy (1873).

found a representative in Francis Verseghy at the beginning of the 19th century, was afterwards revived by Fáy in his *Bélteky ház* (1832), and by the contributors to certain literary magazines, especially the *Aurora*, an almanack conducted by Charles Kisfaludy, 1821-30, and continued by Joseph Bajza to 1837. Almost simultaneously with the rise of the Kisfaludy society, works of fiction assumed a more vigorous tone, and began to present just claims for literary recognition. Far from adopting the levity of style too often observable in French romances, the Magyar novels, although enlivened by touches of humour, have generally rather a serious historical or political bearing. Especially is this the case with Nicholas Jósika's *Abafi* (1836), *A csehek Magyarországon* (The Bohemians in Hungary), and *Az utolsó Bátori* (The Last of the Báthoris), published in 1847. In these, as in many other of the romances of Jósika, a high moral standard is aimed at. The same may be said of Baron Joseph Eötvös's *Karthausi* (1839), and *Falu Jegyzője* (Village Notary), published in 1845, and translated into English (1850) by O. Wenckstern (see Eötvös, vol. viii. p. 455). The *Árvizkönyv* or "Inundation Book," edited by Eötvös, 1839-41, is a collection of narratives and poems by the most celebrated authors of the time. Of the novels produced by Baron Sigismond Kemény the *Gyulai Pál* (1847), in 5 vols., is, from its historical character, the most important. His *Férj és nö* (Husband and Wife) appeared in 1853 (latest ed., 1878), the *Rajongók* (Fanatics), in 4 vols., in 1858-59. The graphic descriptions of Hungarian life in the middle and lower classes by Lewis Kuthy won for him temporary renown; but his style, though flowery, is careless. Another popular writer of great originality was Joseph Radákovics *alias* Vas-Gereben. The romances of Baron Frederick Podmaniczky are simpler, and rather of a narrative than colloquial character. The fertile writer Paul Kovács excels more particularly in humorous narration. Fáy's singular powers in this direction were well shown by his *Jávor orvos és Bakator Ambrus szolgája* (Doctor Jávor and his servant Ambrose Bakator), brought out at Pest in 1855. The *Beszélyek* (Tales) of Ladislaus Beöthy were produced in the same year, his *Puszták fia* (Son of the Pusztas) in 1857. Pleasing humorous sketches are contained also in Ignatius Nagy's *Beszélyek* (1843) and "Caricatures" or *Torzképek* (1844); in Caspar Bernát's *Fresko képek* (1847-50); in Gustavus Lauka's *Vidék*, and his *A jó régi világ* (The Good Old World), published respectively in 1857 and 1863; and in Alexander Balázs's *Beszélyei* (1855) and *Tükördarabok* (1865). Among authors of other historical or humorous romances and tales which have appeared from time to time are Francis Márton *alias* Lewis Abonyi, Joseph Gaal, Paul Gyulai, William Győri, Lazarus Horváth, the short-lived Joseph Irinyi, translator of "Uncle Tom's Cabin," Francis Ney, Albert Pálffy, Alexander Vachott and his brother Emeric (Vahot), Charles Szathmáry, Desider Margittay, Victor Vajda, Joseph Bodon, Atala Kisfaludy, John Krátky, and the several writers whose names and latest works are noticed at the end of this paragraph. But by far the most prolific and talented novelist that Hungary can boast of is Maurice Jókai, whose power of imagination and brilliancy of style, no less than his true representations of Hungarian life and character, have earned for him a European reputation. His earlier romances, published before the revolution of 1848, are chiefly of a social or political tendency. Of his more recent productions the best known are *Egy magyar nábob* (A Magyar Nabob), with its continuation *Kárpáthy Zoltán*, published in 1853 and 1854 respectively; *Szerelem bolondjai* (The Fools of Love, 1867); *Az új földesur* (The New Landlord), translated into English by A. J. Patterson (1868); *Fekete gyémántok* (Black Diamonds, 1870); *A jövö század regénye* (The Romance of the Coming Century, 1873); *Az élet komédiásai* (The Comedians of Life, 1876); the historical romance *Szép Mikhál* (1876) already referred to; and his justly admired and vividly interesting work *Egy az isten* (God is One, 1877). The events of the last-mentioned novel, in which the Unitarians play an important part, are supposed to take place between the years 1848 and 1859, and the scenes are laid partly in Transylvania, partly in Italy. In his *A névtelen vár* (Nameless Castle, 1878), the author connects an epoch of French history with Hungarian, and gives an account of the Hungarian army employed so unsuccessfully against Napoleon in 1809. *Rab Ráby* (Captive Ráby), produced in 1879, is a tale of the times of Joseph II. Defects occasionally observable in Jókai's works are want of unity, consistency, and probability. Of the novels produced by other authors since 1870, we may mention *A hol az ember kezdödik* (Where the Man Begins), by Edward Kavassy (1871), in which he severely lashes the idling Magyar nobility; *Az én ismerőseim* (My Acquaintances), by Lewis Tolnai (1871); and *Anatol*, by Stephen Toldy (1872); the versified romances *Déli bábok hőse* (Hero of the Fata Morgana), generally ascribed to Ladislaus Arany, but anonymously published, *A szerelem hőse* (Hero of Love), by John Vajda (1873), and *Találkozások* (Rencounters) by the same (1877), and *A Tündéröv* (The Fairy Zone), by John Bulla (1876), all four interesting as specimens of narrative poetry; *Kálozdy Béla* (1875), a tale of Hungarian provincial life, by Zoltán Beöthy, a pleasing writer who possesses a fund of humour, and appears to follow the best English models; *Edith története* (History of Edith) by Joseph Prém (1876); *Nyomorúság iskolája* (School of Misery), by the prolific author Arnold Vértesi (1878); *Titkolt szerelem* (Secret Love), by Cornelius Ábrányi (1879), a social-political romance of some merit; and *Uj idők, avult emberek* (Modern Times, Men of the Past), by L. Véka (1879). In the *Itthon* (At Home), by Alois Degré (1877), the tale is made the medium for a satirical attack upon official corruption and Hungarian national vanity; and in the *Álmok álmodója* (Dreamer of Dreams), by John Ásbóth (1878), other national defects are aimed at. *A rosz szomszéd* (The Bad Neighbour), by Charles Vadnay (1878), is a felicitous representation of the power of love. The *Az utolsó Bebek* (The Last of the Bebeks), by the late Charles Pétery, is a work rich in poetic invention, but meagre in historical matter. The reverse is the case with the *Lajos pap* (Priest Lewis), by Charles Vajkay (1879), the scene of which is placed at Pest, in the beginning of the 14th century. In this romance the interest of the narrative is weakened by a superabundance of historical and archæological detail.

As regards works of a scientific character, the Magyars until recently were confessedly behind hand as compared with many other European nations. Indeed, before the foundation of the Hungarian academy in 1830, but few such works claiming general recognition had been published in the native language. Even in 1847 astronomy, physics, logic, and other subjects of the kind had to be taught in several of the lyceums through the medium of Latin. The violent political commotions of the next few years allowed but little opportunity for the prosecution of serious studies; the subsequent quieter state of the country, and gradual re-establishment of the language as a means of education, were, however, more favourable to the development of scientific knowledge.

In the department of philosophy, besides several writers of dissertations bearing an imitative, didactic, or polemical character, Hungary can boast a few authors of independent and original thought. Of these one of the most notable is Cyril Horváth, whose treatises published in the organs of the academy display a rare freedom and comprehensiveness of imagination. John Hetényi and Gustavus Szontagh must be rather regarded as adopters and developers of the ethical teaching of Samuel Köteles in the previous period. Hyacinth Rónay in his *Mutatrány* (Representation) and *Jellemisme* (Characteristics) endeavoured to popularize psychological studies. The philosophical labours of the already mentioned John Erdélyi and of Augustus Greguss won for them well-deserved recognition, the latter especially being famous for his æsthetical productions, in which he appears to follow out the principles of Vischer. The *Tanulmányok* (Studies) of Greguss were brought out at Pest in 1872. The reputation of John Szilasy, John Varga, Fidelius Beély, and Francis Ney arose rather from their works bearing on the subject of education than from their contributions to philosophy.

The labours of Stephen Horváth in the preceding period had prepared the way for future workers in the field of historical literature. Specially meritorious among these are Michael Horváth, Ladislaus Szalay, Paul Jászay, and Count Joseph Teleki. The *Magyarok története* (History of the Magyars), in 4 vols., first published at Pápa (1842-46), and afterwards in 6 vols. at Pest (1860-63), and in 8 vols. (1871-73), is the most famous of Michael Horváth's numerous historical productions. Ladislaus Szalay's *Magyarország története* (History of Hungary), vols. i.-iv. (Leipsic, 1852-54), vols. v.-vi. (Pest, 1856-61), second edition, i.-v. (1861-66), is a most comprehensive work, showing more particularly the progress of Hungarian legislative development in past times. His style is elevated and concise, but somewhat difficult. Magyar history is indebted to Paul Jászay for his careful working out of certain special periods, as, for instance, in his *A Magyar nemzet napjai a legrégibb idötöl az arany bulláig* (Days of the Hungarian nation from the earliest times to the date of the Golden Bull). Count Joseph Teleki is famed chiefly for his *Hunyadiak kora Magyarországon* (The Times of the Hunyadys in Hungary), vols. i.-vi. (Pest, 1852-63), x.-xii. (1853-57), the result of thirty years' labour and research. In particular departments of historical literature we find George Bartal, author of *Commentariorum . . . libri XV.*, tom. i.-iii. (Pozsony, 1847), John Czech, Gustavus Wenczel, Frederick Pesty, and Paul Szlemenics, as writers on legal history; Joseph Bajza, who in 1845 commenced a "History of the World," Alexander Szilágyi, some of whose works, like those of Ladislaus Kövary, bear on the past of Transylvania, others on the Hungarian revolution of 1848-49; Charles Lányi and John Pauer, authors of treatises on Roman Catholic ecclesiastical history; John Szombathi, Emeric Révész, and Balogh, writers on Protestant church history; William Fraknói, biographer of Cardinal Pázmán, and historian of the Hungarian diets; and Anthony Gévay, Aaron Sziládi, Joseph Podhradczky, Charles Szabó, John Jerney, and Francis Salamon, who have investigated and elucidated many special historical subjects. For the mediæval history of Hungary the *Mátyáskori diplomatikai emlékek* (Diplomatic Memorials of the Time of Matthias Corvinus), issued by the academy under the joint editorship of Ivan Nagy and Baron Albert Nyáry, affords interesting material. As a masterly production based on extensive investigation, we note the *Wesselényi Ferencz . . . összeesküvése* (The Secret Plot of Francis Wesselényi, 1664–71), by Julius Pauler (1876). Among the many historians of Magyar literature Francis Toldy *alias* Schedel holds the foremost place. As compilers of useful manuals may be mentioned also Joseph Szvorényi, Zoltan Beöthy, Alexander Imre, Paul Jámbor, Ladislaus Névy, John Környei, and Joseph Szinnyei, junior. For philological and ethnographical research into the origin and growth of the language none excels Paul Hunfalvy. He is, moreover, the warm advocate of the theory of its Ugrio-Finnic origin, as established by the late Uralian traveller Anthony Reguly, the result of whose labours Hunfalvy published in 1864, under the title *A Vogul föld és nép* (The Vogul Land and People). Between 1862 and 1866 valuable philological studies bearing on the same subject were published by Joseph Budenz in the *Nyelvtudományi közlemények* (Philological Transactions). This periodical, issued by the academy, has during the last decade (1870–80) contained also comparative studies, by Arminius Vámbéry and Gabriel Bálint, of the Magyar, Turkish-Tatar, and Mongolian dialects.

As compilers and authors of works in various scientific branches allied to history, may be particularly mentioned—in statistics and geography, Alexius Fényes, Emeric Palugyay, Alexander Konek, John Hunfalvy, Charles Galgóczy, Charles Keleti, Leo Beöthy, Joseph Körösi, Charles Ballagi, and Paul Király, and, as regards Transylvania, Ladislaus Kőváry; in travel, Arminius Vámbéry, Ignatius Goldziher, Ladislaus Magyar, John Xantus, John Jerney, Count Andrássy, Ladislaus Podmaniczky, Paul Hunfalvy; in astronomy, Nicholas Konkoly; in archæology, Bishop Arnold Ipolyi, Florian Rómer, Emeric Henszlmann, John Érdy, Baron Albert Nyáry, Francis Pulszky, and Francis Kiss; in Hungarian mythology, Bishop Ipolyi, Anthony Csengery,[1] and Árpád Kerékgyártó; in numismatics, John Erdy and Jacob Rupp; and in jurisprudence, Augustus Karvassy, Theodore Pauler, Gustavus Wenczel, Emeric Csacskó, John Fogarasi, and Ignatius Frank. Since 1867 great activity has been displayed in history and its allied branches, owing to the direct encouragement given by the Hungarian Historical Society, and by the historical, archæological, and statistical committees of the academy.

Notwithstanding the exertions of Paul Bugát to arouse an interest in the natural sciences by the establishment in 1841 of the "Hungarian Royal Natural Science Association," no general activity was manifested in this department of knowledge, so far as the native literature was concerned, until 1860, when the academy organized a special committee for the advancement of mathematical and natural science.[2] The principal contributors to the "Transactions" of this section of the academy have been—for anatomy and physiology, Coloman Balogh, Eugene Jendrassik, Joseph Lenhossék, and Lewis Thanhoffer; for zoology, John Frivaldszky, John Kriesch, and Theodore Margó; for botany, Frederick Hazslinszky, Lewis Jurányi, and Julius Klein; for mineralogy and geology, Joseph Szabó, Max Hantken, Joseph Krenner, Anthony Koch, and Charles Hoffmann; for physics, Baron Lorando Eötvös, Coloman Szily, and Joseph Sztoczek; for chemistry, Charles Than and Vincent Wartha; for meteorology, Guido Schenzl. As good text-books, for which the so-called "Ladies' Prize" was awarded by the academy, we may mention the *Természettan* (Physics) and *Természettani földrajz* (Physical Geography) of Julius Greguss.

Almost simultaneously with the formation of the above-mentioned committee of the academy, the "Natural Science Association" showed signs of renewed animation, and soon advanced with rapid strides in the same direction, but with a more popular aim than the academy. This may be seen from the fact that between 1868 and 1878 the number of its members increased from some 600 to about 5000. Since 1872, in addition to its regular organs, it has issued Hungarian translations of several popular scientific English works, as, for instance, Darwin's *Origin of Species*; Huxley's *Lessons in Physiology*; Lubbock's *Prehistoric Times*; Proctor's *Other Worlds than Ours*; Tyndall's *Heat as a Mode of Motion*, &c. Versions have also been made of Cotta's *Geologie der Gegenwart* and Helmholtz's *Populäre Vorlesungen*. As important original monographs we note—*Az árapály a Fiumei öbölben* (Ebb and Flow in the Gulf of Fiume), by Emil Stahlberger (1874); *Magyarország pókfaunája* (The Arachnida of Hungary), by Otto Hermann (1876–78); *Magyarország vaskörei és vasterményei* (The Iron Ores and Iron Products of Hungary), by Anthony Kerpely (1877); *Magyarország nevezetesebb dohányfajainak chemiai . . . megvizsgálása* (Chemical Examination of the most famous Tobaccos of Hungary), by Dr Thomas Kosutány (1877).

In order to give a general idea of the dominant position that the native Hungarian literature has obtained during the last half century, we conclude our sketch with a few statistics of the number of books and periodicals issued from the press at various dates since the foundation of the academy. In the year 1831 there were 184 Magyar works published; in 1853 there were 336; this number in 1874 increased to 946; in 1877 to 1067; and in 1878 and 1879 to 1312 and 1154 respectively. In 1879 there appeared also 111 German works, and 185 in other non-Magyar languages. In 1830 the number of Magyar periodicals was 10; in 1848–49 it increased to 80, but fell in 1850 to 9. In 1867, after the restoration of the Hungarian constitution, the number was again 80, and increased so rapidly during the next twelve years that by 1879 it reached 324, and has in the present year (1880) risen to 368. There are now, moreover, 197 newspapers and journals of all kinds in the non-Magyar languages, viz., 114 German, 61 Slavonic, 16 Roumanian, 4 Italian, and 2 Hebrew; so that there are at this date altogether 565 periodicals published in Hungary.

If we take a retrospective glance at the depressed state of the native language and literature as it was a century ago, when the first Magyar newspaper was published at Pozsony, 1st January 1780,[3] and contrast its commanding position now,—or if we consider that, though constantly surrounded and pressed by foreign and antagonistic elements, the native language and literature have not only not been overpowered, but have even gained the mastery, —we cannot fail to admire the determined perseverance of the champions of Magyar literature, and believe that the state language is destined to be a common and enduring bond of union between the various nationalities comprised under the crown of St Stephen.

Bibliography.—The best authorities on Magyar literature are:—F. Toldy, *A Magyar nemzeti irodalom története a legrégibb időktől a jelenkorig* (Pest, 1864-65; 3d ed., 1872); S. Imre, *A Magyar irodalom és nyelv rövid története* (Debreczen, 1865; 4th ed., 1878); J. Szvorényi, *Magyar irodalmi szemelvények* (Pest, 1867), and *A Magyar irodalmi tanulmányok kézikönyve* (Pest, 1868); P. Jámbor, *A Magyar irodalom története* (Pest, 1864); J. Környei, *A Magyar nemzeti irodalomtörténet vázlata* (Pest, 1861; 3d ed., 1874); A. Lonkay, *A Magyar irodalom ismertetése* (Budán, 1855; 3d ed., Pest. 1864); J. Ferencz, *Magyar irodalom és tudományosság története* (Pest, 1854); J. Ferencz és J. Danielik, *Magyar Irók. Életrajz-Gyüjtemény* (2 vols., Pest, 1856–58); and the literary histories of L. Névy, Z. Beöthy, and B. Erödi. One of the most useful monographs on "Magyar Literary History Writing" is that of J. Szinnyei, junior, *A Magyar Irodalomtörténet-Irás ismertetése* (Budapest, 1878). For information as to the most recent literature see A. Dux, *Aus Ungarn* (Leipsic, 1880). (E. D. BU.)

[1] The translator of Macaulay.

[2] See, however, J. Szinnyei and Son's *Bibliotheca Hungarica historiæ naturalis et matheseos*, 1472-1875 (Budapest, 1878), where the number of Magyar works bearing on the natural sciences and mathematics printed from the earliest date to the end of 1875 is stated to be 3811, of which 106 are referred to periodicals.

[3] A Latin periodical, intended only for transmission abroad, and styled *Mercurius Veridicus ex Hungaria*, was issued weekly at Kassa as early as 1705. A German periodical was first published in Hungary about 1731.

INDEX.

HUNS. The authentic history of the Huns in Europe practically begins about the year 372 A.D.,[1] when under a leader named Balamir (or, according to some MSS., Balamber) they began a westward movement from their settlements in the steppes lying to the north of the Caspian. After crushing, or compelling the alliance of, various nations unknown to fame (Alpilzuri, Alcidzuri, Himari, Tuncarsi, Boisci), they at length reached the Alani, a powerful nation which had its seat between the Volga and the Don; these also, after a struggle, they defeated and finally enlisted in their service. They then proceeded, after a short interval, in 374 to invade the empire of the Ostrogoths (Greuthungi), ruled over by the aged Ermanaric, or Hermanric, who died (perhaps by his own hand) while the critical attack was still impending. Under his son Hunimund a section of his subjects promptly made a humiliating peace; under Withemir (Winithar), however, who succeeded him in the larger part of his dominions, an armed resistance was organized; but it resulted only in repeated defeat, and finally in the death of the king. The representatives of his son Witheric put an end to the conflict by accepting the condition of vassalage. Balamir now directed his victorious arms still further westward against that portion of the Visigothic nation (or Tervingi) which acknowledged the authority of Athanaric. The latter entrenched himself on the frontier which had separated him from the Ostrogoths, behind the "Greutung-rampart" and the Dniester; but notwithstanding all his precautions he was surprised by the enemy, who forded the river in the night, fell suddenly upon his camp, and compelled him to abandon his position. Athanaric next attempted to establish himself in the territory between the Pruth and the Danube, and with this object set about heightening the old Roman wall which Trajan had erected in north-eastern Dacia; before his fortifications, however, were complete, the Huns were again upon him, and without a battle he was forced to retreat to the Danube. The remainder of the Visigoths, under Alavivus and Fritigern, now began to seek and ultimately were successful in obtaining (376) the permission of the emperor Valens to settle in Thrace; Athanaric meanwhile took refuge in Transylvania, thus abandoning the field without any serious struggle to the irresistible Huns. For more than fifty years the Roman world was undisturbed by any aggressive act on the part of the new invaders, who contented themselves with overpowering various other tribes which lived to the north of the Danube. In some instances, in fact, the Huns actually lent their aid to the Romans against third parties; thus in 404–5 certain Hunnic tribes, under a chief or king named Uldin, assisted Honorius in the struggle with Radagaisus (Ratigar) and his Ostrogoths, and took a prominent part in the decisive battle which was fought in the neighbourhood of Florence. Once indeed, in 409, they are said to have crossed the Danube and invaded Bulgaria under perhaps the same chief (Uldis), but extensive desertions soon compelled a retreat. About the year 432, a noteworthy Hunnic king, Ruas or Rugulas, is mentioned, who made himself of such importance that he received from Theodosius II. an annual stipend or tribute of 350 pounds of gold (£14,000), along with the rank of Roman general. Quarrels soon arose, partly out of the circumstance that the Romans had sought to make alliances with certain Danubian tribes which Ruas chose to regard as properly subject to himself, partly also because some of the undoubted subjects of the Hun had sought and found refuge on Roman territory; and Theodosius, in reply to an indignant and insulting message which he had received about this cause of dispute, was preparing to send off a special embassy when tidings arrived that Ruas was dead, and that he had been succeeded in his kingdom by Attila and Bleda, the two sons of his brother Mundzuk (433). Shortly afterwards the treaty of Margus (not far from the modern Belgrade), where both sides negotiated on horseback, was ratified. By its stipulations the yearly stipendium or tribute payable to Attila by the Romans was doubled; the fugitives were to be surrendered, or a fine of £8 to be paid for each of those who should be missing; free markets, open to Hun and Roman alike, were to be instituted; and any tribe with which Attila might be at any time at war was thereby to be held as excluded from alliance with Rome. For eight years afterwards there was peace so far as the Romans were concerned; and during this period probably it was that the Huns proceeded to the extensive conquests to which the contemporary historian Priscus so vaguely alludes in the words:—"He (Attila) has made the whole of Scythia his own, he has laid the Roman empire under tribute, and he thinks of renewing his attacks upon Persia. The road to that eastern kingdom is not untrodden by the Huns; already they have marched fifteen days from a certain lake, and have ravaged Media." They also appear before the end of this interval to have pushed westward as far as to the Rhone, and to have come into conflict with the Burgundians. Overt acts of hostility, however, occurred against the Eastern empire when the town of Margus (by the treachery of its bishop) was seized and sacked (441), and against the Western when Sirmium was invested and taken. In 445 Bleda died, and two years afterwards Attila, now sole ruler, undertook one of his most important expeditions against the Eastern empire; on this occasion he pushed southwards as far as Thermopylæ, Gallipoli, and the walls of Constantinople; peace was cheaply purchased by tripling the yearly tribute (which accordingly now stood at 2100 pounds of gold, or £84,000 sterling) and by the payment of a heavy indemnity besides. In 448 again occurred various diplomatic negotiations, and especially the embassy of Maximin, of which many curious details have been recorded by Priscus his companion. Then followed, in 451, that westward movement across the Rhine which was only arrested at last, with terrible slaughter, on the Catalaunian plains (according to common belief, in the neighbourhood of the modern Châlons, but more probably at a point some fifty miles to the south-east, near Mery-sur-Seine). The following year (452), that of the Italian campaign, was marked by such events as the sack of Aquileia, the destruction of the cities of Venetia, and finally, on the banks of the Mincio, that historical interview with Pope Leo I. which resulted in the return of Attila to Pannonia, where in 453 he died (see ATTILA). Almost immediately afterwards, the empire he had amassed rather than consolidated fell to pieces. His too numerous sons began to quarrel about their inheritance, while Ardaric, the king of the Gepidæ, was placing himself at the head of a general revolt of the dependent nations. The inevitable struggle came to a crisis near the river Netad in Pannonia, in a battle in which 30,000 of the Huns and their confederates, including Ellak, Attila's eldest son, were slain. The nation, thus broken, rapidly dispersed; one horde settled under Roman protection in Little Scythia (the Dobrudscha), others in Dacia Ripensis (on the confines of Servia and

[1] In the existing text of Ptolemy (iii. 5, 25), who wrote about the end of the 2d century after the Christian era, a tribe of Chuni (*Χοῦνοι*) is placed between the Basternæ and the Roxolani on the Dnieper; Schafarik, however (*Slav. Alt.*, i. 322, 1842), suggests that this may be an interpolated passage. Dionysius Periegetes (*c.* 200 A.D.) is sometimes quoted as having named the Huns among the borderers on the Caspian in this order—Scyths, Huns (Οὖννοι), Caspiani, Albani; but the true reading appears to be Θοῦννοι or Θῦνοι (Zeuss, *Die Deutschen u. d. Nachbarstämme*, p. 727). Eratosthenes, as quoted by Strabo (p. 514), gives in the same connexion Albani, Caspiani, and Κουΐτιοι, Κουΐντιοι, or Οὐΐτιοι.

Bulgaria) or on the southern borders of Pannonia. The main body, however, appear to have resumed the position on the steppes of the river Ural which they had left less than a century before; soon afterwards they reappear in history as the Bulgari (see Zeuss, *Die Deutschen*, &c., p. 710), divided into two sections, the Kuturguri and the less formidable Uturguri, who for more than seventy years (485–557) were a constant source of annoyance and danger to the Eastern empire, until they themselves fell under the rising power of the Avars. About the year 630 they succeeded in regaining their independence, under the leadership of a chief named Krobat, or more properly Kubrat, a person of great consequence, who made a treaty with the emperor Heraclius. After his death his dominions, according to Theophanes (who wrote about 800 A.D.), were divided among his five sons, of whom the eldest, Batbaias, remained with his own people near the Mæotis, while the third, Asperuch, crossed the Danube. At a later period the first of these divisions came into close relations with the Khazars on the Volga, and their territory is spoken of as Great Bulgaria; for a brief account of the Danubian or "White" Bulgarians the article BULGARIA and the works there referred to may be consulted.

We have no adequate philological data for conclusively determining the ethnological position of the ancient Huns; and, in the attempt to solve the problem by other means, the student is at all points much hampered by the vagueness and inaccuracy with which designations, apparently ethnological, are applied by ancient writers. Since the publication of the *Histoire Générale des Huns, des Turcs, des Mongols, et des autres Tartares Occidentaux* of De Guignes (1756–58), it has been usual to identify the first mentioned with the Heungnoo or Hiungnu, a people who, about the end of the 3d century B.C., according to the Chinese annals, constituted a powerful empire extending from the Great Wall of China to the Caspian, but who, gradually falling into a state of anarchy, ultimately succumbed to the attacks of their enemies towards the close of the 1st Christian century. Their subsequent history is very obscure; but it appears that one section of them fled westward and settled in the neighbourhood of the Ural river, and the extremely tempting hypothesis of De Guignes is that these were the direct ancestors of the Huns, who three centuries afterwards began, under Balamir, to exercise so formidable an influence on the affairs of Europe. If so, then the Huns in all probability belonged to the Turkish branch of the great Turanian race.

According to the totally distinct line of investigation followed by Roesler, however, the Bulgarians, and therefore the Huns whose descendants they were, are to be regarded as of Finnic origin (see *Romänische Studien*, p. 231 *sqq.*). It has only to be added that by mediæval writers, both Byzantine and Western, the word Hun is used much as the word Scythian was used by the ancients, with the utmost generality. No very close connexion can be made out between the Huns and the Magyars (Οὔγγροι, Ugri, Wengri, Ungri, Ungări, Hungari), who first became prominent about the 9th century and who were undoubtedly Finns.

Literature.—The contemporary authorities upon the subject of the Huns during the period of their greatest ascendency in Europe are the fragments of the eight books of the rhetorician Priscus, *Concerning Byzantium and the Occurrences connected with Attila*, with the writings of Ammianus Marcellinus the Roman soldier, and of Jordanis the Gothic bishop. The account of the Huns given by the last-named must always be read in the light of the fact that as a Goth he could hardly avoid giving a somewhat exaggerated picture of the great military power in the presence of which his own people had been able to show so little resistance. The truth of the somewhat elaborate sketch of the Huns by Ammianus has sometimes been doubted, but careful examination tends rather to establish its claim to be regarded as trustworthy. After alluding to their portentous ugliness (of which, however, the only features he specifies are the round shoulders and the scarred beardless cheeks), he proceeds to mention some of the habits which in his opinion stamp them as surpassing all other barbarians in rudeness of life. Their food, in addition to such roots as they are able to find, consists of the half-raw flesh of any sort of animal, prepared for use by being carried for some time between their persons and the backs of the hardy little horses which are their almost inseparable companions. Houses they have none; and their clothing, which is made partly of linen and partly of the skins of field mice sewed together, continues to be worn until it falls to pieces. Their weapons are javelins or spears tipped with bone, and (for close combat) the sword and lasso. In warfare they seldom fight in rank, the method of attack they prefer being to throw the enemy into confusion by repeated onset made in loose array. They are wholly without religion or sense of moral obligation. For later information we are dependent on the writers of the Byzantine history (see Stritter, *Memoriæ populorum olim ad Danubium, Pontum Euxinum, Paludem Mæotidem, Caucasum, &c., incolentium, ex scriptoribus Byzantinis erutæ ac digestæ*, 1771–79, and the edition of the fragments of Menander Protector, published in the Bonn collection). For Chinese notices bearing or supposed to bear on the subject of the Huns, De Guignes, Visdelou, and De Mailla remain our chief authorities; to these should be added M. Stanislas Julien's series of papers on the Thukiu in the 6th series of the *Journal Asiatique*, and Mr Wylie's translations from the Hun annals in the *Journal of the Anthropological Institute*. Other materials on the general subject will be found in the admirable notes to Le Beau's *History of the Byzantine Empire*, and in the editions of the Armenian historians by St Martin, Langlois, and Brosset. See also the *History of Georgia* by the last of these authors; the *Chronicle of Nestor*, which is made available to Western students in the edition of M. Paris; the works of Zeuss, Pallmann, and Roesler already cited; Thierry, *Histoire d' Attila et de ses Successeurs*, 1864; Sayous, *Les Origines et l'Époque Païenne de l'Histoire des Hongrois*, 1874; Jirecek, *Gesch. der Bulgaren*, 1877; Hodgkin, *Italy and her Invaders*, vol. ii., 1880; Kruse's edition of *Al Bekhri*, with notes; the *Account of the Khazars* by M. Harkavy; that of the *Ephthalitæ or White Huns*, by M. Vivien St Martin; and a series of papers by Mr Howorth "On the Westerly Drifting of Nomades," published in the *Journal of the Anthropological Institute*.

HUNT, JAMES HENRY LEIGH (1784–1859), one of the most delightful of English essayists and miscellaneous writers, and especially remarkable for his connexion with the most eminent literati of his time, was born at Southgate, October 19, 1784. His father, the son of a West Indian clergyman, had settled as a lawyer in Philadelphia, and his mother was the daughter of a merchant of that city. Having embraced the loyalist side, Leigh Hunt's father was compelled to fly to England, where he took orders, and acquired some reputation as a popular preacher, but want of steadiness, want of orthodoxy, and want of interest conspired to prevent his obtaining any preferment. Leigh Hunt was educated at Christ's Hospital, of which school as it existed in his time he has left a lively account in his autobiography. An impediment in his speech, afterwards removed, prevented his being sent to the university. "For some time after I left school," he says, "I did nothing but visit my school-fellows, haunt the book stalls, and write verses." These latter were published in 1802 under the title of *Juvenilia*, and, although the mere literary exercises of a clever boy, contributed to introduce him into literary and theatrical society. He began to write for the newspapers, published a volume of theatrical criticisms in 1807, and in 1808 quitted the War Office, where he had for some time filled a situation as clerk, to assume the editorship of the *Examiner* newspaper, a speculation of his brother John. The new journal soon acquired a high reputation for independence, both in political and literary criticism. It was perhaps the only newspaper of the time which owed no allegiance to any political party, but assailed whatever seemed amiss, "from a principle of taste," as Keats happily expressed it. The taste of the attack itself, indeed, was not always unexceptionable; and one upon the prince regent, unseemly and imprudent without doubt, but the chief sting of which lay in its substantial truth, occasioned (1813) a prosecution and a sentence of two years' imprisonment in the Surrey jail. The effect was naturally to make Hunt a hero for the time being, and to give a political direction to the career of a man of letters. The position was an essentially false one, and led to an entire misunderstanding of Leigh Hunt's character and aptitudes alike on the part of his friends and his antagonists. For the time he was exceedingly popular; the cheerfulness and gaiety with which he bore his imprisonment, and his amusing devices to mitigate its severity, attracted general attention and sympathy, and brought him visits from Byron, Moore, Brougham, and others, whose acquaintance exerted much influence on his future destiny. In 1816 he made a permanent mark in English literature by the publication of his *Story of Rimini*. There is perhaps no other instance of a poem short of the highest excellence having produced so important and durable an effect in modifying the accepted standards of literary composition. The secret of Hunt's success consists less in superiority of genius than of taste. His refined critical perception had detected the superiority of Chaucer's versification, as adapted to the present state of our language by Dryden, over the sententious epigrammatic couplet of Pope which had superseded it. By a simple return to the old manner he effected for English poetry in the comparatively restricted domain of metrical art what Wordsworth had already effected in the domain of nature; his is an achievement of the same class, though not of the same calibre. His poem is also a triumph in the art of poetical narrative, abounds with verbal felicities, and is pervaded throughout by a free, cheerful, and animated spirit, notwithstanding the tragic nature of the subject. It has been remarked that it does not contain one hackneyed or conventional rhyme. Other characteristic traits are less commendable, and the writer's occasional flippancy and familiarity, not seldom degenerating into the ludicrous, made him a mark for ridicule and parody on the part of his opponents, whose animosity, however, was rather political than literary. These faults were still more conspicuous in other pieces published by him about this date. Ere long, however, Keats's "Lamia" and Shelley's "Julian and Maddalo" manifested the deliverance which he had wrought for English narrative poetry. Both these illustrious men belonged to the circle gathered around him at Hampstead, which also included Hazlitt, Lamb, Procter, Haydon, Cowden Clarke, Dilke, Coulson, Reynolds, and in general almost all the rising young men of letters of Liberal sympathies. He had now for some years been married to Marianne Kent, who seems to have been sincerely attached to him, but was not in every respect a desirable partner. His own affairs were by this time in the utmost confusion, and he was only saved from ruin by the romantic generosity of Shelley. In return he was lavish of sympathy to Shelley at the time of the latter's domestic distresses, and defended him with spirit in the *Examiner*, although he does not appear to have at this date appreciated his genius with either the discernment or the warmth of his generous adversary, Professor Wilson. Keats he welcomed with enthusiasm, and aided to the uttermost, though Keats seems to have subsequently felt that Hunt's example as a poet had been in some respects detrimental to him. After Shelley's departure for Italy (1818) Leigh Hunt's affairs became still more embarrassed, and the prospects of political reform less and less satisfactory. His health and his wife's failed, and he was obliged to discontinue his charming series of essays entitled the *Indicator*, having, he says, "almost died over the last numbers." These circumstances induced him to listen to a proposal, which seems to have originated with Shelley, that he should proceed to Italy and join Shelley and Byron in the establishment of a periodical work in which Liberal opinions should be advocated with more freedom than was possible at home. The project was injudicious from every point of view; it would have done little for Hunt or the Liberal cause at the best, and depended entirely upon the co-operation of Byron, the most capricious of allies, and the most parsimonious of paymasters. Byron's principal motive for acceding to it appears to have been the expectation of acquiring influence over the *Examiner*, and he was exceedingly mortified on discovering when too late that Hunt had parted, or was considered to have parted, with his interest in the journal. Leigh Hunt left England for Italy in November 1821, but storm, sickness, and misadventure retarded his arrival until June 1822, a rate of progress which Peacock appropriately compares to the navigation of Ulysses.

Hunt's arrival in Italy was almost immediately followed by the tragic death of Shelley, which destroyed every prospect of success for the *Liberal*. Hunt was now virtually a dependant upon Byron, whose least amiable qualities were called forth by the relation of patron to an unsympathetic dependant, burdened with a large and troublesome family, and who was moreover incessantly wounded in the most sensitive part by the representations of his friends that he was losing caste by the connexion. The *Liberal* lived through four quarterly numbers, containing contributions no less memorable than Byron's "Vision of Judgment" and Shelley's translations from *Faust*; but it produced little effect on the whole, and in 1823 Byron sailed for Greece, leaving his coadjutor at Genoa to shift for himself. The Italian climate and manners, however, were entirely to Hunt's taste, and he protracted his residence until 1825, producing in the interim his matchless translation of Redi's *Bacco in Toscana*, and the religious work subsequently published under the title of *The Religion of the Heart*. In 1825 an unfortunate litigation with his brother brought him back to England, and in 1827 he committed the greatest mistake of his life by the publication of his *Lord Byron and his Contemporaries*. The work is of considerable value as a corrective of merely idealized estimates of Lord Byron. But such a corrective should not have come from one who had lain under obligations to Byron, however trifling, or however they might seem to be cancelled by subsequent unkindness. Leigh Hunt should also have considered that the materials for his estimate of Byron were chiefly afforded by a residence under Byron's own roof. Apart from its obvious impropriety, the publication in itself is in general petty and carping. Hunt's attitude towards Byron is always that of the inferior; in proportion, therefore, as Byron is made to look small, Hunt appears still smaller. The book's reception was even more unfavourable than its deserts. British manliness and British cant were for once equally shocked, and the author especially writhed under the withering satire of Moore. For many years ensuing, the history of Hunt's life is that of a painful struggle with poverty and sickness. He worked unremittingly, but one effort failed after another. Two periodical ventures, the *Tatler* and the *London Journal*, were discontinued for want of subscribers, although in the latter Leigh Hunt had able coadjutors, and it contained some of his best writing. His editorship of the *Monthly Repository*, in which he succeeded W. J. Fox, was also unsuccessful. The adventitious circumstances which had for a time made the fortune of the *Examiner* no longer existed, and Hunt's strong and weak points, his refinement and his affectations, were alike unsuited to the general body of readers. *Sir Ralph Esher*, a romance of Charles the Second's period, was more successful, and *Captain Sword and Captain Pen*, a spirited contrast between the victories of peace and the victories of war, deserves to be ranked among his best poems. In 1840 his circumstances were improved by the successful representation of his *Legend of Florence*, a play of great merit, although it has not maintained itself upon the stage. *Lover's Amazements*, a comedy, was acted several years afterwards; and other plays are extant in MS. The pretty narrative poem of *The Palfrey* was published in 1842; and about this time he began to write for the *Edinburgh Review*. In 1844 he was further benefited by the generosity of Mrs Shelley and her son, the present baronet, who, on succeeding to the family estates, settled an annuity of £120 upon him; and in 1847 Lord John Russell procured him a civil list pension of £200. The fruits of the improved comfort and augmented leisure of these latter years were visible in the production of some charming volumes. Foremost among these are the companion books, *Imagination and Fancy* and *Wit and Humour*. In these Leigh Hunt shows himself as within a certain range the most refined, appreciative, and felicitous of critics. Homer and Milton may be upon the whole beyond his reach, though even here he is great in the detection of minor and unapprehended beauties; with Spenser and the old English dramatists he is perfectly at home, and his subtle and discriminating criticism upon them, as well as upon his own great contemporaries, is continually bringing to light beauties unsuspected by the reader, as they were probably undesigned by the writer. His companion volume on the pastoral poetry of Sicily, quaintly entitled *A Jar of Honey from Mount Hybla*, is almost equally delightful. *The Town* and *Men, Women, and Books* are partly made up from former material. The *Old Court Suburb* is an anecdotic sketch of Kensington, where he long resided before his final removal to Hammersmith. In 1850 he published his autobiography, a naive and accurate piece of self-portraiture, full of affectations, but on that very account free from the affectation of unreality. It is more chary of portraits of contemporaries than might have been expected, but contains very detailed accounts of some of the most interesting periods of the author's life, his education at Christ's Hospital, his imprisonment, and his residence in Italy. In 1855 his narrative poems, original and translated, were collected under the title of *Stories in Verse*, with an interesting preface. He died at Putney, on August 28, 1859.

The character of Leigh Hunt is not easy to delineate, not from any difficulty of recognizing or harmonizing its leading features, but from that of depicting the less admirable traits in a manner consistent with the affection and respect to which it is entitled on the whole. His virtues were charming rather than imposing or brilliant; he had no vices, but very many foibles. His great misfortune was that these foibles were for the most part of an undignified sort, and, though it may seem a paradox, that they were so harmless, and on so miniature a scale. Leigh Hunt's affectation, for example, is not comparable to Byron's, or his egotism to Wordsworth's, and therefore its very pettiness excites a sensation of the ludicrous which the colossal self-consciousness of his contemporaries does not produce. The very sincerity of his nature is detrimental to him; the whole man seems to be revealed in everything he ever wrote, and hence the most beautiful productions of his pen appear in a manner tainted by his really very pardonable weaknesses. Some of these, such as his helplessness in money matters, and his facility in accepting the obligations which he would have delighted to confer, were unfortunately of a nature to involve him in painful and humiliating embarrassments, which seem to have been aggravated by the mismanagement of those around him. The notoriety of these things has deprived him of much of the honour due to him for his fortitude under the severest calamities, for his unremitting literary industry under the most discouraging circumstances, and for his uncompromising independence as a journalist and an author. It was his misfortune to be involved in politics, for which he had little vocation, and which embroiled him with many with whom he would otherwise have been on good terms. "Though I was a politician," he says himself, "I had scarcely a political work in my library. Spensers and Arabian Tales filled up the shelves." He was in fact as thorough a man of letters as ever existed, and most of his failings were more or less incidental to that character. But it is not every consummate man of letters of whom it can be unhesitatingly affirmed that he was brave, just, and pious.

Leigh Hunt's character as an author was the counterpart of his character as a man. In some respects his literary position is unique. Few men have effected so much by mere exquisiteness of taste in the absence of high creative power; fewer still, so richly endowed with taste, have so frequently and conspicuously betrayed the want of it. As Wordsworth could never see where simplicity of poetic diction lapsed into mere prose, so Hunt was incapable of discovering where familiarity became flippancy. While Wordsworth, however, is at worst wearisome, Hunt is sometimes positively offensive to fastidious readers. This observation principally refers to his poetry, which, in spite of such vexatious flaws, nevertheless possesses a brightness, animation, artistic symmetry, and metrical harmony, which lift the author out of the rank of minor poets, particularly when the influence of his example upon his contemporaries is taken into account. He excelled especially in narrative poetry, of which, upon a small scale, there are probably no better examples in our language than "Abou ben Adhem" and "Solomon's Ring." He possessed every qualification for a translator, and it is to be regretted that his performances in that department are not more numerous and sustained. As an appreciative critic, whether literary or dramatic, he is hardly equalled; his guidance is as safe as it is genial. The no less important vocation of a censor was uncongenial to his gentle nature, and was rarely essayed by him.

The principal authorities for Leigh Hunt's life are his *Autobiography*, published in 1850, and reprinted since his death with additions and corrections, and the two volumes of his *Correspondence*, published with a connecting thread of biography by his son in 1862. The references to him in the writings and biographies of his contemporaries are innumerable. A full bibliography of his works, with excellent remarks, has been published by Mr Alexander Ireland. (R. G.)

HUNT, William Henry (1790–1864), water-colour painter, was born near Long Acre, London, March 28, 1790. Overcoming the usual parental objections, he was apprenticed about 1805 to John Varley, the landscape-painter, with whom he remained five or six years, exhibiting three oil pictures at the Royal Academy in 1807. He was early connected with the society of painters in water-colour, of which body, then in a transition state, he was elected associate in 1824, and full member in 1827. To its exhibitions he was until the year of his death one of the most prolific contributors. Many years of Hunt's uneventful and industrious life were passed at Hastings. He died of apoplexy, February 10, 1864.

Hunt was one of the creators of the English school of water-colour painting. His subjects, especially those of his later life, are extremely simple; but, by the delicacy, humour, and fine power of their treatment, they take rank second to works of the highest art only. Considered technically, his works exhibit all the resources of the water-colour painter's craft, from the purest transparent tinting to the boldest use of body-colour, rough paper, and scraping for texture. His sense of colour is perhaps as true as that of any English artist. "He was," says Ruskin, "take him for all in all, the finest painter of still life that ever existed." Several fine and characteristic examples of Hunt's work, as the Boy and Goat, Brown Study, and Plums, Primroses, and Birds' Nests, are in the water-colour galleries at South Kensington.

HUNTER, JOHN (1728–1793),—as physiologist and surgeon combined, unrivalled in the annals of medicine,—born February 13,[1] 1728, at Long Calderwood, in the parish of East Kilbride, Lanarkshire, was the youngest of the ten children of John and Agnes Hunter. His father, who died October 30, 1741,[2] aged 78, was descended from the old Ayrshire family of Hunter of Hunterston, and his mother was the daughter of a Mr Paul, treasurer of Glasgow. Hunter is said to have made but little progress at school, being averse to its restraints and pursuits, and fond of country amusements. When seventeen years old he repaired to Glasgow, where he for a short time assisted his brother-in law, Mr Buchanan, a cabinetmaker, who had involved himself in pecuniary difficulties. Being desirous at length of some settled occupation, he obtained from his brother William permission to aid, under Mr Symonds, in making dissections in his anatomical school, then the most celebrated in London, intending, should he be unsuccessful there, to enter the army. He arrived accordingly in the metropolis in September 1748, about a fortnight before the commencement of his brother's autumnal course of lectures. After succeeding beyond expectation with the dissection of the muscles of an arm, he was entrusted with a similar part injected, and from the excellence of his second essay Dr Hunter predicted that he would become a good anatomist. Seemingly John Hunter had hitherto received no instruction in preparation for the special course of life upon which he had entered. His brother, with whom he was now intimately associated, was one of the most brilliant exponents of medical science, and enjoyed the society of the best cultured men of the age; but that it was through this circumstance that, as stated by R. A. Stafford,[3] "he was taught to think," and that his mind, as has been surmised, had previous to his coming to London been "idle, heedless, and aimless," can hardly be concluded in the face of what the future revealed of the practical and inquiring turn and the originality of his mental disposition. Rather we may assume, with B. B. Cooper,[4] that Hunter was naturally gifted with powers of mind which rendered him to some extent independent of the training required by less extraordinary intellects. Dr J. Ridge,[5] speaking of Hunter's permitted truancy from the grammar school, argues that early tuition and attainments, at least of the kind imparted, being inconsistent with a natural education of the senses, are not favourable to the production of extraordinary genius. Hunter's power of estimating what was worth doing, and what could be done, is by Dr Moxon[6] ascribed in part to his being "a man who had a free youth, not over-taught, nor over-strained;" and, if it be true that "the early part of life, the school-time, has long been spent, and is spent, in pursuits which minister but little to the culture of the mind, or to the communication and reception of knowledge useful to any class of society in proportion to the time consumed,"[7] it is possible that his dislike to scholastic exercises may have served to protect Hunter from influences opposed to that very endowment which made him preeminent as a teacher, namely, the power of perceiving the relation of numerous individual facts as illustrations of general principles.

Hard-working, and singularly patient and skilful in dissection, Hunter had by his second winter in London acquired sufficient anatomical knowledge to be entrusted with the charge of his brother's practical class, with the members of which, as also with the resurrection men, he was a universal favourite. In the summer months of 1749–50, at Chelsea Military Hospital, he attended the lectures and operations of Cheselden, on whose retirement in the following year he became a surgeon's pupil at St Bartholomew's, where Pott was one of the senior surgeons. In the summer of 1752 he visited Scotland. Home and, following him, Ottley state that Hunter began in 1754 to assist his brother as his partner in lecturing; according, however, to the *European Magazine* for 1782, the office of lecturer was offered to Hunter by his brother in 1758, but declined by him on account of the "insuperable embarrassments and objections" which he felt to speaking in public. In 1754 he became a surgeon's pupil at St George's Hospital, where he was appointed house-surgeon in 1756.[8] During the period of his connexion with Dr Hunter's school he, in addition to other labours, solved the problem of the descent of the testis in the fœtus, traced the ramifications of the nasal and olfactory nerves within the nose, experimentally tested the question whether veins could act as absorbents, studied the formation of pus, and the nature of the placental circulation, and with his brother earned the chief merit of practically proving the function and importance of the lymphatics in the animal economy. On June 5, 1755,[9] he was induced to enter as a gentleman commoner at St Mary's Hall, Oxford, but his true instincts would not permit him, to use his own expression, "to stuff Latin and Greek at the university." Some three and thirty years later he thus significantly wrote of an opponent:—"Jesse Foot accuses me of not understanding the dead languages; but I could teach him that on the dead body which he never knew in any language dead or living."[10] Doubtless, however, linguistic studies would have served to correct in him what was perhaps a natural defect—a difficulty in the presentation of abstract ideas which was not wholly attributable to the novelty of his doctrines.

An attack of inflammation of the lungs in the spring of 1759, apparently caused by overwork, having produced symptoms threatening consumption, by which the promising medical career of his brother James had been cut short, Hunter, with a view to residence abroad for a season, obtained from Mr Adair in October 1760 the appointment of staff-surgeon in Hodgson and Keppel's expedition to Belleisle. With this he sailed in 1761. In the following year he served with the English forces on the frontier of Portugal. Whilst with the army he acquired the extensive knowledge of gunshot wounds embodied in his important treatise on that subject, published in 1794, in which, amongst other matters of moment, he insists on the rejection of the indiscriminate practice of dilating with the knife followed almost universally by surgeons of his time. When not engaged in the active duties of his profession, he occupied himself with physiological and other scientific researches. Thus, in 1761, off Belleisle, the conditions of

[1] The date is thus entered in the parish register, see Adams, *Memoirs*, Appendix, p. 203. The Hunterian Oration, instituted in 1813 by Dr Baillie and Sir Everard Home, is delivered at the Royal College of Surgeons on the 14th of February, which Hunter used to give as the anniversary of his birth.

[2] Ottley's date, 1738, is inaccurate, see Simmons, *Account of . . . W. Hunter*, p. 7. Hunter's mother died Nov. 3, 1751, aged 66.

[3] *Hunt. Orat.*, 1851, p. 6.

[4] *Hunt. Orat.*, 1853, p. 7.

[5] *Observations on the Life, Disease, and Death of J. Hunter*, p. 19, 1855.

[6] See Oration before Hunterian Society, *Med. Times and Gazette*, March 1877, p. 224.

[7] R. Quain, *Hunt. Orat.*, 1869, p. 19.

[8] So in Home's *Life*, p. xvi., and Ottley's, p. 15. Hunter himself (*Treatise on the Blood*, p. 62) mentions the date 1755.

[9] Ottley incorrectly gives 1753 as the date. In the buttery book for 1755 at St Mary's Hall his admission is thus noted: "Die Junii 5to 1755 Admissus est Johannes Hunter superioris ordinis Commensalis." Hunter apparently left Oxford after less than two months' residence, as the last entry in the buttery book with charges for battels against his name is on July 25, 1755. His name was, however, retained on the books of the Hall till December 10, 1756. The writer is indebted to Dr John Griffiths, Keeper of the Archives, Oxford University, for the following record of Hunter's matriculation:—"Ter° Trin. 1755.—Junii 5to Aul. S. Mar. Johannes Hunter 24 Johannis de Kilbride in Com. Clidesdale Scotiæ Arm. fil."

[10] Ottley, *Life of J. Hunter*, p. 22.

the coagulation of the blood were among the subjects of his inquiries.[1] Later, on land, he continued the study of human anatomy, and arranged his notes and memoranda on inflammation; he also ascertained by experiment that digestion does not take place in snakes and lizards during hibernation, and observed that enforced vigorous movement at that season proves fatal to such animals, the waste so occasioned not being compensated, whence he drew the inference that, in the diminution of the power of a part attendant on mortification, resort to stimulants which increase action without giving real strength is inadvisable.[2] A MS. catalogue by Hunter, probably written soon after his return from Portugal, shows that he had already made a collection of about two hundred specimens of natural and morbid structures.

On arriving in England early in 1763, Hunter, having retired from the army on half-pay, took a house in Golden Square, and commenced the career of a London surgeon. Most of the metropolitan practice at the time was held by Pott, C. Hawkins, Sharpe, Warner, Adair, and Tomkins; and Hunter sought to eke out his at first slender income by teaching practical anatomy and operative surgery to a private class. His leisure was devoted to the study of comparative anatomy, to procure subjects for which he obtained the refusal of animals dying in the Tower menagerie and in various travelling zoological collections. In connexion with his rupture of a tendo Achillis,[3] in 1767, he performed on dogs several experiments which, with the illustrations in his museum of the reunion of such structures after division, laid the foundation of the modern practice of cutting through tendons for the relief of distorted and contracted joints. In the same year he was made a fellow of the Royal Society. His first contribution to the *Philosophical Transactions*, with the exception of a supplement to a paper by J. Ellis in the volume for 1766, was an essay on post-mortem digestion of the stomach, written at the request of Sir J. Pringle, and read June 18, 1772, in which he first correctly explained that phenomenon as a result of the action of the gastric juice.[4] Hunter, on December 9, 1768, was elected a surgeon to St George's Hospital, and, soon after, a member of the Corporation of Surgeons. He now began to take house-pupils. Among these were Edward Jenner, who came to him in 1770, and until the time of Hunter's death corresponded with him on the most intimate and affectionate terms, W. Guy, Kingston, Dr Physick of Philadelphia, and Everard Home, his brother-in-law. Mr Lynn and Sir A. Carlisle, though not inmates of his house, were frequent visitors there. His pupils at St George's included Abernethy, Cline, James Earle, and Astley Cooper. From the high reputation in their profession which these one and all attained, some estimate may be formed of the weight and value of Hunter's personal influence and teaching. In 1770 he settled in Jermyn Street, in the house which his brother William had previously occupied; and in July 1771 he married Anne, the eldest daughter of Mr Robert Home, surgeon to Burgoyne's regiment of light-horse.[5]

From 1772 till his death Hunter resided during autumn at a house built by him at Earl's Court, Brompton, where most of his biological researches were carried on. There he kept for the purpose of study and experiment the fishes, lizards, blackbirds, hedgehogs, and other animals sent him from time to time by Jenner, tame pheasants and partridges, at least one eagle, toads, silkworms, and many more creatures obtained from every quarter of the globe. Bees he had under observation in his conservatory for upwards of twenty years; hornets and wasps were also diligently studied by him. On two occasions his life was in risk from his pets—once in wrestling with a young bull, and again when he fearlessly took back to their dens two leopards which had broken loose among his dogs. Choosing intuitively the only true method of philosophical discovery, Hunter, ever cautious of confounding fact and hypothesis, besought of nature the truth through the medium of manifold experiments and observations. "He had never read Bacon," says Babington, "but his mode of studying nature was as strictly Baconian as if he had."[6] To Jenner, who had offered a conjectural explanation of a phenomenon, he writes, August 2, 1775: "I think your solution is just; but why think? why not try the experiment? Repeat all the experiments upon a hedgehog[7] as soon as you receive this, and they will give you the solution." Perhaps no man busily engaged in professional practice has ever conducted so many physiological and pathological investigations in the animal world as Hunter; and yet it was with him an axiom "that experiments should not be often repeated which tend merely to establish a principle already known and admitted, but that the next step should be the application of that principle to useful purposes" ("Anim. Œcon.," *Works*, iv. 86). During fifteen years he kept a flock of geese simply in order to acquaint himself with the development of birds in eggs, with reference to which he remarked—"It would almost appear that this mode of propagation was intended for investigation." In his toxicological and other researches, in which his experience had led him to believe that the effects of noxious drugs are nearly similar in the brute creation and in man, he had already, in 1780, as he states, "poisoned some thousands of animals."[8]

By inserting shot at definite distances in the leg-bones of young pigs, and also by feeding them with madder, by which all fresh osseous deposits are tinged,[9] Hunter obtained evidence that bones increase in size, not by the intercalation of new amongst old particles, as had been

[1] *Treatise on the Blood*, p. 21.

[2] See Adams, *Memoirs*, pp. 32, 33. *Cf.* Hunter's *Treatise on the Blood*, p. 8, and *Works*, ed. Palmer, i. 604.—On the employment of Hunter's term "increased action" with respect to inflammation, see Paget, *Lect. on Surg. Path.*, 3d ed., p. 321 *sqq.*

[3] According to Hunter, as quoted in Palmer's edition of his lectures, p. 437, the accident was "after dancing, and after a violent fit of the cramp;" Clift, however, who says he probably never danced, believed that he met with the accident "in getting up from the dissecting table after being cramped by long sitting" (see W. Lawrence, *Hunt. Orat.*, 1834, p. 64).

[4] The subjects and dates of his subsequent papers in the *Transactions*, the titles of which give little notion of the richness of their contents, are as follows:—The torpedo, 1773; air-receptacles in birds, and the Gillaroo trout, 1774; the *Gymnotus electricus*, and the production of heat by animals and vegetables (supplemented in 1777), 1775; the recovery of people apparently drowned, 1776; the free martin, 1779; the communication of smallpox to the fœtus in utero, and the occurrence of male plumage in old hen pheasants, 1780; the organ of hearing in fishes, 1782; the anatomy of a "new marine animal" described by Home, 1785; the specific identity of the wolf, jackal, and dog (supplemented in 1789), the effect on fertility of extirpation of one ovarium, and the structure and economy of whales, 1787; observations on bees, 1793; and some remarkable caves in Bayreuth and fossil bones found therein, 1794. With these may be included a paper by Home, from materials supplied by Hunter, on certain horny excrescences of the human body.

[5] Mrs Hunter died January 7, 1821, in Holles Street, Cavendish Square, London, in her seventy-ninth year. She was a handsome and accomplished woman, and well fulfilled the social duties of her position. The words for Haydn's English canzonets were supplied by her, and were mostly original poems; of these the lines beginning "My mother bids me bind my hair" are, from the beauty of the accompanying music, among the best known. (See R. Nares in *Gent. Mag.*, xci., pt. 1, p. 89, quoted in Nichols's *Lit. Anec.*, 2d ser., vii. 638.)

[7] The condition of this animal during hibernation was a subject of special interest to Hunter, who thus introduces it, even in a letter of condolence to Jenner in 1778 on a disappointment in love:—"But let her go, never mind her. I shall employ you with hedgehogs, for I do not know how far I may trust mine."

[8] See his evidence at the trial of Captain Donellan, *Works*, i. 195.

imagined by Duhamel, but by means of additions to their extremities and circumference, excess of calcareous tissue being removed by the absorbents. Some of his most extraordinary experiments were to illustrate the relation of strength of constitution to sex. He exchanged the spurs of a young cock and a young pullet, and found that on the former the transplanted structure grew to a fair size, on the latter but little; whereas a spur from one leg of a cock transferred to its comb, a part well supplied with blood, grew more than twice as fast as that left on the other leg. Another experiment of his, which required many trials for success, was the engrafting of a human incisor on the comb of a cock.[1] The uniting of parts of different animals when brought into contact he attributed to the production of adhesive instead of suppurative inflammation, owing to their possession of "the simple living principle."[2] The effects of habit upon structure were illustrated by Hunter's observation that in a sea-gull which he had brought to feed on barley the muscular parietes of the gizzard became greatly thickened. A similar phenomenon was noticed by him in the case of other carnivorous birds fed on a vegetable diet.

It was in 1772 that Hunter, in order effectually to gauge the extent of his own knowledge, and also to correctly express his views, which had been repeatedly misstated or ascribed to others, commenced his lectures on the theory and practice of surgery, at first delivered free to his pupils and a few friends, but subsequent to 1774 on the usual terms, four guineas. Though Pott, indeed, had perceived that the only true system of surgery is that which most closely accords with the curative efforts of nature, a rational pathology can hardly be said to have had at this time any existence; and it was generally assumed that a knowledge of anatomy alone was a sufficient foundation for the study of surgery. Hunter, unlike his contemporaries, to most of whom his philosophic habit of thought was a mystery, and whose books contained little else than relations of cases, and modes of treatment, sought the reason for each phenomenon that came under his notice. The principles of surgery, he maintained, are not less necessary to be understood than the principles of other sciences; unless, indeed, the surgeon should wish to resemble "the Chinese philosopher whose knowledge consisted only in facts." In that case the science must remain unimproved until fresh facts arise. Too much attention, he remarked, cannot be paid to facts; yet a multitude of facts overcrowd the memory without advantage if they do not lead us to establish principles, by an acquaintance with which we learn the causes of diseases. Hunter's course, which latterly comprised eighty-six lectures, delivered on alternate evenings between the hours of seven and eight, lasted from October to April. Some teachers of his time were content to dismiss the subjects of anatomy and surgery in a course of only six weeks' duration. The task of lecturing is said to have been to Hunter so formidable that at the commencement of each course he was obliged to take half a drachm of laudanum. His class was usually small, and never exceeded thirty. Among its members at various times were Abernethy, Carlisle, Chevalier, Cline, Coleman, Astley Cooper, Home, Lynn, and Macartney. Hunter was deficient in the gifts of a good extempore speaker, being in this respect a remarkable contrast to his brother William; and he read his lectures, seldom raising his eyes from the manuscript. His manner with his auditory is stated to have been embarrassed and awkward, or, as Adams puts it (*Obs. on Morbid Pois.*, p. 272), "frequently ungraceful," and his language always unadorned; but that his "expressions for the explaining of his new theories rendered his lectures often unintelligible" is scarcely evident in his pupils' notes still extant. His own and others' errors and fallacies were exposed with equal freedom in his teaching. Occasionally he would tell his pupils, "You had better not write down that observation, for very likely I shall think differently next year;" and once to a question of Coleman's he replied, "Never ask me what I have said or what I have written; but, if you will ask me what my present opinions are, I will tell you." He was always much gratified when, in the conversations that he encouraged his hearers to hold with him at the end of his lectures, he found that what he said was understood and appreciated.

In January 1776 Hunter was appointed surgeon-extraordinary to the king. He commenced in the same year his Croonian lectures on muscular motion, continued annually, except in 1777, till 1782: they were never published by him, being in his opinion too incomplete. In 1778 appeared the second part of his *Treatise on the Natural History of the Human Teeth*, the first part of which was published in 1771. It was in the waste of the dental alveoli and of the fangs of shedding teeth that in 1754–55, as he tells us, he received his first hint of the use of the absorbents. Abernethy (*Phys. Lect.*, p. 196) relates that Hunter, being once asked how he could suppose it possible for absorbents to do such things as he attributed to them, replied, "Nay, I know not, unless they possess powers similar to those which a caterpillar exerts when feeding on a leaf." Hunter in 1780 read before the Royal Society a paper in which he laid claim to have been the first to make out the nature of the utero-placental circulation. His brother William, who had five years previously described the same in his *Anatomy of the Gravid Uterus*, thereupon wrote to the Society attributing to himself this honour. John Hunter in a rejoinder to his brother's letter, dated February 17, 1780, reiterated his former statement, viz., that his discovery, on the evening of the day in 1754 that he had made it in a specimen injected by a Dr Mackenzie, had been communicated by him to Dr Hunter. Thus arose an estrangement between the two Hunters, which continued until the time of William's last illness, when his brother obtained permission to visit him.

In 1783 Hunter was elected a member of the Royal Society of Medicine and of the Royal Academy of Surgery at Paris, and took part in the formation of "A Society for the Improvement of Medical and Chirurgical Knowledge."[3] It appears from a letter by Hunter that in the latter part of 1783 he, with Jenner, had the subject of colour-blindness under consideration. As in that year the lease of his premises in Jermyn Street was to expire, he purchased the twenty-four years' leasehold of two houses, the one on the east side of Leicester Square, the other in Castle Street, with intervening ground. Between the houses he built in 1783–85, at an expense of above £3000, a museum for his anatomical and other collections. These by 1782 had cost him £10,000, and contained preparations of numerous specimens presented by Sir Joseph Banks, the Honourable C. Greville, and Mr Walsh. The new edifice consisted of a hall 52 feet long by 28 feet wide, and lighted from the top, with a gallery all round, and having beneath it a lecture

[1] *Essays and Observations*, i. 55, 56. "May we not claim for him," says Sir Wm. Fergusson with reference to these experiments, "that he anticipated by a hundred years the scientific data on which the present system of human grafting is conducted?" (*Hunt. Orat.*, 1871, p. 17).

[2] *Essays and Observations*, i. 115; *cf. Works*, i. 391.

[3] The *Transactions* of the Society contain papers by Hunter on inflammation of veins (1784), intussusception (1789), a case of paralysis of the muscles of deglutition (1790), and a case of poisoning during pregnancy (1794), with others written by Home, from materials supplied by him, on Hunter's operation for the cure of popliteal aneurism, on loose cartilages in joints, on certain horny excrescences of the human body, and on the growth of bones.

theatre, and a room used subsequently for the meetings of the Lycæum Medicum, a society instituted by Hunter and Fordyce. In April 1785 Hunter's collections were removed into it under the superintendence of Home and Bell,[1] and another assistant, André. Among the foreigners of distinction that inspected the museum, which was now shown by Hunter twice a year,—in October to medical men, and in May to other visitors,—were Blumenbach, Camper, Poli, and Scarpa. In the acquisition of subjects for his varied biological investigations and of specimens for his museum, expense was a matter of small moment with Hunter. Thus at one time he endeavoured, at his own cost, to obtain information respecting the Cetacea by sending out a surgeon to the North in a Greenland whaler. He is said, moreover, to have given, in June 1783, no less than £500 for the body of O'Brien, or Byrne, the Irish giant, whose skeleton, 7 feet 7 inches high, is so conspicuous an object in the museum of the College of Surgeons of London.[2]

Hunter, who in the spring of 1769–72 had suffered from gout, in spring 1773 from spasm apparently in the pyloric region, accompanied by failure of the heart's action (Ottley, *Life*, p. 44), and in 1777 from vertigo with symptoms of angina pectoris, had in 1783 another attack of the last mentioned complaint, to which he was henceforward subject when under anxiety or excitement of mind.

In May 1785,[3] chiefly to oblige Sharp the engraver, Hunter consented to have his portrait taken by Sir Joshua Reynolds. He proved a bad sitter, and Reynolds made but little satisfactory progress, till one day Hunter, while resting his somewhat upraised head on his left hand, fell into a profound reverie—one of those waking dreams, seemingly, which in his lectures he has so well described, when "the body loses the consciousness of its own existence."[4] The painter had now before him the man he would fain depict, and, turning his canvas upside down, he sketched out the admirable portrait which, since most skilfully restored by Mr H. Farrar, is in the possession of the Royal College of Surgeons. A copy of the same, by Jackson, acquired from Lady Bell, is to be seen at the National Portrait Gallery in South Kensington. St Mary's Hall, Oxford, also possesses a copy. Sharp's engraving of the original, published in 1788, is one of the finest of his productions. The volumes seen in Reynolds's picture are a portion of the unpublished records of anatomical researches left by Hunter at his death, which, with other manuscripts, Sir Everard Home in 1812 removed from his museum, and eventually, in order, it has been supposed, to keep secret the source of many of his papers in the *Philosophical Transactions*, and of facts mentioned in his lectures, committed to the flames.[5]

[1] Bell lived with Hunter fourteen years, *i.e.*, from 1775 to 1789, and was employed by him chiefly in making and drawing anatomical preparations for the museum. He died in 1792 at Sumatra, where he was assistant-surgeon to the East India Company.

[2] O'Brien, dreading dissection by Hunter, had shortly before his death arranged with several of his countrymen that his corpse should be conveyed by them to the sea, and sunk in deep water; but his undertaker, who had entered into a pecuniary compact with the great anatomist, managed that while the escort was drinking at a certain stage on the march seawards, the coffin should be locked up in a barn. There some men he had concealed speedily substituted an equivalent weight of paving-stones for the body, which was at night forwarded to Hunter, and by him taken in his carriage to Earl's Court, and, to avoid risk of a discovery, immediately after suitable division boiled to obtain the bones. See Tom Taylor, *Leicester Square*, chap. xiv., 1874; *cf. Annual Register*, xxvi. 209, 1783.

[5] A transcript of a portion of Hunter's MSS., made by Clift in 1793 and 1800, was edited by Professor Owen, in two volumes with notes, in 1861, under the title of *Essays and Observations in Natural History, Anatomy, Physiology, Psychology, and Geology*. On the destruction of Hunter's papers see Clift's "Appendix" in vol. ii. p. 497, also Prof. Flower, *Introd. Lect.*, 7–9, 1870.

Among the subjects of Hunter's physiological investigations in 1785 was the mode of growth of deer's antlers. As he possessed the privilege of making experiments on the deer in Richmond Park, he in July of that year had a buck there caught and thrown, and tied one of its external carotid arteries. He observed that the antler which obtained its blood supply therefrom, then half-grown, became in consequence cold to the touch. Hunter debated with himself whether it would be shed in due time, or be longer retained than ordinarily. To his surprise he found, on re-examining the antler a week or two later, when the wound around the ligatured artery was healed, that it had regained its warmth, and was still increasing in size. Had, then, his operation been in some way defective? To determine this question, the buck was killed and sent to Leicester Fields. On examination Hunter ascertained that the external carotid had been duly tied, but that certain small branches of the artery above and below the ligature had enlarged, and by their anastomoses had restored the blood supply of the growing part. Thus it was evident that under "the stimulus of necessity," to use a phrase of the experimenter, the smaller arterial channels are capable of rapid increase in dimensions to perform the offices of the larger.[6] It happened that, in the ensuing December, there lay in one of the wards of St George's Hospital a patient of Hunter's, admitted for popliteal aneurism. The disease must soon prove fatal unless by some means arrested. Should the surgeon, following the usual and commonly fatal method of treatment, cut down upon the tumour, and, after tying the artery above and below it, evacuate its contents? Or should he adopt the procedure, deemed by Pott generally advisable, of amputating the limb above it? It was Hunter's aim in his practice, even if he could not dispense with the necessity, at least to diminish the severity of operations, which he considered were an acknowledgment of the imperfection of the art of healing, and compared to "the acts of the armed savage, who attempts to get that by force which a civilized man would get by stratagem." Since, he argued, the experiment with the buck had shown that collateral vessels are capable of continuing the circulation when passage through a main trunk is arrested, why should he not, in his aneurism case, leaving the absorbents to deal with the contents of the tumour, tie the artery in the sound parts, where it is tied in amputation, and preserve the limb? Acting upon this idea, he ligatured his patient's femoral artery in the lower part of its course in the thigh, in the fibrous sheath enclosing the space since known as "Hunter's canal."[7] The leg was found, some hours after the operation, to have acquired a temperature even above the normal.[8] At the end of January 1786, that is, in six weeks' time, the patient was well enough to be able to leave the hospital. Thus it was that Hunter inaugurated an operation which has been the means of preserving to hundreds life with integrity of limb — an operation which, as the Italian Assalini, who saw it first performed, testifies, "excited the greatest wonder,

[6] In his *Treatise on the Blood*, p. 288, Hunter observes :—"We find it a common principle in the animal machine, that every part increases in some degree according to the action required. Thus we find . . . . vessels become larger in proportion to the necessity of supply, as for instance, in the gravid uterus; the external carotids in the stag, also, when his horns are growing, are much larger than at any other time."

[7] See Professor Owen, "John Hunter and Vivisection," *Brit. Med. Journ.*, February 22, 1879, p. 284. In the fourth of his operations for popliteal aneurism, Hunter for the first time did not include the vein in the ligature. His patient lived for fifty years afterwards. The results on the artery of this operation are to be seen in specimen 3472A (Path. Ser.) in the Hunterian Museum.

[8] Home, *Trans. of Soc. for Impr. of Med. and Chirurg. Knowl.*, i. 147, 1793. Excess of heat in the injured limb was noticed also in Hunter's second case on the day after the operation; and in his fourth case it reached 4°–5° on the first day, and continued during a fortnight.

and awakened the attention of all the surgeons in Europe."

Early in 1786 Hunter published his *Treatise on the Venereal Disease*, which, like some of his previous writings, was printed in his own house. Without the aid of the booksellers, 1000 copies of it were sold within a twelvemonth. Although certain views therein expressed with regard to the relationship of syphilis have been proved erroneous, the work is a valuable compendium of observations of cases and modes of treatment (*cf.* Hilton, *Hunt. Orat.*, p. 40). Towards the end of the year appeared his *Observations on certain parts of the Animal Œconomy*, which, besides the more important of his contributions to the *Philosophical Transactions*, contains nine papers on various subjects. By the death of Mr Middleton in 1786, Hunter became deputy surgeon-general to the army; his appointment as surgeon-general and as inspector-general of hospitals followed in 1790, on the death of Mr Adair. In 1787 he received the Royal Society's Copley medal as a testimony to the importance of his discoveries in natural history, and was also elected a member of the American Philosophical Society. On account of the increase in his practice and his impaired health, he now obtained the services of Home as his assistant at St George's Hospital. The death of Pott in December 1788 secured to Hunter the undisputed title of the first surgeon in England. He resigned to Home, in 1792, the delivery of his surgical lectures, in order to devote himself more fully to the completion of his *Treatise on the Blood, Inflammation, and Gunshot Wounds*, which was published by his executors in 1794. In this, his masterpiece, the application of physiology to practice is especially noticeable. Certain experiments described in the first part, pp. 62-64, which demonstrate that arterialization of the blood in respiration takes place by a process of diffusion of "pure air" or "vital air" (*i.e.*, oxygen) through membrane, were made so early as the summer of 1755.

Hunter in 1792 announced to his colleagues at St George's, who, he considered, neglected the proper instruction of the students under their charge, his intention no longer to divide with them the fees which he received for his hospital pupils. Against this innovation, however, the governors of the hospital decided in March 1793. Subsequently, by a committee of their appointing, a code of rules respecting pupils was promulgated, one clause of which, probably directed against an occasional practice of Hunter's, stipulated that no person should be admitted as a student of the hospital without certificates that he had been educated for the medical profession. In the autumn two young Scotchmen, ignorant of the new rule, came up to town and applied to Hunter for admission as his pupils at St George's. Hunter explained to them how he was situated, but promised to advance their request at the next board meeting at the hospital on the 16th October. On that day, having finished a difficult piece of dissection, he went down to breakfast in excellent spirits and in his usual health. After making a professional call, he attended the board meeting. There the interruption of his remarks in behalf of his applicants by a flat contradiction from a colleague brought on one of the old spasmodic heart attacks; he ceased speaking, and retired into an adjoining room only in time to fall lifeless into the arms of Dr Robertson, one of the hospital physicians. After an hour had been spent in vain attempts to restore animation, his body was conveyed to his house in a sedan chair.[1] Thus, in his sixty-fifth year, and in the height of his mental activity, died John Hunter, "whose range of thought nature alone could fill," and to whom, as to but few among all mankind, had been given wisdom to interpret the dark sayings of nature. His remains were interred privately on October 22, 1793, in the vaults of St Martin's in the Fields. Thence, on March 28, 1859, through the instrumentality of Mr Frank Buckland, they were removed to Abbot Islip's chapel in Westminster Abbey, to be finally deposited in the grave in the north aisle of the nave, close to the resting-place of Ben Jonson.

Hunter was of about medium height, strongly built, and high-shouldered and short-necked. He had an open countenance, and large features, eyes light-blue or grey, eyebrows prominent, and hair reddish-yellow in youth, later white, and worn curled behind; and he dressed plainly and neatly. He rose at or before six, dissected till nine (his breakfast hour), received patients from half-past nine till twelve, at least during the latter part of his life, and saw his outdoor and hospital patients till about four, when he dined, taking, according to Home, as at other meals in the twenty years preceding his death, no wine. After dinner he slept an hour; he then superintended experiments, read or prepared his lectures, and made, usually by means of an amanuensis, records of the day's dissections. "I never could understand," says Clift, "how Mr Hunter obtained rest: when I left him at midnight, it was with a lamp fresh trimmed for further study, and with the usual appointment to meet him again at six in the morning." Mr H. Leigh Thomas records[2] that, on his first arrival in London, having by desire called on Hunter at five o'clock in the morning, he found him already busily engaged in the dissection of insects. Rigidly economical of time, Hunter was always at work, and always he had in view some fresh enterprise. He was once heard by Adams to express regret that men must die at all. To his museum he gave a very large share of his attention, being fearful lest the ordering of it should be incomplete at his death, and knowing of none who could continue his work for him. "When I am dead," said he one day to Dr Garthshore, "you will not soon meet with another John Hunter." At the time of his death he had anatomized certainly over 500 different species of animals, some of them repeatedly, and had made numerous dissections of plants. The manuscript works by him appropriated and destroyed by Home, among which were his eighty-six surgical lectures, all in full, are stated to have been "literally a cartload"; and many pages of his records were written by Clift under his directions "at least half a dozen times over, with corrections and transpositions almost without end."

To Hunter, as he himself observed, to think was a delight. His mind was framed for systematic investigation, and hence, perhaps, arose the fatigue which, more particularly during the last ten years of his life, the desultory conversation of a mixed company would occasion him.[3] "My mind is like a bee-hive," was a remark of his to Abernethy, "a simile which struck me," says that writer, "on account of its correctness; for, in the midst of buzz and apparent confusion, there was great order, regularity of structure, and abundant food, collected with incessant industry from the choicest stores of nature."[4] Hunter was generally, though cheerfully, taciturn, and many a morning's labour with Clift was passed with scarcely a word of discourse. When, however, he spoke—as while resting himself, and standing upright from his dissection after stooping for hours as if nailed to the object under investigation—he evinced both shrewdness and wit. In conversation his words were well chosen, and his remarks often wonderfully forcible and pointed; and, when so disposed, he could put things in a very ludicrous point of view. He articulated slowly, and in consultation gave his opinion much as if lecturing, the enunciation of his not seldom novel doctrines being prefaced by some introductory illustration or history. A stranger to artifice and flattery, and open and unceremonious or even blunt in speech, he readily communicated what he knew and thought, and thus did not always inspire others with a higher opinion of their personal consequence. "We are but beginning to learn our profession," he would tell his friends; and he was wont to say that he was conscious of no peculiar talent, but that, if he had promoted professional knowledge, it seemed to him to have arisen chiefly from his disposition to distrust opinions, and to examine every subject for himself. What views of his he confidently offered for acceptance were such as he believed to have a solid foundation in facts; and the blind enunciation by his fellow-practitioners of time-honoured errors vexed

[1] The record of Hunter's death in the *St James Chronicle* for October 15-17, 1793, p. 4, col. 4, makes no allusion to the immediate cause of Hunter's death, but gives the following statement:—"JOHN HUNTER.—This eminent Surgeon and valuable man was suddenly taken ill, yesterday, in the Council-room of St George's Hospital. After receiving the assistance which could be afforded by two Physicians and a Surgeon, he was removed in a close chair to his house, in Leicester Fields, where he expired about two o'clock." Examination of the heart revealed disease involving the pericardium, endocardium, and arteries, the coronary arteries in particular showing ossific change.

[2] *Hunt. Orat.*, 1827, p. 5.

[3] Home, *Life*, p. lxv.

[4] *Hunt. Orat.*, 1819, p. 48.

his mind, which was naturally susceptible, and was rendered the more so by excess of exertion, with repeatedly the additional strain of bodily disease. "I know, I know," said he to Abernethy, "I am but a pigmy in knowledge, yet I feel as a giant when compared with these men." The charges that his language was frequently coarse, and that swearing was with him a habit, as with many of his contemporaries and successors, have been indignantly rebutted by Clift.[1] Leigh Thomas describes the impression left by his first early morning interview with Hunter as "a mingled feeling of profound respect, surprise, and admiration;" and by his assistants, pupils, and all with whom he had lived on intimate terms, he was both loved and venerated. His temper, Home states, was very warm and impatient, and when irritated not easily soothed. The hasty but not altogether illogical outburst of his anger when refused the post-mortem examination of a child, the victim of some obscure malady, in the words, "Then, sir, I heartily hope that yourself and all your family, nay all your friends, may die of the same disease, and that no one may be able to afford any assistance," is in amusing contrast with the acknowledged benevolence of his character. To the kindness of his disposition, his fondness for animals, his aversion to operations, his thoughtful and self-sacrificing attention to his patients, and especially his zeal to help forward struggling practitioners and others in any want abundantly testify. "Every man," said he, "should be an economist, for if he has ever more money than his wants require he can assist the poor." In a letter of his, introducing a patient to his brother William, we read: "He has no money, and you have plenty, so that you are well met." Pecuniary means he valued no further than they enabled him to promote his researches; and to the poor, to non-beneficed clergymen, professional authors, and artists his services were rendered without remuneration. His yearly income in 1763–74 was never £1000; it exceeded that sum in 1778, for several years before his death was £5000, and at the time of that event had reached above £6000. All his earnings not required for domestic expenses were, during the last ten years of his life, devoted to the improvement of his museum; and his property, this excepted, was found on his decease to be barely sufficient to pay his debts. By his contemporaries generally Hunter was respected as a master of the art and science of anatomy, and as a cautious and trustworthy if not an elegant or very dexterous operator. Few, however, perceived the drift of his biological researches. Although it was admitted, even by Foot,[2] that the idea after which his unique museum had been formed—namely, that of morphology as the only true basis of a systematic zoological classification—was entirely his own, yet his investigations into the structure of the lower orders of animals were regarded as, after all, works of unprofitable curiosity. One surgeon, of no inconsiderable repute, is said to have ventured the remark that Mr Hunter's preparations were "just as valuable as so many pig's pettitoes;"[3] and the president of the Royal Society, Sir Joseph Banks, writing in 1796, plainly expressed his disbelief as to the collection being "an object of importance to the general study of natural history, or indeed to any branch of science except to that of medicine." It was "without the solace of sympathy or encouragement of approbation, without collateral assistance,"[4] and careless of achieving fame—for he held that "no man ever was a great man who wanted to be one"—that Hunter laboured to perfect his designs, and established the science of comparative anatomy, and principles which, however neglected in his life-time, became the ground-work of all medical study and teaching.

In accordance with the directions given by Hunter in his will, his collection was offered for purchase to the British Government. But the prime minister, Mr Pitt, on being asked to consider the matter, exclaimed: "What! buy preparations! Why, I have not money enough to purchase gunpowder." He, however, consented to the bestowal of a portion of the king's bounty for a couple of years on Mrs Hunter and her two surviving children. In 1796 Lord Auckland undertook to urge upon the Government the advisability of acquiring the collection, and on June 13, 1799, parliament voted £15,000 for this purpose. Its custodianship, after refusal by the College of Physicians, was unanimously accepted by the Corporation of Surgeons on the terms proposed. These were in brief—that the collection be open four hours in the forenoon, two days every week, for the inspection and consultation of the fellows of the College of Physicians, the members of the Company of Surgeons, and persons properly introduced by them, a catalogue of the preparations and an official to explain it being at those times always at hand; that a course of not less than twenty-four lectures[5] on comparative anatomy and other subjects illustrated by the collection be given every year by some member of the Company; and that the preparations be kept in good preservation at the expense of the Corporation, and be subject to the superintendence of a board of sixteen trustees.[6] The fulfilment of these conditions was rendered possible by the receipt of fees for examinations and diplomas, under the charter by which, in 1800, the Corporation was constituted the Royal College of Surgeons. A board of curators was in that year appointed by the council of the college to provide for the management of the museum and the preparation of catalogues. In 1806 the collection was placed in temporary quarters in Lincoln's Inn Fields, and the sum of £15,000 was voted by parliament for the erection of a proper and commodious building for its preservation and extension. This was followed by a grant of £12,500 in 1807. The collection was removed in 1812 to the new museum, and opened to visitors in 1813. The greater part of the present edifice was built in 1835, at an expense to the college of about £40,000; and the combined Hunterian and collegiate collections, having been rearranged in what are now termed the western and middle museums, were in 1836 made accessible to the public. The erection of the eastern museum in 1852, on premises in Portugal Street bought in 1847 for £16,000, cost £25,000, of which parliament granted £15,000; it was opened in 1855.

Hunter's collection was estimated to contain 13,682 specimens, viz., in the physiological department, 3745 in spirit, 965 osteological, 617 dry, 1968 zoological—total 7295; and in the pathological, 1084 in spirit, 625 dry (including bones), 536 calculi and concretions, 218 monsters and malformations, and 215 microscopic—total 2678; and 3709 fossils. Since its acquisition by the college, it has been greatly increased, notably by presentations from Sir William Blizard (1811) and Sir S. L. Hammick (1851), and by purchase of specimens in the possession of Sir A. Lever (1806), Messrs Joshua Brookes (1828), Heaviside (1829), Langstaff, South (1835), Howship, Taunton (1841), Liston (1842), and Walker (1843), Sir Astley Cooper (1843), and Dr Barnard Davis (Jan. 1880). The histological collection, of which the 215 Hunterian specimens are the nucleus, is the result chiefly of the labours of Professor Quekett, and purchases from Dr Tweedy Todd, Mr Nasmyth, and Professor Lenhossek, and contained in July 1880 upwards of 12,000 specimens. The library, the formation of which commenced in 1801, consisted in July 1880 of 37,668 vols., comprising 14,882 separate works, and 39,021 tracts, pamphlets, essays, theses, and reports.[7] Mr William Clift, whom, on February 14, 1792, Hunter received into his house to train as an assistant in his museum,[8] had the exclusive charge of the collection from the date of its owner's death to that of its purchase by the state. During this period, with two gallons of spirit meted out occasionally, and the pittance of 7s. a week for his own support out of the limited funds at the disposal of Hunter's executors, he contrived to maintain the whole in good condition. He was conservator of the museum, as stated on the pedestal of his bust there, from 1800 to 1849. From 1825 to 1832 he was assisted by his son, William Home Clift. Professor Richard Owen held the office of assistant-conservator in 1832–35, and of conservator in 1836–55, and Professor J. T. Quekett that of assistant-conservator in 1843–51, and of conservator from 1852 till his death in 1861, when he was succeeded by Professor William Henry Flower.

The scope of Hunter's labours may be defined as the explication of the various phases of life exhibited in organized structures, both animal and vegetable, from the simplest to the most highly differentiated. By him, therefore, comparative anatomy was employed, not in subservience to the classification of living forms, as by Cuvier, but as a means of gaining insight into the principle animating and producing these forms, by virtue of which he perceived that, however different in form and faculty, they were all allied to himself. In what does life consist? is a question which in his writings he frequently considers, and which seems to have been ever present in his mind. Life, he taught, was a principle independent of structure,[9] most tenaciously held by the least highly organized beings, but capable of readier destruction as a whole, as, *e.g.*, by deprivation of heat or by pain, in young than in old animals. In life he beheld an agency working under the control of law, and exercising its functions in various modes and degrees. He perceived it, as Abernethy observes, to be "a great chemist," a power capable of manufacturing a variety of substances into one kind of generally distributed nutriment, and of furnishing from this a still greater variety of dissimilar substances. Like Harvey, who terms it the *anima vegetiva*, he regarded it as a principle of self-preservation, which keeps the body from dissolution. Life is shown, said he, in renovation and action; but, although facilitated in its working by mechanical causes, it can exist without action, as in an egg new-laid or undergoing incubation. It is not simply a regulator of temperature; it is a principle which resists cold, conferring on the structures which it endows the capacity of passing some degrees below the freezing-point of ordinary inanimate matter without suffering congelation. Hunter found, in short, that there exists in animals a latent heat of life, set free in the process of death (see *Treatise on*

[9] How clearly he held this view is seen in his remark (*Treatise on the Blood*, p. 28, *cf.* p. 46) that, as the coagulating lymph of the blood is probably common to all animals, whereas the red corpuscles are not, we must suppose the lymph to be the essential part of that fluid. Hunter was the first to discover that the blood of the embryos of red-blooded animals is at first colourless, resembling that of invertebrates. (See Owen, Preface to vol. iv. of *Works*, p. xiii.)

the Blood, p. 80). Thus he observed that sap if removed from trees froze at 32° Fahr., but within them might be fluid even at 15°; that a living snail placed in a freezing mixture acquired first a temperature of 28°, and afterwards of 32° ere it froze; and that, whereas a dead egg congealed immediately at 32°, a living egg did so only when its temperature had risen to that point after a previous fall to 29½°. The idea that the fluid and semifluid as well as the solid constituents of the body contain the vital principle diffused through them he formed in 1755–6, when, in making drawings illustrative of the changes that take place in the incubated egg, he noted specially that neither the white nor the yolk undergoes putrefaction. The blood he, with Harvey, considered to possess a vitality of its own, more or less independent of that of the animal in which it circulates. Life, he held, is preserved by the compound of the living body and the source of its solid constituents, the living blood. It is to the susceptibility of the latter to be converted into living organized tissue that the union of severed structures by the first intention is due. He even inclined to the belief that the chyle has life, and he considered that food becomes "animalized" in digestion. Coagulation of the blood he compared to the contraction of muscles, and believed to be an operation of life distinct from chemical coagulation, adducing in support of his opinion the fact that, in animals killed by lightning, by violent blows on the stomach, or by the exhaustion of hunting, it does not take place. "Breathing," said Hunter, "seems to render life to the blood, and the blood continues it in every part of the body."[1] Life, he held, could be regarded as a fire, or something similar, and might for distinction's sake be called "animal fire." Of this the process of respiration might afford a constant supply, the fixed life supplied to the body in the food being set free and rendered active in the lungs, whilst the air carried off that principle which encloses and retains the animal fire.[2] The living principle, said Hunter, is coeval with the existence of animal or vegetable matter itself, and may long exist without sensation. The principle upon which depends the power of sensation regulates all our external actions, as the principle of life does our internal, and the two act mutually on each other in consequence of changes produced in the brain. Something (the "materia vitæ diffusa") similar to the components of the brain (the "materia vitæ coacervata") may be supposed to be diffused through the body and even contained in the blood; between these a communication is kept up by the nerves (the "chordæ internunciæ").[3] Neither a material nor a chemical theory of life, however, formed a part of Hunter's creed. "Mere composition of matter," he remarked, "does not give life; for the dead body has all the composition it ever had; life is a property we do not understand; we can only see the necessary leading steps towards it."[4] As from life only, said he in one of his lectures, we can gain an idea of death, so from death only we gain an idea of life. Life, being an agency leading to, but not consisting of, any modification of matter, "either is something superadded to matter, or else consists in a peculiar arrangement of certain fine particles of matter, which being thus disposed acquire the properties of life." As a bar of iron may gain magnetic virtue by being placed for a time in a special position, so perhaps the particles of matter arranged and long continued in a certain posture eventually gain the power of life. "I enquired of Mr Hunter," writes one of his pupils,[5] "if this did not make for the Exploded Doctrine of Equivocal Generation; he told me perhaps it did, and that as to Equivocal Generation all we c^d have was negative Proofs of its not taking Place. He did not deny that Equivocal Generation happened; there were neither positive proofs for nor against its taking place."

To exemplify the differences between organic and inorganic growth, Hunter made and employed in his lectures a collection of crystallized specimens of minerals, or, as he termed them, "natural or native fossils." Of fossils, designated by him "extraneous fossils," because extraneous respecting the rocks in which they occur, he recognized the true nature, and he arranged them according to a system agreeing with that adopted for recent organisms. The study of fossils enabled him to apply his knowledge of the relations of the phenomena of life to conditions, as exhibited in times present, to the elucidation of the history of the earth in geological epochs. He observed the non-occurrence of fossils in granite, but with his customary scientific caution and insight could perceive no reason for supposing it to be the original matter of the globe, prior to vegetable or animal, or that its formation was different from that of other rocks. In water he recognized the chief agent in producing terrestrial changes (*cf. Treatise on the Blood*, p. 15, note); but the popular notion that the Noachian deluge might account for the marine organisms discovered on land he pointed out was untenable. From the diversity of the situations in which many fossils and allied living structures are found, he was led to infer that at various periods not only repeated oscillations of the level of the land, lasting thousands of centuries, but also great climatic variations, perhaps due to a change in the ecliptic, had taken place in geological times. Hunter considered that very few fossils of those that resemble recent forms are identical with them. He conceived that the latter might be varieties, but that if they are really different species, then "we must suppose that a new creation must have taken place." It would appear, therefore, that the origin of species in variation had not struck him as possible. That he believed varieties to have resulted from the influence of changes in the conditions of life in times past is shown by a somewhat obscure passage in his "Introduction to Natural History" (*Essays and Observations*, i. 4), in which he remarks, "But, I think, we have reason to suppose that there was a period of time in which every species of natural production was the same, there being then no variety in any species," and adds that "civilization has made varieties in many species, which are the domesticated." Modern discoveries and doctrines as to the succession of life in time are again foreshadowed by him in the observation in his introduction to the description of drawings relative to incubation (quoted in Pref. to *Cat. of Phys. Ser.*, i. p. iv., 1833) that:—

> "If we were capable of following the progress of increase of the number of the parts of the most perfect animal, as they first formed in succession, from the very first, to its state of full perfection, we should probably be able to compare it with some one of the incomplete animals themselves, of every order of animals in the creation, being at no stage different from some of those inferior orders; or, in other words, if we were to take a series of animals from the more imperfect to the perfect, we should probably find an imperfect animal corresponding with some stage of the most perfect."

In pathological phenomena Hunter discerned the results of the perturbation of those laws of life by which the healthy organism subsists. With him pathology was a science of vital dynamics. He afforded principles bearing not on single complaints only, but on the effects of injury and disease in general. To attempt to set forth what in Hunter's teaching was new to pathology and systematic surgery, or was rendered so by his mode of treatment, would be well-nigh to present an epitome of all that he wrote on those subjects. "When we make a discovery in pathology," says Adams, writing in 1818, "we only learn what we have overlooked in his writings or forgotten in his lectures." Surgery, which only in 1745 had formally ceased to be associated with "the art and mystery of barbers," he raised to the rank of a scientific profession. His doctrines were, necessarily, not those of his age: while lesser minds around him were still dim with the mists of the ignorance and dogmatism of times past, his lofty intellect was illumined by the dawn of a distant day.

See, besides the above quoted publications, *An Appeal to the present Parliament . . . . on the subject of the late J. Hunter's Museum*, 1795; Sir C. Bell, *A Lecture . . . . being a Commentary on Mr J. Hunter's preparations of the Diseases of the Urethra*, 1830; The President of the Royal College of Surgeons of England, *Address to the Committee for the Erection of a Statue of Hunter*, Lond., March 29, 1859; Professor Owen, "Sketch of Hunter's Scientific Character and Works," in Tom Taylor's *Leicester Square*, 1874, also in Hunter's *Works*, ed. by Palmer, vol. iv., 1837, and in *Essays and Observations*; the invaluable catalogues of the Hunterian Collection issued by the Royal College of Surgeons; and numerous Hunterian Orations. In the *Journal of a Voyage to New South Wales*, by John White, is a paper containing directions for preserving animals, printed separately in 1809, besides six zoological descriptions by Hunter; and in the *Natural History of Aleppo*, by A. Russell, are remarks of Hunter's on the anatomy of the jerboa and the camel's stomach. Notes of his lectures on surgery, edited by J. W. K. Parkinson, appeared in 1833 under the title of *Hunterian Reminiscences*. Hunter's *Observations and Reflections on Geology*, intended to serve as an introduction to the catalogue of his collection of extraneous fossils, was published in 1859, and his *Memoranda on Vegetation* in 1860. (F. H. B.)

HUNTER, WILLIAM (1718–1783), a celebrated physiologist and physician, and the first great teacher of anatomy in England, was born May 23, 1718, at East Kilbride, Lanark. He was the seventh child of his parents, and an elder brother of John Hunter, the distinguished surgeon. When fourteen years of age he was sent to the university of Glasgow, where he studied for five years. He had originally been intended for the church, but, scruples concerning subscription arising in his mind, he followed the advice of his friend William Cullen (see CULLEN, vol. vi. p. 694), and resolved to devote himself to physic. During 1737–40 he resided with Cullen at Hamilton, and then, with a view to increasing his medical knowledge before settling in partnership with his friend, he spent the winter of 1740–41 at Edinburgh, and thence went to London. There Dr James Douglas, an anatomist and obstetrician of some note, to whom he had been recommended, engaged his services as a tutor to his son, and as a dissector, and assisted him to enter as a surgeon's pupil at St George's Hospital, and to procure the instruction of the anatomist Dr Nicholls. Dr Douglas died in April 1742, but Hunter still continued to live with his family. In 1746 Hunter undertook in place of Mr Samuel Sharpe the delivery, for a society of

naval practitioners, of a series of lectures on operative surgery, and so satisfactorily did he acquit himself of his task that he was requested to include anatomy in his course. It was not long before he attained considerable fame as a lecturer; for not only was his oratorical ability great, but he differed from his contemporaries in the fulness and thoroughness of his teaching, and in the care which he took to provide for his hearers the best possible practical illustrations of his discourses. We read that the syllabus of Mr Nourse, published in 1748, "totam rem anatomicam complectens," comprised only twenty-three lectures, exclusive of a short and defective "Syllabus Chirurgicus," and that at "one of the most reputable courses of anatomy in Europe," which Hunter had himself attended, the professor was obliged to demonstrate all the parts of the body, except the nerves and vessels (shown in a fœtus) and the bones, on a single dead subject, and for the explanation of the operations of surgery used a dog! In 1747 Hunter became a member of the Corporation of Surgeons. In the course of a tour through Holland to Paris with his pupil J. Douglas in 1728, he visited Albinus at Leyden, and inspected with admiration his injected preparations. By degrees Hunter renounced surgical for obstetric practice, in which he excelled. He was appointed a surgeon-accoucheur at the Middlesex Hospital in 1748, and at the British Lying-in Hospital in the year following. The degree of M.D. was conferred upon him by the university of Glasgow, October 24, 1750. About the same time he left his old abode at Mrs Douglas's, and settled as a physician in Jermyn Street. He became a licentiate of the College of Physicians, September 30, 1756. In 1762 he was consulted by Queen Charlotte, and in 1764 was made physician-extraordinary to her Majesty.

On the departure of his brother John for the army, Hunter engaged as an assistant Mr William Hewson, whom he subsequently admitted to partnership in his lectures. Hewson was succeeded in 1770 by Mr Cruikshank. Hunter became in 1767 a fellow of the Royal Society; in 1768 a fellow of the Society of Antiquaries, and third professor of anatomy to the Royal Academy of Arts; and in 1780 and 1782 respectively an associate of the Royal Medical Society and of the Royal Academy of Sciences of Paris. During the closing ten years of his life his health failed greatly. His last lecture, at the conclusion of which he fainted, was given, contrary to the remonstrances of friends, only a few days before his death, which took place March 30, 1783. He was buried in the rector's vault at St James's, Piccadilly.

Hunter had in 1765 requested of the Hon. Mr Grenville the grant of a plot of ground on which he might establish "a museum in London for the improvement of anatomy, surgery, and physic" (see "Papers" at end of his *Two Introductory Lectures*, 1784), and had offered to expend on its erection £7000, and to endow in perpetuity a professorship of anatomy in connexion with it. His application receiving no recognition, he after many months abandoned his scheme, and built himself a house, with lecture and dissecting-rooms, in Great Windmill Street, whither he removed in 1770. In one fine apartment in this house was accommodated his collection, comprising anatomical and pathological preparations, ancient coins and medals, minerals, shells, and corals. His natural history specimens were in part a purchase, for £1200, of the executors of his friend Dr John Fothergill (see vol. ix. p. 475). Hunter's whole collection, together with his fine library of Greek and Latin classics, and an endowment of £8000, by his will became, after the lapse of twenty years, the property of the university of Glasgow. His paternal estate of Long Calderwood was left to his brother-in-law, Dr James Baillie, by whom, as soon as the will was proved, it was made over to John Hunter. Hunter was never married, and was a man of frugal habits. Like his brother John, he was an early riser, and a man of untiring industry. He is described as being in his lectures, which were of two hours' duration, "both simple and profound, minute in demonstration, and yet the reverse of dry and tedious;" and his mode of introducing anecdotal illustrations of his topic was most happy. Lecturing was to him a pleasure, and, notwithstanding his many professional distractions, he regularly continued it, because, as he said, he "conceived that a man may do infinitely more good to the public by teaching his art than by practising it" (see "Memorial" appended to *Introd. Lect.*, p. 120).

Hunter was the author of several contributions to the *Medical Observations and Enquiries* and the *Philosophical Transactions*. In his paper on the structure of cartilages and joints, published in the latter in 1743, he anticipated what Bichat sixty years afterwards wrote concerning the structure and arrangement of the synovial membranes. His *Medical Commentaries* (pt. i., 1762, supplemented 1764) contains, among other like matter, details of his disputes with the Munros as to who first had successfully performed the injection of the *tubuli testis* (in which, however, both he and they had been forestalled by Haller in 1745), and as to who had discovered the true office of the lymphatics (*cf.* ANATOMY, vol. i. p. 815), and also a discussion on the question whether he or Pott ought to be considered the earliest to have elucidated the nature of *hernia congenita*, which, as a matter of fact, had been previously explained by Haller. In the *Commentaries* is exhibited Hunter's one weakness—an inordinate love of controversy. His impatience of contradiction he averred to be a characteristic of anatomists, in whom he once jocularly condoned it, on the plea that "the passive submission of dead bodies" rendered the crossing of their will the less bearable. His great work, *The Anatomy of the Gravid Uterus, exhibited in Figures*, fol. (see ANATOMY, vol. i. p. 816), was published in 1774. His posthumous works are *Two Introductory Lectures*, 1784, and *Anatomical Description of the Human Gravid Uterus*, 1794, which was re-edited by Dr Rigby in 1843.

Munk, *The Roll of the Royal College of Physicians of London*, ii. 205, 1878; and the preceding article. (F. H. B.)

HUNTING. The circumstances which render necessary the habitual pursuit of wild animals, either as a means of subsistence or for self-defence, generally accompany a phase of human progress distinctly inferior to the pastoral and agricultural stages; resorted to as a recreation, on the other hand, the practice of the chase in most cases indicates a considerable degree of civilization, and sometimes ultimately becomes the almost distinctive employment of the classes which are possessed of most leisure and wealth. It is only in some of its latter aspects, viz., as a "sport," pursued on fixed rules and principles, that hunting requires notice here.

The information we possess as to the field sports of the ancients is in many directions extremely fragmentary. With regard to the ancient Egyptians, however, we learn that the huntsmen constituted an entire subdivision of the great second caste; they either followed the chase on their own account, or acted as the attendants of the chiefs in their hunting excursions, taking charge of the dogs, and securing and bringing home the game. The game was sought in the open deserts which border on both sides the valley of the Nile; but (by the wealthy) sometimes in enclosed spaces into which the animals had been driven, or in preserves. Besides the noose and the net, the arrow, the dart, and the hunting pole or *venabulum* were frequently employed. The animals chiefly hunted were the gazelle, ibex, oryx, stag, wild ox, wild sheep, hare, and porcupine; also the ostrich for its plumes, and the fox, jackal, wolf, hyæna, and leopard for their skins, or as enemies of the farm-yard. The lion was occasionally trained as a hunting animal instead of the dog. The sportsman appears, occasionally at least, in the later periods, to have gone to cover in his chariot or on horseback; according to Wilkinson, when the dogs threw off in a level plain of great extent, it was even usual for him "to remain in his chariot, and, urging his horses to their full speed, endeavour to turn or intercept them as they doubled, discharging a well-directed arrow whenever they came within its range."[1] The partiality for the chase which the ancient Egyptians manifested was shared by the Assyrians and Babylonians, as is shown by the frequency with which hunting scenes are found depicted on the walls of their temples and palaces, and also by the alleged fact that even their dresses and furniture were ornamented with similar subjects.[2] The game pursued included the lion, the wild ass, the gazelle, and the hare, and the implements chiefly employed seem to have been the javelin and the bow. There are indications that hawking was also known. The Assyrian kings also maintained magnificent parks, or "paradises," in which game of every kind was enclosed; and perhaps it was from them that the Persian sovereigns borrowed the practice mentioned both by Xenophon in the *Cyropædia*, and by Curtius. According to Herodotus, Cyrus devoted the revenue of four great towns to meet the expenses of his hunting establishments. The circumstances under which the death of the son of Crœsus is by the same writer (i. 34–45) related to have occurred incidentally show in what high estimation the recreation of hunting was held in Lydia. In Palestine game has always been plentiful, and the Biblical indications that it was much sought and duly appreciated are numerous. As means of capture, nets, traps, snares, and pitfalls are most frequently alluded to; but the arrow (Isa. vii. 24), the spear, and the dart (Job xli. 26–29) are also mentioned. There is no evidence that the use of the dog (Jos., *Ant.*, iv. 8, 10, notwithstanding) or of the horse in hunting was known among the Jews during the period covered by the Old Testament history; Herod, however, was a keen and successful sportsman, and is recorded by Josephus (*B. J.*, i. 21, 13, compare *Ant.*, xv. 7, 7; xvi. 10, 3) to have killed no fewer than forty head of game (boar, wild ass, deer) in one day. The sporting tastes of the ancient Greeks, as may be gathered from many references in Homer (*Il.*, ix. 538–545; *Od.*, ix. 120; xvii. 295, 316; xix. 429 *sq.*), had developed themselves at a very early period; they first found adequate literary expression in the work of Xenophon entitled *Cynegeticus*,[3] which expounds his principles and embodies his experience in his favourite art of hunting. The treatise chiefly deals with the capture of the hare; in the author's day the approved method was to find the hare in her form by the use of dogs; when found she was either driven into nets previously set in her runs, or else run down in the open. Boar-hunting is also described; it was effected by nets into which the animal was pursued, and in which when fairly entangled he was speared. The stag, according to the same work, was taken by means of a kind of wooden trap (ποδοστράβη) which attached itself to the foot. Lions, leopards, lynxes, panthers, and bears are also specially mentioned among the large game; sometimes they were taken in pitfalls, sometimes speared by mounted horsemen. As a writer on field sports Xenophon was followed by Arrian, who in his *Cynegeticus*, in avowed dependence on his predecessor, seeks to supplement such deficiencies in the earlier treatise as arose from its author's unacquaintance with the dogs of Gaul and the horses of Scythia and Libya. Four books of *Cynegetica*, extending to about 2100 hexameters, by Oppian have also been preserved; the last of these is incomplete, and it is probable that a fifth at one time existed. The poem contains some good descriptive passages, as well as some very curious indications of the state of zoological knowledge in the author's time. Hunting scenes are frequently represented in ancient works of art, especially the boar-hunt, and also that of the hare. In Roman literature allusions to the pleasures of the chase (wild ass, boar, hare, fallow deer, being specially mentioned as favourite game) are not wanting (Virg., *Georg.*, iii. 409–413; *Ecl.*, iii. 75; Hor., *Od.*, i. 1, 25–28); it seems to have been viewed, however, with less favour as an occupation for gentlemen, and to have been chiefly left to inferiors and professionals. The immense *vivaria* or *theriotropheia*, in which various wild animals, such as boars, stags, and roe-deer, were kept in a state of semi-domestication, were developments which arose at a comparatively late period; as also were the *venationes* in the circus, although these are mentioned as having been known as early as 186 B.C. The bald and meagre poem of Gratius Faliscus on hunting (*Cynegetica*) is modelled upon Xenophon's prose work; a still extant fragment (315 lines) of a similar poem with the same title, of much later date, by Nemesianus, seems to have at one time formed the introduction to an extended work corresponding to that of Oppian. That the Romans had borrowed some things in the art of hunting from the Gauls may be inferred from the name *canis gallicus* (Spanish *galgo*) for a greyhound, which is to be met with both in Ovid and Martial; also in the words (*canis*) *vertragus* and *segusius*, both of Celtic origin.[4] According to Strabo (p. 200) the Britons also bred dogs well adapted for hunting purposes. The addiction of the Franks in later centuries to the chase is evidenced by the frequency with which not only the laity but also the clergy were warned by provincial councils against expending so much of their time and money on hounds, hawks, and falcons; and we have similar proof with regard to the habits of other Teutonic nations subsequent to the introduction of Christianity.[5] Originally among the northern nations sport was open to every one[6] except to slaves, who were not permitted to bear arms; the growth of the idea of game-preserving was a gradual one, and kept pace with the development of feudalism. For its ultimate development in Britain see FOREST LAW, where also the distinction between beasts of forest or venery, beasts of chase, and beasts and fowls of warren is explained. See also GAME LAWS.

The English word "hunt" (from *henten*, "to capture," and thus nearly equivalent to "chase," which is the doublet of the verb "to catch"; compare Ital. *caccia*, Fr. *chasse*) has come specially to be applied to the pursuit of the stag, hare, and fox, especially of the last-named, with horse, hound, and horn, as distinguished from other modes of capturing game. It thus corresponds to the French *chasse au courre*, as distinguished from *chasse au tir*, *à l'oiseau* &c., and to the German *Hetzjagd* as distinguished from *Birsch*. The origin of the sport in Britain does not admit of being historically traced. Doubtless the early inhabitants shared to a large extent in the habits of the other Celtic peoples; the fact that at least they kept good hunting dogs is vouched for, as we have seen, by Strabo; and an interesting illustration of the manner in which these were used is given in the inscription quoted by Orelli (*n.* 1603)—"Silvano Invicto Sacrum—ob aprum eximiæ formæ captum, quem multi antecessores prædari non potuerunt." When the period of Alfred the Great is reached, we have it on the authority of Asserius, his biographer, that before he was twelve years of age he "was a most expert and

active hunter, and excelled in all the branches of that noble art, to which he applied with incessant labour and amazing success."[1] Of his grandson Athelstan it is related by William of Malmesbury that after the victory of Brunanburgh he imposed upon the vanquished king of Wales a yearly tribute, which included a certain number of "hawks and sharp-scented dogs fit for hunting wild beasts." According to the same authority, one of the greatest delights of Edward the Confessor was "to follow a pack of swift hounds in pursuit of game, and to cheer them with his voice." It was under the Anglo-Saxon kings that the distinction between the higher and lower chase first came to be made,—the former being expressly for the king or those on whom he had bestowed the pleasure of sharing in it, while only the latter was allowed to the proprietors of the land. To the reign of Cnut belong the "Constitutiones de Foresta," according to which four thanes were appointed in every province for the administration of justice in all matters connected with the forests; under them were four inferior thanes to whom was committed immediate care of the vert and venison [2] The severity of the forest laws which prevailed during the Norman period is sufficient evidence of the sporting ardour of William and his successors. The Conqueror himself, we are told by his contemporaries, "loved the high game as if he were their father;" and the penalty for the unauthorized slaughter of a hart or hind was loss of both eyes.

Stag hunting.

Stag Hunting.—Although at an early period stag hunting was a favourite recreation with royalty, it is difficult to say when the royal buckhounds were first established. It seems probable that in the reign of Henry VIII. the royal pack was kennelled at Swinley, where, in the reign of Charles II. (1684), a deer was found that went away to Lord Petre's seat in Essex; only five got to the end of this 70 miles' run, one being the king's brother, the duke of York. George III. was a great stag hunter, and met the royal pack as often as possible.

The Devon and Somerset staghounds are the only pack in England that now pursue the wild red deer. In his interesting work, *The Chase of the Wild Red Deer*, Mr Collyns says that the earliest record of a pack of staghounds in the Exmoor district is in 1598, when Hugh Polland, Queen Elizabeth's ranger, kept one at Simonsbath. The succeeding rangers of Exmoor forest kept up the pack until nearly 200 years ago, the hounds subsequently passing into the possession of Mr Walter of Stevenstone, an ancestor of the Rolle family. Successive masters continued the sport until 1825, when the fine pack, descended probably from the blood hound crossed with the old southern hound, was sold in London. It is difficult to imagine how the dispersion of such a pack could have come about in such a sporting country, but in 1827 the late Sir Arthur Chichester got a pack together, and the country has been hunted ever since, the present master being Mr Fenwick Bissett. Stag hunting begins on the 12th of August, and ends on the 8th of October; there is then a cessation until the end of the month, when the hounds are unkennelled for hind hunting, which continues up to Christmas; it begins again about Ladyday, and lasts till the 10th of May. The mode of hunting with the Devon and Somerset hounds is briefly this:—the whereabouts of a warrantable stag is communicated to the master by that important functionary the harbourer; two couple of steady hounds called tufters are then thrown into cover, and, having singled out a warrantable deer, follow him until he is forced to make for the open, when the body of the pack are laid on. Very often two or three hours elapse before the stag breaks, but a run over the wild country fully atones for the delay. With all other packs of staghounds, except one in the New Forest, which hunts fallow deer, the quarry is the carted deer; the animal is turned out from a vehicle resembling a prison van in appearance, and the hounds are laid on after a quarter of an hour's law.

Fox hunting.

Fox Hunting.—It is only within comparatively recent times that the fox has come to be considered as an animal of the higher chase. William Twici, indeed, who was huntsman-in-chief to Edward II., and who wrote in Norman French a treatise on hunting, which still exists in an English translation, mentions the fox as a beast of venery, but obviously as an altogether inferior object of sport. Strutt also gives an engraving, assigned by him to the 14th century, in which three hunters, one of whom blows a horn, are represented as unearthing a fox, which is pursued by a single hound. The precise date of the establishment of the first pack of hounds kept entirely for fox hunting cannot be accurately fixed. In the work of "Nimrod" (C. J. Apperley), entitled *The Chase*, there is (p. 4) an extract from a letter from Lord Arundel, dated February 1833, in which the writer says that his ancestor, Lord Arundel, kept a pack of foxhounds between 1690 and 1700, and that they remained in the family till 1782, when they were sold to the celebrated Hugh Meynell, of Quorndon Hall, Leicestershire. Lord Wilton again, in his *Sports and Pursuits of the English*, says that "about the year 1750 hounds began to be entered solely to fox." The *Field* of November 6, 1875, p. 512, contains an engraving of a hunting-horn then in the possession of the late master of the Cheshire hounds, and upon the horn is the inscription:—"Thomas Boothby, Esq., Tooley Park, Leicester. With this horn he hunted the first pack of foxhounds then in England fifty-five years. Born 1677. Died 1752. Now the property of Thomas d'Avenant, Esq., county Salop, his grandson." These extracts do not finally decide the point, because both Mr Boothby's and Lord Arundel's hounds may have hunted other game besides fox, just as in Edward IV.'s time there were "fox dogs" though not kept exclusively for fox. On the whole, it is probable that Lord Wilton's surmise is not far from correct. Since fox hunting first commenced, however, the system of the sport has been much changed. In our grandfathers' time the hounds met early, and found the fox by the drag, that is, by the line he took to his kennel on his return from a foraging expedition. Hunting the drag was doubtless a great test of nose, but many good runs must have been lost thereby, for the fox must often have heard the hounds upwind, and have moved off before they could get on good terms with him. At the present day, the woodlands are neither so large nor so numerous as they formerly were, while there are many more gorse covers; therefore, instead of hunting the drag up to it, a much quicker way of getting to work is to find a fox in his kennel; and, the hour of meeting being later, the fox is not likely to be gorged with food, and so unable to take care of himself at the pace at which the modern foxhound travels.

The maste[r]

On hunting days it is the master's duty to say what covers are to be drawn, and to request the field to take up such positions as will enable the fox to have fair play. The management of the field requires considerable firmness, but the very strong language one sometimes hears is better avoided. Where a professional huntsman is employed, he is responsible for the actual hunting, and the less he is interfered with by the master or anybody else the better. The country should be hunted fairly through-

[1] See Strutt, *Sports and Pastimes*, who also gives an illustration, "taken from a manuscriptal painting of the 9th century in the Cotton Library," representing "a Saxon chieftain, attended by his huntsman and a couple of hounds, pursuing the wild swine in a forest."

[2] See Lappenberg, *Hist. of England under the Anglo-Saxon Kings* (ii. 361, Thorpe's transl.).

out its length and breadth, not only for the sake of the subscribers living in the different districts, but with a view to sport. Woodlands of greater or less extent are to be found even in countries denominated open, and these places are generally strongholds for foxes, and should be regularly rattled throughout the season; if this be neglected, the foxes, instead of breaking quickly, will ring about the cover all day, and, what is worse, many small covers will be drawn blank by reason of their inhabitants seeking the quietude of the wood. The frequent hunting of woodlands, though conducive in the long run to sport, is not popular with the field. It is on the whole a matter for congratulation that most packs of hounds are now carried on by subscription. Little by little the expense attending a pack of hounds has increased until it has now assumed large proportions: the hounds must be of the best blood; at least five horses per hunting day (exclusive of the master's) must be allowed for the hunt servants; no makeshifts for kennel or stable will be tolerated; and the hunt servants must be men of known character. Under these circumstances, a master undertaking to keep hounds at his own expense incurs great cost for the benefit of others, or else, being judged by the standard of great establishments, lays himself open to a charge of only half doing what he has put his hand to. If hunting is as popular as it is supposed to be, it is for every reason advisable that those who derive amusement from it should contribute something towards the general expenses. In establishments conducted upon a liberal scale, the annual cost will amount to about £620 a year for each day in the week that the pack hunts; thus, a three days a week pack will cost about £1860 per annum, a four days a week pack £2480, and so on; but absolute efficiency cannot be maintained much under £520 per day.

[Th]e [Hun]ts[ma]n. The author of the *Diary of a Huntsman* says that, to be perfect, "a huntsman should possess the following qualifications—health, memory, decision, temper, patience, a good ear, voice, and sight, courage and spirits, perseverance and activity; and with these he will make a slow pack quick." Should the master be his own huntsman, he will save about £300 a year, but he should unite as many as possible of the above list of virtues to those he is possessed of in his capacity of master. The position of a huntsman is a peculiar one; he is the servant of the master, yet the latter must to a certain extent make a confidant of him, as in cases of breeding, drawing the hounds for a day's hunting, and other matters. A huntsman must be fond of his calling, or he will not be energetic in the pursuit of it; he must also be a bold horseman,—if a good one so much the better,—for nothing is more annoying to the master and the field than to see a huntsman refuse to cast his hounds in an obviously probable direction, because the doing so would necessitate jumping an ugly fence. Observation and decision are also indispensable. When hounds check, the proper course to pursue is very often suggested by some trifling incident which occurred perhaps ten minutes before, and which was noticed at the time without any particular weight being attached to it; for instance, some rooks might have been hovering on the left or right of the line the hounds were running; or again, some hound that can be depended on diverges for a moment from the rest of the pack. The huntsman remembers this when the check takes place, and tries in that direction, often with success. When once a check occurs, decision should be shown in acting promptly; right or wrong, the huntsman must do something, and must have a reason for what he does. Authorities are not wanting who reckon youth as one of a huntsman's qualities; but huntsmen, like hunters, are not at their best until half worn out. There is so much to learn in the nature of the fox, so many isolated cases must have been observed in order to deduce a principle from them, that a young man cannot possibly have the experience necessary to show the best sport, and our hunting records tell of men who have continued to ride boldly and to show no signs of age when fifty years old.

The method of hunting a pack of hounds varies somewhat in different countries. One of the most accepted canons is that the huntsman should not interfere with his hounds more than is necessary. So long as hounds can hunt, it is best to let them do so, for if their heads are once got up by hallooing and lifting, they will not so readily settle down again; while hounds that are in the habit of being lifted and galloped off to a distant point whenever a check occurs, will generally look for assistance, and will make but little use of their own noses on cold scenting days. Some countries are naturally bad-scenting ones, and, in order to kill a fox in them, hounds must be lifted more than in others.

Huntsmen are often much abused, when drawing a large cover, for not going away with the first fox. There is a difference of opinion whether, if hounds are running one fox in cover, they should be stopped and put on the line of one that has gone away. Something will depend upon whether the cover was well worked during cub hunting or not, and whether foxes are plentiful or scarce, but after the 1st of February the rule should be to go away with the first fox that breaks, or the hounds may get on a vixen.

The whipper-in. The whipper-in, to be a success, must be content to suppress himself for the public good. When a "good thing" occurs, and the huntsman is going as hard as he can, and many of the field harder than they like, the whip, or, if two be kept, the second whip, should wait in cover and come on with the tail hounds. A good whip can do more in the furtherance of sport than any huntsman; in the interest, therefore, of fox hunting, there must be no rivalry, or rather no manifestation of it, between the huntsman and the whip. A noisy fellow is an abomination; and the whip should carefully avoid rating a hound after seeing that his voice is entirely disregarded. If needs be a hound must be flogged and that soundly, but he should never be struck without knowing what it is for; thus, it is of no use, twenty minutes after a hound has ceased to run riot, to get alongside of him, bellow out his name, and then flog him; to warrant the use of the lash, he must be caught *flagrante delicto*, and must pay no heed to rating. Where, however, hounds have been properly entered and treated, they will require but little chastisement. On approaching a cover, one whip should go on in advance and station himself on the lee side of it, where he may often see a fox steal away as soon as the hounds are thrown in. Although some packs have only one whip, a second is very desirable, especially before Christmas, and in countries where there is much woodland. One whip can then go into cover and keep near the huntsman in readiness to obey any directions he may give, and the other is free to see to other matters.

The earth-stopper. The earth-stopper is an important functionary in countries where there are many earths, for if he neglects his business blank days will probably result with annoying frequency. When properly carried out, earth-stopping consists in a man going round and stopping all the earths in the district to be hunted over during the day, so that when foxes return from finding their food, which they do some hours before it is light, they shall find their own door barred against them. This involves the earth-stopper being astir shortly after 2 A.M., not the most pleasant hour of the twenty-four on a winter's day. If he gets to work late, he stops all the foxes in instead of out; and, when the cover is drawn, no one can understand how the fox which has been seen about for the last fortnight cannot be found at the moment when his presence is particularly desired.

Cub hunting. Cub hunting carried out on a proper principle is one of the secrets of a successful season. To the man who cares for hunting, as distinct from riding, September and October are not the least enjoyable months of the whole hunting season. As soon as the young entry have recovered from the operation of "rounding," arrangements for cub hunting begin. The hounds must have first of all walking, then trotting and fast exercise, so that their feet may be hardened, and all superfluous fat worked off by the last week in August. So far as the hounds are concerned, the object of cub hunting is to teach them their duty; it is a dress rehearsal of the November business. In company with a certain proportion of old hounds, the youngsters learn to stick to the scent of a fox, in spite of the fondness they have acquired for that of a hare, from running about when at walk. When cubbing begins, a start is made at 4 or 5 A.M., and then the system is adopted of tracking the cub by his drag. A certain amount of blood is of course indispensable for hounds, but it should never be forgotten that a fox cub of seven or eight months old, though tolerably cunning, is not so very strong; the huntsman should not therefore be over-eager in bringing to hand every cub he can find. It would be a move in the right direction if noses were not to be counted until the first of November.

Hare hunting. *Hare hunting*, which must not be confounded with COURSING (*q.v.*), is an excellent school both for men and for horses. It is attended with the advantages of being cheaper than any other kind, and of not needing so large an area of country. Hare hunting requires considerable skill; Beckford even goes so far as to say—"There is more of true hunting with harriers than with any other description of hounds. . . . . . In the first place, a hare, when found, generally describes a circle in her course which naturally brings her upon her foil, which is the greatest trial for hounds. Secondly, the scent of the hare is weaker than that of any other animal we hunt, and, unlike some, it is always the worse the nearer she is to her end." Hare hunting is essentially a quiet amusement; no hallooing at hounds nor whip cracking should be permitted; nor should the field make any noise when a hare is found, for, being a timid animal, she might be headed into the hounds' mouths. Capital exercise and much useful knowledge are to be derived by running with a pack of beagles. There are the same difficulties to be contended with as in hunting with the ordinary harrier, and a very few days' running will teach the youthful sportsman that he cannot run at the same pace over sound ground and over a deep ploughed field, up hill and down, or along and across furrows.

Otter hunting. *Otter hunting*, which is less practised now than formerly, begins just as all other hunting is drawing to a close. When the waterside is reached an attempt is made to hit upon the track by which the otter passed to his "couch," which is generally a hole communicating with the river, into which the otter often dives on first hearing the hounds. When the otter "vents" or comes to the surface to breathe, his muzzle only appears above water, and when he is viewed or traced by the mud he stirs up, or by air bubbles, the hounds are laid on. Notwithstanding the strong scent of the otter, he often escapes the hounds, and then a cast has to be made. When he is viewed an attempt is made to spear him by any of the field who may be within distance; if their spears miss, the owners must wade to recover them. Should the otter be transfixed by a spear, the person who threw it goes into the water and raises the game over his head on the spear's point. If instead of being speared, he is caught by the hounds, he is soon worried to death by them, though frequently not before he has inflicted some severe wounds on one or more of the pack.

Oth[er] kin[ds of] hun[ting]. Quitting the United Kingdom, we find that the elephant, hyæna, hunting leopard, and a small species of panther known as the ounce, are not only objects of chase, but are themselves trained to assist in the capture of other animals. The elephant has been found of great service in lion and tiger hunting, his size affording comparative safety to the hunters seated on his back. The hyæna, which resembles a dog in many particulars, is said to be as tractable, when properly trained, and to be of much use in the pursuit of game. The hunting leopard or cheetah and the ounce are used in hunting a species of antelope. They have hoods put over their heads, and are taken in a small waggon into the field; when the deer is seen the hood is taken off and the animal starts in pursuit, followed by the hunter; when the game is secured the hood is again put on. In India field sports are largely indulged in, owing partly to natural facilities, and partly to the taste for hunting characteristic of the English resident there. Tigers are sometimes caught in traps, and sometimes shot in the jungle from the back of an elephant; they seek to conceal themselves, and very rarely commence hostilities against mankind, but when severely wounded and brought to bay they fight courageously. Hunting the wild hog, or "pig sticking," as it is often termed, is a favourite sport in India; the ground is walked over by beaters, and when a hog is roused the two mounted huntsmen nearest to him start in pursuit, and endeavour to spear him. The riding requires judgment and very good nerves: hollows, ravines, and cracks in the ground caused by the sun are numerous, and, as they are hidden by the tall grass, the horse cannot avoid them; it is said that no horse can run down a hog in less than a mile, even over the best ground, while over a rough country the distance travelled amounts to three or four. The rider's aim is to blow the hog sufficiently before getting within spearing distance—for the charge of an untired hog is a dangerous affair; but when near a thick cover the sportsman must try to spear him at all hazards, or make up his mind to lose him. The proper management of the spear requires considerable practice. Besides the above mentioned animals, the fox, jackal, wolf, hyæna, buffalo, and four-horned antelope are also objects of the chase.

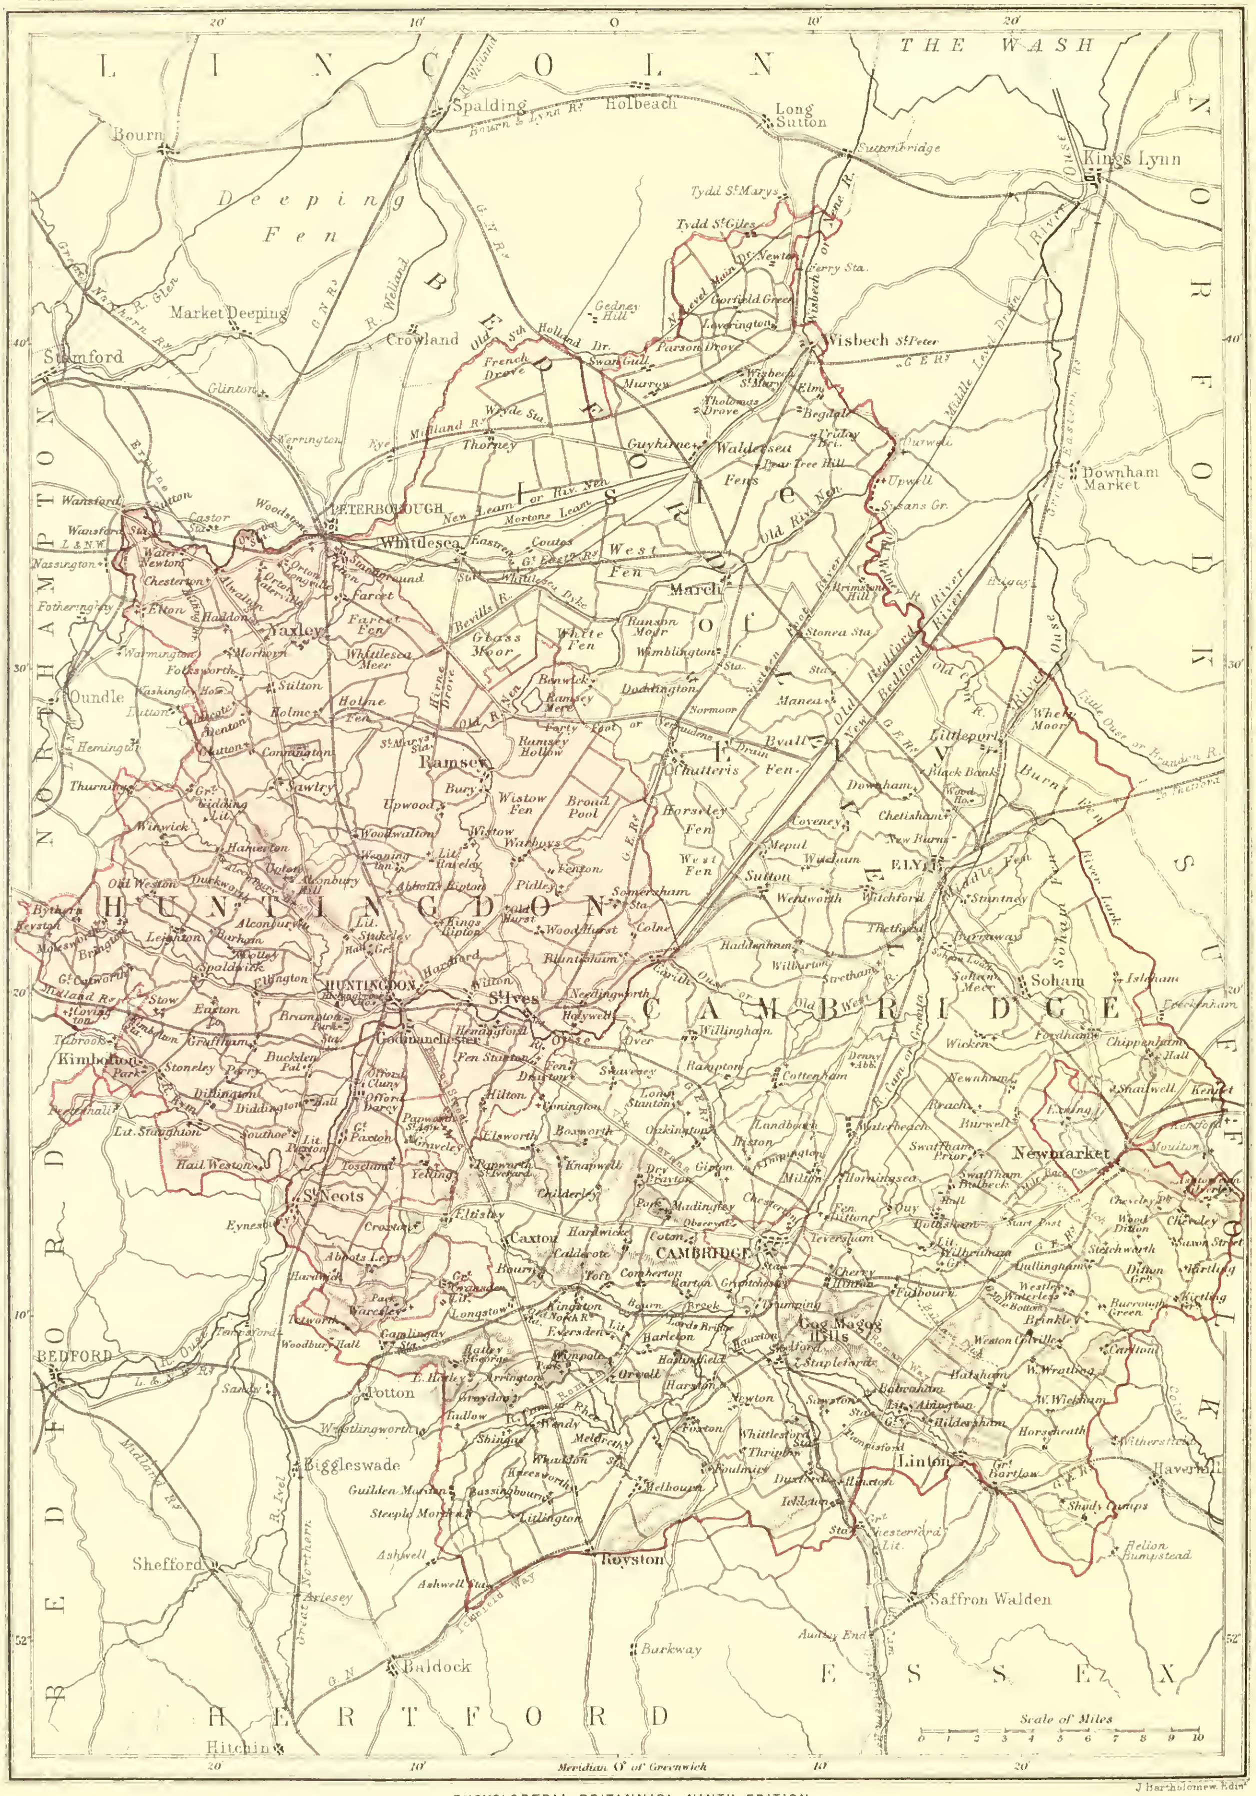
Australia was formerly the scene of a great deal of kangaroo hunting, but that animal is now comparatively scarce.

In Africa there is plenty of big-game hunting, the list including the elephant, lion, giraffe, hippopotamus, antelopes of various kinds, leopard, hyæna, buffalo, jackal, and ostrich. Of these the larger and more dangerous animals are killed as opportunity offers, but the jackal is hunted by English settlers like a fox. Ostrich hunting is somewhat peculiar; the bird is pursued by men on horseback, and, though over the ground it is swifter than a horse, it generally runs in a large circle, so that the riders, by describing a smaller circle and relieving one another, are enabled to keep tolerably near to it, and so to ride it down.

In North America the bison, an animal sometimes when full grown weighing as much as 142 stone, is pursued by the natives on horseback and then shot. The moose is chased towards a ravine or a snowdrift, and when he begins to flounder in the snow he is shot at by the hunters. The red deer is now hunted with staghounds upon the English principle. South America affords hunting after the puma, tapir, and wild bull, the lasso being the usual means of capture.

In Russia, bears, wolves, and wild boars are hunted. Wolves are found in Germany, where they are not only hunted by properly trained wolf-hounds, but are killed by any available means.

France offers facilities for hunting the wolf, wild boar,



ENCYCLOPÆDIA BRITANNICA, NINTH EDITION.

and deer, but the sport, though followed up with a considerable amount of enthusiasm, is not carried out in a manner strictly in accordance with English ideas. The weak point in French hunting is that the huntsmen do not seem to possess a particularly accurate knowledge of the habits and characteristics of the animal they pursue. Then again their system of kennel management is not what it might be. To show sport in the vast forests, the hounds should be in good health and well-trained, and there should be plenty of them. Of late years, however, more attention has been paid to hound breeding and kennel management, and with encouraging results. (E. D. B.)

te III. HUNTINGDON, or HUNTS, an inland county of England, situated between 52° 9′ and 52° 35′ N. lat. and 0° 3′ E. and 0° 30′ W. long., and bounded on the N. and W. by Northampton, S. by Bedford, and E. by Cambridge. Its extreme breadth is at the middle, from which it narrows gradually and irregularly towards its north and south ends. Its extreme length from north to south is about 30 miles, and its extreme breadth from east to west about 23 miles. The area extends to 229,575 imperial acres, or 358 square miles. Among English counties it is the smallest, with the exception of Middlesex and Rutland; and Rutland is the only English county it surpasses in population.

The surface of the county is low, and, with the exception of the Fen district, pleasantly undulating. For the most part it is bare of trees. A low ridge of hills enters the county from the south near Potton, and runs in a northward direction until it terminates in the Ouse valley near Huntingdon; and a branch of the Cambridgeshire hills enters the south-east part of the county, and from Huntingdon runs north-west to Wansford. The north-eastern part of the county, comprising 50,000 acres, or one-fifth of its whole extent, belongs to the great "Fen" district extending throughout the counties of Cambridge, Lincoln, Northampton, Norfolk, and Suffolk. The principal rivers are the Ouse and Nen. The Ouse from Bedfordshire skirts the borders of the county near St Neots, and after flowing north to Huntingdon takes an easterly direction past St Ives into Cambridgeshire on its way to the Wash. It is navigable for barges as far as Bedford, and in the fen district constitutes a means of transport for the agricultural produce of the county. The Nen, which is also navigable, skirts the northern border, and quitting it at Peterborough enters the Wash below Wisbeach, in Cambridgeshire. Various cuts and drains which join the Nen and Ouse are also made use of for navigation.

Geology, Soil, and Agriculture.—Geologically Huntingdonshire belongs to what is known as the Oolite system. The low round hills in the south-eastern part of the county are composed of ironsand. They contain a band of coprolites, and there is a strip of greensand on the south-eastern border. The central and larger part of the county displays the Oxford clay, which lies between the middle and lower Oolite. It reaches a depth of nearly 100 feet, and passes under the Fens. The Fens are composed of fine mud, deposited formerly by the sea, intermixed with beds of peat, in which are frequently found the remains of animals, frequenters of the old forest, such as the elk, the red-deer, the bear, the beaver, and the wolf. The hills on the border of Northampton are of the stonebrash or forest marble. The Oolite formation is very fossiliferous. Large masses of fossil wood converted into jet or iron pyrites are found in the Oxford clay. Glacier or boulder clay containing chalk and flint deposits is met with in nearly every part of the county. The soil is generally fertile, and cultivation is of an advanced kind. In the fen district the soil is of a blue peaty nature, resting on a subsoil of white marly clay. After being drained and mixed with clay it is very productive, but much damage is often done to the crops by the prevalence of frost and fogs. In the fen districts a four-years' system of cropping—green-crops, barley, seed-clovers, and wheat—is the most common. The "Meres" of Whittlesea, Ramsey, and Ugg, at one time much resorted to by sportsmen for their wildfowl and fish, have now been drained, and, notwithstanding the expensiveness of the process, such is the fertility of their beds that the outlay was speedily more than repaid. The Oxford clay, which extends to an area of 120,000 acres, is of very various soils according as the Oolite rocks crop to the surface. The greater part is under cultivation, and much improvement has lately been effected by drainage; on account of the tenacity of the clay the drains often require to be placed very close. Much of the soil is, however, undrained and uncultivated, and, though partly used for pasturage, must on the whole be regarded as mere waste land. On the drained pasturage a large number of cattle are fed. In this district the system of cropping varies considerably, but a modification of the four-course shift is the most common—fallow sown sometimes with winter tares, turnips, mangold, or mustard; barley; beans where tares were sown on the fallow, and clover where green crops were sown; wheat. A six-years' course of fallow, barley, seed-clovers, wheat, beans, and wheat is, however, not uncommon, especially on the best soils. The third district, comprising the gravel of the Ouse valley, embraces an area of 50,000 acres. On the banks of the Ouse it consists of fine black loam deposited by the overflow of the river, and its meadows form very rich pasture grounds. The upland district is under arable culture, and is generally cultivated on a four-course system of wheat, green crops, barley, and seed-clover. Market-gardening is prosecuted; and willows are largely grown in the fen district. The farms vary in size from 200 to 500 acres, ranging chiefly between 200 and 300. The farm-houses are generally of an inferior kind, and the farm-buildings are often quite inadequate for the shelter and accommodation of the stock. The labourers generally live in villages and hamlets, in cottages of the most miserable description, having mostly mud walls; but many cottages of a better class have been built within the last few years. The county is well supplied with turnpike roads; and the parish and occupation roads, formerly in a bad state of repair, have been lately much improved. The most modern improvements in farm implements are in general use.

According to the agricultural returns for 1879 the total area of arable land was 209,610 acres, of which 96,533 were under corn crop, 21,931 under green crop, 17,121 under rotation grasses, 60,484 permanent pasture, and 13,531 fallow. The area under woods was 20,714 acres. Wheat, which in 1879 cropped 43,129 acres, is much more largely grown than any other grain, and occurs twice in the six-years' shift system in use on the better lands. Barley (27,118 acres) is the more frequent corn crop in the four-years' shift system,—only 10,247 acres being under oats. The quality of barley on many soils is lean and inferior, and unsuitable for malting purposes. Beans and pease occupied 8948 and 6929 respectively. Mangold (3430 acres) and cabbage and similar green crops (2863 acres) are chiefly used for the feeding of sheep. Under turnips there were only 3778 acres, and under potatoes 3083. The number of cattle in 1879 was 27,358, or an average of 13 to every 100 acres under cultivation, as compared with 16·9 for England and 21·0 for the United Kingdom. Of these the number of cows and heifers in milk or in calf was 7536. Though Stilton in Huntingdon gives its name to a celebrated cheese, that variety is now made exclusively in the counties of Lincoln and Leicester; and dairy farming is not now much followed. The milk is now chiefly used for rearing calves. Large numbers of cattle are fattened in the field or the fold-yard, and are sold when rising three years old. They are mostly of the shorthorn breed, large numbers of Irish shorthorns being wintered in the fens. Where there are no upland pastures the farmer usually purchases cattle in the autumn and sells them in the spring. The number of horses in 1879 was 11,057, or an average of 4·2 to every 100 acres under cultivation, as compared with 4·5 for England and 4·1 for the United Kingdom. Of these the number used solely for agricultural purposes was 7583. Most of the farmers breed cart horses, and the large farmers often rear weight-carrying hunters. The number of sheep in 1879 was 157,790, or an average of 75·3 to every 100 acres under cultivation, as compared with the same average for England and 68·0 for the United Kingdom. Great improvement in the breed has lately taken place, Leicesters and Lincolns being most common; they usually attain great weights at an early age. Lambs are occasionally sold at weaning time, but more frequently they are kept through the winter on the grass lands, being fed also on mangolds and other roots, with an addition of cake and corn. The number of pigs in 1879 was 19,990, or an average of 9·5 to every 100 acres under cultivation, as compared with 7·2 for England and 6·7 for the United Kingdom. They include Berkshire, Suffolk, and Neapolitan breeds, and a number of crosses. Many after having gleaned the stubbles are fattened on whey and various preparations of inferior barley; but breeding is also extensively practised.

According to the owners of lands return for 1873 the land was divided among 3903 proprietors, holding land the gross annual value of which was £444,890. Of the owners 45⅗ per cent. possessed less than 1 acre, and the average value all over was £1, 19s. 4¾d. per acre. There were 13 proprietors holding upwards of 3000 acres, viz., Edward Fellowes, 15,629; Duke of Manchester, 13,835; William Wells, 5792; Marquis of Huntly, 5711; Hon. G. W. Fitzwilliam, 5202; Lord Chesham, 3787; Earl of Carysfort, 3654; Ecclesiastical Commissioners, 3559; Colonel Duncombe, 3407; W. Duberley, 3224; Earl of Sandwich, 3219; G. D. Newton, 3209; Richard H. Hussey, 3135.

Manufactures and Trade.—Agriculture is the principal industry, and none of the manufactures are extensive, the chief being paper and parchment. Madder is obtained in considerable quantities, and in nearly every part of the shire lime burning is carried on. Lace-making is practised by the female peasantry; and the other industries, which are not prosecuted beyond what is necessary to meet local wants, are printing, iron-founding, tanning, currying, brick and tile making, malting, and brewing.

Railways.—The middle of the county is traversed from south to north by the Great Northern, which enters it at St Neots and passes by Huntingdon to Peterborough. A branch from the Midland enters the middle of the county from Northampton, and passes by Graffham to Huntingdon, where it is joined by a branch which passes by St Ives to the Great Eastern in Cambridgeshire. From St Ives there is a branch to Wisbeach in Cambridgeshire, and another has been constructed to Stilton. On the Great Northern there is a branch from Holme to Ramsey.

Administration.—Huntingdonshire comprises four "hundreds." For parliamentary purposes it is an undivided constituency returning two members; and it contains one parliamentary borough, that of Huntingdon, formed of Huntingdon (4243) and Godmanchester (2363), and returning one member. Part of the represented city of Peterborough is also in the county. The principal other towns are Ramsey (2378), St Ives (3291), St Neots (3200), and Kimbolton (1509). The county has one court of quarter sessions. It is included in the south-eastern circuit, and circuit courts are held at Huntingdon. It forms part of the shrievalty of Cambridge, and ecclesiastically is in the diocese of Ely.

Population.—The population in 1841 amounted to 58,549, in 1851 to 64,183, in 1861 to 64,250, and in 1871 to 63,708 (31,381 males and 32,327 females). The increase in thirty years from 1841 has been 8·8 per cent., and since 1801 it has been 69·5 per cent.

History and Antiquities.—Previous to the Roman invasion Huntingdonshire, like the other Fen counties, was inhabited by the British tribe the Iceni, originally of Celtic origin, but considerably intermixed from Teutonic sources, although the Belgæ in all probability did not subdue the country as far north as Huntingdon. During the Roman occupation it was included in the Roman province of *Flavia Cæsariensis.* Two Roman stations are supposed to have been situated in the county, *Durolipons* (Godmanchester) and *Durobrivæ* at Water Newton on the Nen. The Roman road *Via Devana* from Cambridge joined Ermine Street at Godmanchester, Ermine Street passing north-west by Water Newton into Northampton. Under the name of Huntandunscyre, Huntingdon formed part of the kingdom of East Anglia, afterwards joined to Mercia. Shortly before the Conquest the earldom of Huntingdon was held by Swend, who, on receiving the earldom of Northampton, granted it to his son Waltheof, who married a niece of William the Conqueror; and, on Waltheof's execution for high treason, it passed to a Norman soldier, Simon de St Liz, who married a daughter of Waltheof. On the death of St Liz, David, afterwards king of Scotland, married his widow, and inherited the earldom in her right, but on account of the subsequent feuds between the English and Scottish monarchs the earldom frequently exchanged hands between the heirs of St Liz and the heirs of David. It is at present borne by a branch of the Hastings family. A great part of the county was held by the monks, who erected two great abbeys at Ramsey and at Sawtry St Judith, and priories at Huntingdon, St Ives, St Neots, and Hinchingbrook. Of these buildings all that now remains is the richly decorated ruined gateway of the abbey of Ramsey, and a dovehouse, a barn, and a few unimportant fragments at St Ives. There were two ancient castles at Huntingdon and Kimbolton; the one at the latter place, now the seat of the Montagues, dukes of Manchester, was the residence of Catherine of Aragon after her divorce from Henry VIII. Another mansion of interest is Hinchingbrook House, the ancient seat of the Cromwell family. Among the old churches may be mentioned Alwalton, Conington, Hartford, Leighton Bromswold, and Ramsey, which contain remains of Roman architecture; Buckden, Elton, Godmanchester, and St Neots, which contain good specimens of the Perpendicular; Chesterton, Holywell, Sawtry, Upton, and Wooton, which are partly Early English. The only events of historical importance connected with the shire are the capture of the castle of Huntingdon by the Royalists under Charles I. in 1645, and the rout at St Neots of one hundred horse under the command of the duke of Buckingham and the earl of Holland by the Parliamentary soldiers, who took the earl of Holland prisoner.

Huntingdon, a municipal and parliamentary borough of England, capital of the above county, is situated on the left bank of the Ouse, and on three railway lines, 58 miles north of London, 15 miles north-west of Cambridge, and 19 miles south of Peterborough. It consists principally of one street about a mile in length, from which small streets branch off at various points. By a fine bridge erected in the 13th century it is connected with the municipal borough of Godmanchester, which, consisting principally of cottages, forms practically one of its suburbs, and is included in the parliamentary borough of Huntingdon. In Huntingdon there are two old churches—All Saints, probably dating originally from the time of the Normans, but re-erected in the time of Henry VIII., and St Mary's, probably occupying the site of the old priory, but rebuilt in the Gothic style after the fall of the old building in 1608, and restored in 1876. The church of Godmanchester, of the date 1625, is also a fine structure in the late Perpendicular, with a tower and spire. At the grammar school of Huntingdon, founded in 1200 by David, king of Scotland, but pulled down in 1877 for the erection of a new building, Oliver Cromwell received his education. Among the other schools are Walden's school for 64 boys, and a national school. There are also in Godmanchester a grammar school and a national school. The principal other buildings of Huntingdon are the county jail, completed in 1827; the militia barracks, erected in 1852; the town and county hospital, erected in 1853; the corn exchange; the town-hall, whose ground floor is used for the courts of justice; and the rooms of the literary and scientific institution. The house in which Oliver Cromwell was born is still standing. Of the three old monastic foundations formerly belonging to the town there are now no remains. The industries of Huntingdon and Godmanchester are very much alike. They possess iron-foundries, breweries, tile-works, and oil and flour mills. The area of the parliamentary borough of Huntingdon is 6086 acres, the municipal boroughs of Godmanchester and Huntingdon occupying 4970 acres and 1116 acres respectively. In 1871 the population of the parliamentary borough was 6606, that of the municipal boroughs of Godmanchester and Huntingdon being respectively 2363 and 4243.

Huntingdon existed in the time of the Saxons under the name of Huntantun, and in the Norman survey it is mentioned as Huntersdune. The castle erected at it by Edward the Elder in 919, and afterwards enlarged by David, king of Scotland, was demolished by the orders of Henry II. In 1645 the town was plundered by the Royalists under Charles I. The origin of the town was doubtless closely connected with that of Godmanchester, which occupied the site of the Roman station *Durolipons*, and at which a castle is said to have been founded by Gormund (hence the name of the town, formerly Gormunchester), a Danish chief in the reign of Alfred the Great. Huntingdon was first incorporated in 1206 and Godmanchester in 1605. From an early period Huntingdon returned two members to parliament; but the Reform Act of 1867 reduced the representation to one member.

HUNTINGDON, Selina, Countess of (1707–1791), leader of a sect of Calvinistic methodists, known as the Countess of Huntingdon's Connexion, was the daughter of Washington Shirley, second Earl Ferrers. She was born at Stanton Harold, a mansion near Ashby-de-la-Zouch in Leicestershire, August 24, 1707, and in her twenty-first year was married to Theophilus, ninth earl of Huntingdon. The religious influence of her husband's sisters, and a dangerous illness soon after her marriage, tended to deepen the serious impressions which the young countess had experienced from childhood; and on the death of her husband in 1746, coming under the influence of the religious revival in which Wesley and Whitfield were at that time conspicuous, she resolved to join these preachers in actively furthering their aims. In 1748 she gave Whitfield a scarf as her chaplain, and in that capacity he frequently preached in her town house to the most fashionable audiences, in which sometimes such men as Chesterfield, Walpole, and Bolingbroke were found. Reducing her personal expenditure, and disregarding the sneers of her aristocratic acquaintances, Lady Huntingdon spent her ample means in building chapels in different parts of England, and appointed ministers to officiate in them, under the impression that as a peeress she had a right to employ as many chaplains as she would. In 1768 she converted the old mansion of Trevecca, near Talgarth, in South Wales, into a theological seminary for training young ministers for the Connexion; and this, which she made her chief residence, she continued to support alone till her death. Up to 1779 Lady Huntingdon and her chaplains continued members of the Church of England, but in that year the prohibition of her chaplains by the consistorial court from preaching in the Pantheon, a large building in London rented for the purpose by the countess, compelled her in order to evade the injunction to take shelter under the Toleration Act. This reluctant step, which placed her legally among dissenters, had the effect of severing from the Connexion several eminent and useful members. Till her death in London, June 17, 1791, Lady Huntingdon continued to exercise an active, and even autocratic, superintendence over her chapels and chaplains, and maintained her leading position as well by her genuine earnest piety and force of character as by her high social station and generous liberality. Her chapels and college were bequeathed to trustees; and in 1792 the latter was removed to Cheshunt, in Hertfordshire, where it has since flourished. Several congregations of the Connexion have become nominally as well as virtually Congregational chapels; while, even by those which retain the original name, the Congregational polity is practically adopted.

The Life of the Countess of Huntingdon was published at London, in 2 vols., in 1844; *The Coronet and the Cross, or Memorials of Selina, Countess of Huntingdon*, by A. H. New, appeared in 1857.

HUPFELD, Hermann (1796–1866), an eminent Orientalist and Biblical commentator and critic, was born March 31, 1796, at Marburg, where he studied philosophy and theology from 1813 to 1817; in 1819 he became a teacher in the gymnasium at Hanau, but in 1822 he resigned that appointment. After studying for some time under Gesenius at Halle, he in 1824 "habilitated" in philosophy at that university, and in the following year he was appointed professor extraordinarius of theology at Marburg. There he received the ordinary professorships of Oriental languages and of theology in 1827 and 1830 respectively; thirteen years later he removed as successor of Gesenius to Halle. In 1865 he was accused by some theologians of the Hengstenberg school, before the minister of public worship, of having taught exegesis in a sense inconsistent with the recognized character of the Old Testament as a divine revelation. From this charge, however, he successfully vindicated himself, the entire theological faculty, including J. Müller and Tholuck, bearing testimony to his essential orthodoxy. He died at Halle April 24, 1866.

His earliest works in the department of Semitic philology (*Exercitationes Æthiopicæ*, 1825, and *De emendanda ratione lexicographiæ Semiticæ*, 1827) were followed by the first part (1841), mainly historical and critical, of an *Ausführliche Hebräische Grammatik*, which he did not live to complete, and by a "program" on the early history of Hebrew grammar among the Jews (*De rei grammaticæ apud Judæos initiis antiquissimisque scriptoribus*, 1846). His principal contribution to Biblical literature, a valuable though prosaic exegetical and critical *Uebersetzung u. Auslegung der Psalmen*, began to appear in 1855, and was completed in 1861 (2d ed. by Riehm, 1867–1871). Other writings are *Ueber Begriff u. Methode der sogenannten biblischen Einleitung* (1844); *De primitiva et vera festorum apud Hebræos ratione* (1851–1864); *Die Quellen der Genesis von neuem untersucht* (1853), in which he dissects that book into an original writing, or "Urschrift," by the older Elohist, and the contributions by the younger Elohist and by the Jehovist respectively, the work of the "redactor" having been comparatively trifling; *Die heutige theosophische u. mythologische Theologie u. Schrifterklärung* (1861); and various contributions to the *Studien u. Kritiken*, to the *Journal* of the Deutsche Morgenländische Gesellschaft, and to the *Neue Evangelische Kirchenzeitung*. See Riehm, *Hermann Hupfeld* (1867).

HURD, Richard (1720–1808), bishop of Winchester, was born at Congreve, in the parish of Penkridge, Staffordshire, where his father was a farmer, on January 13, 1720. He received his early education at the grammar school of Brewood, in his native county, and made such progress in his studies that in October 1733 he was admitted a sizar of Emmanuel College, Oxford; he did not begin residence, however, till a year or two afterwards. In 1739 he took the degree of B.A., and in 1742 he was ordained deacon, and for a short time had charge of the parish of Reymerston, between Thetford and Norwich; but, having in the same year proceeded M.A. and been elected fellow of his college, he returned to Cambridge early in 1743. While residing there he was ordained priest in 1744, and in 1748 he published his *Remarks on a late Book, entitled an Enquiry into the Rejection of the Christian Miracles by the Heathen, by William Weston, B.D.*, 1746. This controversial treatise, which was characterized by considerable learning and ingenuity, was followed in 1749 by an edition of the *Ars Poetica* of Horace (*Q. Horatii Flacci Epistola ad Pisones, with an English Commentary and Notes*), which, as Gibbon has remarked, fully proved the title of its author to "the great but prostituted name of critic," and may still be read with interest, less, however, as an exposition of the original than as containing "a more valuable and better digested collection of criticisms than Horace ever wrote or intended to write." In 1750 Hurd was, through the recommendation of his friend Warburton, appointed one of the preachers at Whitehall; and in 1751 he published *Q. Horatii Flacci Epist. ad Augustum, with an English Commentary and Notes*, justly held by Gibbon to be superior in merit to the edition of the *Ars Poetica*.

In 1756 he accepted the college living of Thurcaston, Leicestershire, in the studious retirement of which he wrote and published a volume of *Dissertations* ("On the Province of the Drama," "On Poetical Imitation," and "On the Marks of Imitation," 1757), and another entitled *Moral and Political Dialogues* ("On Sincerity in the Commerce of the World," "On Retirement," "On the Age of Queen Elizabeth," and "On the Constitution of the English Government," 1759). The latter has proved the most popular of his writings, and was chiefly instrumental in procuring for him at a later period of his life the royal favour. In 1766 he was appointed preacher of Lincoln's Inn, and in 1767 he became archdeacon of Gloucester; his elevation to the see of Lichfield and Coventry followed in 1774, and in 1776 he was selected to be preceptor of the prince of Wales and the duke of York. In 1781 he was translated to Worcester, and in 1783, on the death of Dr Cornwallis, he was pressed to accept the primacy, but declined it as "a charge not suited to his temper and talents, and much too heavy for him to sustain, especially in these times." He died May 28, 1808.

Besides various sermons, charges, and other compositions of a more or less occasional character, Hurd published, in addition to the works already mentioned, a *Dissertation on the Delicacy of Friendship* (1755), a severe attack on Jortin, by whom Warburton had been assailed; *Letters on Chivalry and Romance* (1762); *Dissertation on the Idea of Universal Poetry* (1762); *Dialogues on Foreign Travel* (1764); and *Discourse by way of Preface to the Quarto edition of Bishop Warburton's Works, containing some Account of the Life, Writings, and Character of the Author* (1794). *Remarks on Hume's Natural History of Religion* (1757), a controversial tract which caused considerable irritation to that philosopher, was the joint production of Hurd and Warburton. The collected works of Hurd appeared in an edition of 8 vols. 8vo, in 1811; his *Memoirs* by Kilvert, were published in 1860.

HUSBAND AND WIFE, Law relating to. For the modes in which the relation of husband and wife may be constituted and dissolved, see Marriage and Divorce. The present article will deal only with the effect of marriage on the legal position of the spouses. The person chiefly affected is the wife, who probably in all political systems becomes subject, in consequence of marriage, to some kind of disability. The most favourable system scarcely leaves her as free as an unmarried woman; and the most unfavourable subjects her absolutely to the authority of her husband. In modern times the effect of marriage on property is perhaps the most important of its consequences, and on this point the laws of different states show wide diversity of principles.

The history of Roman law exhibits a transition from an extreme theory to its opposite. The position of the wife in the earliest Roman household was regulated by the law of *Manus*. She fell under the "hand" of her husband,—became one of his family, along with his sons and daughters, natural or adopted, and his slaves. The dominion which, so far as the children was concerned, was known as the *patria potestas*, was, with reference to the wife, called the *manus*. The subject members of the family, whether wife or children, had, broadly speaking, no rights of their own; all were merged in the *potestas* of the husband and father. If this institution implied the complete subjection of the wife to the husband, it also implied a much closer bond of union between them than we find in the later Roman law. The wife was at least a member of the family, and on her husband's death she succeeded, like the children, to freedom and a share of the inheritance. *Manus*, however, was not essential to a legal marriage; its restraints were irksome and unpopular, and in course of time it absolutely ceased to exist, leaving no equivalent protection of the stability of family life. The later Roman marriage left the spouses comparatively independent of each other. The bond was easily dissolved, and while it lasted was loose and easy. The distance between the two modes of marriage may be estimated by the fact that, while under the former the wife was one of the husband's immediate heirs, under the latter she was called to the inheritance only after his kith and kin had been exhausted, and only in preference to the treasury. It seems doubtful how far she had, during the continuance of marriage, a legal right to enforce aliment from her husband, although if he neglected her she had the unsatisfactory remedy of an easy divorce. The law in fact preferred to leave the parties to arrange their mutual rights and obligations by private contracts. Hence the importance of the Law of Settlements (*Dotes*). The *Dos* and the *Donatio ante nuptias* were settlements by or on behalf of the husband or wife, during the continuance of the marriage, and the law seems to have looked with some jealousy on gifts made by one to the other in any less formal way, as possibly tainted with undue influence. During the marriage the husband had the administration of the property, and its destination afterwards might depend on the nature of the settlement and the conduct of the parties.

The *manus* of the Roman law appears to be only one instance of an institution common to all primitive societies, and suitable only to society in a primitive state. On the continent of Europe after many centuries, during which local usages were brought under the influence of principles derived from the Roman law, a theory of marriage became established, the leading feature of which is the *community of goods* between husband and wife. Describing the principle as it prevails in France, Story (*Conflict of Laws*, § 130) says—"This community or nuptial partnership (in the absence of any special contract) generally extends to all the movable property of the husband and wife, and to the fruits, income, and revenue thereof. . . . . It extends also to all immovable property of the husband and wife acquired during the marriage, but not to such immovable property as either possessed at the time of the marriage, or which came to them afterwards by title of succession or by gift. The property thus acquired by this nuptial partnership is liable to the debts of the parties existing at the time of the marriage; to the debts contracted by the husband during the community, or by the wife during the community with the consent of the husband; and to debts contracted for the maintenance of the family. . . . . The husband alone is entitled to administer the property of the community, and he may alien, sell, or mortgage it without the concurrence of the wife." But he cannot dispose by will of more than his share of the common property, nor can he part with it gratuitously *inter vivos*. The community is dissolved by death (natural or civil), divorce, separation of body, or separation of property. On separation of body or of property the wife is entitled to the full control of her movable property, but cannot alien her immovable property without her husband's consent, or legal authority. On the death of either party the property is divided in equal moities between the survivor and the heirs of the deceased.

Law of England.—The English common law has as usual followed its own course in dealing with this subject, and in no department are its rules more entirely insular and independent. The text writers all assume two fundamental principles, which between them establish a system of rights totally unlike that we have just described. Husband and wife are said to be one person in the eye of the law—*unica persona, quia caro una et sanguis unus.* Hence a man cannot grant or give anything to his wife, because she is himself, and if there are any compacts between them before marriage they are dissolved by the union of persons. Hence, too, the old rule of law, now greatly modified, that husband and wife could not be allowed to give evidence against each other, in any trial, civil or criminal. The unity, however, is one-sided only; it is the wife who is merged in the husband, not the husband in the wife. And when the theory does not apply, the disabilities of "coverture" suspend the active exercise of the wife's legal faculties. The old technical phraseology describes husband and wife as *baron* and *femme*; the rights of the husband are baronial rights. From one point of view the wife is merged in the husband, from another she is as one of his vassals. A curious example is the immunity of the wife in certain cases from punishment for crime committed in the presence and on the presumed coercion of the husband. "So great a favourite," says Blackstone, "is the female sex of the laws of England."

The application of these principles with reference to the property of the wife, and her capacity to contract, may now be briefly traced.

The *freehold property* of the wife becomes vested in the husband and herself during the coverture, and he has the management and the profits. If the wife has been in actual possession at any time during the marriage of an estate of inheritance, and if there has been a child of the marriage capable of inheriting, then the husband becomes entitled on his wife's death to hold the estate for his own life as tenant by the *curtesy of England* (*curialitas*).[1] Beyond this, however, the husband's rights do not extend, and the wife's heir at last succeeds to the inheritance. The wife cannot part with her real estate without the concurrence of the husband; and even so she must be examined apart from her husband, to ascertain whether she freely and voluntarily consents to the deed.

With regard to personal property, it passes absolutely at common law to the husband. Specific things in the possession of the wife (*choses* in possession) become the property of the husband at once; things not in possession, but due and recoverable from others (*choses* in action), may be recovered by the husband. A *chose* in action not reduced into actual possession, when the marriage is dissolved by death, reverts to the wife if she is the survivor; if the husband survives, he can obtain possession by taking out letters of administration. A *chose* in action is to be distinguished from a specific thing which, although the property of the wife, is for the time being in the hands of another. In the latter case the property is in the wife, and passes at once to the husband; in the former the wife has a mere *jus in personam*, which the husband may enforce if he chooses, but which is still capable of reverting to the wife if the husband dies without enforcing it.

The *chattels real* of the wife (*i.e.*, personal property, dependent on, and partaking of, the nature of reality, such as leaseholds) pass to the husband, subject to the wife's right of survivorship, unless barred by the husband by some act done during his life. A disposition by will does not bar the wife's interest; but any disposition *inter vivos* by the husband will be valid and effective.

The courts of equity, however, greatly modified the rules of the common law by the introduction of the wife's *separate estate, i.e.*, property settled to the wife for her separate use, independently of her husband. The principle seems to have been originally admitted in a case of actual separation, when a fund was given for the maintenance of the wife while living apart from her husband. And the conditions under which separate estate may be enjoyed have taken the court of chancery many generations to develop. No particular form of words is necessary to create a separate estate, and the intervention of trustees, though common, is not necessary. A clear intention to deprive the husband of his common law rights will be sufficient to do so. In such a case a married woman is entitled to deal with her property as if she was unmarried, although the earlier decisions were in favour of requiring her binding engagements to be in writing or under seal. But it is now held that any engagements, clearly made with reference to the separate estate, will bind that estate, exactly as if the woman had been a *femme sole*. Connected with the doctrine of separate use is the equitable contrivance of *restraint on anticipation*, whereby property may be so settled to the separate use of a married woman that she cannot, during coverture, alienate it or anticipate the income. No such restraint is recognized in the case of a man or of a *femme sole*, and it depends entirely on the separate estate; and the separate estate has its existence only during coverture, so that a woman to whom such an estate is given may dispose of it so long as she is unmarried, but becomes bound by the restraint as soon as she is married. In yet another way the court of chancery interfered to protect the interests of married women. When a husband sought the aid of that court to get possession of his wife's *choses* in action, he was required to make a provision for her and her children out of the fund sought to be recovered. This is called the wife's *equity to a settlement*, and is said to be based on the original maxim of chancery jurisprudence, that "he who seeks equity must do equity." Two other property interests of minor importance are recognized. The wife's *pin-money* is a yearly allowance settled on her before marriage for the purchase of clothes and ornaments suitable to her husband's station, but it is not an absolute gift to the separate use of the wife; and a wife surviving her husband cannot claim for more than one year's arrears of pin-money. *Paraphernalia* are jewels and other ornaments given to the wife for the purpose of being worn by her, but not as her separate property. The husband may dispose of them by act *inter vivos* but not by will, unless the will confers other benefits on the wife, in which case she must elect between the will and the paraphernalia.

The corresponding interest of the wife in the property of the husband is much more meagre and illusory. Besides a general right to maintenance at her husband's expense, she has at common law a right to *dower* in her husband's lands, and to a *pars rationabilis* (third) of his personal estate, if he dies intestate. The former, which originally was a solid provision for widows, has by the ingenuity of conveyancers, as well as by positive enactment, been reduced to very slender dimensions. It may be destroyed by a mere declaration to that effect on the part of the husband, as well as by his conveyance of the land or by his will.

The common practice of regulating the rights of husband, wife, and children by marriage settlements obviates the hardships of the common law—at least for the women of

[1] Curtesy or courtesy has been explained by legal writers as "arising *by favour* of the law of England." The word has nothing to do with courtesy in the sense of complaisance.

the wealthier classes. The legislature by the Married Women's Property Acts of 1870 and 1874 has introduced changes, the benefit of which will probably be most keenly felt among the poor. The chief provisions are shortly these:—(1) the earnings of a married woman in an occupation carried on by her apart from her husband are to be held as property settled to her separate use, independent of her husband, and her investments of such earnings are similarly protected; (2) when a woman, married after the passing of the Act, becomes entitled during marriage to personal property as next of kin, or to any sum not exceeding £200 under a deed or will, such property shall belong to her for her separate use; where real property descends to her as heiress of an intestate, the rents and profits thereof shall belong to her for her separate use; (3) in respect of property thus declared to be her "separate estate," she may sue in her own name; on the other hand, her husband is not liable for debts contracted by her before marriage, except to the extent to which he has received property in her right. Married women having separate estates are made liable for the maintenance of their husbands who may become chargeable to any union or parish, and of their children.

A married woman cannot make any contract binding on herself except as to separate estate. She can only bind her husband as his agent, but from the relation of the parties the fact of agency is easily implied. The strongest case is that of a wife whose husband unjustifiably refuses to maintain her; in that case she is his agent, in the sense that he is bound by her contracts for *necessaries* supplied to her. By the Act of 1870 she can insure her own or her husband's life for her separate use.

Law of Scotland.—The law of Scotland on this head differs less from English law than the use of a very different terminology would lead us to suppose. The phrase *communio bonorum* has been employed to express the interest which the spouses have in the *movable* property of both, but its use has been severely censured by a high authority as essentially inaccurate and misleading. Mr Patrick Fraser, in his elaborate and valuable treatise on *Husband and Wife*, contends that there is no real community of goods, and no partnership or societas between the spouses. The wife's movable property, with certain exceptions, and subject to special agreements, becomes as absolutely the property of the husband as it does in English law. The notion of a *communio* is, however, favoured by the peculiar rights of the wife and children on the dissolution of the marriage. Previous to the Act 18 & 19 Vict. c. 23 the law stood as follows. The fund formed by the movable property of both spouses may be dealt with by the husband as he pleases during life; it is increased by his acquisitions and diminished by his debts. The respective shares contributed by husband and wife return on the dissolution of the marriage to them or their representatives if the marriage be dissolved within a year and a day, and without a living child. Otherwise the division is into two or three shares, according as children are existing or not at the dissolution of the marriage. On the death of the husband, his children take one-third (*legitim*), the widow takes one-third (*jus relictæ*), and the remaining one-third (the *dead's part*) goes according to his will or to his next of kin. If there be no children, the *jus relictæ* and the dead's part are each one-half. If the wife die before the husband, her representatives, whether children or not, are creditors for the value of her share. The statute above-mentioned, however, enacts that "where a wife shall predecease her husband, the next of kin, executors, or other representatives of such wife, whether testate or intestate, shall have no right to any share of the goods in communion; nor shall any legacy or bequest, or testamentary disposition thereof by such wife, affect or attach to the said goods or any portion thereof." It also abolishes the rule by which the shares revert if the marriage does not subsist for a year and a day. Two later Acts apply to Scotland the principles of the English Married Women's Property Acts. These are the Act 40 & 41 Vict. c. 29, which protects the earnings, &c., of wives, and limits the husband's liability for antenuptial debts of the wife, and the Act 43 & 44 Vict. c. 26, which enables a woman to contract for a policy of assurance for her separate use.

A wife's *heritable* property does not pass to the husband on marriage, but he acquires a right to the administration and profits. His courtesy, as in English law, is also recognized. On the other hand, a widow has a *terce* or liferent of a third part of the husband's heritable estate, unless she has accepted a conventional provision.

American Law.—In the American States, the revolt against the common law theory of husband and wife has been carried further than in England, and legislation tends in the direction of absolute equality between the sexes. "What are familiarly known as the Married Women's Acts," says a recent writer, "the product of American legislation during the last quarter of a century, aim to secure to the wife the independent control of her own property, and the right to contract, sue, and be sued without her husband, under reasonable conditions" (Schouler's *Law of Domestic Relations*). Each State has, however, taken its own way and selected its own time for introducing modifications of the existing law, so that the legislation on this subject is now exceedingly complicated and difficult. Schouler (*op. cit.*, p. 212) gives an account of the general result in the different States, from which the following is condensed:—In Maine, a liberal right in married women of holding property independently of husband's control, which the wife may, however, relax by written instrument authorizing her husband to manage it; in New Hampshire, the right to hold from strangers, and from her husband (not in fraud of creditors), and to keep earnings when deserted; in Vermont, similar result effected by the Chancery Courts without special legislation; in Massachusetts, a liberal right to acquire separate property; in Rhode Island, property exempt from husband's debts, but his control recognized; in Connecticut, somewhat limited recognition of separate estate; in New York, the most liberal provisions as to property held before or acquired after marriage—a complete emancipation from marital dominion; a similar policy in the laws of New Jersey, Pennsylvania, and Maryland, effected in the last case by the courts rather than by statute; in Ohio, general exemption of wife's estate from her husband's debts; in Indiana, a peculiar policy, on the community system, wife's powers of transfer limited; Illinois, Wisconsin, Minnesota, and Kansas follow closely the legislation of Massachusetts; in Iowa, limited recognition of wife's estate; in California, community of goods recognized after the Spanish system, formerly prevalent there,—so in Nevada; in Oregon, wife's property exempt from husband's debts; in Nebraska, liberal rights recognized in married women; in Missouri, wife's property in land more particularly exempt from husband's debts; in Kentucky, peculiar restraint on husband's marital rights; in Tennessee, wife's property protected, but her right to control not recognized; in Arkansas a liberal policy prevails. The Southern States have been later in taking up this movement, but it is considered likely that they will follow the rest. The peculiar system of Homestead Laws in the Southern and Western States (described in article HOMESTEAD) constitutes an inalienable provision for the wife and family of the householder. (E. R.)

HUSCH, HUSHI, or HUSI, chief town of the Roumanian province of Falciu, Moldavia, is situated on the right bank of the Pruth, about 40 miles south-east of Jassy. It is the seat of the district courts of justice, and of a bishop of the Greek Church. It possesses a cathedral and a normal school, and carries on an active trade in tobacco. The population in 1870 was estimated at 18,000. At Husch was signed in 1711 the treaty of the Pruth, between Russia and Turkey, which freed the army of Peter the Great from a position of great danger.

HUSHIÁRPUR, a British district in the lieutenant-governorship of the Punjab, India, lying between 30° 58′ and 32° 5′ N. lat. and between 75° 31′ and 76° 41′ 15″ E. long. It forms the central district of the Jalandhar division, and is bounded N.E. by the district of Kángra and the native state of Nálagarh, N. and N.W. by the river Bías, S.W. by Jalandhar, and S. by the river Satlaj (Sutlej) and Ambála (Umballa) district.

The district of Hushiárpur falls into two nearly equal portions of hill and plain country. Its eastern face consists of the westward slope of the Kángra Mountains; parallel with that ridge, a line of lower heights traverses the district from south to north, while between the two chains stretches a valley of uneven width, known as the Jaswán Dún. Its upper portion is crossed by the Soán torrent, while the Sutlej sweeps into its lower end by a break in the hills, and flows in a southerly direction till it turns the flank of the central range, and debouches westwards upon the plains. This western plain consists of alluvial formation, with a general westerly slope owing to the deposit of silt from the mountain torrents in the submontane tract. The Bías has a fringe of lowland, open to moderate but not excessive inundations, and considered very fertile. A considerable area is covered by Government woodlands, under the care of the forest department.

The census of 1868 was taken over an area of 2086 square miles, and showed a total population of 938,890 (males, 504,393; females, 434,497). Of these, the Hindus numbered 415,471; Mahometans, 317,967; Síkhs, 79,417; and "others," 126,035. The district contained nine municipalities in 1875-76, namely,—Hushiárpur (see below), Urmar Tanda (13,970), Mukerián (5116), Dasuya (8677), Anandpur (6405), Hariáná (7802), Garhdiwála (3874), Una (4908), and Miáni (Meeanee) (7942). The total imperial revenue in 1872-73 was £148,708; the local revenue for expenditure on works of public utility, £14,856. Fifteen civil and revenue judges exercised jurisdiction in the district. There were 321 schools, with 7066 pupils, receiving £2291 from the public funds.

The cultivated area in 1868 amounted to 751,707 acres, out of an assessed total of 1,335,245. Rice is largely grown, owing to the abundance of marshy flats along the banks of the Bías. The other products are wheat, barley, gram, tobacco, *joár*, maize, *moth*, *mash*, cotton, and sugar-cane. The state of agricultural knowledge is very backward, and implements are of the simplest description. Only 17,836 acres are under irrigation, chiefly from an old canal in the northern corner. The trade of Hushiárpur is confined to its raw material, including grain, sugar, hemp, safflower, fibres, tobacco, indigo, and cotton; of these, sugar forms by far the most important commercial item. The manufactures are of no importance. Several religious fairs are held, at Anandpur, Mukerián, and Achintpurni, all of which attract an enormous concourse of people. The Jalandhar and Kángra road forms the chief route; and good roads connect Hushiárpur and other centres with the neighbouring towns. The district, owing to its proximity to the hills, possesses a comparatively cool and humid climate. Malarious fever, cholera, and bowel complaints are the prevailing illnesses. The annual rainfall in 1871-72 was 32·6 inches. There are five charitable dispensaries.

The country around Hushiárpur formed part of the Katoch kingdom of Jalandhar. The state was eventually broken up, and the present district was divided between the rájás of Ditárpur and Jaswán. They retained undisturbed possession of their territories until 1759, when the rising Síkh chieftains commenced a series of encroachments upon the hill tracts. In 1815 the aggressive mahárájá, Ranjít Sinh, forced the ruler of Jaswán to resign his territories in exchange for an estate on feudal tenure; three years later the rájá of Ditárpur met with similar treatment. By the close of the year 1818 the whole country from the Sutlej to the Bías had come under the Government of Lahore, and after the first Síkh war in 1846 passed into the hands of the English Government. The deposed rájás of Ditárpur and Jaswán received cash pensions from the new rulers, but expressed bitter disappointment at not being restored to their former sovereign position. Accordingly the outbreak of the Mooltan war, and the revolt of Chatthr Sinh in 1848, found the disaffected chieftains ready for rebellion. They organized a revolt, but the two rájás and the other ringleaders were captured, and their estates confiscated.

HUSHIÁRPUR, municipal town and administrative headquarters of the above district, is situated on the bank of a broad sandy torrent. The population in 1868 numbered 13,022, comprising 6350 Hindus, 6002 Mahometans, 119 Síkhs, 62 Christians, and 489 "others." The town was founded, according to tradition, about the early part of the 14th century. In 1809 it was occupied by Ranjít Sinh. The mahárájá and his successors maintained a considerable cantonment one mile south-east of the town, and the British Government kept it up for several years after the annexation. Floods often cause much damage, to guard against which an embankment was raised in 1852. The civil station contains the district court-house and treasury, sessions-house, *tahsíl* and police offices, dispensary, staging bungalow, and *saráí*. Both station and town are plentifully wooded, and enjoy a good sanitary reputation. There is a trade in grain, sugar, and tobacco.

HUSKISSON, WILLIAM (1770-1830), statesman and financier, was descended from an old Staffordshire family of moderate fortune, and was born at Birch Moreton, Worcestershire, March 11, 1770. Having been placed in his fourteenth year under the charge of his uncle Dr Gem, physician to the English embassy at Paris, he passed his early years amidst a political fermentation which led him to take a deep and absorbing interest in politics. But though he approved of the French Revolution, his sympathies were with the more moderate party, and he became a member of the "club of 1789," instituted to support the new form of constitutional monarchy in opposition to the anarchical attempts of the Jacobins. Even at this early period he displayed his mastery of the principles of finance by a *Discours* delivered in August 1790 before this society, in regard to the issue of assignats by the Government. The *Discours* gained him considerable reputation, but as it failed in its purpose he withdrew from the society. In January 1793 he was appointed by Mr Dundas to an office created with a view to direct the execution of the Aliens Act; and in the discharge of his delicate duties he manifested such ability that in 1795 he was appointed under secretary in the colonial department. In the following year he entered parliament as member for Morpeth, but for a considerable period he took scarcely any part in the debates. On the retirement of Pitt in 1801 he resigned office, and after contesting Dover unsuccessfully he withdrew for a time into private life. Having in 1804 been chosen to represent Liskeard, he was on the restoration of the Pitt ministry appointed secretary of the treasury, holding office till the dissolution of the ministry after the death of Pitt in January 1806. After being elected for Harwich in 1807, he accepted the same office under the duke of Portland, but he withdrew from the ministry along with Canning in 1809. In the following year he published a pamphlet on the currency system, which confirmed his reputation as the ablest financier of his time; but his free-trade principles did not accord with those of his party. When in 1814 he re-entered the public service, it was only as chief commissioner of woods and forests, but his influence was from this time very great in the commercial and financial legislation of the country. He took a prominent part in the corn-law debates of 1814 and 1815; and in 1819 he presented a memorandum to Lord Liverpool advocating a large reduction in the unfunded debt, and explaining a method for the resumption of cash payments, which was embodied in the Act passed the same year. In the following year he was named a member of the committee appointed to inquire into the causes of the agricultural distress then prevailing in the country, and the proposed relaxation of the corn laws embodied in the report was understood to have been chiefly due to his strenuous advocacy. In 1823 he was appointed president of the board of trade and treasurer of the navy, and shortly afterwards he received a seat in the cabinet. In the same year he was returned for Liverpool, having from 1812 represented Chichester. Among the more important legislative changes with which he was principally connected were a reform of the Navigation Acts, admitting other nations to a full equality and reciprocity of shipping duties; the repeal of the labour laws; the introduction of a new sinking fund; the reduction of the duties on manufactures and on the importation of foreign goods, and the repeal of the quarantine duties. In accordance with his suggestion Canning in 1827 introduced a measure on the corn laws proposing the adoption of a sliding scale to regulate the amount of duty. The bill passed the House of Commons, but a misapprehension between Huskisson and the duke of Wellington led to the duke proposing an amendment, the success of which caused the abandonment of the measure by the Government. After the death of Canning in the same year Huskisson accepted the secretaryship of the colonies under Lord Goderich, an office which he continued to hold in the new cabinet formed by the duke of Wellington in the following year. From the beginning the cabinet was rent by internal disputes, and, after succeeding with great difficulty in inducing the cabinet to agree to a compromise on the corn laws, Huskisson finally resigned office in May 1829 on account of a difference with his colleagues in regard to the disfranchisement of East Retford. On the 15th September of the following year he was accidentally killed by a locomotive engine while present at the opening of the Liverpool and Manchester Railway.

HUSS, JOHN (1369–1415), the Bohemian reformer and martyr, was born at Hussinecz,[1] a market village at the foot of the Böhmerwald, and not far from the Bavarian frontier, most probably in 1369, and, according to some accounts, on July 6. His parents appear to have been well-to-do Czechs of the peasant class. Of his early life nothing is recorded except that, notwithstanding the early loss of his father, he obtained a good elementary education, first at Hussinecz, and afterwards at the neighbouring town of Prachaticz. At, or only a very little beyond, the usual age he entered the recently (1348) founded university of Prague, where he became bachelor of arts in 1393, bachelor of theology in 1394, and master of arts in 1396. In 1398 he was chosen by the Bohemian "nation" of the university to an examinership for the bachelor's degree; in the same year he began to lecture also, and there is reason to believe that the philosophical writings of Wickliffe, with which he had been for some years acquainted, were his text-books. In October 1401 he was made dean of the philosophical faculty, and for the half-yearly period from October 1402 to April 1403 he held the office of rector of the university. In 1402 also he was made rector or curate (capellarius) of the Bethlehem Chapel, which had in 1391 been erected and endowed by some zealous citizens of Prague for the purpose of providing good popular preaching in the Bohemian tongue. This appointment, which, so far as the aims of the pious founders were concerned, proved a singularly successful one, had a deep influence on the already vigorous religious life of Huss himself; and one of the effects of the earnest and independent study of Scripture into which it soon led him was a profound conviction of the great value not only of the philosophical but also of the theological writings of Wickliffe.

This newly-formed sympathy with the English reformer did not, however, in the first instance at least, involve Huss in any conscious opposition to the established doctrines of Catholicism, or in any direct conflict with the authorities of the church; and for several years he continued to act in full accord with his archbishop (Sbynjek, or Sbynko, of Hasenburg). Thus in 1405 he, along with other two masters, was commissioned to examine into certain reputed miracles at Wilsnack, near Wittenberg, which had caused that church to be made a resort of pilgrims from all parts of Europe. The result of their report was that all pilgrimage thither from the province of Bohemia was prohibited by the archbishop on pain of excommunication, while Huss, with the full sanction of his superior, gave to the world his first published writing, entitled *De Omni Sanguine Christi Glorificato*, in which he declaimed in no measured terms against forged miracles and ecclesiastical greed, urging Christians at the same time to desist from looking for sensible signs of Christ's presence, but rather to seek Him in His enduring word. More than once also Huss, along with his friend Stanislaus of Znaim, was appointed to be synod preacher, and in this capacity he delivered at the provincial councils of Bohemia many faithful admonitions. As early as May 28, 1403, it is true, there had been held a university disputation about the new doctrines of Wickliffe, which had resulted in the condemnation of certain propositions presumed to be his; five years later (May 20, 1408) this decision had been refined into a declaration that these, forty-five in number, were not to be taught in any heretical, erroneous, or offensive sense. But it was only slowly that the growing sympathy of Huss with Wickliffe unfavourably affected his relations with his colleagues in the priesthood. In 1408, however, the clergy of the city and archiepiscopal diocese of Prague laid before the archbishop a formal complaint against Huss, arising out of strong expressions with regard to clerical abuses of which he had made use in his public discourses; and the result was that, having first been deprived of his appointment as synodal preacher, he was, after a vain attempt to defend himself in writing, publicly forbidden the exercise of any priestly function throughout the diocese. Simultaneously with these proceedings in Bohemia, international negotiations had been going on which had for their object the removal of the long-continued papal schism, and it had in the interval become apparent that a satisfactory solution of the difficulties involved could only be secured if, as seemed not impossible, the supporters of the rival popes, Benedict XIII. and Gregory XII., could be induced, in view of the approaching council of Pisa, to pledge themselves to a strict neutrality. With this end King Wenceslaus of Bohemia had requested the co-operation of the archbishop and his clergy, and also the support of the university, in both instances unsuccessfully, although in the case of the latter the Bohemian "nation," with Huss at its head, had only been overborne by the votes of the Bavarians, Saxons, and Poles. There followed an expression of nationalist and particularistic as opposed to ultramontane and also to German feeling, which undoubtedly was of supreme importance for the whole of the subsequent career of Huss. In compliance with this feeling a royal edict (January 18, 1409) was issued, by which, in alleged conformity with Paris usage, and with the original charter of the university, the Bohemian "nation" received three votes, while only one was allotted to the other three "nations" combined; whereupon all the foreigners, to the number of several thousands, almost immediately withdrew from Prague, an occurrence which led to the formation shortly afterwards of the university of Leipsic.

It was a dangerous triumph for Huss; for his popularity at court and in the general community had been secured only at the price of clerical antipathy everywhere and of much German ill-will. Among the first results of the changed order of things were on the one hand the election of Huss (October 1409) to be again rector of the university, but on the other hand the appointment by the archbishop of an inquisitor to inquire into charges of heretical teaching and inflammatory preaching which had been brought against him. He had spoken disrespectfully of the church, it was said, had even hinted that Antichrist might be found to be in Rome, had fomented in his preaching the quarrel between Bohemians and Germans, and had, notwithstanding all that had passed, continued to speak of Wickliffe as both a pious man and an orthodox teacher. The direct result of this investigation is not known, but it is impossible to disconnect from it the promulgation by Pope Alexander V., on December 20, 1409, of a bull which ordered the abjuration of all Wickliffite heresies and the surrender of all his books, while at the same time—a measure specially levelled at the pulpit of Bethlehem Chapel—all preaching was prohibited except in localities which had been by long usage set apart for that use. This decree, as soon as it was published in Prague (March 9, 1410), led to much popular agitation, and provoked an appeal by Huss to the pope's better informed judgment; the archbishop, however, resolutely insisted on carrying out his instructions, and in the following July caused to be publicly burned, in the courtyard of his own

[1] From which the name Huss, or more properly Hus, an abbreviation adopted by himself about 1396, is derived. Prior to that date he was invariably known as Johann Hussynecz, Hussinecz, Hussenicz, or De Hussynecz.

palace, upwards of 200 volumes of the writings of Wickliffe, while he pronounced solemn sentence of excommunication against Huss and certain of his friends, who had in the meantime again protested and appealed to the new pope (John XXIII.). Again the populace rose on behalf of their hero, who, in his turn, strong in the conscientious conviction that "in the things which pertain to salvation God is to be obeyed rather than man," continued uninterruptedly to preach in the Bethlehem Chapel, and in the university began publicly to defend the so-called heretical treatises of Wickliffe, while from king and queen, nobles and burghers, a petition was sent to Rome praying that the condemnation and prohibition in the bull of Alexander V. might be quashed. Negotiations were carried on for some months, but in vain; in March 1411 the ban was anew pronounced upon Huss as a disobedient son of the church, while the magistrates and councillors of Prague who had favoured him were threatened with a similar penalty in case of their giving him a contumacious support. Ultimately the whole city, which continued to harbour him, was laid under interdict; yet he went on preaching, and masses were celebrated as usual, so that at the date of Archbishop Sbynko's death in September 1411, it seemed as if the utmost efforts of ecclesiastical authority had resulted in absolute failure.

The struggle, however, entered on a new phase with the appearance at Prague in May 1412 of the papal emissary charged with the proclamation of the papal bulls by which a religious war was decreed against the excommunicated King Ladislaus of Naples, and indulgence was promised to all who should take part in it, on terms similar to those which had been enjoyed by the earlier crusaders to the Holy Land. By his bold and thorough-going opposition to this mode of procedure against Ladislaus, and still more by his doctrine that indulgence could never be sold without simony, and could not be lawfully granted by the church except on condition of genuine contrition and repentance, Huss at last isolated himself, not only from the archiepiscopal party under Albik of Unitschow, but also from the theological faculty of the university, and especially from such men as Stanislaus of Znaim and Stephen Paletz, who until then had been his chief supporters. A popular demonstration, in which the papal bulls had been paraded through the streets with circumstances of peculiar ignominy and finally burnt, led to intervention by Wenceslaus on behalf of public order; three young men, for having openly asserted the unlawfulness of the papal indulgence after silence had been enjoined, were sentenced to death (June 1412); the excommunication against Huss was renewed, and the interdict again laid on all places which should give him shelter,—a measure which now began to be more strictly regarded by the clergy, so that in the following December he had no alternative but to yield to the express wish of the king by temporarily withdrawing from Prague. A provincial synod, held at the instance of Wenceslaus in February 1413, broke up without having reached any practical result; and the labours of a commission appointed shortly afterwards were equally unsuccessful in the attempt to bring about a reconciliation between Huss and his adversaries. The so-called heretic meanwhile spent his time partly at Kozihradek, some 45 miles south of Prague, and partly at Krakowitz in the immediate neighbourhood of the capital, sometimes varying the monotony of his life with an occasional course of open-air preaching, but finding his chief employment in maintaining with his numerous friends that copious correspondence of which some precious fragments still are extant, and in the composition of the largest and most exhaustive of all his printed works, the *De Ecclesia*, which subsequently furnished most of the material for the capital charges brought against him.

During the year 1413 the arrangements for the meeting of a general council at Constance were agreed upon between Sigismund and Pope John XXIII. The objects originally contemplated had been the restoration of the unity of the church and its reform in head and members; but so great had become the prominence of Bohemian affairs that to these also a first place in the programme of the approaching œcumenical assembly required to be assigned, and for their satisfactory settlement the presence of Huss was obviously necessary. His attendance was accordingly requested, and the invitation was willingly accepted as giving him a long-wished-for opportunity both of publicly vindicating himself from charges which he felt to be grievous and of loyally making confession for Christ. He set out from Bohemia on October 14, 1414, not, however, until he had carefully ordered all his private affairs, with a presentiment, which he did not conceal, that in all probability he was going to his death. The journey, which appears to have been undertaken with the usual passport, and under the protection of several powerful Bohemian friends (John of Chlum, Wenceslaus of Duba, Henry of Chlum) who accompanied him, was a very prosperous one; and at almost all the halting places he was received with a consideration and enthusiastic sympathy which he had hardly expected to meet with anywhere in Germany. On November 3 he arrived at Constance, and took up quarters in the house which is still pointed out (Paulsgasse, 328); shortly afterwards there was put into his hands the famous imperial "safe conduct," the promise of which had been one of his inducements to quit the comparative security he had enjoyed in Bohemia. Of this safe conduct, the formal words of which have often been quoted, it would be absurd to say that it was intended to guarantee its holder against the infliction of due punishment should he be convicted by existing law of any crime; but there can be no doubt that both the letter and the spirit of it were scandalously violated, when on November 28 Huss was arbitrarily seized and thrown into prison before any accusation whatever had been formulated. Sigismund himself never sought to defend this act, which was not done with his consent or authority; the only excuse he ever alleged for having tolerated it was that otherwise in all likelihood the council would have been broken up. On December 4 the pope appointed a commission of three bishops to investigate the case against the heretic, and to procure witnesses; to the demand of Huss that he might be permitted to employ an agent in his defence a favourable answer was at first given, but afterwards even this concession to the forms of justice was denied. While the commission was engaged in the prosecution of its inquiries, the flight of Pope John XXIII. took place on March 20, an event which furnished a pretext for the removal of Huss from the Dominican convent to a more secure and more severe place of confinement under the charge of the bishop of Constance at Gottlieben on the Rhine. On May 4 the temper of the council on the doctrinal questions in dispute was for the first time fully revealed in its unanimous condemnation of Wickliffe, especially of the so-called "forty-five articles" as erroneous, heretical, revolutionary. It was not, however, until June 5 that the case of Huss himself came up for hearing; the meeting, which was an exceptionally full one, took place in the refectory of the Franciscan cloister. Autograph copies of his work *De Ecclesia*, and of the controversial tracts which he had written against Paletz and Stanislaus of Znaim, having been laid before him and duly acknowledged, the extracted propositions on which the prosecution based their charge of heresy were read; but as soon as the accused began to analyse them and to enter upon his defence, he was assailed by violent outcries, amidst which it was impossible for him to be heard, so that he was compelled to bring his speech to an abrupt close, which he did with the calm remark; "In such a council as this I had expected to find more propriety, piety, and order." It was found necessary to adjourn the sitting until June 7, on which occasion the outward decencies were better observed, partly no doubt from the circumstance that the emperor was present in person. The propositions which had been extracted from the *De Ecclesia* were again brought up, and the relations between Wickliffe and Huss were discussed, the object of the prosecution being to fasten upon the latter the charge of having entirely adopted the doctrinal system of the former, including especially a denial of the doctrine of transubstantiation. The accused defended himself by repudiating the charge of having abandoned the Catholic doctrine, while at the same time he gave expression to his hearty admiration and respect for the memory of Wickliffe. Being next asked to make an unqualified submission to the council, he expressed himself as unable to do so, while at the same time stating his willingness in all humility to amend his teaching wherever it had been shown to be false. With this the proceedings of the day were brought to a close. On June 8 the propositions extracted from the *De Ecclesia* were once more taken up with some fulness of detail; some of these he repudiated as incorrectly given, others he defended; but when asked to make a general recantation he steadfastly declined on the ground that to do so would be a dishonest admission of previous guilt. Among the propositions he could heartily abjure was that relating to transubstantiation; among those he felt constrained unflinchingly to maintain was one which had given great offence, to the effect that Christ, not Peter, is the head of the church to whom ultimate appeal must be made. The council, however, showed itself inaccessible to all his arguments and explanations, and its final resolution, as announced by D'Ailly, was threefold:—first, that Huss should humbly declare that he had erred in all the articles cited against him; secondly, that he should promise on oath neither to hold nor teach them in the future; thirdly, that he should publicly recant them. On his declining to make this submission he was removed from the bar, and it was obvious that the end could not be far off. The emperor himself gave it as his opinion that it had been clearly proved by many witnesses that the accused had taught many pernicious heresies, and that even should he recant he ought never to be allowed to preach or teach again or to return to Bohemia, but that should he refuse recantation there was no remedy but the stake. During the next four weeks no effort was spared to shake the determination of Huss; but the spirit of the martyr rose within him as he saw his end approaching, and he steadfastly refused to swerve from the path which conscience had once made clear. "I write this," says he, in a letter to his friends at Prague, "in prison and in chains, expecting tomorrow to receive sentence of death, full of hope in God that I shall not swerve from the truth, nor abjure errors imputed to me by false witnesses." The sentence he expected was pronounced on July 6 in the presence of the emperor and a full sitting of the council; once and again he attempted to remonstrate, but in vain, and finally he betook himself to silent prayer. After he had undergone the ceremony of degradation with all the childish formalities which are usual on such occasions, his soul was formally consigned by all those present to the devil, while he himself with clasped hands and uplifted eyes reverently committed it to Christ. He was then handed over to the secular arm, and immediately led off to the place of execution, the council meanwhile proceeding unconcernedly with the rest of its business for the day. Many touching incidents recorded in the histories make manifest the meekness, fortitude, and even cheerfulness with which he went to his dreadful death. After he had been tied to the stake and the faggots had been piled, he was for the last time urged to recant, but his only reply was:—"God is my witness that I have never taught or preached that which false witnesses have testified against me. He knows that the great object of all my preaching and writing was to convert men from sin. In the truth of that gospel which hitherto I have written, taught, and preached, I now joyfully die." The fire was then kindled, and his voice as it audibly prayed in the words of the "Kyrie Eleison" was soon stifled in the smoke. When the flames had done their office, the ashes that were left and even the soil on which they lay were carefully removed and thrown into the Rhine.

Not many words are needed to convey a tolerably adequate estimate of the character and work of the "pale thin man in mean attire," who in sickness and poverty thus completed the forty-sixth year of a busy life at the stake. Huss was much less remarkable for the amount of his mental endowments and acquirements than for the candour with which he formed his convictions, the tenacity with which he held them, the unselfish enthusiasm with which he spoke them. He cannot be said to have added a single new item to the intellectual wealth of the world, but his contribution to its moral capital was immense. It might not be easy to formulate very precisely the doctrines for which he died, and certainly some of them, as, for example, that regarding the church, were such as many Protestants even would regard as unguarded and difficult to harmonize with the maintenance of external church order; but his is undoubtedly the honour of having been the chief intermediary in handing on from Wickliffe to Luther the torch which kindled the Reformation, and of having been one of the bravest of the martyrs who have died in the cause of honesty and freedom, of progress and of growth towards the light.

The works of Huss are usually classed under four heads:—the dogmatical and polemical, the homiletical, the exegetical, and the epistolary. Of those belonging to the first category, the earliest was that *De Omni Sanguine Christi Glorificato*, already referred to; others, besides the *De Ecclesia*, are a *Quæstio de Indulgentiis*, relating to the bull of Pope John XXIII. against Ladislaus, *Responsio ad Scripta M. S. Paletz*, *Responsio ad Scripta M. S. de Znoyma*, and a *Refutation of the Writing of the Eight Doctors of Prague*. The sermons include several discourses relating to Antichrist. It is worthy of note, in connexion with these, that by means of them and his other public teaching Huss exercised a considerable influence, not only on the religious life of his time, but on the literary development of his native tongue. His exegetical writings include *A History of Jesus Christ according to the Four Gospels*, *A History of the Passion*, *An Exposition of* 1 Cor. i.–vii., *Commentaries* on the epistles of James, Peter, John, and Jude, and an *Enarratio* on Psalms cx.–cxviii. The *Letters* are arranged in two series, one of which, numbering fifteen, relates to the period of his exile under the interdict, while the other, fifty-six in all, belongs to the time when he lived in Constance. The *De Ecclesia* was printed by Ulrich von Hutten as early as 1520, others of the controversial writings by Otto Brunnfels in 1524; and Luther wrote an interesting preface to *Epistolæ Quædam* published in 1537. The earliest collected edition of the Latin works was that of Nuremberg (*Historia et Monumenta Joh. Huss atque Hieron. Pragensis*), published in 1558 in 2 vols. folio; this was reprinted with a considerable quantity of new matter in 1715. The Bohemian works have recently been edited by K. J. Erben (3 vols., Prague, 1866).

On Huss the best and most easily accessible information for the English readers is to be found in the Church Histories, especially in that of Neander (vol. ix., Engl. trans. 1858), and pre-eminently in Lechler's *Wiclef* (1873), translated by Lorimer (1878). Among the earlier authorities is Æneas Sylvius, *De Bohemorum Origine ac Gestis Historia* (1475). The *Acta* of the council of Constance (Labbe *Conc.*, vol xvi., 1731, or Von der Hardt, *Concilium Constantiense*, 1697–1700), as also Lenfant's *Histoire*, must of course be consulted. Palacky's *Geschichte Böhmens* (1836–65) contains much valuable material carefully sifted. The earliest biography is that of Zitte, *Lebensbeschreibung des Magisters Joh. Hus* (1789–95). Monographs have in recent years been very numerous: among others may be mentioned Helfert, *Studien über Hus u. Hieronymus* (1853; this work is ultramontane in its sympathies); Becker, *Hus u. Hieronymus von Prag* (Nördlingen, 1858); Friedrich, *Johann Hus* (1863); Krummel, *Joh. Hus, eine Kirchenhist. Studie* (1863); Id., *Geschichte der böhm. Reformation* (1866); Höfler, *Hus u. der Abzug der Deutschen* (1864); Id., *Die Geschichtschreiber der Husitischen Bewegung* (1856–65); Id., *Fontes Rerum Husiticarum*; Berger, *Joh. Hus u. König Sigismund* (1872); Denis, *Huss et la Guerre des Hussites* (Paris, 1878). (J. S. BL.)

HUSSITES. The arbitrary arrest and imprisonment of Huss at Constance in November 1415 created a very painful impression among all classes in Moravia and Bohemia, and called forth angry remonstrances as soon as it was known. While the nobles resorted to diplomacy, the masses rioted and in many instances attacked the clergy. The excitement was immensely intensified by the tidings of his death, which was freely characterized as a judicial murder; several priests were put to death by the infuriated populace, who cherished the memory of Huss as that of a patriot and a saint; and the archbishop himself, after having been beset in his own palace, with difficulty saved his life by flight. Public feeling found its first organized expression in a diet which was hastily summoned to meet at Prague early in September; there a solemn protest, ultimately signed by 452 magnates and barons, was drawn up, in which the personal character of Huss as man, teacher, preacher, and author was warmly upheld, and the freedom of Bohemia and Moravia from error and heresy was as energetically asserted. Three days later the nobles who had signed this document formed themselves into a league, headed by two Bohemian barons and one from Moravia, by which they bound themselves to protect liberty of preaching on their estates, and to yield obedience to bishop or pope only in so far as might be in accordance with Scripture and the will of God. Matters of dispute were to be subjected to the arbitration of the rector and doctors in theology of the university of Prague. Soon afterwards a counter league was formed for the support of the council and curia; and civil war appeared to be imminent. The tension was further increased by the arrival of the bishop of Leitomischl, long the enemy of Huss, as legate from the council for the extirpation of heresy; and by the pressure of the interdict under which the city of Prague continued to lie. In February 1416 the 452 nobles who had signed the protest in favour of Huss were summoned to appear before the council, while the anti-Hussite league was encouraged to prepare for a crusade; and the burning of Jerome of Prague in the following May still further revealed the prevailing disposition of Catholic Christendom. Owing to the slowness, however, with which matters moved at Constance, it was not until February 1418 that the new pope, Martin V. (Otto di Colonna), was able to issue various bulls and briefs, in which he laid all obstinate Hussites under the ban, and called upon all the ecclesiastical and civil authorities to proceed against them. The council also, shortly before its dissolution, drew up twenty-four articles for withdrawing the Bohemians from the prevailing heresy, bidding King Wenceslaus protect the rights of the Romish Church in his dominion, restore the banished clergy to their benefices, repress the Hussite preaching and hymn singing, dissolve the Hussite associations, and take the ringleaders into custody. To this policy the king after much vacillation began to give effect early in 1419, and forthwith the more prominent Hussites withdrew from court; among these were Nicolaus of Pistna, an able statesman, and the famous John Zizka, a practised soldier, who placed themselves at the head of the malcontents. By the end of the year the war, though it is usually reckoned from 1420, may be said to have begun. It divides itself into two periods—the defensive, which lasted from 1420 to 1425, and the offensive, which began with Procopius's invasion of Germany in 1427, and lasted until the commencement of negotiations with the council of Basel in 1431. The struggle had not proceeded very far, however, before it became manifest that the Hussite party was itself sharply divided in views and aims. All were agreed in warm and tender reverence for the memory of Huss, the evangelical preacher and the faithful servant of Christ; equally unanimous were they in holding the distinctive doctrine of the supreme authority of Holy Scripture, and in urging the reformation of the church. But all were not prepared to go equally far in the amount of reform they proposed. While the more radical section rejected such doctrines as those of purgatory and of the mediation of saints, held that priests in mortal sin could validly administer no sacrament, disapproved of penances, images, relics, mass in a foreign tongue, maintained the right of the pious laity, even of women, to preach, and regarded every building as in itself at least suitable for acts of divine worship, the more moderate or conservative section formulated their much simpler programme in the famous four articles of Prague (July 1420). These were—(1) free preaching of the word of God throughout the kingdom of Bohemia; (2) the administration of the eucharist to all believers not in mortal sin, under both species according to the institution of Christ; (3) deprivation of the clergy of the secular lordship they had assumed and of the secular property they had acquired to their own injury and to the prejudice of the civil power; (4) prohibition and repression of all mortal sins and public scandals. The supporters of these articles, who were led by Baron Czenko of Wartenberg, and had in their number such men as Jakob von Mies, were strong in the town and university of Prague, and occasionally received the name of the Praguers, but ultimately came to be more generally known as Calixtines (from "calix") or Utraquists (from their claim to receive the communion "sub utraque specie"). The more radical party, from having taken up their headquarters at a stronghold which had been fortified by Zizka and called Mount Tabor, some 65 miles southwards of Prague, received the name of Taborites. Whatever differences, however, may have separated the Hussites, all were united in offering resistance to the efforts made by Sigismund to crush them; and at Deutschbrod in 1422, at Aussig in 1426, and finally at Taus (August 14, 1431), they inflicted signal defeats on his troops. Negotiations begun in 1431 with the council of Basel reached a termination only in November 1433, when the so-called "Compactata" or articles of agreement were signed by which the Calixtines were satisfied, communion under both species being granted to all who desired it, although the other concessions in the direction of the four articles of Prague were made in a somewhat illusory manner. The Taborites, or "Orphans" (as the followers of Zizka were sometimes called after his death in 1424), failed, however, to find in the Compactata all that they required, and they speedily took the field again in a campaign which terminated disastrously for them at Hrib near Böhmischbrod on May 30, 1434. In this battle both Procopius and his brother perished; and soon afterwards the Taborites were compelled to surrender all the fortresses to which they had betaken themselves. Thenceforward they rapidly disappeared as a political party, although as a religious body they can be traced to about the middle of the century, when they gradually became merged in the so-called Moravians, or United Brethren of Bohemia. The Calixtines obtained from Sigismund in 1436 the formal recognition of the Compactata, which from that time had the force of law. Satisfied with this somewhat empty achievement (which, however, was jealously guarded against the hostile attack of Pius II. in 1462), they gradually subsided into an inert conformity, so as to be but little distinguished from the Catholics around them At the time of the Reformation some returned to the Roman Church, while the rest attached themselves either to the Lutheran or to the Reformed creed, and Hussitism as a distinct form of Christian profession became extinct.

HUSUM, a town in the Prussian province of Schleswig-Holstein, situated in a fertile district about 2½ miles inland from the German Ocean, on the canalized Husumer Au, which forms its harbour and roadstead. It is a station on the branch railway from Tönning which joins the main line at Jübek; and it has steam communication with the North Frisian Islands (Nordstrand, Pellworm, Föhr, Sylt) and with England. Besides the old ducal palace and park, it possesses two court-houses and a gymnasium, and its public endowments are reckoned at £100,000. There is a considerable local trade; grain and cattle are exported; and the oyster-beds in the neighbourhood yield during the season about 60,000 oysters daily. The population of the town in 1875 was 5765. Husum is first mentioned in 1252, and its first church was built in 1431. Wisby rights (see vol. xi. p. 449) were granted it in 1582, and in 1608 it was raised to the rank of a town by Duke Adolphus, who was also the builder of the castle. Husum is the birthplace of Forchhammer the archæologist, Forchhammer the mineralogist, and Theodor Storm the poet.

HUSZT, a market-town in the county of Máramaros, Hungary, is situated at the confluence of the Nagy-Ág with the Theiss, and about midway on the line of railway from Szatmár-Németi to Máramaros-Sziget, 48° 10′ N. lat., 23° 18′ E. long. At Huszt there are Calvinist, Roman Catholic, and Old United Greek churches, royal law courts, and other Government offices. On an elevated and picturesque position near the town are the ruins of an old fortress. In the neighbourhood of Huszt flax and cereals are largely grown, and many of the inhabitants find employment in fishing. The population in 1870 was 6413, consisting for the most part of Magyars and Ruthenians.

HUTCHESON, Francis (1694–1746), an eminent writer on mental and moral philosophy, was born on the 8th of August 1694. His birthplace was probably the townland of Drumalig, in the parish of Saintfield and county of Down, Ireland.[1] Though the family had sprung from Ayrshire in Scotland, both his father and grandfather were ministers of dissenting congregations in the north of Ireland. Young Hutcheson was educated partly by his grandfather, partly at an academy, where he is stated by his biographer, Dr Leechman, to have been taught "the ordinary scholastic philosophy which was in vogue in those days." In the year 1710, at the age of sixteen, he entered the university of Glasgow, where he spent the next six years of his life, at first in the study of philosophy, classics, and general literature, and afterwards in the study of theology. On quitting the university, he returned to the north of Ireland, received a licence to preach, and was just on the point of settling down as the minister of a small dissenting congregation, when it was suggested to him by some gentlemen living in the neighbourhood of Dublin to start a private academy in that city. At Dublin his literary accomplishments soon made him generally known, and he appears to have rapidly formed the acquaintance of the more notable persons, lay and ecclesiastical, who then resided in the metropolis of Ireland. Among these is specially to be noted Archbishop King, author of the well-known work *De Origine Mali*, who, to his great honour, steadily resisted all attempts to prosecute Hutcheson in the archbishop's court for keeping a school without having previously subscribed to the ecclesiastical canons and obtained the episcopal licence. Hutcheson's relations with the clergy of the Established Church, especially with the archbishops of Armagh and Dublin, Boulter and King, seem to have been of the most cordial description; and "the inclination of his friends to serve him, the schemes proposed to him for obtaining promotion," &c., of which his biographer speaks, probably refer to some offers of preferment, on condition of his accepting episcopal ordination. These offers, however, of whatever nature they might be, were unavailing; "neither the love of riches nor of the elegance and grandeur of human life prevailed so far in his breast as to make him offer the least violence to his inward sentiments."

[1] See *Belfast Magazine* for August 1813.

While residing in Dublin, Hutcheson published anonymously the four essays by which he still remains best known, namely, the *Inquiry concerning Beauty, Order, Harmony, Design*, and the *Inquiry concerning Moral Good and Evil*, in 1725, and the *Essay on the Nature and Conduct of the Passions and Affections*, and *Illustrations upon the Moral Sense*, in 1728. The original title of the former work (which reached a second edition in the next year) was—*An Inquiry into the Original of our Ideas of Beauty and Virtue in two Treatises, in which the Principles of the late Earl of Shaftesbury are explained and defended against the Author of the Fable of the Bees; and the Ideas of Moral Good and Evil are established, according to the Sentiments of the Ancient Moralists, with an attempt to introduce a Mathematical Calculation on subjects of Morality.* The alterations and additions made in the second edition of these *Essays* were published in a separate form in 1726. To the period of his Dublin residence are also to be referred the "Thoughts on Laughter" (a criticism of Hobbes) and the "Observations on the Fable of the Bees," being in all six letters contributed to *Hibernicus' Letters*, a periodical which appeared in Dublin, 1725–27 (2d ed., 1734). At the end of the same period occurred the controversy in the columns of the *London Journal* with Mr Gilbert Burnet (probably the second son of Dr Gilbert Burnet, bishop of Salisbury), on the "True Foundation of Virtue or Moral Goodness." All these letters were collected in one volume, and published by Foulis, Glasgow, 1772.

In 1729 Hutcheson was elected as the successor of his old master, Gerschom Carmichael, to the chair of moral philosophy in the university of Glasgow. It is curious that up to this time both his essays and letters had all been published anonymously, though their authorship appears to have been perfectly well known. In 1730 he entered on the duties of his office, delivering an inaugural lecture (afterwards published), *De Naturali Hominum Socialitate*. The prospect of being delivered from the miscellaneous drudgery of school work, and of securing increased leisure for the pursuit of his favourite studies, occasions an almost boisterous outburst of joy:—"laboriosissimis, mihi, atque molestissimis negotiis implicito, exigua admodum erant ad bonas literas aut mentem colendam otia; non levi igitur lætitia commovebar cum almam matrem Academiam me, suum olim alumnum, in libertatem asseruisse audiveram." And yet the works on which Hutcheson's reputation was to rest had already been published.

The rest of Hutcheson's life, down to his death in 1746, was mainly spent in the assiduous performance of the duties of his professorship, including, of course, the preparation of lectures for his classes. His reputation as a teacher attracted many young men, belonging to dissenting families, from England and Ireland, and he appears to have enjoyed a well-deserved popularity among both his pupils and his colleagues. Though somewhat quick-tempered, he was remarkable for his warm feelings and generous impulses. "He was all benevolence and affection," says Dr Leechman; "none who saw him could doubt of it; his air and countenance bespoke it. It was to such a degree his prevailing temper that it gave a tincture to his writings, which were perhaps as much dictated by his heart as his head; and if there was any need of an apology for the stress that in his scheme seems to be laid upon the friendly and public affections, the prevalance of them in his own temper would at least form an amiable one."

In addition to the works already named, the following were published during Hutcheson's lifetime:—a pamphlet entitled *Considerations on Patronage, addressed to the Gentlemen of Scotland*, 1735; *Philosophiæ Moralis Institutio Compendiaria, Ethices et Jurisprudentiæ Naturalis Elementa continens, Lib. III.*, Glasgow, Foulis, 1742; *Metaphysicæ Synopsis Ontologiam et Pneumatologiam complectens*, Glasgow, Foulis, 1742. The last work was published anonymously.

After his death, his son, Francis Hutcheson, M.D., published in two volumes, quarto, what is much the longest, though by no means the most interesting, of his works, *A System of Moral Philosophy, in Three Books*, London, 1755. To this is prefixed a life of the author, by Dr William Leechman, professor of divinity in the university of Glasgow. The only remaining work that we are able to assign to Hutcheson is a small treatise on *Logic*, which, according to his biographer, was "not designed for the public eye," but which was published by Foulis at Glasgow in 1764. This compendium, together with the *Compendium of Metaphysics*, was republished at Strasburg in 1772.

Of all these works, however, those alone on which Hutcheson's philosophical reputation rests are the four essays, and perhaps the letters, all published during his residence in Dublin. To the more distinctive features of his philosophical system, so far as they may be gathered from these and his other works, we now proceed to draw attention. In the publication of the first two essays, Hutcheson acted quite rightly in connecting his name on the title-page with that of Shaftesbury. There are no two names, perhaps, in the history of English moral philosophy, which stand in a closer connexion. The analogy drawn between beauty and virtue, the functions assigned to the moral sense, the position that the benevolent feelings form an original and irreducible part of our nature, and the unhesitating adoption of the principle that the test of virtuous action is its tendency to promote the general welfare, or good of the whole, are at once obvious and fundamental points of agreement between the two authors.

According to Hutcheson, man has a variety of senses, internal as well as external, reflex as well as direct, the general definition of a sense being "any determination of our minds to receive ideas independently on our will, and to have perceptions of pleasure and pain" (*Essay on the Nature and Conduct of the Passions*, sect. 1). He does not attempt to give an exhaustive enumeration of these "senses," but, in various parts of his works, he specifies, besides the five external senses commonly recognized (which, he rightly hints, might be added to),—(1) consciousness, by which each man has a perception of himself and of all that is going on in his own mind ("Sensus quidam internus, aut conscientia, cujus ope nota sunt ea omnia, quæ in mente geruntur; hac animi vi se novit quisque, suique sensum habet," *Metaph. Syn.*, pars i. cap. 2); (2) the sense of beauty (sometimes called specifically "an internal sense"); (3) a public sense, or sensus communis, "a determination to be pleased with the happiness of others and to be uneasy at their misery;" (4) the moral sense, or "moral sense of beauty in actions and affections, by which we perceive virtue or vice, in ourselves or others;" (5) a sense of honour, or praise and blame, "which makes the approbation or gratitude of others the necessary occasion of pleasure, and their dislike, condemnation, or resentment of injuries done by us the occasion of that uneasy sensation called shame"; (6) a sense of the ridiculous. It is plain, as the author confesses, that there may be "other perceptions, distinct from all these classes," and, in fact, there seems to be no limit to the number of "senses" in which a psychological division of this kind might result.

Of these "senses" that which plays the most important part in Hutcheson's ethical system is the "moral sense." It is this which pronounces immediately on the character of actions and affections, approving of those which are virtuous, and disapproving of those which are vicious. "His principal design," he says in the preface to the two first treatises, "is to show that human nature was not left quite indifferent in the affair of virtue, to form to itself observations concerning the advantage or disadvantage of actions, and accordingly to regulate its conduct. The weakness of our reason, and the avocations arising from the infirmity and necessities of our nature are so great that very few men could ever have formed those long deductions of reason, which show some actions to be in the whole advantageous to the agent, and their contraries pernicious. The Author of nature has much better furnished us for a virtuous conduct than our moralists seem to imagine, by almost as quick and powerful instructions as we have for the preservation of our bodies. He has made virtue a lovely form, to excite our pursuit of it, and has given us strong affections to be the springs of each virtuous action." Passing over the appeal to final causes involved in this and similar passages, as well as the assumption that the "moral sense" has had no growth or history, but was "implanted" in man exactly in the condition in which it is now to be found among the more civilized races, an assumption common to the systems of both Hutcheson and Butler, it may be remarked that the employment of the term "sense" to designate the approving or disapproving faculty has a tendency to obscure the real nature of the process which goes on in an act of moral approbation or disapprobation. For, as is so clearly established by Hume, this act really consists of two parts:—one an act of deliberation, more or less prolonged, resulting in an intellectual judgment; the other a reflex feeling, probably instantaneous, of either satisfaction or repugnance,—of satisfaction at actions of a certain class which we denominate as good or virtuous, of dissatisfaction or repugnance at actions of another class which we denominate as bad or vicious. By the intellectual part of this process we refer the action or habit to a certain class, and invest it with certain characteristics; but no sooner is the intellectual process completed than there is excited in us a feeling similar to that which myriads of actions and habits of the same class, or deemed to be of the same class, have excited in us on former occasions. Now, supposing the latter part of this process to be instantaneous, uniform, and exempt from error, the former certainly is not. All mankind may, apart from their selfish interests, approve of that which is virtuous or makes for the general good, but surely they entertain the most widely divergent opinions, and, if left to their own judgment, would frequently arrive at directly opposite conclusions as to the nature of the particular actions and habits which fall under this class. This distinction is undoubtedly recognized by Hutcheson, as it could hardly fail to be, in his analysis of the mental process preceding moral action, nor does he invariably ignore it, even when treating of the moral approbation or disapprobation which is subsequent on action. Witness the following passages:—"Men have reason given them, to judge of the tendencies of their actions, that they may not stupidly follow the first appearance of public good; but it is still some appearance of good which they pursue" (*Inquiry concerning Moral Good and Evil*, sect. 4). "All exciting reasons presuppose instincts and affections; and the justifying presuppose a moral sense" (*Illustrations upon the Moral Sense*, sect. 1). "When we say one is obliged to an action, we either mean—(1) that the action is necessary to obtain happiness to the agent, or to avoid misery; or (2) that every spectator, or he himself upon reflexion, must approve his action, and disapprove his omitting it, if he considers fully all its circumstances. The former meaning of the word obligation presupposes selfish affections, and the sense of private happiness; the latter meaning includes the moral sense" (*Ibid.*). Notwithstanding these passages, however, it remains true that Hutcheson, both by the phrases which he employs to designate the moral faculty, and by the language in which he ordinarily describes the process of moral approbation, has done much to favour that loose and popular view of morality which, ignoring the difficulties that often attend our moral decisions, and the necessity of deliberation and reflexion, encourages hasty resolves and unpremeditated judgments. The term "moral sense" (which, it may be noticed, had already been employed by Shaftesbury, not only, as Dr Whewell appears to intimate in the margin, but also in the text of his *Enquiry*), if invariably coupled with the term "moral judgment," would be open to little objection; but, taken alone, as designating the complex process of moral approbation, it is liable to lead not only to serious misapprehension but to grave practical errors. For, if each man's decisions are solely the result of an immediate intuition of the moral sense, why be at any pains to test, correct, or review them? Or why educate a faculty whose decisions are infallible? The expression has, in fact, the fault of most metaphorical terms; it leads to an exaggeration of the truth which it is intended to suggest.

But though Hutcheson usually describes the moral faculty as acting instinctively and immediately, he does not, like Butler, confound the moral faculty with the moral standard. The test or criterion of right action is with Hutcheson, as with Shaftesbury, its tendency to promote the general welfare of mankind. "In comparing the moral qualities of actions, in order to regulate our election among various actions proposed, or to find which of them has the greatest moral excellency, we are led by our moral sense of virtue to judge thus—that, in equal degrees of happiness expected to proceed from the action, the virtue is in proportion to the number of persons to whom the happiness shall extend (and here the dignity or moral importance of persons may compensate numbers), and, in equal numbers, the virtue is as the quantity of the happiness or natural good; or that the virtue is in a compound ratio of the quantity of good and number of enjoyers. In the same manner, the moral evil, or vice, is as the degree of misery and number of sufferers; so that that action is best which procures the greatest happiness for the greatest numbers, and that worst which, in like manner, occasions misery" (*Inquiry concerning Moral Good and Evil*, sect. 3). What was subsequently called the utilitarian standard is here unhesitatingly adopted by Hutcheson; and it is curious to notice that he actually employs the very phrase which became so celebrated in the mouth of Bentham, though afterwards reduced by that writer to the more simple expression "greatest happiness."

The adoption of an external standard, requiring much care and reflexion in its application, ought to have led Hutcheson to see that the moral faculty, by which the standard was to be applied, is by no means so simple and instinctive as he imagined it to be, and that, consequently, these two parts of his system are in reality inconsistent.

As connected with Hutcheson's virtual adoption of the utilitarian standard, may be noticed a kind of moral algebra, proposed for the purpose of "computing the morality of actions." This calculus occurs in the *Inquiry concerning Moral Good and Evil*, sect. 3.

The most distinctive of Hutcheson's ethical doctrines, still remaining to be noticed, is what has been called the "benevolent theory" of morals. Hobbes had maintained that all our actions, however disguised under apparent sympathy, have their roots in self-love. Hutcheson not only maintains that benevolence is the sole and direct source of many of our actions, but, by a not unnatural recoil from the repellent doctrine of Hobbes, that it is the only source of those actions of which, on reflexion, we approve. "If we examine all the actions which are accounted amiable anywhere, and inquire into the grounds upon which they are approved, we shall find that, in the opinion of the person who approves them, they always appear as benevolent, or flowing from love of others and a study of their happiness, whether the approver be one of the persons beloved or profited or not; so that all those kind affections which incline us to make others happy, and all actions supposed to flow from such affections, appear morally good, if, while they are benevolent toward some persons, they be not pernicious to others. Nor shall we find anything amiable in any action whatsoever, where there is no benevolence imagined; nor in any disposition, or capacity, which is not supposed applicable to and designed for benevolent purposes" (*Inquiry concerning Moral Good and Evil*, sect. 3). Consistently with this position, actions which flow from self-love only are pronounced to be morally indifferent: "The actions which flow solely from self-love, and yet evidence no want of benevolence, having no hurtful effects upon others, seem perfectly indifferent in a moral sense, and neither raise the love or hatred of the observer" (*Ibid.*). But surely, by the common consent of civilized men, prudence, temperance, cleanliness, industry, self-respect, and in general, the "personal virtues," as they are called, are regarded, and rightly regarded, as fitting objects of moral approbation. This consideration could hardly escape any author, however wedded to his own system, and Hutcheson attempts to extricate himself from the difficulty by laying down the position that a man may justly regard himself as a part of the rational system, and may thus "be, in part, an object of his own benevolence" (*Ibid.*),—a curious abuse of terms, which really concedes the question at issue. Moreover, he acknowledges that, though self-love does not merit approbation, neither, except in its extreme forms, does it merit condemnation. "We do not positively condemn those as evil who will not sacrifice their private interest to the advancement of the positive good of others, unless the private interest be very small, and the public good very great" (*Illustrations upon the Moral Sense*, sect. 6). The satisfaction of the dictates of self-love, too, is one of the very conditions of the preservation of society. "Self-love is really as necessary to the good of the whole as benevolence,—as that attraction which causes the cohesion of the parts is as necessary to the regular state of the whole as gravitation" (*Inquiry concerning Moral Good and Evil*, sect. 17). To press home the inconsistencies involved in these various statements would be a superfluous task.

Hutcheson's benevolent view of human nature is illustrated also by his denying that malevolence is an original principle in the constitution of man. "Perhaps our nature is not capable of desiring the misery of any being calmly, farther than it may be necessary to the safety of the innocent; we may find, perhaps, that there is no quality in any object which would excite in us pure disinterested malice, or calm desire of misery for its own sake" (*On the Nature and Conduct of the Passions*, sect. 3). Against this position of Hutcheson, propounded also by Butler (*Serm.* ix.), it might be objected that, even amongst very young children, we often find a singular and precocious love of cruelty. This is, undoubtedly, one of the most curious facts in moral psychology, but it may perhaps be accounted for by supposing it to originate in a combination of morbid curiosity with an equally morbid love of power.

The vexed question of liberty and necessity appears to be carefully avoided in Hutcheson's professedly ethical works. But, in the *Synopsis Metaphysicæ*, he touches on it in no less than three places, briefly stating both sides of the question, but evidently inclining to that which he designates as the opinion of the Stoics in opposition to what he designates as the opinion of the Peripatetics. This is substantially the same as the doctrine propounded by Hobbes and Locke (to the latter of whom Hutcheson refers in a note), namely, that our will is determined by motives in conjunction with our general character and habit of mind, and that the only true liberty is the liberty of acting as we will, not the liberty of willing as we will. Though, however, his leaning is clear, he carefully avoids dogmatizing, and speaks of the difficulty as "ardua quæstio," "quæstio vexatissima, quæ doctorum et piorum ingenia semper torserat, atque de qua utrinque frustra ad sensum cujusque internum provocatur," earnestly deprecating the angry controversies and bitter dissensions to which the speculations on this subject had given rise.

If our limits allowed us sufficient space, it would be easy to trace the influence of Hutcheson's ethical theories on the systems of Hume and Adam Smith. The prominence given by these writers to the analysis of moral action and moral approbation, with the attempt to discriminate the respective provinces of the reason and the emotions in these processes, is undoubtedly due to the influence of Hutcheson. To a study of the writings of Shaftesbury and Hutcheson we might, probably, in large measure, attribute the unequivocal adoption of the utilitarian standard by Hume, and, if this be the case, the name of Hutcheson connects itself, through Hume, with the names of Priestley, Paley, and Bentham. Butler's *Sermons* appeared in 1726, the year after the publication of Hutcheson's two first essays, and the parallelism between the "conscience" of the one writer and the "moral sense" of the other is, at least, worthy of remark.

In the sphere of mental philosophy and logic, Hutcheson's contributions are by no means so important or original as in that of moral philosophy. In the former subject, the influence of Locke is apparent throughout. All the main outlines of Locke's philosophy seem, at first sight, to be accepted as a matter of course. Thus, in stating his theory of the moral sense, Hutcheson is peculiarly careful to repudiate the doctrine of innate ideas (see, for instance, *Inquiry concerning Moral Good and Evil*, sect. 1 *ad fin.*, and sect. 4; and compare *Synopsis Metaphysicæ*, pars i. cap. 2). At the same time, it may be noticed that he shows more discrimination than does Locke in distinguishing between the two uses of this expression, and between the legitimate and illegitimate form of the doctrine (*Syn. Metaph.*, pars i. cap. 2). All our ideas are, as by Locke, referred to external or internal sense, or, in other words, to sensation and reflexion (see, for instance, *Syn. Metaph.*, pars i. cap. 1; *Logicæ Compend.*, pars. i. cap. 1; *System of Moral Philosophy*, book i. ch. 1). It is, however, a most important modification of Locke's doctrine, and one which connects Hutcheson's mental philosophy with that of Reid, when he states that the ideas of extension, figure, motion, and rest "are more properly ideas accompanying the sensations of sight and touch than the sensations of either of these senses;" that the idea of self accompanies every thought; and that the ideas of number, duration, and existence accompany every other idea whatsoever (see *Essay on the Nature and Conduct of the Passions*, sect. i. art. 1; *Syn. Metaph.*, pars i. cap. 1, pars ii. cap. 1; Hamilton on *Reid*, p. 124, note). Other important points in which Hutcheson follows the lead of Locke are his depreciation of the importance of the so-called laws of thought, his distinction between the primary and secondary qualities of bodies, the position that we cannot know the inmost essences of things ("intimæ rerum naturæ sive essentiæ"), though they excite various ideas in us, and the assumption that external things are known only through the medium of ideas (*Syn. Metaph.*, pars i. cap. 1), though, at the same time, we are assured of the existence of an external world corresponding to these ideas. Hutcheson attempts to account for our assurance of the reality of an external world by referring it to a natural instinct ("Idearum plurimas ad res externas, tanquam earundem imagines aut repræsentationes, referre cogimur ab ipsa natura," *Syn. Metaph.*, pars i. cap. 1). Of the correspondence or similitude between our ideas of the primary qualities of things and the things themselves God alone can be assigned as the cause. This similitude has been effected by Him through a law of nature. "Hæc prima qualitatum primariarum perceptio, sive mentis actio quædam sive passio dicatur; non alia similitudinis aut convenientiæ inter ejusmodi ideas et res ipsas causa assignari posse videtur, quam ipse Deus, qui certa naturæ lege hoc efficit, ut notiones, quæ rebus præsentibus excitantur, sint ipsis similes, aut saltem earum habitudines, si non veras quantitates, depingant" (pars ii. cap. 1). Locke had repeatedly stated that "the primary qualities of bodies are resemblances of them, and their patterns do really exist in the bodies themselves" (see, for instance, *Essay*, bk. ii. ch. 8, sect. 15), and he also speaks of God "annexing" certain ideas to certain motions of bodies (*Ibid.*, sect. 13, and elsewhere); but nowhere, we believe, does he propound a theory so precise and definite as that here propounded by Hutcheson, which reminds us at least as much of the speculations of Malebranche as of those of Locke.

Amongst the more important points in which Hutcheson diverges from Locke is his account of the idea of personal identity, which he appears to have regarded as made known to us directly by consciousness. "Mentem suam eandem manere, sibi conscius est quisque, repetentia illa, sive perceptione interna, certissima, ast ineffabili, qua novit suam mentem a mente quavis alia omnino diversam esse" (*Syn. Metaph.*, pars. i. cap. 3). The distinction between body and mind, "corpus" or "materia" and "res cogitans," is more emphatically accentuated by Hutcheson than by Locke. Generally, he speaks as if we had a direct consciousness of mind as distinct from body (see, for instance, *Syn. Metaph.*, pars ii. cap. 3), though, in the posthumous work on *Moral Philosophy*, he expressly states that we know mind as we know body "by qualities immediately perceived though the substance of both be unknown" (bk. i. ch. 1). The distinction between perception proper and sensation proper, which occurs by implication though it is not explicitly worked out (see Hamilton's *Lectures on Metaphysics*, Lect. 24; Hamilton's edition of *Dugald Stewart's Works*, vol. v. p. 420), the imperfection of the ordinary division of the external senses into five classes, the limitation of consciousness to a special mental faculty (severely criticized in Sir W. Hamilton's *Lectures on Metaphysics*, Lect. xii.), and the disposition to refer on disputed questions of philosophy not so much to formal arguments as to the testimony of consciousness and our natural instincts ("ad gravissima quædam in philosophia dogmata amplectenda, non argumentis aut ratiocinationibus, ex rerum perspecta natura petitis, sed potius sensu quodam interno, usu, atque naturæ impulsu quodam aut instinctu ducimur," pars ii. cap. 3) are also amongst the points in which Hutcheson supplemented or departed from the philosophy of Locke. The last point can hardly fail to suggest to our readers the "common-sense philosophy" of Reid, and here it may be remarked that the interest attaching to Hutcheson's psychological and metaphysical views consists very largely in the intermediate position which they occupy between the system of Locke and that of Reid and the later Scottish school. If we confine ourselves to merely enumerating detached questions, he perhaps stands nearer to Locke, but in the general spirit of his philosophy he seems to approach more closely to his Scottish successors.

The short *Compendium of Logic*, which is more original than such works usually are, is chiefly remarkable for the large proportion of psychological matter which it contains. In these parts of the book Hutcheson mainly follows Locke. The technicalities of the subject are passed lightly over, and the book is eminently readable. It may be specially noticed that he distinguishes between the mental result and its verbal expression [idea—term; judgment—proposition], that he constantly employs the word "idea," and that he defines logical truth as "convenientia signorum cum rebus significatis" (or "propositionis convenientia cum rebus ipsis," *Syn. Metaph.*, pars i. cap. 3), thus implicitly repudiating a merely formal view of logic.

Hutcheson may claim to have been one of the earliest modern writers on æsthetics. His speculations on this subject are contained in the *Inquiry concerning Beauty, Order, Harmony, and Design*, the first of the two treatises published in 1725. He maintains that we are endowed with a special sense by which we perceive beauty, harmony, and proportion. This is a *reflex* sense, because it presupposes the action of the external senses of sight and hearing. It may be called an internal sense, both in order to distinguish its perceptions from the mere perceptions of sight and hearing, and because "in some other affairs, where our external senses are not much concerned, we discern a sort of beauty, very like, in many respects, to that observed in sensible objects, and accompanied with like pleasure" (*Inquiry*, &c., sect. 1). The latter reason leads him to call attention to the beauty perceived in universal truths, in the operations of general causes, and in moral principles and actions. Thus, the analogy between beauty and virtue, which was so favourite a topic with Shaftesbury, becomes also prominent in the writings of Hutcheson. Scattered up and down the treatise, there are many important and interesting observations which our limits prevent us from noticing. But to the student of mental philosophy it may be specially interesting to remark that Hutcheson both applies the principle of association to explain our ideas of beauty and also sets limits to its application, insisting on there being "a natural power of perception or sense of beauty in objects, antecedent to all custom, education, or example" (see *Inquiry*, &c., sects. 6, 7; Hamilton's *Lectures on Metaphysics*, Lect. 44 *ad fin.*).

Hutcheson's writings gave rise, as they could hardly fail to do, to much controversy among those who were interested in ethical speculations. To say nothing of minor opponents, such as "Philaretus" (Mr Gilbert Burnet, already alluded to), Dr John Balguy, author of two tracts on *The Foundation of Moral Goodness*, and Dr John Taylor of Norwich, a Presbyterian minister of considerable reputation in his time, the essays appear to have suggested, by antagonism, at least two works which hold a permanent place in the literature of English ethics. One of these is Butler's *Dissertation on the Nature of Virtue*, which is, throughout, a criticism of the main positions maintained by Hutcheson. The other is an answer of a far more complete and systematic character, Dr Richard Price's *Treatise of Moral Good and Evil*, which first appeared in 1757. In this work, the author maintains, in opposition to Hutcheson, that actions are *in themselves* right or wrong (an ambiguous expression, which he is not sufficiently careful to explain), that right and wrong are simple ideas incapable of analysis, and that these ideas are perceived immediately by the understanding. Price's work is remarkable for the close similarity between many of the ideas and even expressions contained in it and those which subsequently became so celebrated in the speculations of Kant. We thus see that, not only by its direct but also by its indirect influence, through the replies which it called forth, the system of Hutcheson, or at least the system of Hutcheson combined with that of Shaftesbury, may be regarded as having contributed, in very large measure, to the formation and development of some of the most important of the modern schools of ethics.

The original editions of Hutcheson's various works have been already mentioned. Several additions and alterations were made in the second edition (1726) of the *Inquiry into the Original of our Ideas of Beauty and Virtue*. This, as well as most of his other works, passed through various editions. Of the *System of Moral Philosophy*, however, published after Hutcheson's death, there is, we believe, one edition only. Notices of Hutcheson occur in most histories, both of general philosophy and of moral philosophy, as, for instance, in part vii. of Adam Smith's *Theory of Moral Sentiments*; Mackintosh's *Progress of Ethical Philosophy*; Cousin, *Cours d' Histoire de la Philosophie Morale du XVIIIième Siècle*; Whewell's *Lectures on the History of Moral Philosophy in England*; Bain's *Mental and Moral Science*; Dr Noah Porter's Appendix to the English translation of Ueberweg's *History of Philosophy*; Mr Leslie Stephen's *History of English Thought in the Eighteenth Century*, &c. Of Dr Leechman's *Biography* of Hutcheson we have already spoken. Professor Veitch gives an interesting account of his professorial work in Glasgow, *Mind*, vol. ii. pp. 209-211. (T. F.)

HUTCHINSON, JOHN (1616–1664), a Puritan soldier, son of Sir Thomas Hutchinson, was born at Nottingham in September 1616. After completing his education at Cambridge University he entered Lincoln's Inn, but soon became tired both of the study of law and the amusements of London, and was meditating travel on the Continent when he accidentally made the acquaintance of Lucy, daughter of Sir Allan Apsley, whom he married in 1638. After his marriage he returned to Owthorpe, where the study of divinity and politics gradually led to a change of his sentiments in regard to the dispute between the parliament and the king At first he did not find a clear call to join the Parliamentary army, but the efforts of the Royalists to seize him as a disaffected person soon dissipated his neutrality, and, becoming governor of Nottingham, he with great firmness and courage held the town and castle against internal treachery and external attacks till the triumph of the parliamentary cause. Having been chosen to represent Nottingham in the new parliament, he became a member of the high court of justice for the trial of the king, and gave his vote for his execution, but, disapproving of the subsequent political conduct of Cromwell, he took no further part in politics during the lifetime of the Protector. After the Restoration he became member for the county of Nottingham, and he was included in the Act of Amnesty passed in favour of certain of the regicides. Subsequently, however, he was arrested upon suspicion of being concerned in a treasonable conspiracy; and after an imprisonment of ten months in the Tower of London, and of one month in Sandown Castle, Kent, he died 11th September 1664. The life of Colonel Hutchinson is now only of interest from the manner in which it is narrated in the *Memoirs* written by his wife, and first published in 1806, a work not only valuable for the picture which it gives of the time in which he lived, but for the simple beauty of its style, and the naiveté with which the writer records her sentiments and opinions, and details the incidents of her private life.

HUTCHINSON, JOHN (1674-1737), the author of *Moses's Principia* and other works in which the so-called Hutchinsonian system is expounded, was born at Spennithorne, Yorkshire, in 1674, and after receiving an adequate elementary education there, served as steward in several families of position, latterly in that of the duke of Somerset, who ultimately obtained for him the post of riding purveyor to the master of the horse, a sinecure worth about £200 a year. In this employment he became acquainted with Dr Woodward, physician to the duke, and author of a work entitled *The Natural History of the Earth*, to whom he entrusted a large number of fossils of his own collecting, along with a mass of manuscript notes, for arrangement and publication. A misunderstanding as to the manner in which these should be dealt with was the immediate occasion of the publication by Hutchinson in 1724 of *Moses's Principia*, part i., in which Woodward's *Natural History* was bitterly ridiculed, his conduct with regard to the mineralogical specimens not obscurely characterized, and a refutation of the Newtonian doctrine of gravitation seriously attempted. It was followed by part ii. in 1727, and by various other works published at frequent intervals. Hutchinson died in 1737. A complete edition of all the publications of this author, along with his posthumous pieces, edited by Robert Spearman and Julius Bate, appeared in 1748 (12 vols.); an *Abstract* of these followed in 1753; and a *Supplement*, with *Life* by Spearman prefixed, in 1765.

Although the crude ideas of Hutchinson at the time of their first promulgation were successful, by their seeming devoutness, in commending themselves to some of the pious but dim-sighted and over-timid souls of that period, who had taken alarm at the atheistic conclusions they believed to be deducible from the Newtonian doctrines, they are now too uninfluential, as well as too glaringly inconsistent with the universally recognized principles of physics and philology, to call for any detailed analysis. Their nature may be almost sufficiently gathered from the titles of some of the works in which they are set forth, such as *Moses's Principia, Part I.; of the Invisible Parts of Matter, of Motion, of Visible Forms, and of their Dissolution and Reformation*; *Moses's Principia, Part II.; of the Circulation of the Heavens; of the Cause of the Motion and Course of the Earth, Moon, &c.; of the Religion, Philosophy, and Emblems of the Heathens before Moses writ, and of the Jews after; in Confirmation of the Natural History of the Bible*; *Moses's Sine Principio, represented by Names, Words, Types, Emblems; with an introduction to show the Nature of the Fall, of Paradise, and of the Body and Soul*; *The Confusion of Tongues and Trinity of the Gentiles* (*being an account of the origin of Idolatry*); *Power Essential and Mechanical, or what power belongs to God and what to his creatures, in which the design of Sir I. Newton and Dr Samuel Clarke is laid open*; *Glory or Gravity, wherein the Objects and Articles of the Christian Faith are exhibited*; *The Religion of Satan, or Antichrist Delineated.* Bishop Horne of Norwich, it may be mentioned, was during some of his earlier years an avowed Hutchinsonian; and Jones of Nayland continued to be so to the end of his life.

HUTCHINSON, Thomas (1711–1780), governor of the province of Massachusetts, son of a wealthy merchant of Boston, was born there September 9, 1711. The son, being unsuccessful in commerce, studied law, and adopted it as his profession. He was representative of Boston in the general court for ten years, and was three times chosen speaker. From 1749 to 1766 he was a counsellor, in 1752 he was appointed judge of probate, from 1758 to 1771 he was lieutenant-governor, and in 1760 he became chief justice. In 1748 he carried a measure to substitute gold and silver for the paper currency, which had depreciated one-eighth in value. During the Stamp Act riots of 1765 his house was sacked by the mob; and by his subsequent support of the general policy of the British Government he incurred increasing unpopularity. In 1767 he laid claim to a seat in the council on the ground of being lieutenant-governor, but on account of his political views his claims were set aside. On his appointment to the governorship of Massachusetts in 1769, he used every method to support the measures which the mother country sought to enforce against the colonists; and in December 1773, on account of his refusal to permit the reshipment of teas on which a duty had been laid by the Government, several of the inhabitants of Boston emptied the tea into the bay. In January 1774 Hutchinson asked leave to resign his office, and in June he sailed to England, where he spent the remainder of his life. As the result of official inquiry into his conduct while governor of Massachusetts, he was rewarded with a pension. He died at Brompton in June 1780.

Hutchinson was the author of the following works:—*A Brief Statement of the Claim of the Colonies*, 1764; *Collection of Original Papers relative to the History of the Colony of Massachusetts Bay*, 1769; *History of the Colony of Massachusetts Bay from 1628 to 1750*, 2 vols., London, 1765–67; *History of Massachusetts from 1749 to 1774*, published posthumously in 1828.

HUTTEN, Ulrich von (1488–1523), is one of those men who, like Erasmus or Pirckheimer, form the bridge between Humanists and Reformers. He lived with both, sympathized with both, though he died before the Reformation had time fully to develop itself. His life may be divided into four parts:—his youth and cloister-life (1488–1504); his wanderings in pursuit of knowledge (1504–1515); his strife with Ulrich of Würtemburg (1515–1519); and his connexion with the Reformation (1519–1523). Each of these periods had its own special antagonism, which coloured Hutten's career: in the first, his horror of dull monastic routine; in the second, the ill-treatment he met with at Greifswald; in the third, the crime of Duke Ulrich; in the fourth, his disgust with Rome and with Erasmus. He was born April 21, 1488, at the castle of Steckelberg, near Fulda, in Franconia, the eldest son of a poor and not undistinguished knightly family. As he was mean of stature and sickly his father destined him for the cloister, and he was sent to the Benedictine house at Fulda; the thirst for learning there seized on him, and in 1504 he fled from the monastic life, and won his freedom with the sacrifice of his worldly prospects, and at the cost of incurring his father's undying anger. From the Fulda cloister he went first to Cologne, next to Erfurt, and then to Frankfort-on-the-Oder on the opening in 1506 of the new university of that town; there in that year he appears to have graduated in philosophy. When, however, the scholastic party displaced the Humanists, he wandered forth again; in 1508 we find him a shipwrecked beggar on the Pomeranian coast. In 1509 the university of Greifswald welcomed him; "Ulricus Huttenus poeta clericus Herbipolensis gratis intitulatus quia spoliatus omnibus bonis" is the honourable record on the books of this his second Alma Mater. Here too the friends who at first received him so kindly became his foes; the sensitive ill-regulated youth, who took the liberties of genius, wearied his burgher patrons; they could not brook the poet's airs and vanity, and ill-timed assertions of his higher rank. Wherefore he left Greifswald, and as he went was robbed of clothes and books, his only baggage, by the servants of his late friends; in the dead of winter, half starved, frozen, penniless, he reached Rostock. Here again the Humanists, who were throughout full of charity and sympathy towards the luckless young scholar, received him gladly, and under their protection he wrote against his Greifswald patrons, thus beginning the long list of his satires and fierce attacks on personal or public foes. Rostock could not hold him long; he wandered on to Wittenberg and Leipsic, and thence to Vienna, where he hoped to catch the emperor Maximilian's favour by an elaborate national poem on the war with Venice. But neither Maximilian nor the university of Vienna would lift hand for him, and he passed into Italy, that holy land of Humanist enthusiasm, where, at Pavia, he sojourned throughout 1511 and part of 1512. In the latter year his studies were rudely interrupted by war; in the siege of Pavia by papal troops and Swiss, he was plundered by both sides, and escaped sick and penniless to Bologna; on his recovery he even took service as a private soldier in the emperor's army.

This dark period lasted no long time; in 1514 he was again in Germany, where, thanks to his poetic gifts and the friendship of Eitelwolf von Stein, he won the favour of the elector of Mainz, Archbishop Albert of Brandenburg. Here high dreams of a learned career rose on him; Mainz should be made the metropolis of a grand Humanist movement, the centre of good style and literary form. This golden dream was scattered by the murder in 1515 of his cousin John of Hutten by Ulrich, duke of Würtemburg. This outrage changed the whole course of Hutten's life; satire, chief refuge of the weak, became his weapon; with one hand he took his part in the famous *Epistolæ Obscurorum Virorum*, and with the other launched scathing letters, eloquent Ciceronian orations, or biting satires against the duke. Though the emperor was too lazy and indifferent to smite a great prince, he condescended to bestow on Hutten the inexpensive honour of a laureate crown in 1517; as the poet tells us with pleased pride, the wreath was woven by the hands of fair Constantia, Conrad Peutinger's daughter. As recognized poet laureate of Germany, Hutten, who had been to Italy, again attached himself to the electoral court at Mainz; and he was there when in 1518 his true friend Pirckheimer wrote, urging him to abandon the court and dedicate himself to letters. We have the poet's long reply, in an epistle on his "way of life," an amusing mixture of earnestness and vanity, self-satisfaction and satire; he tells his friend that his career is just begun, that he has had twelve years of wandering, and will now enjoy himself a while in patriotic literary work; that he has by no means deserted the humaner studies, but carries with him a little library of standard books. Pirckheimer in his burgher life may have ease and even luxury; he, a knight of the empire, how can he condescend to obscurity? He must abide where he can shine. And so, dazzled by his dream of an intellectual reform, Hutten chose the path which presently led him to his ruin.

In 1519 he issued in one volume his attacks on Duke Ulrich, and then, drawing sword, took part in the private war which overthrew that prince; in this affair he became intimate with Franz von Sickingen, the champion of the knightly order (Ritterstand). Henceforth Hutten takes part in the Lutheran movement, while he becomes mixed up in the attempt of the "Ritterstand" to recover its position, and to assert itself as the militia of the empire against the independence of the German princes. It was soon after this time that he discovered at Fulda a copy of the manifesto of the emperor Henry IV. against Hildebrand, and published it with comments as an attack on the papal claims over Germany. He hoped thereby to interest the new emperor Charles V., and the higher orders in the empire, in behalf of German liberties; but the appeal failed. What Luther had achieved by speaking to cities and common folk in homely phrase, because he touched heart and conscience, that the far finer weapons of Hutten failed to effect, because he tried to touch the more cultivated sympathies and dormant patriotism of princes and bishops, nobles and knights. And so he at once gained an undying name in the republic of letters and ruined his own career. He showed that the artificial verse-making of the Humanists could be connected with the new outburst of genuine German poetry. The Minnesinger was gone; the new national singer, a Luther or a Hans Sachs, was heralded by the stirring lines of Hutten's pen. These form a distinct epoch in the history of German national literature; they have in them a splendid natural swing and ring, strong and patriotic, though unfortunately addressed to knight and landsknecht rather than to the German people.

The poet's high dream of a knightly national regeneration had a rude awakening. The attack on the papacy, and Luther's vast and sudden popularity, frightened Elector Albert, who dismissed Hutten from his court. Hoping for imperial favour, he betook himself to Charles V.; but that cold young prince, who cared little for Humanists, and was not a German, would have none of him. So he returned to his friends, and they rejoiced greatly to see him still alive; for Pope Leo X. had ordered him to be arrested and sent to Rome, and assassins dogged his steps. He now attached himself more closely to Franz von Sickingen and the knightly movement. This also came to a disastrous end in the capture of the Ebernberg, and Sickingen's death; the higher nobles had triumphed; the archbishops avenged themselves on Lutheranism as interpreted by the knightly order. With Sickingen Hutten also finally fell. He fled to Basel, where Erasmus refused to see the sick hero, both for fear of his loathsome diseases, and also because the beggared knight was sure to borrow money from him. A paper war consequently broke out between the two Humanists, which embittered Hutten's last days, and stained the memory of Erasmus. From Basel Ulrich dragged his limbs to Mulhausen; and when the vengeance of Erasmus drove him thence, he went to Zurich. There the large heart of Zwingli welcomed him; he helped him with money, and found him a quiet refuge with the pastor of the little isle of Ufnau on the Zurich Lake. There the frail and worn-out poet, writing swift satire to the end, fell a victim to his infirmities, and died (29th August 1523) at the age of thirty-five. He left behind him some debts due to compassionate friends; he did not even own a single book, and all his goods amounted to the clothes on his back, a bundle of letters, and that valiant pen which had fought so many a sharp battle, and had won for the poor knight-errant a sure place in the annals of literature.

Ulrich von Hutten is one of those men of genius at whom propriety is shocked, and whom the mean-spirited avoid. Yet through his short and buffeted life he was befriended, with wonderful charity and patience, by the chief leaders of the Humanist movement. For, in spite of his irritable vanity, his immoral life and habits, his odious diseases, his painful restlessness, Hutten had much in him that strong men could love. He passionately loved the truth, and was ever open to all good influences. He was a patriot, whose soul yearned for what was high, and soared to ideal schemes and a grand utopian restoration of his country. In spite of all, his was a frank and noble nature; his faults chiefly the faults of genius ill-controlled, and of a life cast in the eventful changes of an age of novelty. A swarm of writings issued from his pen; at first the smooth elegance of his Latin prose and verse seemed strangely to miss his real character; he was the Cicero and Ovid of Germany before he became its Lucian.

His chief works were his *Ars versificandi* (1511); the *Nemo*, (1518); a work on the *Morbus Gallicus* (1519); the volume of Steckelberg complaints against Duke Ulrich (including his four *Ciceronian Orations*, his *Letters*, and the *Phalarismus*) also in 1519; the *Vadismus* (1520); and the controversy with Erasmus at the end of his life. Besides these were many admirable poems in Latin and German. It will never be known with certainty how far Hutten was the parent of the celebrated *Epistolæ Obscurorum Virorum*, that famous satire on monastic ignorance as represented by the theologians of Cologne with which the friends of Reuchlin defended him. At first the cloister-world, not discerning its irony, welcomed the work as a defence of their position; though their eyes were soon opened by the favour with which the learned world received it. The *Epistolæ* were eagerly bought up; the first part (41 letters) appeared at the end of 1515; early in 1516 there was a second edition; later in 1516 a third, with an appendix of seven letters; in 1517 appeared the second part (62 letters), to which a fresh appendix of eight letters was subjoined soon after. Hutten, in a letter addressed to Robert Crocus, denied that he was the author, and is followed by Bayle in his *Dictionary*; but there is no doubt as to his direct connexion with the book. Erasmus was of opinion that there were three authors, of whom Crotus Rubianus was the originator of the idea, and Hutten a chief contributor. D. F. Strauss, who dedicates to the subject a chapter of his admirable work on Hutten, concludes that he had no share in the first part, but that his hand is clearly visible in the second part, which he attributes in the main to him. To him is due the more serious and severe tone of that bitter portion of the satire.

For a complete catalogue of the writings of Hutten, see Böcking's *Index Bibliographicus Huttenianus* (1858). The best biography (though it is also somewhat of a political pamphlet) is that of

Strauss (*Ulrich von Hutten*, 1857; 2d ed., 1871; English translation by Sturge, 1874), with which may be compared the monographs by Potton (accompanying his translation in French of the *Morbus Gallicus*, 1865), Mohnicke, Wagenseil, Von Brunnow, Bürck, and Göhring. See also Panzer (*Ulrich von Hutten in literarischer Hinsicht*, 1798); and K. Hagen ("Ulrich von Hutten in politischer Beziehung" in his *Zur politischen Geschichte Deutschlands*, 1824). (G. W. K.)

HUTTON, Charles (1737–1823), the youngest son of Henry and Eleanor Hutton, was born at Newcastle-on-Tyne, August 14, 1737. His father was an underviewer in the coal-works in the neighbourhood, and died in June 1742; but his mother's second husband, Francis Frain, proved kind to the boy, and, in consequence of a slight accident to the elbow-joint of his right arm, sent him to school while his brothers worked in the pits. The most of his education he received in a school at Jesmond, kept by Mr Ivison, a clergyman of the church of England. There is reason to believe, on the evidence of two pay-bills, that for a short time in 1755 and 1756 Hutton worked in Old Long Benton colliery; at any rate, on Ivison's promotion to a living, Hutton succeeded to the Jesmond school, whence, in consequence of increasing pupils, he removed to Stote's Hall. While he taught during the day at Stote's Hall, he studied mathematics in the evening at a school in Newcastle. In 1760 he married, and began the work of tuition on a larger scale in Newcastle, where he had among his pupils John Scott, afterwards Lord Eldon, chancellor of England. In 1764 he published his first work, *The Schoolmaster's Guide, or a Complete System of Practical Arithmetic*, which in 1770 was followed by his *Treatise on Mensuration both in Theory and Practice*. In 1772 appeared a tract on *The Principles of Bridges*, suggested by the destruction of Newcastle bridge by a high flood on 17th November 1771. On a vacancy occurring in the professorship of mathematics at the Royal Military Academy, Woolwich, in 1773, Hutton became a candidate, and after a severe competitive contest was appointed to the post. He was made a fellow of the Royal Society in 1774, and at their request drew up an account of the calculations to determine the mean density and mass of the earth made by him from the measurements taken in 1774–76 at Schiehallion in Perthshire. This account appeared in the *Philosophical Transactions* for 1778, was afterwards reprinted in the second volume of his *Tracts on Mathematical and Philosophical Subjects*, and procured for Hutton the degree of LL.D. from the university of Edinburgh. He was elected foreign secretary to the Royal Society in 1779, but his resignation in 1783 was brought about by the president Sir Joseph Banks, whose behaviour to the mathematical section of the society was somewhat high-handed (see Kippis's *Observations on the late Contests in the Royal Society*, London, 1784). After his *Tables of the Products and Powers of Numbers*, 1781, and his *Mathematical Tables*, 1785, he issued, for the use of the Royal Military Academy, in 1787 *Elements of Conic Sections*, and in 1798 his *Course of Mathematics*. The last, at the time it appeared, was much superior in mode of treatment to any existing work on the subject, and in succeeding editions the author incorporated many new discoveries and methods. The two volumes of his *Mathematical and Philosophical Dictionary*, a most valuable contribution to scientific biography, were published in 1795, and the four volumes of *Recreations in Mathematics and Natural Philosophy*, mostly a translation from the French, in 1803. One of the most laborious of his works was the abridgment, in conjunction with Drs Shaw and Pearson, of the *Philosophical Transactions*. This undertaking, the mathematical and scientific parts of which fell to Hutton's share, was completed in 1809, and filled eighteen volumes quarto. Hutton's long-continued connexion (it extended over fifty-six years) with the mathematical periodicals of his time, whether as contributor or editor, deserves a word of notice. His name first appears in the *Ladies' Diary* (a poetical and mathematical almanac which was begun in 1704, lasted on till 1871, and which "contributed more to the study and improvement of mathematics than half the books professedly written on the subject") in the year 1764; ten years later he was appointed editor of the almanac, a post which he retained till 1817. Previous to his editorship of the *Diary*, he had begun a small periodical, *Miscellanea Mathematica*, which extended only to thirteen numbers; subsequently to it, he published in five volumes *The Diarian Miscellany*, which consisted of all the useful and entertaining parts of the *Diary* down to 1773, with many additional solutions and improvements. On the resignation, owing to failing health, of his professorship in 1807, he was allowed a pension of £500 a year. He died on 27th January 1823.

All the biographical notices of Hutton are unanimous in describing him as one of the most skilful of teachers, and the most amiable of men. His modesty and simplicity were as remarkable as his intellectual gifts. To his friends and pupils he exhibited a warmth of personal affection that attached both to him in a very rare degree. It was also with him a sacred duty to seek out the poor and unbefriended student of science, and promote and otherwise assist him to the best of his power.

HUTTON, James (1726–1797), one of the great founders of geological science, was born in Edinburgh on 3d June 1726. Educated at the high school and university of his native city, he acquired while still a student a passionate love of scientific inquiry. It had been decided that he should pursue a professional career, and he was accordingly apprenticed to a lawyer. But as instead of copying law papers he was sometimes found amusing his fellow-clerks with chemical experiments, his employer with much sagacity advised that a more congenial profession than the law should be chosen for him. The young apprentice, released from his engagement, chose medicine as the pursuit nearest akin to his favourite study of chemistry. He studied for three years at Edinburgh, and completed his medical education by an attendance of nearly two years at the medical classes in Paris, returning by the Low Countries, and taking his degree of doctor of medicine at Leyden in 1749. At the end of that year he came back to England, only to find, however, that though he had qualified himself to practise as a medical man there seemed hardly any opening for him. In the summer of the ensuing year he definitively abandoned the idea of following out the medical profession, and, having inherited a small property in Berwickshire from his father, resolved to devote himself to agriculture. With the zeal and thoroughness characteristic of his disposition, he then went to Norfolk to learn the practical work of farming. Thereafter he extended his experience by a tour in Holland, Belgium, and the north of France. During these years he began to study the surface of the earth, looking into every pit, ditch, or river-bed that he saw, and gradually shaping in his mind the problem to which he afterwards devoted his energies. In the summer of 1754 he established himself on his own farm in Berwickshire, where he resided for fourteen years, and where he introduced the most improved forms of husbandry. As the farm was brought into excellent order, and as its management, becoming more easy, grew less interesting, he was finally induced to let it, and establish himself for the rest of his life in Edinburgh. This took place about the year 1768.

From this period until his death in 1797 he lived unmarried with his three sisters. Surrounded by congenial literary and scientific friends, he devoted himself to those researches which have had so important an influence upon the progress of science. At that time geology in any proper sense of the term did not exist. Mineralogy, however, had made considerable progress. Hutton's taste for chemistry naturally led him into mineralogy. But he had conceived larger ideas than were entertained by the mineralogists of his day. He desired to trace back the origin of the various minerals and rocks, and thus to arrive at some clear understanding of the history of the earth. For many years he continued to ponder over the subject, making during that time many excursions to different parts of the country to obtain materials for his researches, or to test the hypotheses he had been led to form. At last, in the spring of the year 1785, he communicated his views to the recently established Royal Society of Edinburgh in a paper entitled *Theory of the Earth, or an Investigation of the Laws Observable in the Composition, Dissolution, and Restoration of Land upon the Globe.* In this remarkable work the doctrine is expounded that geology is not cosmogony, but must confine itself to the study of the materials of the earth; that everywhere evidence may be seen that the present rocks of the earth's surface have been formed out of the waste of older rocks; that these materials having been laid down under the sea were there consolidated under great pressure, and were subsequently disrupted and upheaved by the expansive power of subterranean heat; that during these convulsions veins and masses of molten rock were injected into the rents of the dislocated strata; that every portion of the upraised land, as soon as exposed to the atmosphere, is subject to decay; and that this decay must tend to advance until the whole of the land has been worn away and laid down on the sea-floor, whence future upheavals will once more raise the consolidated sediments into new land. In some of these broad and bold generalizations Hutton was anticipated by the Italian geologists; but to him belongs the credit of having first perceived their mutual relations, and combined them in a luminous coherent theory everywhere based upon observation.

It was not merely the ground beneath us to which Hutton directed his attention. He had long studied the changes of the atmosphere. The same volume in which his *Theory of the Earth* appeared contained also a *Theory of Rain*, which was read to the Royal Society of Edinburgh in February 1784. He contended that the amount of moisture which the air can retain in solution increases with augmentation of temperature, and therefore that on the mixture of two masses of air of different temperatures a portion of the moisture must be condensed and appear in visible form. He investigated the data available in his time regarding rainfall and climate in different regions of the globe, and came to the conclusion that the rainfall is everywhere regulated by the humidity of the air on the one hand, and the causes which promote mixtures of different aerial currents in the higher atmosphere on the other.

The vigour and versatility of his genius may be understood from the variety of works which, during his thirty years' residence in Edinburgh, he gave to the world. In the year 1792 he published a quarto volume entitled *Dissertations on different Subjects in Natural Philosophy*, in which he discussed the nature of matter, fluidity, cohesion, light, heat, and electricity. Some of these subjects were further illustrated by him in papers read before the Royal Society of Edinburgh. He did not restrain himself within the domain of physics, but boldly marched into that of metaphysics, publishing three quarto volumes with the title *An Investigation of the Principles of Knowledge, and of the Progress of Reason—from Sense to Science and Philosophy.* In this work he develops the idea that the external world, as conceived by us, is the creation of our own minds influenced by impressions from without, that there is no resemblance between our picture of the outer world and the reality, yet that the impressions produced upon our minds, being constant and consistent, become as much realities to us as if they precisely resembled things actually existing, and therefore that our moral conduct must remain the same as if our ideas perfectly corresponded to the causes producing them. His closing years were devoted to the extension and republication of his *Theory of the Earth*, of which two volumes octavo appeared in 1795. A third volume, necessary to complete the work, was left by him in manuscript, and is referred to by his biographer Playfair, but seems to have disappeared. No sooner had this task been performed than he set to work to collect and systematize his numerous writings on husbandry, which he proposed to publish under the title of *Elements of Agriculture.* He had nearly completed this labour when an incurable disease brought his active career to a close on 26th March 1797.

It is by his *Theory of the Earth* that Hutton will be remembered with reverence while geology continues to be cultivated. The author's style, however, being somewhat heavy and obscure, the book did not attract during his lifetime so much attention as it deserved. Happily for science Hutton numbered among his friends John Playfair, professor of mathematics in the university of Edinburgh, whose enthusiasm for the spread of Hutton's doctrine was combined with a rare gift of graceful and luminous exposition. Five years after Hutton's death he published a volume, *Illustrations of the Huttonian Theory of the Earth*, in which he gave an admirable summary of that theory, with numerous additional illustrations and arguments. This work is justly regarded as one of the classical contributions to geological literature. To its influence much of the sound progress of British geology must be ascribed. In the year 1805 a biographical account of Hutton, written by Playfair, was published in vol. v. of the *Transactions of the Royal Society of Edinburgh.* (A. GE.)

HUY, in Flemish HOEY, a town of Belgium, at the head of an arrondissement in the province of Liége, situated in the most romantic portion of the Meuse valley near the confluence of the Hoyoux, on the railway between Liége and Namur, and about 20 miles west of the former city. It lies on both banks of the river, and the two portions are united by a bridge about 460 feet long. Of best note among the buildings are the town-house, the court-house, the hospital, and the collegiate church of Notre Dame, which is an excellent specimen of Gothic architecture, dating originally from the 14th century, but restored in the course of the 16th and the 19th. The citadel of Huy is now demolished. It was a powerful fortress, constructed between 1817 and 1822 on the site of the older castle dismantled by the Dutch in 1718. Part of the works were excavated in the solid rock, and the whole building looked down on the valley of the Meuse with picturesque defiance. Of the industrial activity of the town the most important results are paper, tin-plate, zinc, iron, earthenware, and brandy; and iron, zinc, and coal are extensively wrought in the vicinity. The population in 1876 was 11,774.

Huy, in modern Latin *Hoium*, *Hogum*, *Huyum*, and *Huum*, existed at least as early as the 7th century, and according to some authorities it was founded in 148 by the emperor Antoninus. Coins of Charles the Simple are extant with the legend *in Vico Hoio.* The older name of the district in which it is situated was the Condroz, or territory of the Condrosii. Under the prince-bishops of Liége Huy was a prosperous place, and it possessed no fewer than fifteen churches, as well as a number of monasteries, for a population of about 5000. It was in one of its suburbs that the abbey of Neufmoustier was founded by Peter the Hermit, who died and was buried within its precincts (1115). Part of the cloisters are still standing; and a monument was erected in 1858 by M. Godin, the owner of the grounds, to mark the site of the hermit's tomb. Huy was captured by the Dutch in 1595, and in 1693 it was taken and burned by the French. The Dutch were in possession from 1702 till 1718, when they restored the town to the emperor. See Gorissen's edition of Melard, *Hist. de la ville et du château de Huy*, Huy, 1839.

HUYGENS, CHRISTIAAN (1629-1695), mathematician, mechanician, astronomer, and physicist, was born at the Hague, April 14, 1629. He was the second son of Constantin Huygens, noticed below. From his father Christiaan received the rudiments of his education, which was continued at Leyden under Vinnius and Schooten, and completed in the juridical school of Breda. His mathematical bent, however, soon diverted him from his legal studies, and the perusal of some of his earliest theorems enabled Descartes to predict his future greatness. In 1649 he accompanied the mission of Henry, count of Nassau, to Denmark, and in 1651 entered the lists of science as an assailant of the unsound system of quadratures adopted by Gregory of St Vincent. This first essay (*Exetasis quadraturæ circuli*, Leyden, 1651) was quickly succeeded by his *Theoremata de quadratura hyperboles, ellipsis, et circuli*; while, in a treatise entitled *De circuli magnitudine inventa*, he made, three years later, the closest approximation hitherto obtained to the ratio of the circumference to the diameter of a circle.

But another class of subjects was about to engage his attention. The improvement of the telescope was then justly regarded as a *sine qua non* for the advancement of astronomical knowledge. Owing, however, to the difficulties interposed by spherical and chromatic aberration, little progress had been made in that direction when, in 1655, Huygens, working with his brother Constantin, hit upon a new method of grinding and polishing lenses. The immediate results of the clearer definition obtained were the detection of a satellite to Saturn (the sixth in order of distance from its primary), and the resolution into their true form of the abnormal appendages to that planet. Each discovery in turn was, according to the prevailing custom, announced to the learned world under the veil of an anagram—removed, in the case of the first, by the publication, early in 1656, of the little tract *De Saturni luna observatio nova*; but retained, as regards the second, until 1659, when in the *Systema Saturnium* the varying appearances of the so-called "triple planet" were clearly explained as the phases of a ring inclined at an angle of 20° to the ecliptic. His application of the pendulum to regulate the movement of clocks was another fruit of his astronomical labours, springing, as it did, from his experience of the need for an exact measure of time in observing the heavens. The invention dates from 1656; the *Horologium*, containing a description of the requisite mechanism, was published in the following year, and on the 16th of June 1657 Huygens presented his first "pendulum-clock" to the states-general.

His reputation now became cosmopolitan. As early as 1655 the university of Angers had distinguished him with an honorary degree of doctor of laws. In 1663, on the occasion of his second visit to England, he was elected a fellow of the Royal Society, and imparted to that body in January 1669 a clear and concise statement of the laws governing the collision of elastic bodies. Although these conclusions were arrived at independently, and, as it would seem, several years previous to their publication, they were in great measure anticipated by the communications on the same subject of Wallis and Wren, made respectively in November and December 1668.

Huygens had before this time fixed his abode in France. In 1665 Colbert made to him on behalf of Louis XIV. an offer too tempting to be refused, and between the following year and 1681 his residence in the philosophic seclusion of the Bibliothèque du Roi was only interrupted by two short visits to his native country. His *magnum opus* dates from this period. The *Horologium Oscillatorium*, published with a dedication to his royal patron in 1673, contained original discoveries sufficient to have furnished materials for half a dozen striking disquisitions. His solution of the celebrated problem of the "centre of oscillation" formed in itself an important event in the history of mechanics. Assuming as an axiom that the centre of gravity of any number of interdependent bodies cannot rise higher than the point from which it fell, he arrived, by anticipating in the particular case the general principle of the conservation of *vis viva*, at correct although not strictly demonstrated conclusions. His treatment of the subject is especially noteworthy as being the first successful attempt to deal with the dynamics of a system. The determination of the true relation between the length of a pendulum and the time of its oscillation; the invention of the theory of evolutes; the discovery, hence ensuing, that the cycloid is its own evolute, and is strictly isochronous; the ingenious although practically inoperative idea of correcting the "circular error" of the pendulum by applying cycloidal cheeks to clocks—were all contained in this remarkable treatise. The theorems on the composition of forces in circular motion with which it concluded formed the true prelude to the *Principia*, and would alone suffice to establish the claim of Huygens to the highest rank among mechanical inventors.

In 1681 he finally severed his French connexions, and returned to Holland. The harsher measures which about that time began to be adopted towards his co-religionists in France are usually assigned as the motive of this step. He now devoted himself during six years to the production of lenses of enormous focal distance, which, mounted on high poles, and connected with the eye-piece by means of a cord, formed what were called "aerial telescopes." Three of his object-glasses, of respectively 123, 180, and 210 feet focal length, are still in the possession of the Royal Society. He also succeeded in constructing an almost perfectly achromatic eye-piece, still known by his name. But his researches in physical optics constitute his chief title-deed to immortality. Although Hooke first proposed the wave theory of light, Huygens gave reality to the conception, establishing it on a foundation so sure that it has never since been shaken. His powerful scientific imagination enabled him to perceive that an undulation may be broken up into an indefinite number of parts, each of which is the origin of a partial wave, and that the aggregate effect of all these partial waves will reconstitute the primary wave at any subsequent stage of its progress. This resolution of the main undulation is the well-known "Principle of Huygens," and by its means he was enabled to prove the fundamental laws of optics, and to assign the correct construction for the direction of the extraordinary ray in uniaxial crystals. These investigations, together with his discovery of the "wonderful phenomenon" of polarization, are recorded in his *Traité de la Lumière*, published at Leyden in 1690, but composed in 1678. In the appended treatise *Sur la Cause de la Pésanteur*, he rejected gravitation as a universal quality of matter, although admitting the Newtonian theory of the planetary revolutions. From his views on centrifugal force he deduced the oblate figure of the earth, estimating its compression, however, at little more than one-half its actual amount.

Huygens was never married. He died at the Hague, June 8, 1695, bequeathing his manuscripts to the university of Leyden, and his considerable property to the sons of his younger brother. In character he was as estimable as he was brilliant in intellect. Although, like most men of strong originative power, he assimilated with difficulty the ideas of others, his tardiness sprang rather from inability to depart from the track of his own methods than from reluctance to acknowledge the merits of his competitors.

In addition to the works already mentioned, his *Cosmotheoros*—a speculation concerning the inhabitants of the planets—was printed posthumously at the Hague in 1698, and appeared almost simultaneously in an English translation. A volume entitled *Opera Posthuma*, Leyden, 1703, contained his "Dioptrica," in which the ratio between the respective focal lengths of object-glass and eye-glass is given as the measure of magnifying power, together with the shorter essays *De vitris figurandis*, *De corona et parheliis*, &c. An early tract *De* *ratiociniis in ludo aleæ*, printed in 1657 with Schooten's *Exercitationes Mathematicæ*, is notable as one of the first formal treatises on the theory of probabilities; nor should his investigations of the properties of the cissoid, logarithmic, and catenary be left unnoticed. His invention of the spiral watch-spring was explained in the *Journal des Savants*, February 25, 1675. An edition of his works was published by 'S Gravesande, of which two quarto volumes appeared under the heading *Opera varia*, Leyden, 1724, and two supplementary ones entitled *Opera reliqua*, Amsterdam, 1728. His scientific correspondence, edited from manuscripts preserved at Leyden by P. J. Uylenbroek, was published with the title *Christiani Hugenii aliorumque seculi XVII. virorum celebrium Exercitationes Mathematicæ et Philosophicæ*, The Hague, 1833. (A. M. C.)

HUYGENS, Sir Constantijn or Constantin (1596–1687), Dutch poet and diplomatist, was born at the Hague on the 4th of September 1596. His father, Christiaan Huygens, was secretary to the state council, and a man of great political importance. At the baptism of the child, the city of Breda was one of his sponsors, and the famous admiral Justinus van Nassau the other. From his earliest childhood he was trained in every polite accomplishment, and before he was seven he could speak French with fluency. He was taught Latin by Johannes Dedelus, and soon became a master of classic versification. As he grew up, he developed not only extraordinary intellectual gifts but great physical beauty and strength, and was one of the most accomplished athletes and gymnasts of his age; his skill in playing the lute and in the arts of painting and engraving attracted general attention before he began to develop his genius as a writer. In 1616 he proceeded, with his elder brother, to the university of Leyden. He stayed there only one year, and in 1618 proceeded to London with the English ambassador Carleton; he remained in London for some months, and then went to Oxford, where he studied for some time in the Bodleian Library, and to Woodstock, Windsor, and Cambridge; he was introduced at the English court, and played the lute before James I. The most interesting feature of this visit was the intimacy which sprang up between the young Dutch poet and the famous Dr Donne, for whose genius Huygens preserved through life an unbounded admiration. He returned to Holland in company with the English contingent of the synod of Dort, and in 1620 he proceeded to Venice in the diplomatic service of his country; on his return he nearly lost his life by a foolhardy exploit, namely, the scaling of the topmost spire of Strasburg cathedral. In 1621 he published one of his most weighty and popular poems, his *Batava Tempe*, and in the same year he proceeded again to London, as secretary to the ambassador, Wijngaerdan, but returned in three months. His third diplomatic visit to England lasted longer, from the 5th of December 1621 to the 1st of March 1623. During his absence, his volume of satires, *Costelick Mal*, dedicated to Jacob Cats, appeared at the Hague. In the autumn of 1622 he was knighted by James I. He published a large volume of miscellaneous poems in 1625 under the title of *Otiorum libri sex*; and in the same year he was appointed private secretary to the stadholder. In 1627 Huygens married Suzanna van Baerle, and the young couple settled in a handsome house in the best part of the Hague; four sons and a daughter were born to them. In 1630 Huygens was called to a seat in the privy council, and he continued to exercise political power with wisdom and vigour for many years, under the title of the lord of Zuylichem. In 1634 he completed his long-talked-of version of the poems of Donne. In 1637 he had the misfortune to lose his admirable wife, and he immediately began to celebrate the virtues and pleasures of their married life in the remarkable didactic poem called *Dagwerck*, which was not published till long afterwards. From 1639 to 1641 he occupied himself by building a magnificent house and garden outside the Hague, and by celebrating their beauties in a poem entitled *Hofwijck*, which saw the light in 1654. In 1647 he wrote his beautiful poem of *Oogentroost* or "Eye Consolation," to gratify his blind friend Lucretia van Trollo. He made his solitary effort in the dramatic line in 1659, when he brought out his comedy of *Trijntje Cornelis*, which deals, in rather broad humour, with the adventures of the wife of a ship's captain at Zaandam. In 1658 he rearranged his poems, and issued them with many additions, under the title of *Corn Flowers*. He proposed to the Government that the present highway from the Hague to the sea at Scheveningen should be constructed, and during his absence on a diplomatic mission to the French court in 1666 the road was made as a compliment to the venerable statesman, who expressed his gratitude in a descriptive poem entitled *Zeestraet*. Huygens edited his poems for the last time in 1672, and died in his ninety-first year, on the 28th of March 1687. His second son, Christiaan, the eminent astronomer, is noticed above.

Constantijn Huygens is the most brilliant figure in Dutch literary history. Other statesmen surpassed him in political influence, and at least two other poets surpassed him in the value and originality of their writings. But his figure was more dignified and splendid, his talents were more varied, and his general accomplishments more remarkable than those of any other person of his age, the greatest age in the history of the Netherlands. Huygens is the *grand seigneur* of the republic, the type of aristocratic oligarchy, the jewel and ornament of Dutch liberty. When we consider his imposing character and the positive value of his writings, we may well be surprised that he has not found a modern editor. It is a disgrace to Dutch scholarship that no complete collection of the writings of Huygens exists. His autobiography, *De vita propria sermones*, did not see the light until 1827, and his remarkable poem, *Cluyswerck*, was not printed until 1842. As a poet Huygens shows a finer sense of form than any other Dutch writer; the language, in his hands, becomes as flexible as Italian. His epistles and lighter pieces, in particular, display his metrical ease and facility to perfection. (E. W. G.)

HUYSMANS. Four painters of this family matriculated in the Antwerp guild in the 17th century. Cornelis the elder, apprenticed in 1633, passed for a mastership in 1636, and remained obscure. Jacob, apprenticed to Frans Wouters in 1650, wandered to England towards the close of the reign of Charles II., and competed with Lely as a fashionable portrait painter. He executed a portrait of the queen, Catherine of Braganza, now in the national portrait gallery, and Horace Walpole assigns to him the likeness of Lady Bellasys, now catalogued at Hampton Court as a work of Lely. His portrait of Izaak Walton in the National Gallery shows a disposition to imitate the styles of Rubens and Van Dyke. According to most accounts he died in London in 1696. Jan Baptist Huysmans, born at Antwerp in 1654, matriculated in 1676–77, and died there in 1715–16. He was younger brother to Cornelis Huysmans the second, who was born at Antwerp in 1648, and educated by Gaspar de Wit and Jacob van Artois. Of Jan Baptist little or nothing has been preserved, except that he registered numerous apprentices at Antwerp, and painted a landscape dated 1697 now in the Brussels museum. But for the signature critics would assign this piece to his brother. Cornelis the second is the only master of the name of Huysmans whose talent was largely acknowledged. He chanced to receive lessons from two artists, one of whom was familiar with the Roman art of the Poussins, whilst the other inherited the scenic style of the school of Rubens. He combined the two in a rich, highly coloured, and usually effective style, which, however, was not free from monotony. Seldom attempting anything but woodside views with fancy backgrounds, half Italian, half Flemish, he painted with great facility, and left numerous examples behind. At the outset of his career he practised at Malines, where he married in 1682, and there too he entered into some business connexion with Van der Meulen, for whom he painted some backgrounds. In 1706 he withdrew to Antwerp, where he resided till 1717, returning then to Malines, where he died on the 1st of June 1727.

Though most of his pictures were composed for cabinets rather than churches, he sometimes emulated Van Artois in the production of large sacred pieces, and for many years his Christ on the Road to Emmaus adorned the choir of Notre Dame of Malines. In the gallery of Nantes, where three of his small landscapes are preserved, there hangs an Investment of Luxembourg, by Van der Meulen, of which he is known to have laid in the background. The two national galleries of London and Edinburgh contain each one example of his skill. Blenheim, too, and other private galleries in England, possess one or more of his pictures. But most of his works are on the Continent,—four a-piece in the Louvre, Augsburg, and Stuttgart; three a-piece in Berlin, Brunswick, Cologne, and Munich; two in Cassel and St Petersburg; one at Antwerp, Brussels, Carlsruhe, Copenhagen, Dresden, and Hanover.

HUYSUM, JAN VAN (1682–1749), was born at Amsterdam in 1682, and died in his native city on the 8th of February 1749. He was the son of Justus van Huysum, whose practice remained entirely local, but who is said to have been expeditious in decorating doorways, screens, and vases. A picture by this artist is still preserved in the gallery of Brunswick, representing Orpheus and the Beasts in a wooded landscape, and here we have some explanation of his son's fondness for landscapes of a conventional and Arcadian kind; for Jan van Huysum, though skilled as a painter of still life, believed himself to possess the genius of a landscape painter. Half his pictures in public galleries are landscapes, views of imaginary lakes and harbours with impossible ruins and classic edifices, and woods of tall and motionless trees,—the whole very glossy and smooth, and entirely lifeless. The earliest dated work of this kind is that of 1717, in the Louvre, a grove with maidens culling flowers near a tomb, ruins of a portico, and a distant palace on the shores of a lake bounded by mountains. In the picture market these landscapes are worth comparatively little, whilst the master's fruit and flower pieces are all the more appreciated, and good examples readily fetch from £800 to £900. It is doubtful whether any artist in this peculiar walk of art ever surpassed Van Huysum in representing fruit and flowers. It has been said that his fruit has no savour and his flowers have no perfume,—in other words, that they are hard and artificial,—but this is scarcely true. In substance fruit and flower are delicate and finished imitations of nature in its more subtle varieties of matter. The fruit has an incomparable blush of down, the flowers have a perfect delicacy of tissue. Van Huysum too shows supreme art in relieving flowers of various colours against each other, and often against a light and transparent background. He is always bright, sometimes even gaudy. Great taste and much grace and elegance are apparent in the arrangement of bouquets and fruit in vases adorned with bas reliefs or in baskets on marble tables. There is exquisite and faultless finish everywhere. But what Van Huysum has not is the breadth, the bold effectiveness, and the depth of thought of De Heem from whom he descends through Abraham Mignon.

Some of the finest of Van Huysum's fruit and flower pieces have been in English private collections:—those of 1723 in the earl of Ellesmere's gallery, others of 1730–32 in the collections of Hope and Ashburton. One of the best examples is now in the National Gallery (1736–37), which came from Mr Wells of Redleaf and Abraham Darby. No public museum has finer and more numerous specimens than the Louvre, which boasts of four landscapes and six panels with still life; then come Berlin and Amsterdam with four fruit and flower pieces; then St Petersburg, Munich, Hanover, Dresden, The Hague, Brunswick, Vienna, Carlsruhe, and Copenhagen.

HWEN T'SANG (HIOUEN THSANG, HIWEN T'SANG) is the most eminent representative of a remarkable and valuable branch of Chinese literature, known during the last half century, chiefly through the labours of Continental scholars. It consists of the narratives of Chinese Buddhists who travelled to India, whilst their religion flourished there, with the view of visiting the sites consecrated by the history of Sakya Muni, of studying at the great convents which then existed in India, and of collecting books, reliques, and other sacred objects. In short, their objects and their narratives bear a strong analogy to the objects and narratives of the many pilgrimages to Palestine in the same and later ages which have come down to us in ecclesiastical collections.

The importance of these writings as throwing light on the geography and history of India and adjoining countries, during a very dark period, is great, and they have been the subject of elaborate commentaries by students in our own day, some of the chief of which will be noted at the end of this article. Several Chinese memoirs of this kind appear to have perished; and especially to be regretted is a great collection of the works of travellers to India, religious and secular, in sixty books, with forty more of maps and illustrations, published at the expense of the emperor Kao-T'song of the T'ang dynasty, 666 A.D., with a preface from the imperial hand. We will mention the clerical travellers of this description who are known to us by name.

1. *Shi-tao-'an* (died 385) wrote a work on his travels to the "western lands" (an expression applying often to India), which is supposed to be lost. 2. *Fa-hian* travelled to India in 399, and returned by sea in 414. His work, called *Fo-Kwé-Ki, or Memoirs on the Buddha Realms*, has been translated by Abel-Rémusat and Landresse, and again into English by the Rev. S. Beale; Mr Laidlay of Calcutta also published a translation from the French, with interesting notes. 3. *Hwai Seng* and *Sung-Yun*, monks, travelled to India to collect books and reliques, 518–521. Their short narrative has been translated by the late Karl Fried. Neumann, and also by Mr Beale (along with Fa-hian). 4. *Hwen T'sang*, the subject of this notice. In relation to his travels there are two Chinese works, both of which have been translated with an immense appliance of labour and learning by M. Stanislas Julien, viz., (*a*) the *Ta-T'ang-Si-Yu-Ki, or Memoirs on Western Countries issued by the T'ang Dynasty*, which was compiled under the traveller's own supervision, by order of the great emperor Tai-T'sung; and (*b*) a *Biography of Hwen T'sang* by two of his contemporaries. 5. *The Itinerary of Fifty-six Religious Travellers*, compiled and published under imperial authority, 730. 6. *The Itinerary of Khi-Nie*, who travelled (964–976) at the head of a large body of monks to collect books, &c. Neither of the last two has been translated.

Hwen T'sang was born in the district of Keu-Shi, near Honan-Fu, about 605, a period at which Buddhism appears to have had a powerful influence upon a large body of educated Chinese. From childhood grave and studious, he was taken in charge by an elder brother who had adopted the monastic life, in a convent at the royal city of Loyang in Honan. Hwen T'sang soon followed his brother's example. For some years he travelled over China, teaching and learning, and eventually settled for a time at the capital Chang-ngan (now Si-ngan-fu in Shensi), where his fame for learning became great. The desire which he entertained to visit India, in order to penetrate all the doctrines of the Buddhist philosophy, and to perfect the collections of Indian books which existed in China, grew irresistible, and in August 629 he started upon his solitary journey, eluding with difficulty the strict prohibition which was in force against crossing the frontier.

The "master of the law," as his biographers call him, plunged alone into the terrible desert of the Gobi, then known as the Sha-ho or "Sand River," between Kwa-chau and Igu (now Hami or Kamil). At long intervals he found help from the small garrisons of the towers that dotted the desert track. Very striking is the description, like that given six centuries later by Marco Polo, of the quasi-supernatural horrors that beset the lonely traveller in the wilderness—the visions of armies and banners; and the manner in which they are dissipated singularly recalls passages in Bunyan's *Pilgrim's Progress.* After great suffering Hwen T'sang reached Igu, the seat of a Turkish principality, and pursued his way along the southern foot of the T'ien-shan, which he crossed by a glacier pass (vividly described) in the longitude of Lake Issikul. In the valley of the Talas river he encounters the great khan of the Turks on a hunting party,—a rencontre which it is interesting to compare with the visit of Zemarchus to the great khan Dizabulus, sixty years before, in the same region. Passing by the present Tashkend, and by Samarkand, then inhabited by fire worshippers, he reached the basin of the Upper Oxus, which had recently been the seat of the powerful dominion of the Haiathelah, Ephthalites, or White Huns, known in earlier days to the Greeks as *Tochari*, and to Hwen T'sang (by the same name) as *Tuholo* or Tukhāra. His account of the many small states into which the Tukhara empire had broken up is of great interest, as many of them are identical in name and topography with the high valley states and districts on the Upper Oxus, which are at this day the object of so much geographical and political interest.

Passing by Bamian, where he speaks of the great idols still so famous, he crosses Hindu-Kush, and descends the valley of the Cabul river to Nagarahara, the site of which, still known as Nagara, adjoining Jalálábád, has recently been explored by Mr W. Simpson. Travelling thence to Pesháwar (*Purushapúra*), the capital of Gandhára, he made a digression, through the now inaccessible valley of Swat and the Dard states, to the Upper Indus, returning to Peshawar, and then crossing the Indus (*Sintu*) into the decayed kingdom of *Taxila* (Ta-cha-si-lo, Takshasilá), then subject to Kashmir. In the latter valley he spent two whole years (631-633), studying in the convents, and visiting the many monuments of his faith. We cannot follow his further travels in detail, and can only mention some of the chief points in his devious route. Such are Mathura (*Mot'ulo*), whence he turned north to Thánesar and the upper Jumna and Ganges, returning south down the valley of the latter to Kanyákubja or Kanauj, then one of the great capitals of India. The pilgrim next entered on a circuit of the most famous sites of Buddhist and of ancient Indian history, such as Ayodhyá, Prayaga (Allahábád), Káusámbhí, Srávastí, Kapilavastu the birthplace of Sákya, Kusinagara his death place, Pátalipútra (Patna, the *Palibothra* of the Greeks), Gayá, Rájagriha, and Nálanda, the most famous and learned monastery and college in India, adorned by the gifts of successive kings, of the splendour of which he gives a vivid description, and of which traces have recently been recovered. There he again spent nearly two years in mastering Sanskrit and the depths of Buddhist philosophy. Again, proceeding down the banks of the Ganges, he diverged eastward to Kámarúpa (Assam), and then passed by the great port of Támralipti (Tamlúk, the misplaced *Tamalitis* of Ptolemy), and through Orissa to Kanchipára (Conjeveram), about 640. Thence he went northward across the Carnatic and Maháráshtra to Barakacheva (Baróch of our day, *Barygaza* of the Greeks). After this he visited Malwa, Kach'h, Suráshtra (peninsular Guzerat, *Syrastrene* of the Greeks), Sindh, Multán, and Ghazni, whence he rejoined his former course in the basin of the Cabul river.

This time, however, he crosses Pamir, of which he gives a remarkable account, and passes by Kashgar, Khotan (*Kustana*), and the vicinity of Lop (*Navapa*) across the desert to Kwa-chau, whence he had made his venturous and lonely plunge into the waste fifteen years before. He carried with him great collections of books, precious images, and reliques, and was received (April 645) with public and imperial enthusiasm. The emperor Tai-T'sung desired him to commit his journey to writing, and also that he should abandon the eremitic rule and serve the state. This last he declined, and devoted himself to the compilation of his narrative and the translation of the books he had brought with him from India. The former was completed 648 A.D. In 664 Hwen T'sang died in a convent at Chang-ngan. Some things in the history of his last days, and in the indications of beatitude recorded, strongly recall the parallel history of the saints of the Roman calendar. But on the other hand we find the Chinese saint, on the approach of death, causing one of his disciples to frame a catalogue of his good works, of the books that he had translated or caused to be transcribed, of the sacred pictures executed at his cost, of the alms that he had given, of the living creatures that he had ransomed from death. "When Kia-shang had ended writing this list, the master ordered him to read it aloud. After hearing it the devotees clasped their hands, and showered their felicitations on him." Thus the "well-done, good and faithful," comes from the servant himself in self-applause.

The book of the biography, by the disciples Hwae-li and Yen t'song, as rendered with judicious omissions by Stan. Julien, is exceedingly interesting; its Chinese style receives high praise from the translator, who says he has often had to regret his inability to reproduce its grace, elegance, and vivacity. We cannot here give any idea of the uses which the accounts of Hwen T'sang have served in illustrating geography and history, but must refer to the appended list of works.

Fo-Koue-Ki, trad. du Chinois, par Abel-Rémusat, revu et complété par Klaproth et Landresse, Paris, 1836; *H. de la Vie de Hiouen-Thsang*, &c., trad. du Chinois par Stanislas Julien, Paris, 1853: *Mémoires sur les Contrées Occidentales* . . . trad. du Chinois en Français (par le même), 2 vols., Paris, 1857-58; *Mémoire Analytique*, &c., attached to the last work, by L. Vivien de St Martin; "Attempt to identify some of the Places mentioned in the Itinerary of Hiuan Thsang," by Major Wm. Anderson, C.B., in *Journ. As. Soc. Bengal*, xvi. pt. 2, p. 1183 (the enunciation of a singularly perverse theory); "Verification of the Itinerary of Hwan Thsang," &c., by Capt. Alex. Cunningham, Bengal Engineers, *ibid.*, xvii. pt. 1, p. 476; *Travels of Fah-hian and Sung-Yun, Buddhist Pilgrims*, &c., by Sam. Beal, 1869; *The Ancient Geography of India*, by Major-Gen. Alex. Cunningham, R.E., 1871; "Notes on Hwen Thsang's Account of the Principalities of Tokharistan," by Col. H. Yule, C.B., in *Journ. Roy. As. Soc.*, new ser., vol. vi. p. 82; "On Hiouen Thsang's Journey from Patna to Ballabhi," by James Fergusson, D.C.L., *ibid.*, p. 213. (H. Y.)

HYACINTH, also called JACINTH, one of the most popular of garden flowers, "supreme amongst the flowers of spring." It is no new favourite, having been in cultivation prior to 1597, at which date Gerard records the existence of six varieties, which are not indicated as particularly rare or novel. Rea in 1676 mentions several single and double varieties as being then in English gardens, and Justice in 1754 describes upwards of fifty single-flowered varieties, and nearly one hundred double-flowered ones, as a selection of the best from the catalogues of two then celebrated Dutch growers. One of the Dutch sorts, called La Reine de Femmes, a single white, is said to have produced from thirty-four to thirty-eight flowers in a spike, and on its first appearance to have sold for 50 guilders a bulb; while one called Overwinnaar or Conqueror, a double blue, sold at first for 100 guilders, Gloria Mundi for 500 guilders, and Koning Saloman for 600 guilders. Several sorts are at that date mentioned as blooming well in water-glasses. Justice relates that he himself raised several very valuable double-flowered kinds from seeds, which many of the sorts he describes are noted for producing freely.

The original of the cultivated hyacinth, *Hyacinthus orientalis*, is by comparison an insignificant plant, bearing on a spike only a few small narrow-lobed washy blue flowers. So great has been the improvement effected by the florists, and chiefly by the Dutch, that the modern hyacinth would scarcely be recognized as the descendant of the type above referred to, the spikes being long and dense, composed of a large number of flowers; the spikes produced by strong bulbs not unfrequently measure 6 or 7 inches in length and from 7 to 9 inches in circumference, with the flowers closely set on from bottom to top. Of late years much improvement has been effected in the size of the individual flowers and the breadth of their recurving lobes, as well as in securing increased brilliancy and depth of colour.

The peculiarities of the soil and climate of Holland are so very favourable to their production that Dutch florists have made a specialty of the growth of those and other bulbous-rooted flowers. An area of 125 acres is devoted to the growth of hyacinths in the vicinity of Haarlem, and is estimated to bring in a revenue of nearly £30,000. Some notion of the vast number imported into England annually may be formed from the fact that, for the supply of flowering plants to Covent Garden, one market grower alone produces from 60,000 to 70,000 in pots under glass, their blooming period being accelerated by artificial heat, and extending from Christmas onwards until they bloom naturally in the open ground.

In the spring flower garden few plants make a more effective display than the hyacinth. Dotted in clumps in the flower borders, and arranged in masses of well-contrasted colours in beds in the flower garden, there are no flowers which impart during their season—March and April—a gayer tone to the parterre. The bulbs are rarely grown a second time, either for indoor or outdoor culture, though with care they might be utilized for the latter purpose; and hence the enormous numbers which are procured each recurring year from Holland.

The first hyacinths were single-flowered, but towards the close of the 17th century double-flowered ones began to appear, and till a recent period these bulbs were the most esteemed. At the present time, however, the single-flowered sorts are in the ascendant, as they produce more regular and symmetrical spikes of blossom, the flowers being closely set and more or less horizontal in direction, while most of the double sorts have the bells distant and dependent, so that the spike is loose and by comparison ineffective. For pot culture, and for growth in water-glasses especially, the single-flowered sorts are greatly to be preferred. Few if any of the original kinds are now in cultivation, a succession of new and improved varieties having been raised, the demand for which is regulated in some respects by fashion. At the present day our nurserymen offer in their annual catalogues of select sorts between two and three hundred distinct varieties.

The earliest of all the hyacinths, and one which is very valuable for forcing into flower in winter, is called the white Roman hyacinth. It is small-flowered, but very sweet, and, if potted in September or October, as soon as the bulbs can be procured after importation, may easily be had in blossom by Christmas, when white flowers are so much sought after. Of course this is done with the aid of a forcing-house, but a very high temperature is not required. The best soil for pot hyacinths is made up of two parts turfy loam, one part decayed leaf-mould, and one part well-decomposed cow dung, with sand enough to make it porous, and with sufficient drainage.

The name of hyacinth is applied to several other plants having bulbous roots. The Cape hyacinth is *Scilla corymbosa*; the grape hyacinth, *Muscari botryoides*; the tassel hyacinth, *Muscari comosum*, and the feathered hyacinth, *Muscari comosum monstrosum*; the starch hyacinth, *Muscari racemosum*; the star hyacinth, *Scilla amœna*; the lily hyacinth, *Scilla Liliohyacinthus*; the hyacinth of Peru, *Scilla peruviana*; the wild hyacinth or blue-bell, *Hyacinthus non scriptus*; the wild hyacinth of America, *Camassia esculenta*; the Missouri hyacinth, *Hesperoscordum lacteum*; and the native hyacinth of Tasmania, *Thelymitra media*.

HYACINTHUS, a mythological figure connected with the Hyacinthia, a festival celebrated by the Spartans in honour of Apollo of Amyclæ, whose primitive image, standing on a throne, is described by Pausanias (iii. 19, 4). The legend attached to the festival is to the effect that Hyacinthus, a beautiful youth beloved by the god, was accidentally killed by him with a discus. From his blood sprang a dark-coloured flower called after him hyacinth, on whose petals is the word *αἰαῖ*, alas. The myth, like that of Linus (v. Brugsch, *Die Adonis-Klage und das Linos-Lied*), is one of the many popular representations of the beautiful spring vegetation slain by the hot sun of summer (which is here and in many other legends denoted by the symbol of a discus). The sister of Hyacinthus is Polybœa, the much nourishing fertility of the rich Amyclæan valley; while his brother is Cynortas, the rising of the dog (the hot) star. But with the death of the spring is united the idea of its certain resuscitation in a new year; like Dionysus, the hero is not merely dead but elevated to heaven. The festival took place on the three hottest days of summer, 7th to 10th of the month Hecatombeus (which was called in Sicily Hyacinthius), and its rites were a mixture of mourning and rejoicing (Athen., iv. 17).

HYADES, five stars forming the head of the larger constellation, the Bull. Their rising along with the sun marks the opening of the rainy season, hence their name Hyades—the Rainy. As mythological figures they were said to be daughters of Atlas, who as a reward for some pious act were translated to heaven. The nature of the deed is variously stated: sometimes it is their long-continued grief for their brother Hyas, who was slain by a snake (or boar or lion); at other times it is their having acted as nurses of Dionysus Hyes. In the latter case they are counted as nymphs of Nysa. When their charge was threatened by Lycurgus they fled with him to Thetis or to Ino in Thebes. They are also described as nymphs of Dodona, who acted as nurses of the infant Zeus. In any case their character as clouds and rain-givers is obvious. Their number is sometimes given as two, also as three, especially in Attica, which leads Brunn to see them in the pediment of the Parthenon in the figures usually spoken of as "The Fates."

HYÆNA (*Hyænidæ*), a family of digitigrade carnivorous mammals, approaching the *Felidæ* or cats in the character of the dentition, while resembling the *Viverridæ* or civets in the possession of a glandular pouch beneath the anus, and therefore usually classed as a transition group between these two families. It comprises a single genus (*Hyæna*), and three species, which resemble each other and differ from all other carnivores in having both pairs of feet with four toes each. They are further characterized by the greater length of their fore legs as compared with those behind, by their well-developed although non-retractile claws, by their prickly cat-like tongue, and by the enormous strength of their jaws and teeth, which enables them to break open the hardest bones, and to retain what they have seized with the most unrelaxing grip.

The Striped Hyæna (*Hyæna striata*) is the most widely distributed and best known form, being found throughout India, Persia, Asia Minor, and the northern half of Africa, while, if the strand wolf (*Hyæna villosa*) of the Cape colonists is only a variety of this species, as many naturalists suppose, its range will be thereby extended to the southern extremity of the African continent. It resembles a wolf in size, and is of a greyish-brown colour, marked with indistinct longitudinal stripes of a darker hue, while the legs are transversely striped as in the zebra. The hairs on its body are long, especially on the ridge of the neck and back, where they form a distinct mane, which is continued along the tail. The hyæna is nocturnal in its habits, preferring by day the gloom of caves and ruins, or of the burrows which it occasionally forms, but coming forth at sunset to make night hideous with its unearthly howling, which, when the animal is excited, changes into what has been compared to demoniac laughter, and hence the name of "laughing hyæna," by which it is also known. The food of those creatures consists chiefly of carrion, and they thus perform a highly useful service in hot countries by devouring the remains of dead animals which might otherwise pollute the air. So ravenous, however, are they that even the bodies of the buried dead are not safe from their attacks, their powerful claws enabling them to gain access to the newly interred bodies in the Eastern cemeteries, which they are said habitually to frequent. They also feed on the flesh of animals, which they hunt in packs. When driven by hunger they have thus been frequently known to enter villages by night and to carry off such domestic animals as they might chance to find. Bruce, the African traveller, states that everywhere in Abyssinia they were a plague. "Gondar," he says, "was full of them from the time it turned dark till the dawn. In short, the hyæna was the plague of our lives, the terror of our night walks, the destruction of our mules and asses, which above all others are his favourite food." Although, in proportion to its size, possessing probably the most powerful teeth and jaws in the whole mammalian series, the pusillanimity of the hyæna is such as to prevent its attacking animals greatly inferior to itself in strength. The

FIG. 1.—Striped Hyæna.

Arab, for this reason, holds it in contempt; and, when he condescends to hunt the hyæna, he does not waste his ammunition upon it, but runs it down with dogs. It has usually been regarded as untameable; this, however, is not the case, for when properly treated in captivity, it has been known to exhibit the greatest docility and attachment to its keepers; and Colonel Sykes states that in certain districts of Central India where those creatures abound they are as susceptible of domestication as ordinary dogs.

The Spotted Hyæna (*Hyæna crocuta*) takes the place of the striped species in the southern half of the African continent, to which it is confined. It resembles the other in size, but differs from it considerably in appearance, the stripes of the one being replaced by dark brown spots on a yellowish ground in the other, while in the "tiger-wolf," as this species is called at the Cape, the mane is much less distinct. According to Schweinfurth, who met with it in the heart of Africa, it is a much more powerful and savage animal than the northern form. Although averse to hunting living prey, it takes to the chase when carrion is not to be had, and the same traveller was on one occasion startled by a spotted hyæna which darted past him, like lightning, in pursuit of an antelope. At the Cape it was formerly very common, and occasionally committed great havoc among the cattle, while it did not hesitate to enter the Kaffre dwellings at night and carry off the child sleeping by its mother's side. By persistent trapping and shooting, its numbers have now been considerably reduced, with the result, however, of making it, like the hippopotamus of the same regions, exceedingly wary, so that it is not readily caught in any trap with which it has had an opportunity of becoming acquainted. Like the northern species, the

FIG. 2.—Spotted Hyæna.

spotted hyæna has been tamed, and has occasionally been trained to take the place of the dog. Its skin exhibits a considerable variety of colour and marking, and Schweinfurth found many skins in use among the Niamniams of Central Africa, in the form of aprons. The brown hyæna (*Hyæna rufa*) is also a native of South Africa.

Although hyænas are now confined to the warmer regions of the Old World, their fossil remains show that they had a much more northerly range during Tertiary times. Abundant remains of a larger species than any now living have been found in the caves of England, France, and Germany. This species, known as the cave hyæna (*Hyæna spelæa*), is supposed to have been most nearly allied to the spotted hyæna of South Africa, but does not appear to have extended farther south than the middle of Europe. Remains which have been doubtfully identified as belonging to the striped species have also been found in the south of France, and others in Sicily and Algeria, undoubtedly belonging to the spotted form of South Africa, which must thus have had a much more northerly extension in Tertiary times. No remains of the hyæna are known to occur in the New World.

HYBLA is the name of several cities in Sicily. A Sicilian goddess was named Hyblæa (Paus. v. 23. 6); hence doubtless the name was so common. The Hybla of which we hear most was founded by the Megarians, about the year 726 B.C., and is probably the same as Megara Hyblæa. For some time it was a flourishing city; a century after its foundation it founded in its turn the colony of Selinus. But about the year 481 B.C. it was completely destroyed by Gelon, tyrant of Syracuse. The mass of the inhabitants were sold as slaves; the richer were transported to Syracuse and there admitted as citizens. Among these was Epicharmus of Cos, who had been brought up in Megara. During the Athenian expedition to Sicily, Lamachus urged that they should occupy the deserted site. It must therefore have had a fine harbour, whence we may consider that it probably lay beside the modern city of Agosta. A small settlement seems afterwards to have grown up on the site. An older city called Hybla, belonging to the native Siculi, lay not far off on the southern slope of Mount Etna, near the river Symæthus. It is mentioned in the history of the Second Punic War; and in the time of Cicero (*Verr.*, iii. 43) it was a flourishing place. It is exceedingly difficult to separate the history of these two cities; and no doubt the ancient writers themselves often do not clearly distinguish between them. The Hyblæan honey, which was produced on the hills beside them, is often celebrated by the Latin poets. There was a third city of the same name on the road from Syracuse to Agrigentum.

HYBRIDISM. The Latin word *hybrida*, or *hibrida*, a hybrid or mongrel, is commonly derived from the Greek ὕβρις, an insult or outrage, with special reference to lust; hence an outrage on nature, a mongrel.

As a general rule animals or plants belonging to distinct species are not able, when crossed with each other, to produce offspring. There are, however, innumerable exceptions to this rule; and hybridism is the word employed to denote these exceptions. It is an abstract term which signifies the more or less fertile crossing of distinct species. In scientific usage, the term "hybrid" is exclusively reserved to denote the result of a fertile cross between two distinct species, while the term "mongrel" is the one which is as exclusively reserved to denote the result of a fertile cross between two varieties of the same species.

Until recently the interest attaching to hybridism was almost entirely of a practical nature, and arose from the fact, which is of considerable importance in horticulture, that hybrids are often found to present characters somewhat different from those of either parent species. But of late years the subject has acquired a high degree of scientific interest in relation to the theory of descent. On this account it has been so carefully and thoroughly treated by Mr Darwin that a brief exposition of its main facts and principles must necessarily be little more than a condensation of his already closely packed material.

Looking first to the general facts and principles of hybridism, apart from their bearing upon the theory of descent, the following may be regarded as the most important:—

1. The laws governing the production of hybrids are identical, or nearly identical, in the animal and vegetable kingdoms.

2. The sterility which so generally attends the crossing of two specific forms is to be distinguished as of two kinds, which, although often confounded by naturalists, are in reality quite distinct. For the sterility may obtain between the two parent species when first crossed, or it may first assert itself in their hybrid progeny. In the latter case the hybrids, although possibly produced without any appearance of infertility on the part of their parent species, nevertheless prove more or less infertile among themselves, and also with members of either parent species.

3. The degree of both kinds of infertility varies in the case of different species, and in that of their hybrid progeny, from absolute sterility up to complete fertility. Thus, to take the case of plants, "when pollen from a plant of one family is placed on the stigma of a plant of a distinct family, it exerts no more influence than so much inorganic dust. From this absolute zero of fertility, the pollen of different species, applied to the stigma of some one species of the same genus, yields a perfect gradation in the number of seeds produced, up to nearly complete, or even quite complete, fertility; so, in hybrids themselves, there are some which never have produced, and probably never would produce, even with the pollen of the pure parents, a single fertile seed; but in some of these cases a first trace of fertility may be detected, by the pollen of one of the pure parent species causing the flower of the hybrid to wither earlier than it otherwise would have done; and the early withering of the flower is well known to be a sign of incipient fertilization. From this extreme degree of sterility we have self-fertilized hybrids producing a greater and greater number of seeds up to perfect fertility."

4. Although there is, as a rule, a certain parallelism, there is no fixed relation between the degree of sterility manifested by the parent species when crossed and that which is manifested by their hybrid progeny. There are many cases in which two pure species can be crossed with unusual facility, while the resulting hybrids are remarkably sterile; and, contrariwise, there are species which can only be crossed with extreme difficulty, though the hybrids, when produced, are very fertile. Even within the limits of the same genus, these two opposite cases may occur.

5. When two species are reciprocally crossed, *i.e.*, male A with female B, and male B with female A, the degree of sterility often differs greatly in the two cases. The sterility of the resulting hybrids may differ likewise.

6. The degree of sterility of first crosses and of hybrids runs, to a certain extent, parallel with the systematic affinity of the forms which are united. "For species belonging to distinct genera can rarely, and those belonging to distinct families can never, be crossed. The parallelism, however, is far from complete; for a multitude of closely allied species will not unite, or unite with extreme difficulty, whilst other species, widely different from each other, can be crossed with perfect facility. Nor does the difficulty depend on ordinary constitutional differences; for annual and perennial plants, deciduous and evergreen trees, plants flowering at different seasons, inhabiting different stations, and naturally living under the most opposite climates, can often be crossed with ease. The difficulty or facility apparently depends exclusively on the sexual constitution of the species which are crossed, or on their sexual elective affinity."

Such being the principal facts of hybridism, we may next consider the relation which they bear to the theory of descent. It is obvious that the most important point of contact between the former and the latter consists in this—that, although hybridism is occasionally possible as an exception to the general infertility of species *inter se*, it is only, as it were, a partial exception; for, even when produced, the hybrid progeny almost invariably manifest some greater or less degree of sterility, and this not only when crossed among themselves, but even when crossed with either of their parent species. The main facts of hybridism thus at first sight seem to support the time-honoured doctrine that there are placed between all species the barriers of mutual sterility, for the purpose of preventing any admixture of specific qualities by heredity, and so for the purpose of maintaining the immutability of specific types. And the apparent support which this doctrine thus receives from the main facts of hybridism is still further strengthened when these facts are contrasted with those which are supplied by the breeding of our domestic "varieties." For, in the latter case, and as an almost invariable rule, neither the organisms when crossed nor their resulting progeny show any indications of sterility, although the two parent varieties may differ from one another even more widely than do many natural species which are wholly infertile when crossed. This very general distinction between natural species and domestic varieties has appeared to many competent persons in the present generation so profound and significant that they deem it to be in itself sufficient to discredit, if not to negative, the whole theory of the transmutation of species.

Now, when this distinction is thus posited as an objection to the theory of descent, we must first of all remember that this theory does not require the possibility of the commingling of specific types; it requires, indeed, that specific types should not be immutably fixed, but it does not require that the causes of their mutation should depend upon their mutual crossing. The whole difficulty, therefore, which the theory of descent has here to meet is to explain why it is that natural species are fenced about, as it were, with the mysterious barriers of sterility, while no such seeming care appears to have been taken in the case of our domestic breeds—even though in the latter case artificial selection by the breeders may have produced more visible difference between the two parent races than that which natural selection is supposed to have produced between two natural species.

In answer to this difficulty, the most important consideration to begin with is one that is very generally lost sight of. The consideration is that mutual sterility between organic forms has been constituted by naturalists the chief criterion of specific distinction, and therefore it is merely to argue in a circle to maintain that specific distinction is of some transcendental nature *because* it is so invariably associated with this mutual sterility. If it were not for the fact of their mutual sterility, this and that species would probably not have been classified as such; and therefore it is now scarcely to be considered a matter of any great significance that all species present more or less of the peculiarity in virtue of which they are recognized as species. Or, otherwise stated, on the supposition that species have had a derivative origin, whenever the modification of a specific type has proceeded sufficiently far to induce sterility with allied types, the modified type is, *for this reason*, classified as a distinct species; otherwise, upon the supposition, the species could scarcely have become separated out as a distinct type. The argument which points to such sterility as evidence against this supposition is, therefore, so far inconclusive.

The case, however, ought not in fairness to be stated quite so strongly as this; for mutual sterility, although the chief, is not the only criterion of specific distinction. In forming their classifications, naturalists endeavour as much as possible to have regard to organisms in the totality of their structures and functions. It may therefore still be maintained that, although the above consideration as to mutual sterility being selected as the chief criterion of specific distinction greatly mitigates the force of the argument that natural species differ from artificial breeds in being more or less sterile with one another, still this consideration does not altogether destroy that argument. For, on the one hand, it is not mutual sterility alone which is taken as a test of specific distinction; and, on the other hand, it generally so happens that the other qualities distinctive of any given species do not differ more widely from those which are distinctive of allied species than is the case with many of our domestic breeds. It therefore still remains a significant circumstance that, *along with* the differences distinctive of natural species, there almost invariably goes the protective attribute of mutual sterility; while the possibly greater differences distinctive of our domestic breeds are unaccompanied by any such protective attribute. But, again, this more refined objection can be met and satisfactorily excluded by the general consideration that "as species rarely or never become modified in one character, without being at the same time modified in many, and as systematic affinity includes all visible resemblances and dissimilarities, any difference in sexual constitution between two species would naturally stand in more or less close relation with their systematic position."

But we are not confined to this general consideration alone. There are several other general considerations which tend still further to mitigate the difficulty, and there are several particular facts which together prove that the alleged distinction between natural species and domestic varieties is one, not of kind, but of degree. We shall, therefore, next proceed to state these general considerations and particular facts.

Upon the theory of descent, mutual sterility between specific types is nothing more than the expression of some certain amount of modification having taken place in the reproductive system of a changing form, which up to that time, and but for the fact of this modification, would have been classified by naturalists as a mere variety. Now the causes which act upon the reproductive system, both of animals and plants, and whether in the direction of sterility or prolificness, are at present hopelessly obscure. We cannot, therefore, expect to distinguish the causes which in the case of any given species have determined sterility. Nor is it necessary, for the meeting of the present difficulty, that this should be done; it is enough for this purpose to show that the causes which thus act upon the reproductive system are much too indistinct to admit of any argument being raised upon them. And this it is most easy to show; for it is not too much to say that the reproductive system is, generally speaking, of all parts of an organism the most delicately susceptible to slight changes in the conditions of life. Mr Darwin has adduced a vast array of facts on this head in his *Variation of Animals and Plants under Domestication*. As a result of this delicacy, there arises an apparent capriciousness in the ways and degrees in which the reproductive system is affected by slight changes in the conditions of life, by too close interbreeding, by grafting, and by many other causes. Thus, for example, the influences of domestication produce more or less sterility in numberless species of wild animals and plants, while in other species—and this, as we shall presently see, is a matter of great importance in the present connexion—such influences are favourable to fertility. Now if we suppose, as in consistency we must suppose, that throughout the course of evolution the reproductive system has always been characterized by a sensitiveness to slight changes similar to that which we now observe, and if we remember that, in any case where these slight changes were sufficient to cause mutual sterility between the modified descendants of a common progenitor, a distinction of species must necessarily have arisen,—we shall cease to regard the present sterility of species *inter se* as anything more than what might be expected *a priori*, supposing the theory of descent with gradual modification to be true.

As evidence of the apparent capriciousness with which sterility may be manifested, owing to the slight and imperceptible causes on which it depends, special allusion must here be made to a highly remarkable and significant fact that has been brought to light by the direct experiments of Mr Darwin. The following is his account of these experiments:—

"Several plants belonging to distinct orders present two forms, which exist in about equal numbers, and which differ in no respect except in their reproductive organs,—one form having a long pistil with short stamens, the other a short pistil with long stamens; both with differently-sized pollen grains. With trimorphic plants there are three forms likewise differing in the length of their pistils and stamens, in the size and colour of the pollen grains, and in some other respects; and, as in each of the three forms there are two sets of stamens, there are altogether six sets of stamens and three kinds of pistils. These organs are so proportioned in length to each other that, in any two of the forms, half the stamens in each stand on a level with the stigma of the third form. Now I have shown, and the result has been confirmed by other observers, that in order to obtain full fertility with other plants, it is necessary that the stigma of the one form should be fertilized by pollen taken from the stamens of corresponding height in the other form. So that with dimorphic species two unions, which may be called legitimate, are fully fertile, and two which may be called illegitimate are more or less infertile. With trimorphic species six unions are legitimate or fully fertile, and twelve are illegitimate or more or less infertile. The infertility which may be observed in various dimorphic and trimorphic plants when they are illegitimately fertilized, that is, by pollen taken from stamens not corresponding in height with the pistil, differs much in degree up to absolute and utter sterility,—just in the same manner as occurs in crossing distinct species."

In this case we appear to have actual evidence of different stages of increasing sterility *in transitu*, and this even within the limits of the same natural species. And if even such evidence as this can be resisted, there still remains one very important fact, which directly affects the whole alleged distinction between the sterility of natural species and the fertility of domestic breeds. This fact is that plants belonging to several species of the genus *Passiflora* have been amply proved, not only to be completely fertile with plants belonging to other species, but even to be as completely infertile with plants belonging to their own. Thus fruit could not be obtained from *P. alata* and *P. racemosa* except by reciprocally fertilizing them with each other's pollen; and similar facts have been observed by several experimentalists with regard to four or five other species of this genus. The fullest details on the subject are those given by Mr Scott in the *Journal of the Linnean Society*, vol. viii. p. 168. Plants belonging to three species of the genus, viz., *P. racemosa, cœrulea,* and *alata*, flowered for many years in Edinburgh, but, though repeatedly fertilized by Mr Scott and others with their own pollen, never produced seed. But when mutually crossed in various ways they all produced seed. After quoting this case Mr Darwin adds :—

"Returning to *P. alata,* I have received (1866) some interesting details from Mr Robinson Munro. Three plants, including one in England, have already been mentioned which were inveterately self-sterile, and Mr Munro informs me of several others which, after repeated trials during many years, have been found in the same predicament. At some other places, however, this species fruits readily when fertilized with its own pollen. At Taymouth Castle there is a plant which was formerly grafted by Mr Donaldson on a distinct species, name unknown, and ever since the operation it has produced fruit in abundance by its own pollen, so that this small and unnatural change in the state of this plant has restored its self-fertility. Some of the seedlings from the Taymouth Castle plant were found to be not only sterile with their own pollen, but with each other's pollen and with the pollen of distinct species. Pollen from the Taymouth plant failed to fertilize certain plants of the same species, but was successful on one plant in the Edinburgh Botanic Gardens. Seedlings were raised from this latter union, and some of their flowers were fertilized by Mr Munro with their own pollen; but they were found to be as self-impotent as the mother plant had always proved, except when fertilized by the grafted Taymouth plant, and except, as we shall see, when fertilized by her own seedlings. Yet Mr Munro fertilized eighteen flowers on the self-impotent mother plant with pollen from these her own self-impotent seedlings, and obtained, remarkable as the fact is, eighteen fine capsules full of excellent seed. I have met with no case in regard to plants which shows so well as this of *P. alata* on what small and mysterious causes complete fertility or complete sterility depends."

These cases in the genus *Passiflora*, although so highly remarkable, are not wholly unique. There is not, indeed, any other case of a natural species, the members of which are only fertile with members of another species; but there are several cases of natural species, the members of which are self-impotent, though freely fertile either with other plants of the same species, or with plants of different though allied species. This may perhaps be regarded as a transitional stage between the ordinary condition of plants and the extraordinary condition that obtains among species of the genus *Passiflora*. It occurs in individual plants of certain species of *Lobelia* and *Verbascum*, and among several genera of orchids. The cases of the latter are particularly remarkable, inasmuch as Fritz Müller found from numerous experiments, not only that individual plants belonging to the several species were not fertilized by their own pollen, while freely so by pollen taken from distinct species, and even from distinct genera, but that the plant's own pollen was positively deleterious to its stigma, and acted as a poison to the destruction of the flower.

So much, then, for the facts which go to prove on what slight constitutional differences sterility may depend, and the consequent probability there is that it should generally be found to accompany a change of organization which is sufficiently great to be regarded by naturalists as a specific distinction. But the pleading must not end here. For there still remains to be adduced the fact, already mentioned as one of the general facts of hybridism, that "the degree of both kinds of fertility varies in the case of different species, and in that of their hybrid progeny, from absolute sterility up to complete fertility." As a matter of fact, the distinction between natural species and domestic varieties, upon which the whole discussion has hitherto proceeded, is in itself untenable; the infertility of natural species when crossed, although without question the general rule, is nevertheless not the invariable rule. We need not point to the highly anomalous case of *Passiflora* recently mentioned in another connexion, and probably to be explained as the result of cultivation; for we appear to have sufficient evidence without it. It is true that a great deal of negative evidence has been published upon this point by very competent experimentalists; but it seems impossible to resist the positive evidence of the Hon. and Rev. W. Herbert, whose distinguished success in hybridizing Mr Darwin attributes to "great horticultural skill, and to his having hot-houses at his command." Of his many results, which from being of a positive kind can scarcely be suspected of inaccuracy, it will be enough to quote the following:—"Every ovule in a pod of *Crinum capense* fertilized by *C. revolutum* produced a plant, which I never saw to occur in a case of its natural fecundation." Thus, as Mr Darwin in alluding to this case remarks, "we have perfect, or even more than commonly perfect, fertility in a first cross between two distinct species."

So far, then, as one side of the question before us is concerned, or that relating to the mutual infertility of natural species, enough has been said to show that it presents no real difficulty to the theory of descent. Indeed, in view of all that has now been said, the difficulty, as Mr Darwin has observed, is not so much to account for the sterility of natural species, as it is to account for the continued, or even increased, fertility of our domestic varieties. Turning, therefore, to this other side of the question, we have to remember that the very same sensitiveness of the reproductive system, which in some cases leads to infertility under a change in the conditions of life, in other cases leads to increased fertility under an apparently similar change in the conditions of life. Thus it is that domestication produces such apparently capricious results with regard to fertility—inducing all degrees of infertility in some wild species, while not at all impairing, or even increasing, fertility in others. Consequently, when the question is as to why our domestic varieties do not become sterile *inter se* when so many natural species have become so, the answer is that the mere fact of their domestication proves that their wild or parent stocks must have been some of those species whose reproductive systems were not highly sensitive to changes in their condition of life, and therefore species which "might be expected to produce varieties little liable to have their reproductive systems injuriously affected by the act of crossing with other varieties which had originated in a like manner." Thus, on the inherently necessary view that our domestic varieties have all proceeded from species which were not easily affected in the direction of sterility, we are not surprised that under variation their reproductive systems should continue to manifest a high degree of tolerance. To this must be added that domestication, if it does not produce sterility, seems well calculated to increase fertility. For if the causes inducing sterility (whatever they may be) are absent, ample and regular nutrition, combined with innumerable lesser benefits attending domestication, may well be supposed to favour fertility. And, as a matter of fact, according to Pallas, there is a great deal of evidence to indicate that prolonged domestication has a tendency to eliminate sterility; so that wild species which when first domesticated intercross with difficulty, become in time able to intercross with facility. Such, for instance, appears to have been the case with the dog; for on the one hand all the domestic varieties of this animal are now freely fertile among themselves, and, on the other hand, there is independent evidence that these varieties have sprung from more than one natural species. Again, mention must not be omitted of the important fact that, although in the case of none of our varieties of domesticated animals is there any evidence of mutual sterility, yet among our varieties of domesticated plants a few cases have been observed of complete mutual sterility, which is in every way analogous to that which occurs between natural species. Thus, Gärtner observed this to be the case with certain varieties of maize and *Verbascum*, Kölreuter with one kind of tobacco, and other experimentalists with sundry varieties of gourd and melon. And here, let it be observed, we have the exact counterpart that evolutionists would desire to the experiments of Herbert above mentioned; for while he was able to break down the general distinction between natural species and domestic varieties on the side of proving perfect fertility between certain natural species, these experimentalists have broken down the distinction on the side of proving perfect sterility between certain of our domestic varieties. Therefore, we may conclude that this side of the question, or that as to the fertility of our domestic varieties, presents as harmless an aspect towards the theory of descent as we have already seen to be presented by the other side of the question, or that as to the sterility of natural species.

Finally, there are two complementary considerations to be adduced, which may now be stated together. One is that the general principles of hybridism, as briefly stated at the beginning of this article, are really far from indicative of having been instituted with any design of simply preventing species from intercrossing. For, upon the view that they were so instituted, scarcely any one of them admits of a rational explanation. Thus, upon this view, no reason can be assigned why the degree of sterility should be so extremely variable in different species, when it must be supposed equally important that all species should be kept distinct; nor can it be said why the degree of sterility should vary even among individuals of the same species. Neither can it be said why some species should cross with facility, and yet produce sterile hybrids, while other species cross with difficulty, and yet produce fertile hybrids. Why should species living in countries remote from one another, and therefore not able in a state of nature to come together, nevertheless prove as sterile *inter se* as species inhabiting the same country? Why, again, should there often be so great a difference in the result of a reciprocal cross between two species? Or why, indeed, should the production of hybrids have been permitted at all? As Mr Darwin observes, "to grant to species the special power of producing hybrids, and then to stop their further propagation by different degrees of sterility, not strictly related to the facility of the first union between their parents, seems a strange arrangement."

The other and complementary consideration which has to be mentioned is that, on the counter supposition of all these general principles of hybridism being "simply incidental," or dependent on unknown differences in the reproductive systems of species,—on this supposition we meet with sundry differences between wild species and domestic varieties which are fully analogous to their difference of fertility, and which yet cannot reasonably be supposed to serve any transcendental purpose. Thus, again to quote Mr Darwin:—

"Some allied species of trees cannot be grafted on each other—all varieties can be so grafted. Some allied animals are affected in a very different manner by the same poison, but with varieties no such case until recently was known, but now it has been proved that immunity from certain poisons stands in some cases in correlation with the colour of the hair. The period of gestation generally differs much with distinct species, but with varieties until lately no such difference had been observed. The time required for the germination of seeds differs in an analogous manner, and I am not aware that any difference in this respect has as yet been detected with varieties. Here we have various physiological differences, and no doubt others could be added, between one species and another of the same genus, which do not occur, or occur with extreme rarity, in the case of varieties; and these differences are apparently wholly or in chief part incidental on other constitutional differences, just in the same manner as the sterility of crossed species is incidental on differences confined to the sexual system. Why, then, should these latter differences, however serviceable they may indirectly be in keeping the inhabitants of the same country distinct, be thought of such paramount importance in comparison with other incidental and functional differences? No sufficient answer to this question can be given."

Upon the whole, therefore, it may be concluded that the difficulty which the facts of hybridism seem at first sight to raise against the theory of descent may be explained in harmony with the main requirements of that theory.

Animal Hybrids.—A few words may here be added with special reference to animal hybrids. As a general statement it may be said that hybrids, not only between specific but generic forms, are more easily produced in the case of animals than in that of plants. The hybrids, however, when produced are, as a general rule, more sterile. Indeed, it is doubtful whether there is any single instance of a perfectly fertile hybrid having emanated from a cross between two animal species. Mr Darwin, however, says—"I have reason to believe that the hybrids from *Cervulus vaginalis* and *Reevesii*, and from *Phasianus colchicus* with *P. torquatus*, are perfectly fertile." Also M. Quatrefages states that the hybrid progeny of two moths (*Bombyx cynthia* and *B. arrindia*) showed themselves to be fertile *inter se* for eight generations. The hare and rabbit are said occasionally to breed together, and their offspring to be highly fertile when crossed with either parent species. Lastly, Mr Darwin observes:—

"The hybrids from the common and Chinese geese (*A. cygnoides*), species which are so different that they have sometimes been ranked in distinct genera, have often bred in this country with either pure parent, and in several instances *inter se*. This was effected by Mr Eyton, who raised two hybrids from the same parents, but from different hatches; and from these two birds he raised no less than eight hybrids (grandchildren of the pure geese) from one nest. In India, however, these cross-bred geese must be far more fertile; for I am assured by two eminently capable judges, namely, Mr Blyth and Captain Hutton, that whole flocks of these crossed geese are kept in various parts of the country; and, as they are kept for profit where neither pure parent-species exists, they must certainly be highly or perfectly fertile."[1]

It is somewhat remarkable that hitherto direct experiments on the hybridization of animals have been so few in number as compared with those on the hybridization of plants. This is the more to be regretted, because, as already observed, animals appear to display a somewhat greater aptitude for hybridizing than plants, and consequently furnish better material for ascertaining the furthest limits of systematic affinity within which a cross may prove fertile. But here direct experiments are wanting, and all we can say with certainty is that in animals, as in plants, no authentic instance is on record of progeny resulting from a union of two individuals separated from one another by more than a generic distinction.

[1] Since the above was published, Mr Darwin has himself procured two of these hybrid geese, and from them (brother and sister) raised five "extremely fine birds from two hatches." These five hybrids "resembled in every detail their hybrid parents" (see *Nature*, Jan. 1, 1880).

Graft-Hybridism.—The only other subject of importance that falls under the present heading, is that which has been appropriately called "graft-hybridism." It is well known that, when two varieties or allied species are grafted together, each retains its distinctive characters. But to this general, if not universal, rule there are on record several alleged exceptions, in which either the scion is said to have partaken of the qualities of the stock, the stock of the scion, or each to have affected the other. Supposing any of these influences to have been exerted, the resulting product would deserve to be called a graft-hybrid. It is clearly a matter of great interest to ascertain whether such formation of hybrids by grafting is really possible; for, if even one instance of such formation could be unequivocally proved, it would show that sexual and asexual reproduction are essentially identical.

The cases of alleged graft-hybridism are exceedingly few, considering the enormous number of grafts that are made every year by horticulturists, and have been so made for centuries. Of these cases the most celebrated are those of Adam's laburnum (*Cytisus Adami*) and the bizzarria orange. Adam's laburnum is now flourishing in numerous places throughout Europe, all the trees having been raised as cuttings from the original graft, which was made by inserting a bud of the purple laburnum into a stock of the yellow. M. Adam, who made the graft, has left on record that from it there sprang the existing hybrid. There can be no question as to the truly hybrid character of the latter—all the peculiarities of both parent species being often blended in the same raceme, flower, or even petal; but until the experiment shall have been successfully repeated, there must always remain a strong suspicion that, notwithstanding the assertion and doubtless the belief of M. Adam, the hybrid arose as a cross in the ordinary way of seminal reproduction. Similarly, the bizzarria orange, which is unquestionably a hybrid between the bitter orange and the citron,—since it presents the remarkable spectacle of these two different fruits blended into one,—is stated by the gardener who first succeeded in producing it to have arisen as a graft-hybrid; but here again a similar doubt, similarly due to the need of corroboration, attaches to the statement. And the same remark applies to the still more wonderful case of the so-called trifacial orange, which blends three distinct kinds of fruit in one, and which is said to have been produced by artificially splitting and uniting the seeds taken from the three distinct species, the fruits of which now occur blended in the triple hybrid.

The other instances of alleged graft-hybridism are too numerous to be here noticed in detail; they refer to jessamine, ash, hazel, vine, hyacinth, potato, beet, and rose. Of these the cases of the vine, beet, and rose are the strongest as evidence of graft-hybridization, from the fact that some of them were produced as the result of careful experiments made by very competent experimentalists. On the whole, the results of some of these experiments, although so few in number, must be regarded as making out a strong case in favour of the possibility of graft-hybridism. For it must always be remembered that in experiments of this kind, negative evidence, however great in amount, may be logically dissipated by a single positive result.

History and Literature.—From time immemorial the leading facts of hybridism have been known in the case of the horse and the ass. The knowledge of corresponding facts as occurring in the vegetable kingdom necessarily dates from a time subsequent to that at which the sexual functions of plants became known, *i.e.*, towards the end of the 17th century. The earliest recorded observation of a hybrid plant is one by Gmelin; the next is that of Thomas Fairchild, who in the second decade of the 18th century produced the cross which is still grown in gardens under the name of "Fairchild's Sweet William." Later on in that century Linnæus made a number of experiments on the cross fertilization of plants, and produced various hybrids; but it was reserved for the laborious investigations of Kölreuter, towards the end of that century (1751-1799), to found and largely to build the existing structure of our scientific knowledge upon this subject. To him also belongs the credit of first discovering the part played by insects in the fertilization of flowers. He published most of his results at the St Petersburg Academy of Sciences. Next in order of time deserve mention the works of Graf Lavola (*Discorso della Irri'abilita d'alcuni Fiori nuovamente scoperta*, 1764), and of Conrad Sprengel (*Das entdeckte Geheimniss der Natur im Bau und in der Befruchtung der Blumen*, 1793). The latter work is full of interesting observations on the connexion between the structure of flowers and the visitation of insects. Next we come to the celebrated horticulturist, Thomas Andrew Knight, who from 1787 for a number of years devoted an immense amount of labour, with a large measure of results, to the improvement of fruit trees and vegetables by crossing. He published in the *Philosophical Transactions* and in the *Trans. Hort. Soc.* During the first quarter of the present century the only names that in the present connexion call for mention are those of J. E. Smith (*Flora Britannica*, 1800), Villars (*Ro. Coll. Bot.*, 1809), Hoppe (*Neues Bot. Taschenb.*, 1810), Guillemin and Dumas ("Obs. sur l'Hybridité d. Plant.," in *Mém. Paris Soc. Hist. Nat.*, 1833), Henschel, and Godron. During this period, besides Knight, already mentioned, there were two other English experimentalists at work, whose names deserve to be placed in the first rank among those which are associated with this subject. These are Sweet, who published an important work on *Geraniaceæ*, and Herbert, whose work on *Amaryllidæ*, together with sundry publications in the *Journal of the Horticul ural Society*, very materially advanced both the facts and the theory of hybridism. We say "theory," because it was in these publications that Herbert carried on his celebrated controversy with Knight regarding the alleged sterility of hybrids. In 1828 there was published a prize essay by Wiegmann on a thesis which was set several years before by the Berlin Academy of Sciences, and which embodied the question whether hybrid plants are necessarily sterile. We next come, in the second quarter of the present century, to the laborious researches of Gärtner, the number of whose experiments in hybridizing has certainly not been surpassed, and probably has not been equalled, by that of any other experimentalist. His principal work is *Versuche und Beobachtungen über die Bastarderzeugung im Pflanzenreiche.* In connexion with this period we may also mention the names of Braun, Wallroth, Zuccarini, Meyer, Ziz, Koch, Schiede, Lasch, Reichenbach, A. P. de Candolle, Wimmer, Hornschuh, and Nägeli. In 1854 a research of value was published by Klotzsch (*Verhandl. Kgl. Preuss. Akad. Berlin*), and others later by Regel, Godron, and Jordon. In 1860 a prize was offered by the French Academy of Sciences for the best essay on hybridism, with special reference to three points,—the fertility or sterility of hybrids, the cause of their sterility, and the constancy of type manifested by fertile hybrids. In 1865 this prize was awarded jointly to Naudin and Godron, the latter name being identified with researches upon the character of hybrids which deserve to be considered among the most important of the present century. The next work of note appeared in 1865, by Max Wichura, on *Die Bastardbefruchtung in Pflanzenreich*, &c. He combined, in one complex hybrid, six different species of *Salix*; confirmed, in opposition to Godron, the doctrine of Kölreuter, Herbert, Gärtner, and Naudin, that a hybrid is best fertilized by its own pollen; and found, in opposition to Naudin, that the progeny of hybrid willows retains its hybrid character. In 1865-6 Nägeli published his important observations on naturally produced hybrids (*Sitzungsber. Akad. München, Math. Phys.*). The highly important experiments of Darwin on dimorphic and trimorphic plants have been already alluded to. Those who within still more recent years have contributed to the literature of hybridism are Caspary, Mendel, Seden, Dominy, Kellermann, Fr. Schultz, Timbal-Lagrave, Grenier, A. Kerner, Wirtgen, Michalet, Ritschl, Beckhaus, P. Ascherson, R. von Uechtritz, J. Schmalhausen, C. Haussknecht, V. von Borbás, Kuntze, Henniger, and W. O. Focke. The last-named author has just published an elaborate and valuable work on hybridism in plants (*Die Pflanzen-Mischlinge*, Berlin, 1881), giving a tabular series of all the known vegetable hybrids, and treating the entire subject in a very comprehensive manner.

On the subject of animal hybrids there is virtually no literature, save scattered records of fertile crosses among sundry species confined in various menageries; and these are without interest as bearing on any of the principles of hybridism. (G. J. R.)

HYDE, a township of England in the parish of Stockport, Cheshire, is situated near the river Tame and the Peak Forest canal, and on the Midland, and the Manchester, Sheffield, and Lincolnshire Railways, 7½ miles east from Manchester and 6 north-east from Stockport. It is under the government of a local board, and a county court is held there every Wednesday. St George's church, in the Perpendicular style, was erected in 1832, and St Thomas, in the Early English, was erected in 1868. The principal other public buildings are the mechanics' institute, the temperance hall, and the court-house. The town owes its importance to the cotton manufacture, and possesses weaving factories, spinning-mills, print-works, iron-foundries, and machine-works. There are extensive coal-mines in the vicinity. The old family of Hyde, to which the line of earls of Clarendon belonged, held possession of the township as early as the reign of John, but it was a mere village until the establishment of the cotton manufacture at the beginning of the present century. The population of the township in 1861 was 13,722, and in 1871 it was 14,223.

HYDE, EDWARD, Earl of Clarendon. See CLARENDON.

HYDE, THOMAS (1636-1703), a distinguished Orientalist, was born at Billingsley, near Bridgnorth, in Shropshire, June 29, 1636. He inherited his taste for linguistic studies, and received his first lessons in some of the Eastern tongues, from his father, who was rector of the parish. In his sixteenth year Hyde entered King's College, Cambridge, where, under Wheelock, professor of Arabic, he made such rapid progress in the Oriental languages that, after only one year of residence, he was invited to London to assist Brian Walton in his edition of the *Polyglot Bible.* Besides correcting the Arabic, Persic, and Syriac texts for that work, Hyde transcribed into Persic characters the Persian translation of the Pentateuch, which had been printed in Hebrew letters at Constantinople in 1546. To this work, which Archbishop Ussher had thought well-nigh impossible even for a native of Persia, Hyde appended the Latin version which accompanies it in the *Polyglot.* Having successfully accomplished these difficult tasks amidst the flattering acknowledgments of the most learned men of the day, Hyde entered Queen's College, Oxford, in 1658, where he was chosen Hebrew reader; and in 1659, in consideration of his singular erudition in Oriental tongues, he was admitted to the degree of M.A. In the same year he was appointed under-keeper of the Bodleian library, and in 1665 he became librarian-in-chief. Next year he was collated to a prebend at Salisbury, and in 1673 to the archdeaconry of Gloucester, receiving the degree of D.D. shortly afterwards. In 1691 the death of Pocock opened up to Hyde the Laudian professorship of Arabic; and in 1697, on the deprivation of Altham, he succeeded to the regius chair of Hebrew and a canonry of Christ Church. Under Charles II., James II., and William III., Hyde discharged the duties of Eastern interpreter to the court. Worn out by his unremitting labours, he resigned his librarianship in 1701, and died at Oxford, February 18, 1703. Hyde was an excellent classical scholar, and there was hardly an Eastern tongue accessible to foreigners with which his wide erudition had not made him familiar. He had even acquired Chinese, while his writings are the best testimony to his mastery of Turkish, Arabic, Syriac, Persic, Hebrew, and Malay. His books are still valuable; and, although later investigations and additional authorities have partially superseded and corrected his conclusions, he still deserves respect as one of the first scholars to direct attention to the vast treasures of Oriental antiquity.

In his chief work, *Historia Religionis veterum Persarum*, 1700, Hyde made the first attempt to correct from Oriental sources the errors of the Greek and Roman historians who had described the religion of the ancient Persians, but through ignorance of the ancient language of Persia he has been often misled by Mahometan authorities. His other writings and translations comprise *Tabulæ Longitudinum et Latitudinum Stellarum fixarum ex observatione principis Ulugh Beighi*, 1665, to which his notes have given additional value; *Quatuor Evangelia et Acta Apostolorum lingua Malaica, caracteribus Europæis*, 1677; *Epistola de Mensuris et Ponderibus Serum sive Sinensium*, 1688, appended to Bernard's *De Mensuris et Ponderibus antiquis*; *Abraham Peritsol Itinera Mundi*, 1691; and *De Ludis Orientalibus Libri II.*, 1694. With the exception of the *Historia Religionis*, which was republished by Hunt and Costard in 1760, the writings of Hyde, including some unpublished MSS., were collected and printed by Dr Gregory Sharpe in 1767 under the title *Syntagma Dissertationum quas olim . . . Thomas Hyde separatim edidit.* There is a life of the author prefixed. Hyde also published a catalogue of the Bodleian Library in 1674.

HYDER ALI, or HAIDAR 'ALI, (*c.* 1702–1782), the Mahometan soldier-adventurer who, followed by his son Tippoo, became the most formidable Asiatic rival the English have ever had in India, was the great grandson of a fakir or wandering ascetic of Islam, who had found his way from the Punjab to Kulburga in the south, and the second son of the Arab wife of a naik or chief constable at Budikote, near Colar, in Mysore, and was born about the beginning of the 18th century. The elder brother who, like himself, was early turned out into the world to seek his own fortune, became a naik, and ultimately rose to command a brigade in the Mysore army, while Hyder, who never learned to read or write, passed the first forty-seven years of his life aimlessly in sport and sensuality, sometimes, however, acting as the agent of his brother, and meanwhile acquiring a useful familiarity with the tactics of the French when at the height of their reputation under Dupleix. He is said to have induced his brother to employ a Parsee to purchase artillery and small arms from the Bombay Government, and to enrol some thirty sailors of different European nations as gunners, and is thus credited with having been "the first Indian who formed a corps of sepoys armed with firelocks and bayonets, and who had a train of artillery served by Europeans." At the siege of Deonhully (1749) Hyder's services attracted the attention of Nunjeraj, the minister of the maharajah of Mysore, and he at once received an independent command; within the next twelve years his energy and ability had made him completely master of minister and maharajah alike, and in everything but in name he was ruler of the kingdom. In 1763 the conquest of Canara gave him possession of the treasures of Bednore, which he resolved to make the most splendid capital in India, under his own name, thenceforth changed from Hyder Naik into Hyder Ali Khan Bahadoor; and in 1765 he retrieved previous defeat at the hands of the Marhattas by the destruction of the Nairs or military caste of the Malabar coast, and the conquest of Calicut. Hyder Ali now began to occupy the serious attention of the Madras Government, which in 1766 entered into an agreement with the nizam to hold the district known as the Northern Circars from him, and to furnish him with troops to be used against the common foe. But hardly had this alliance been formed when a new and secret arrangement was come to between the two Indian powers, the result of which was that Colonel Smith's small force was met with a united army of 80,000 men and 100 guns. British dash and sepoy fidelity, however, prevailed, first in the battle of Changama (September 3, 1767), and again still more remarkably in that of Trinomalee, which lasted two days; and the nizam's own capital of Hyderabad was threatened by Colonel Peach's expedition sent from Bengal. On the loss of his recently made fleet and forts on the western coast, Hyder Ali now began to make overtures for peace; on the rejection of these, bringing all his resources and strategy into play, he forced Colonel Smith to raise the siege of Bangalore, and brought his army within five miles of Madras. The result was the treaty of April 1769, providing for the mutual restitution of all conquests, and for mutual aid and alliance in defensive war; it was followed by a commercial treaty in 1770 with the authorities of Bombay. Under these arrangements Hyder Ali, when defeated by the Marhattas in 1772, claimed English assistance, but in vain; this breach of faith stung him to fury, and thenceforward he and his son did not cease to thirst for vengeance. His time came when in 1778 the English, on the declaration of war, resolved to drive the French out of India. The capture of Mahe on the coast of Malabar in 1779, followed by the annexation of lands belonging to a dependant of his own, gave him the needed pretext. Again master of all that the Marhattas had taken from him, and with empire extended to the Kistna, he now summoned the French to his assistance, and, descending through the Changama pass amid burning villages, reached Conjeveram, only forty-five miles from Madras, unopposed. Not till the smoke was seen from St Thomas's Mount, where Sir Hector Munro commanded some 5200 troops, was any movement made; then, however, the British general sought to effect a junction with a smaller body under Colonel Baillie recalled from Guntoor. The incapacity of these officers, notwithstanding the splendid courage of their men, resulted in the total loss of Baillie's force of 2800 (September 10, 1780). Hastings, again appealed to, sent from Bengal Sir Eyre Coote, who, though repulsed at Chillumbrum, defeated Hyder thrice successively in the battles of Porto Novo, Polliloor, and Sholingur, while Tippoo was forced to raise the siege of Wandewash, and Vellore was provisioned. On the arrival of Lord Macartney as governor of Madras, the English fleet captured Negapatam, took Trincomalee from the Dutch, and forced Hyder Ali to confess that he could never ruin a power which had such command of the sea. He was directing his attention to the west coast, where he sought the assistance of the French fleet, when his death took place suddenly at Chittore in December 1782.

For the personal character and administration of Hyder Ali see the *History of Hyder Naik*, written by Meer Hussein Ali Khan Kirmani (translated from the Persian by Colonel Miles, and published by the Committee of the Oriental Translation Fund), and the curious work written by M. Le Maître de La Tour, commandant of his artillery (*Histoire d'Hayder-Ali Khan*, Paris, 1783). For the whole life and times see Wilks, *Historical Sketches of the South of India*, 1810-17; Aitchison's *Treaties*, vol. v. (2d ed., 1876); and Pearson, *Memoirs of Schwartz*, 1834.

HYDERABAD, or Haidarábád ("the Territory of the Nizám"), an extensive realm of Southern India. This territory, inclusive of the Hyderabad Assigned Districts, known as Berar, lies between 15° 10′ to 21° 41′ N. lat., and 74° 40′ to 81° 31′ E. long., and is 475 miles in length from south-west to north-east, and about the same distance in breadth. The area of Berar is 17,728 square miles, and of the Nizám's Territories 80,000 square miles,—the total area of the whole state being about 98,000 square miles. It is bounded N. and N.E. by the Central Provinces, and S. and S.E. by territory subject to the presidency of Madras, and W. by territory subject to the presidency of Bombay. The Country of the Nizám presents much variety of surface and feature. In some parts it is mountainous, wooded, and picturesque, in others flat and undulating. The champaign lands are of all descriptions, including many rich and fertile plains, much good land not yet brought under cultivation, and numerous tracts too sterile ever to be cultivated. The geological formations are on a large scale: in the north-west the formations are volcanic, consisting principally of trap, but in some parts of basalt; in the middle, southern, and south-western parts the country is overlaid with gneissic formations. In the valley of the Wardha there are coal-fields; the quality of the coal is inferior, but good enough for railway purposes. Quarries of excellent limestone are worked for a considerable distance along the line of the Nizám's State Railway. The territory is well watered, rivers being numerous, and tanks or artificial pieces of water very abundant. The principal rivers are—the Godávari, with its tributaries the Dudna, the Manjira, and Pranhíta; the Wardha, with its tributaries the Pengangá and Waingangá; and the Kistna, with its tributary the Tungabhadra. Many other streams (considerable rivers during the annual periodical rains) are discharged into these main channels of drainage. The climate may be considered in general good; and as there are no arid, bare deserts, the hot winds are less felt. In the vicinity of Hyderabad city, the annual mean temperature in the shade is 81° F., and the annual rainfall is estimated at 28 to 32 inches.

The soil is in general fertile, though in some parts it consists of *chilka*, a red and gritty mould, little fitted for purposes of agriculture. A low jungle springs up in any ground left uncultivated even for a year or two, and in process of time is enlivened by the growth of numerous trees. The principal crops are rice, wheat, maize, *joár, bájra, rági*, oil-seeds of various kinds, fruits and garden produce in great variety, cotton, indigo, sugar-cane, and tobacco. Silk, the material known as *tusser*, the produce of a wild species of worm, is utilized on a large scale. Lac, suitable for use as a resin or dye, gums, and oils are found in great quantities. Hides, raw and tanned, are articles of some importance in commerce. The chief mart for Deccan-bred horses, adapted for military or general purposes, is at a fair at Malegáon in the Bedar district. There is also a horse bazaar near the capital, which is resorted to by merchants from almost every quarter of Asia.

The principal exports are cotton, oil-seeds, country cloths, hides, metal ware, and agricultural produce; the imports are salt, grain, timber, European piece goods, and hardware. Among the manufactures of the country may be mentioned the ornamental ware of Bedar, the gold embroidered cloths of Aurangábád, Gulbarga, and other towns, and the excellent paper of different kinds which is made by the inhabitants of Kaghazpur, near the fortress of Daulatábád. Several railway lines pass through the state. The line connecting Bombay with Madras traverses the south-western part; the Great Indian Peninsula Railway runs the line as far as Ratchur, where it is joined by the Madras Railway; and from Wadi the Nizám's State Railway branches off to Hyderabad and Secunderabad. The three principal roads in the state all pass through Hyderabad city.

No census of the population has been attempted in Hyderabad territory, with the exception of Berar or the Assigned Districts. But the population in the Nizám's Territory has been estimated at 9,000,000 persons. In the different parts of the territory the Marathí, the Kanarese, and the Telugu languages are spoken. The Marhattás are most numerous in the west. The Musálmans are chiefly to be met with in the capital, and everywhere in the service of Government. In addition there is a large admixture of Parsís, Síkhs, Arabs, Rohillas, aborigines, and others. The revenue of the Nizám's Territories, including Berar, may be stated in round numbers at 40,000,000 rupees (say £4,000,000), including receipts from all sources. About two-thirds of the above large sum is collected by the nizám's own Government from tracts under British rule. The remaining one-third is realized by British officers, principally from Berar. The native Government has a mint situated at Hyderabad, and a currency of its own. It issues a rupee,—namely, the *hali sicca*, or "rupee of the period."

History.—The fortunes of the family of the nizám were founded by Kamr-ud-dín Asaf Jah, a distinguished soldier of the emperor Aurangzeb, who in 1713 was appointed Nizám-ul-Mulk (Regulator of the State) and Subahdár of the Deccan, but eventually threw off the control of the Delhi court. Asaf Jah died in 1748, and the right of accession to his power and authority was contested by his descendants. The claimants most favoured were two; the one, Naár Jang, a son of the deceased ruler, secured the support of the English, the other Muzaffar Jang, a grandson, was supported by the French. After a brief period of contest Muzaffar Jang became the prisoner of his rival, who, however, soon perished by the hands of some of his followers, and Muzaffar Jang was proclaimed subahdár of the Deccan. He, too, soon perished in a fray with some Pathán chiefs, so the seat of power was now unoccupied. Two brothers of Nasír Jang now claimed the dignity, but the contest was averted by the sudden death of Ghazi-ud-dín, the elder brother. The English and French continued a struggle for power and influence in the Deccan, but the latter had to withdraw from the support of Salabat Jang, through the danger threatening their own possessions from the victories gained by Clive. In 1761 this weak prince was dethroned by his younger brother Nizám Alí, who afterwards put him to death. In 1765 he ravaged the Carnatic, but retired on the approach of a British force. Still the British Government was anxious to be on better terms with him, partly from a desire to obtain his concurrence to their retention of a maritime district known as the Northern Circars, which they now occupied. In 1766 a treaty was concluded by which, on condition of a gift of the Circars, the British Government agreed to support the nizám, who on his part engaged to assist the British with his troops. In 1790, on the breaking out of a war with Tippoo, son of Hyder Ali Khán, a treaty of offensive and defensive alliance was concluded between the nizám, the peshwá, and the British Government. Tippoo purchased peace (1792) at the price of half his dominions, and the nizám had no reason to be dissatisfied with his share of the spoil. On the fall of Seringapatam and the death of Tippoo Sultán, the nizám participated largely in the division of territory, under the treaty of 1799, and his share was increased on the peshwá's withdrawal from the treaty. In 1800 the subsidiary force with the nizám was further augmented, and the pecuniary payment for its maintenance was commuted for a cession of territory. This territory is known to the present time under the title of the Ceded Districts. By the treaty of 1853 the nizám still retained the full use of the subsidiary force and contingent, but was released from the unlimited obligation of service in time of war; and the contingent ceased to be part of the nizám's army, and became an auxiliary force kept up by the British Government for the nizám's use. In 1857, when the mutiny had broken out, the state of Hyderabad and the nizám's dominions became critical; and an attack, which was repulsed, was made upon the residency. The Hyderabad contingent displayed its loyalty in the field against the rebels. In 1860 a fresh treaty was made by which the territorial acquisitions of the nizám were increased, a debt of 50 lákhs of rupees was cancelled, and assigned districts in Berar, making up a gross revenue of 3,200,000 rupees (say £320,000), were taken in trust by the British Government. The nizám is the principal Mahometan ruler in India, and is entitled to a salute of twenty-one guns.

HYDERABAD, the chief city and capital of the above state, is situated in 17° 21′ 45″ N. lat. and 78° 30′ 10″ E. long., on the river Musí, and stands at a height of about 1700 feet above sea level. No census of the population has been taken, but it has been estimated at 200,000. The scenery around Hyderabad is wild and picturesque, the country being hilly and dotted with numerous granite peaks and isolated rocks. Approached from the west, the appearance of the city is very striking,—the palace, the mosques, and the magnificent pile of buildings erected for the British residency towering above the outer wall. A large lake, a few miles south of Hyderabad, covering an area of 10,000 acres, supplies the town with water. The palace of the nizám, the mosques, and the British residency are the principal buildings. The palace has no pretensions to splendour, but is of considerable size. Hyderabad is a great Mahometan stronghold, and contains several mosques. The Jamá Masjíd or "cathedral" mosque, so called after the one at Mecca from which it is designed, is large, and is crowned by minarets of an extraordinary height. In the environs of Hyderabad there are many fine gardens with gorgeous pavilions; that of the nizám's minister has long been celebrated for its beauty. One of the most interesting places is the college, or *Chár Minár* (so called from its four minarets), built upon four grand arches at which the four principal streets of the city meet. Above are several stories of rooms, and formerly each story was devoted to a science. On the north side of the Musí is an extensive suburb known as the Begam or "Princess" bazaar. The British residency is in this quarter, and communication between it and the palace of the nizám is maintained by a fine bridge. The residency is a very handsome building, and is remarkable as having been raised entirely by native workmen. It stands in ornamental pleasure grounds enclosed by a wall with two gateways. The staircase is the handsomest in India, each step being a single block of the finest granite. The principal private residence in the city is the palace of the *Bára Dari*, or "Twelve Doors," which is now occupied by the minister of the nizám, Sir Sálar Jang.

History.—Hyderabad was founded in 1589, by Kutáb Sháh Muhammad Kulí, a descendant of Sultán Kulí Kutab Shah, the founder of the dynasty at Golconda in 1512. Muhammad Kulí removed the seat of government on account of its want of water and consequent unhealthiness, and built a new city on the banks of the Musí river, 7 miles from his former capital. He called it *Bhágnagar*, "Fortunate City," from his favourite mistress, Bhágmati; but after her death he named it Hyderabad. The history of Golconda and of Hyderabad after 1589 are almost identical. Soon after establishing himself in his new metropolis, Muhammad Kulí carried on an aggressive war with the neighbouring Hindu rájás. He extended his conquests south of the Kistna river; the strong fortress of Gandikota was captured; and the town of Cuddapah was sacked. His troops penetrated to the frontiers of Bengal, and Muhammad Kulí defeated the rájá of Orissa and subjugated the Northern Circars. In 1603 an ambassador from the king of Persia arrived with a ruby studded crown and other magnificent gifts. When he returned six years afterwards, he was accompanied by an officer of the court of Hyderabad, bearing return presents. In 1611 Muhammad Kulí died, after a most prosperous reign of thirty-four years. The principal memorials of this monarch are the palace and gardens of Iláhí Mahál, the Muhammadí gardens, the palace of Nabat Ghát, and the Jamá Masjíd or "cathedral" mosque. During his reign nearly £3,000,000 was expended on public works, and £24,000 was distributed every year among the poor.

Muhammad Kulí was succeeded by his son, Sultán Abdullah Kutab Sháh. Mír Jumlá, the prime minister, whose son had involved him in a dispute with the court, finding himself unable to obtain favour from his own sovereign, determined to throw himself on the protection of the Mughal emperor. Sháh Jahán, espousing his cause, issued a mandate to Abdullah to redress the complaints of his minister; but Abdullah was so incensed that he sequestrated Mír Jumlá's property, and committed his son to prison. Sháh Jahán now despatched Aurangzeb, his son, to carry his demands into effect by force of arms. Abdullah Kutab Sháh was preparing an entertainment for Aurangzeb's reception, when he suddenly advanced as an enemy, and took the king so completely by surprise that he had only time to flee to the hill-fort of Golconda, whilst Hyderabad fell into the hands of the Mughals, and was plundered and half burned before the troops could be brought into order. Abdullah did all in his power to negotiate reasonable terms, but the Mughals were inexorable, and he was at last forced to accept the severe conditions imposed on him.

Abdullah died in 1672, and was succeeded by his son-in-law Abú Husáin, who in his youth had been notorious for dissipated habits. He fell entirely under the influence of a Marhattá Bráhman, named Madhuna Panth, who became his prime minister. During this reign Aurangzeb again marched upon the city. The king shut himself in the fort of Golconda, and Hyderabad was again left open to plunder. Madhuna Panth was killed in a popular tumult, and the king accepted such terms as he could obtain. A payment of £2,000,000 sterling in money and jewels was demanded. In 1687 Aurangzeb formally declared war against Abú Husáin. The king bravely defended the fort of Golconda, but lost it by treachery, and was sent a captive to Daulatábád, where he resided until his death. Abú Husáin was a very popular monarch, and many anecdotes of his virtue are still current in the Deccan. Aurangzeb immediately took possession of all the territories of Bijápur and Golconda, but his occupation was little more than military.

No event of any importance occurred at Hyderabad until 1707, the year of Aurangzeb's death, when a dispute for the crown took place. His son, Prince Muazím, was victorious, and ascended the throne as Bahádur Sháh. After he made a truce with the Marhattás, affairs in the Deccan remained quiet until the end of his reign, in 1712. His death was followed by struggles amongst his sons. A battle ensued; Azím-ush-Shán was slain, and Jalándhar Sháh remained master of the throne. Among those he could not get into his power was Farrukh Siyyar, the only son of Azím-ush-Shán; but the cause of this prince was espoused by the governor of Behar, Sayyid Husáin Alí. The rivals met near Agra; and on the 1st January 1713 Farrukh Siyyar ascended the throne, and conferred dignities upon all his adherents. Among these was Chin-Kilich Khán, to whom was given the title of Nizám-ul-Mulk Asaf Jáh, and Sayyid Husáin Alí was appointed viceroy of the Deccan. In 1719 Husáin Alí and Sayyid Abdullah Khán, his brother, advanced upon Delhi, and soon their troops took possession of the royal citadel and palace. Farrukh Siyyar was deposed, and two months later put to death. The Sayyids now (1719) selected Muhammad Sháh, who was the last emperor that sat on the Peacock throne of Sháh Jahán. In 1720 Husáin Alí was assassinated, and at the end of the year Abdullah Khán was defeated and taken prisoner by Muhammad Sháh; but the power of this monarch was fast declining. In 1722 Chin-Kilich Khán, also called Asaf Jáh, arrived at Delhi, and assumed the office of vizier. In 1723 he resigned his post, and set off for the Deccan, a proceeding amounting to a declaration of independence. The emperor sent orders to Mobaríz, the local governor of Hyderabad to assume the government of the entire Deccan. Asaf was forced to come to open war, and soon gained a decisive victory over Mobaríz, who lost his life in the battle, fought in October 1724. He then fixed his residence at Hyderabad, and became the founder of an independent kingdom, now ruled over by his descendants, who derive from him the title of the Nizáms of Hyderabad state.

HYDERABAD, or HAIDARÁBÁD, a British district in the commissionership of Sind, India, lying between 24° 13′ and 27° 15′ N. lat., and between 67° 51′ and 69° 22′ E. long., with an area of 9053 square miles. It is bounded N. by Kairpur state, E. by Thar and Párkar political superintendency, S. by the same tract and the river Kori, and W. by the river Indus and Karáchí district. The district is a vast alluvial plain, 216 miles long and 48 broad. Fertile along the course of the Indus, it degenerates towards the east into sandy wastes, sparsely populated, and defying cultivation. The monotony is relieved by the fringe of forest which marks the course of the river, and by the avenues of trees that line the irrigation channels which branch eastward from this stream. The south of the district has a special feature in its large natural water-courses (called *dhoras*) and basin-like shallows (*chhaus*), which retain the rains for a long time. A limestone range called the Gánga and the pleasant frequency of garden lands break the monotonous landscape. The soil, wherever irrigated, is very fertile. Very few species of the large wild animals are found; among birds, the bustard alone is remarkable. Venomous reptiles abound. The Indus supplies a large variety of fish, one of which, the *pala*, is peculiar to the river.

Of the total area of the district about one-half is uncultivable; 2,300,000 acres are cultivable though not cultivated, and 566,800 are under irrigation. Agriculture is entirely dependent upon artificial irrigation, and is looked upon as a lottery, in which the cultivator stakes a certain amount of labour and seed, and takes his chance of getting a return. If the water rises either too high or not high enough, he loses his crop. There are 317 canals, fifty of which are main channels, and tap the Indus direct; the remainder are connecting branches. The principal crops are wheat, barley, oil-seeds, pulses, vegetables, *joár*, *bájra*, *til*, rice, cotton, sugar-cane, *chana*, hemp, tobacco, water-melons, and indigo. The manufactures of the district maintain the excellence for which they have been famous from early times, namely, that for lacquered work, gold and silver embroidery, striped and brilliant cloths known as *süsis* and *rhesis*, and glazed pottery. The manufacture of carpets, silk thread, and gold and silver ornaments is carried on to a large extent; salt also is produced in such quantities as to allow of a considerable exportation. The total number of fairs is 33, and the average attendance about 5000. The roads of the district extend to 1925 miles in length, of which 263 are metalled, bridged, and marked with milestones. The ferries number 68; the one at Gidu-Bandar (3½ miles from Hyderabad) is a steam ferry connecting Hyderabad with Kotri, on Sind Railway. There are 10 travellers' bungalows, 16 *dharmsálás*, 4 dispensaries, a civil and police hospital, a convict hospital, and a charitable dispensary.

Considerable variations of climate are found within the district. In the north, the hot season of April and May is followed by two months of floods, the rest of the year being cold and dry. In the central divisions, the cold season succeeds the hot without any intervening inundations to graduate the transition; and the change occurs sometimes with such suddenness that, to quote a local saying, "sunstroke and frost-bite are possible in one and the same day." In the south the temperature is more equable throughout the year, 60° F. and 100° F. representing the extremes. The rainfall is very moderate; and the district is healthy as compared with other parts of India.

The population is divided as follows:—Mahometans, 560,349; Hindus, 118,652; other creeds and tribes, 44,882;—total, 723,883. Of the Mahometans 373,705, or more than three-fifths, are Sinds. More important, however, as regards social status and personal character, are the Patháns, found chiefly about Hyderabad and Upper Sind; they number only 15,815 persons. As regards occupation, the Hindus of the district may be called the shopkeeping class, the Mahometans the artisan and agricultural.

The chief revenue and magisterial authority is vested in a collector and magistrate. He is assisted by the four deputy collectors of Hála, Tando Muhammad Khan, Naushahro, and Hyderabad *táluks*, of which the district is composed. The police force is under the charge of a European district superintendent, and comprises a total of 876 men, with 4 inspectors and 19 chief constables. The average land revenue for 6 years (1868–74) was £111,655; drug revenue (1873–74), £5304; receipts from the farming of liquor-shops (1873–74), £9640; imperial revenue (1874), £144,944; local revenue (1874), £12,434; forests yield an annual revenue of £11,216. The Government boys' schools numbered 55 in 1874, with 3227 pupils; the girls' schools 12, with 368 pupils. These figures include the returns for the high, normal, engineering, and Anglo-vernacular schools in Hyderabad city.

The local history of Hyderabad district is so mixed up with that of the province that little could be said of it separately which will not more properly find a place under the history of Sind. The battles of Miani (Meeanee) and Dabo, which decided the fate of Sind in favour of the British, were fought within its limits.

Hyderabad, the chief town of the above district, in 25° 23′ 5″ N. lat. and 68° 24′ 51″ E. long., had in 1872 a population of 35,272, of whom 13,065 were Mahometans, 16,889 Hindus, 367 Christians, and 4951 "others." The municipal area is about 15 square miles. Upon the site of the present fort is supposed to have stood the ancient town of Neránkot, which in the 8th century submitted to Muhammad Kásim Sakífí. Its situation near the apex of the delta of the Indus had commended itself to invaders and conquerors of still earlier date. It is identified with Patala, a town which has been connected with a prehistoric Scythian migration into India (*c.* 625 B.C.?). Alexander the Great founded or refounded a city called Patala in or near the same place, 325 B.C., and left in it a military settlement. The best archæological authorities regard the modern Hyderabad as the representative of this Patala of the Greeks. In 1768 the present city was founded by Ghulám Sháh Kalhora; and it remained the chief town of the province until 1843, when, after the battle of Meeanee, it was surrendered to the British, and the capital transferred to Kurrachee (Karáchi). The city is built on the most northerly hills of the Gánga range, a site of great natural strength. In the fort, which covers an area of 36 acres, are the arsenal of the province, transferred hither from Kurrachee in 1861, and the residences of the ex mírs of Sind. Hyderabad is the centre of all the provincial communications—road, telegraphic, postal. From the earliest times its manufactures—ornamented silks, silver and gold work, and lacquered ware—have been the chief of the province, and in recent times have gained prizes at the industrial exhibitions of Europe. The chief public institutions and buildings are the jail, Government schools, post-office, municipal markets, court-houses, civil and police hospital, charitable dispensary, library, travellers' bungalow, and lunatic asylum. The barracks—occupied by artillery and infantry, European and native—are built in twelve blocks, with hospitals, bazaar, &c., to the north-west of the city. The only noteworthy antiquities are the tombs of the Kabhora and Tálpur mírs.

HYDRA (the name is also found as Sidra, Nidra, Idero, &c., and the ancient form was Hydrea), an island of Greece, lying about 4 miles off the south-east coast of Argolis in the Peloponnesus, and forming along with the neighbouring island of Dhoko the Bay of Hydra. The length of the main axis of the island, which runs from south-west to north-east, is about 11 miles, and the area is about 21 square miles; but it is little better than a rocky and treeless ridge with hardly a patch or two of arable soil. There was little exaggeration in the reply made by Antonios Kriezes to the queen of Greece: "The island produces prickly pears in abundance, splendid sea captains, and excellent prime ministers." The highest point, Mount Ere, so called (according to Miaoules) from the Albanian word for wind, has an elevation of 1958 feet. The next in importance is known as the Prophet Elias, from the large convent of that name on its summit. It was there that the patriot Theodorus Colocotronis was imprisoned, and a large pine tree is still called after him. The fact that in former times the island was richly clad with woods is indicated by the name still employed by the Turks, *Tchamliza*, the place of pines; but it is only in some favoured spots that a few trees are now to be found. Tradition also has it that it was once a well-watered island (hence the designation Hydrea), but the inhabitants are now wholly dependent on the rain supply, and they have sometimes had to bring water from the mainland. This lack of fountains is probably to be ascribed in part to the effect of earthquakes, which are not infrequent; that of 1769 continued for six whole days. Hydra, the chief town, is built near the middle of the northern coast, on a very irregular site, consisting of three hills and the intervening ravines. From the sea its white and handsome houses present a picturesque and noble appearance, and its streets though narrow are clean and attractive. Besides the principal harbour, round which the town is built, there are three other ports on the north coast—Mandraki, Molo, Panagia, but none of them is sufficiently sheltered. Almost all the population of the island is collected in the chief town, which is the seat of a bishop, and has a local court, numerous churches, and a high school. Cotton and silk weaving, tanning, and ship-building are carried on, and there is a fairly active trade. The population in 1877 was 6811.

Hydra was of no importance in ancient times. The only fact in its history is that the people of Hermione (a city on the neighbouring mainland now known by the common name of *Kastri*) surrendered it to Samian refugees, and that from these the people of Trœzen received it in trust. It appears to be completely ignored by the Byzantine chroniclers. In 1580 it was chosen as a refuge by a body of Albanians from Kokkinyas in Trœzenia; and other emigrants followed in 1590, 1628, 1635, 1640, &c. At the close of the 17th century the Hydriotes took part in the reviving commerce of the Peloponnesus; and in course of time they extended their range. About 1716 they began to build *sakturia* (of from 10 to 15 tons burden), and to visit the islands of the Ægean; not long after they introduced the *latinadika* (40-50 tons), and sailed as far as Alexandria, Constantinople, Trieste, and Venice; and by and by they ventured to France and even America. From the grain trade of South Russia more especially they derived great wealth. In 1813 there were about 22,000 people in the island, and of these 10,000 were seafarers. At the time of the outbreak of the war of Greek independence the total population was 28,190, of whom 16,460 were natives and the rest foreigners. One of their chief families, the Konduriotti, was worth £2,000,000. Into the struggle the Hydriotes flung themselves with rare enthusiasm and devotion, and the final deliverance of Greece was mainly due to the service rendered by their fleets.

D. Kriezes, *Ιστορια της νησου Υδρας*, Patras, 1860.

HYDRANGEA, a popular flower much in request for the decoration of conservatories during the late summer season, many thousands being annually produced for the London market. The plant to which the name is most commonly applied is the *Hydrangea Hortensia*, a low deciduous shrub, producing rather large oval strongly-veined leaves in opposite pairs along the stem. It is terminated by a massive globular corymbose head of flowers, which remain a long period in an ornamental condition. The normal colour of the flowers, the majority of which have neither stamens nor pistil, is pink; but by the influence of sundry agents in the soil, such as alum or iron, they become changed to blue. The part of the inflorescence which appears to be the flower is an exaggerated expansion of the calyx-leaves, the other parts being generally abortive. The perfect flowers are small, rarely produced in the species above referred to, but well illustrated by others, in which they occupy the inner parts of the corymb, the larger showy neuter flowers being produced at the circumference. A pure white variety, named Thomas Hogg, has been recently introduced, and is a very desirable plant.

There are upwards of thirty species, found chiefly in Japan, in the mountains of India, and in North America, and many of them are familiar in gardens. *H. Hortensia* is the most useful for decoration, as the head of flowers lasts long in a fresh state, and by the aid of forcing can be had for a considerable period for the ornamentation of the greenhouse and conservatory. Their natural flowering season is towards the end of the summer, but they may be had earlier by means of forcing. *H. japonica* is another fine conservatory plant, with foliage and habit much resembling the last-named, but this has flat corymbs of flowers, the central ones small and perfect, and the outer ones only enlarged and neuter. This also produces pink or blue flowers under the influence of different soils.

The Japanese species of hydrangea are sufficiently hardy to grow in any tolerably favourable situation, but except in the most sheltered localities they seldom blossom to any degree of perfection in the open air, the head of blossom depending on the uninjured development of a well-ripened terminal bud, and this growth being frequently affected by late spring frosts. They are much more useful for pot-culture indoors, and should be reared from cuttings of shoots having the terminal bud plump and prominent, put in during summer, these developing a single head of flowers the succeeding summer. Somewhat larger plants may be had by nipping out the terminal bud and inducing three or four shoots to start in its place, and these, being steadily developed and well-ripened, should each yield its inflorescence in the following summer, that is, when two years old. Large plants grown in tubs and vases are fine subjects for large conservatories, and may be used for decorating terrace walks and similar places during summer, being housed in winter, and started under glass in spring.

The Indian and American species, especially the latter, are quite hardy, and some of them are extremely effective. The finest of these by far is the *Hydrangea paniculata grandiflora*, the branched inflorescence of which is under favourable circumstances a yard or more in length, and consists of large spreading masses of crowded white neuter flowers which completely conceal the few inconspicuous fertile ones. The plant attains a height of 8 to 10 feet, and when in flower late in summer and in autumn is a very attractive object in the shrubbery.

HYDRAULICS. See HYDROMECHANICS.

HYDROCEPHALUS (ὕδωρ, water, κεφαλή, the head), a term in medicine applied to two different forms of disease of the brain, both of which are attended with the effusion of fluid into its cavities. They are named respectively *Acute* and *Chronic Hydrocephalus*. They have different pathological associations, and have no necessary connexion with each other.

Acute Hydrocephalus is the term still largely employed to describe the disease now known to physicians as tubercular cerebral meningitis, that is, inflammation of the membranes of the brain produced by the presence of tubercle. This disease is most common in children under ten years of age, but is by no means limited to that period of life, and may affect adults. The scrofulous or tubercular constitution is an important factor in this malady, which is admitted to be one of strongly hereditary tendency; yet unquestionably there are many instances in which no such taint can be traced. In numerous cases it is manifestly connected with bad hygienic conditions, with insufficient or improper feeding, or with over exercise of the mental powers, all of which will doubtless more readily exert their influence where an inherited liability exists, and the same may be said regarding its occasional occurrence as one of the after consequences of certain of the diseases of childhood, especially measles and hooping-cough.

Acute hydrocephalus is usually described as passing through certain stages; but it must be observed, as regards at least its earlier manifestations, that, so far from being well defined, they are often exceedingly vague, and render this disease in an especial manner liable to escape detection for a length of time, or to be confounded with others to which at its commencement it bears an acknowledged resemblance, such, for instance, as typhoid fever or gastro-intestinal derangements. Nevertheless, there are certain typical features characterizing the disease in each of its stages which it is important to describe, as in many instances these present themselves with greater or less distinctness.

The premonitory symptoms of acute hydrocephalus are mostly such as relate to the general nutrition. A falling off in flesh and failure of strength are often observed for a considerable time before the characteristic phenomena of the disease appear. The patient, if a child, becomes listless and easily fatigued, loses appetite, and is restless at night. There is headache after exertion, and the temper often undergoes a marked change, the child becoming unusually peevish and irritable. These symptoms may persist during many weeks; but on the other hand such premonitory indications may be entirely wanting, and the disease be developed to all appearance quite suddenly.

The onset is in most instances marked by the occurrence of vomiting, often severe, but sometimes only slight, and there is in general obstinate constipation. In not a few cases the first symptoms are convulsions, which, however, may in this early stage subside, and remain absent, or reappear at a later period. Headache is one of the most constant of the earlier symptoms, and is generally intense and accompanied with sharper paroxysms, which cause the patient to scream, with a peculiar and characteristic cry. There is great intolerance of light and sound, and general nervous sensitiveness. Fever is present to a greater or less extent, the temperature ranging from 100° to 103° Fahr.; yet the pulse is not quickened in proportion, being on the contrary rather slow, but exhibiting a tendency to irregularity, and liable to become rapid on slight exertion. The breathing, too, is somewhat irregular. Symptoms of this character, constituting the stage of excitement, continue for a period varying from one to two weeks, when they are succeeded by the stage of depression. There is now a marked change in the symptoms, which is apt to lead to the belief that a favourable turn has taken place. The patient becomes quieter and inclines to sleep, but it will be found on careful watching that this quietness is but a condition of apathy or partial stupor into which the child has sunk. The vomiting has now ceased, and there is less fever; the pulse is slower, and shows a still greater tendency to irregularity than before, while the breathing is of markedly unequal character, being rapid and shallow at one time, and long drawn out and sinking away at another. There is manifestly little suffering, although the peculiar cry may still be uttered, and the patient lies prostrate, occasionally rolling the head uneasily upon the pillow, or picking at the bedclothes or at his face with his fingers. He does not ask for food, but readily swallows what is offered. The countenance is pale, but is apt to flush up suddenly for a time. The eyes present important alterations, the pupils being dilated or unequal, and scarcely responding to light. There may be double vision, or partial or complete blindness. Squinting is common in this stage, and there may also be drooping of an eyelid, due to paralysis of the part, and one or more limbs may be likewise paralysed.

To this succeeds the third or final stage, in which certain of the former symptoms recur, while others become intensified. There is generally a return of the fever, the temperature rising sometimes to a very high degree. The pulse becomes feeble, rapid, and exceedingly irregular, as is also the case with the breathing. Coma is profound, but yet the patient may still be got to swallow nourishment, though not so readily as before. Convulsions are apt to occur, while paralysis, more or less extensive, affects portions of the body or groups of muscles. The pupils are now widely dilated, and there is generally complete blindness and often deafness. In this condition the patient's strength undergoes rapid decline, and the body becomes markedly emaciated. Death takes place either suddenly in a fit, or more gradually from exhaustion. Shortly before the fatal event it is not uncommon for the patient, who, it may be for many days previously, lay in a state of profound stupor, to awake up, ask for food, and talk to those around. But the hopes which may thus be raised are quickly dispelled by the setting in of the symptoms of rapid sinking.

The duration of a case of acute hydrocephalus varies somewhat, but in general death takes place within three weeks from the onset of the symptoms. The disease may be said to be almost invariably fatal, yet it must be admitted that cases presenting all the principal symptoms of acute hydrocephalus do occasionally recover, though such instances are undoubtedly very rare. Indeed, the condition of the brain in this disease, as revealed on *post mortem* examination, renders its fatal character in no way surprising. The peculiar formation called tubercle is found deposited in the membranes of the brain, more particularly at its base. The irritation set up as a consequence of this is accompanied with the effusion of fluid into the arachnoid and ventricles, which by its pressure tends to produce softening and destruction of the brain substance, and hence to abolish its functions. In many instances the brain is found to be reduced to a state of complete disorganization.

Besides this condition of the brain, there exists in most cases deposition of tubercle elsewhere, as in the lungs and abdominal glands, and this may have given evidence of its presence even before the head symptoms had appeared. This is especially the case in adults, in whom acute hydrocephalus is more apt to arise as a complication in the course of pulmonary or other disease of tubercular origin than in the manner in which it occurs in children as above described.

With respect to treatment, little can be stated of an encouraging nature. Still it must be observed that much may be done in the way of prevention of this disease, and, in its earlier stages, even in the way of cure. It is most important in families where the history indicates a tuberculous or scrofulous tendency, and particularly where acute hydrocephalus has already occurred, that every effort should be used to fortify the system and avoid the causes already alluded to as favouring the development of the disease during that period in which children are liable to suffer from it. With this view wholesome food, warm clothing, cleanliness, regularity, and the avoidance of overexertion, physical and mental, are of the utmost consequence.

Although there is but little that can be done when the disease has set in, yet the timely use of remedies may mitigate and even occasionally remove the symptoms. The severe headache may often be relieved by the application of one or two leeches to the temples, and by the frequent use of cold water or ice applied to the head. The treatment by blistering the scalp and administering mercury, formerly so much practised, is now acknowledged to be of no real efficacy; and on the whole the maintenance of the patient's strength by light nourishment and the use of sedatives to compose the nervous system are the measures most likely to be attended with success. The bromide, with which may be combined the iodide of potassium, is the medicinal agent of most value for this purpose. Should convulsions occur, they are best treated by chloral or chloroform.

Chronic Hydrocephalus is a different form of disease from that last described, both as regards its pathology and its effects. It consists in an effusion of fluid into the serous cavities (arachnoid and ventricles) of the brain, not preceded by tuberculous deposit or acute inflammation, but apparently depending on chronic inflammatory changes affecting the membranes, and is to be regarded as a kind of dropsy. The disease is frequently congenital, and its presence in the fœtus is apt to be a source of difficulty in parturition. It is, however, more commonly developed in the course of the first six months of life; but it occasionally arises in older children, or even in adults, as in the well-known instance of Dean Swift, who died from this disease.

Chronic hydrocephalus affects mostly children who bear evidence of a scrofulous, ricketty, or otherwise delicate constitution. The chief symptoms observed are the gradual increase in size of the upper part of the head out of all proportion to the face or the rest of the body. Occurring at an age when as yet the separate bones constituting the skull have not become welded, this enlargement may go on to a very considerable extent in all directions, but chiefly in the transverse and antero-posterior diameters, the spaces between the bones becoming more and more expanded, though ultimately, should the child survive, ossification takes place. In a well-marked case the deformity is very striking. The upper part of the forehead projects abnormally, and the orbital plates of the frontal bone being inclined forwards give a downward direction to the eyes, which have also peculiar rolling movements. The face is small, and this, with the enlarged head, gives a remarkably aged expression to the child. There is generally defective development in other respects, the body being ill nourished, the bones thin, the hair scanty and fine, and the teeth carious or absent.

As illustrating the extent to which this disease may proceed, it may be mentioned that the average circumference of the adult head is about 22 inches, while in the child it is of course considerably less. In chronic hydrocephalus the head of an infant three months old has been known to measure 29 inches; and in the well-known case of the man Cardinal, who died in Guy's Hospital, the head measured 33 inches. In the museum of the faculty of medicine in Paris there is a hydrocephalic skull measuring 39 inches. In aggravated cases the head cannot be supported by the neck, and the patient has to keep in the recumbent posture. The expansibility of the skull prevents destructive pressure on the brain, yet this organ is materially affected by the presence of the fluid. The cerebral ventricles are widely distended, and the convolutions flattened, while occasionally the fluid escapes into the cavity of the cranium, which it fills, pressing down the brain to the base of the skull. As a consequence of such changes, the functions of the brain are interfered with, and in general the mental condition of the patient is impaired to a greater or less extent. The child is dull and listless, irritable, and sometimes imbecile. The special senses become affected as the disease advances, especially vision, and sight is often lost, as is also hearing. Towards the close paralysis is apt to occur. Hydrocephalic children rarely live long, generally dying from the malady in a few years, or succumbing to some of the disorders of childhood, which they are little able to resist. Nevertheless there have been many instances of persons with this disease reaching maturity, and even living to old age. It must also be borne in mind that there are grades of this affection, and that children may present many of the symptoms of it in a comparatively slight degree, and yet recover, the head ceasing to expand, and becoming firmly ossified.

Various methods of treatment have been employed in this disease, but the results are seldom satisfactory. Compression of the head by bandages, and the administration of mercury with the view of promoting absorption of the fluid, are now little resorted to. Tapping the fluid from time to time through one of the spaces between the bones, drawing off a little, and thereafter employing gentle pressure, has been tried, but seldom with permanent benefit. On the whole, the plan of treatment which aims at maintaining the patient's nutrition by appropriate food and tonics, is at once the most rational and successful, provided it be resorted to in time to admit of the arrest of the progress of the symptoms. (J. O. A.)

HYDROGEN (from ὕδωρ, water, and γεννάω, to generate) is a chemical element which in the free state occurs in volcanic gases, but exists for the most part in combination with oxygen as water. As its elemental characteristics and the chief compounds of hydrogen have already been described in the article CHEMISTRY, vol. v. pp. 478, 483, 491, 499, 544, &c., it is here only necessary to refer to the liquefaction of gaseous hydrogen.[1]

At the close of 1877 and in the beginning of 1878, not only hydrogen, but all the so-called permanent gases, were reduced to the liquid state, an achievement the more remarkable as it was the result of the simultaneous but entirely independent labours of two distinguished physicists, M. Cailletet of Châtillon-sur-Seine and M. Pictet of Geneva. The experiments of the former, who clearly demonstrated the possibility of liquefying acetylene, carbonic oxide, hydrogen, methane, nitric oxide, nitrogen, and oxygen, are described in detail in the *Annales de Chimie et de Physique*, ser. 5, vol. xv. p. 132; those of M. Pictet, who operated only upon oxygen and hydrogen, are detailed in the same journal, ser. 5, vol. xiii. p. 145. The instrumental means employed by them were very different, as will be evident from the following description.

M. Cailletet's apparatus is represented in the annexed sketch (fig. 1). The gas under experiment is contained in a stout glass tube of narrow bore of the form shown in fig. 2.

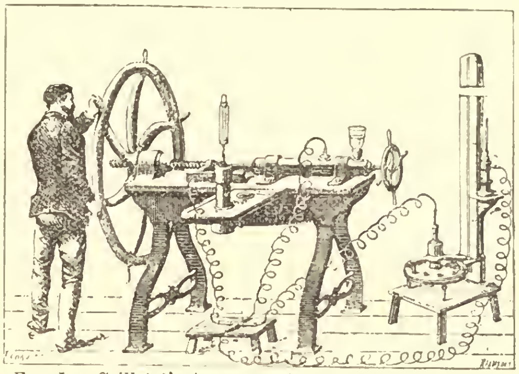

FIG. 1.—Cailletet's Apparatus for Liquefaction of Gases.

To fill this tube with gas, both ends being open, a globule of mercury is first introduced at the lower curved extremity; the tube is then placed in a nearly horizontal position, the curved extremity is connected with the holder containing the gas, or with the apparatus in which the gas is being evolved, by means of caoutchouc tubing, and a current of the pure dry gas is passed through the tube until the air is entirely expelled; this being effected, the point opposite to the curved extremity is sealed in the blowpipe flame; the tube is then brought into a vertical position, so that the globule of mercury closes the lower extremity, the caoutchouc tube is withdrawn, and the tube AA thus filled is screwed into its place in the cylinder B. The lower part of the cylinder contains mercury, the upper part water. The pressure is exerted by forcing a plunger into a massive steel cylinder filled with water by means of the screw and wheel seen on the left in fig. 1, the water being forced from this cylinder through the fine coiled tube into the upper part of the cylinder in which the glass tube is fixed; by rapidly turning the wheel seen on the right of the figure, a valve may be opened, allowing of the escape of the water, and thus the pressure on the gas may be suddenly withdrawn. The pressure to which the gas is submitted is measured by means of either of the manometers seen on the right. The gas may be cooled by surrounding the tube A with liquid sulphur dioxide, carbon dioxide, or nitrous oxide, and the deposition of ice on the outside of the cylinder containing the refrigerating liquid is prevented by covering it with a glass cylinder or bell jar, under which is placed some desiccating material. By strongly compressing a gas in this apparatus, and then suddenly relieving it from pressure, an enormous reduction in its temperature is effected, owing to the sudden expansion of the gas, and it is under these circumstances that liquefaction takes place in cases where pressure alone is ineffective. On submitting hydrogen to a pressure of nearly 300 atmospheres, and then suddenly withdrawing the pressure, M. Cailletet observed the formation of a fine mist in the interior of the tube; the experiments of Andrews and his own previous observations had shown that this result afforded incontestable proof of the presence of liquid, if not of solid, particles.

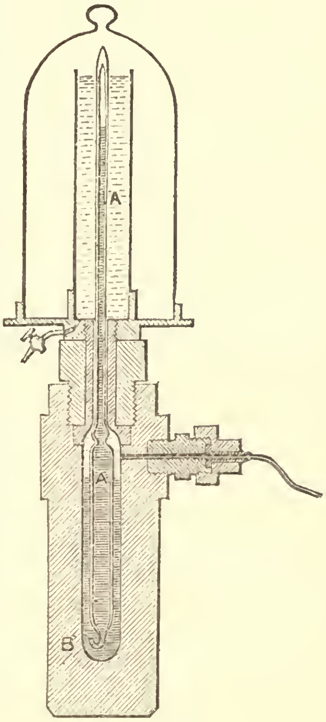

Fig. 2.

[1] The statement in the article CHEMISTRY, vol. v. p. 479, that hydrogen has never been liquefied, was true at the date of publication.

The general disposition of M. Pictet's apparatus is seen in fig. 3. It is of a much more complex character, but permits of the experiment being made on a comparatively very large scale. The condensation of the gas is effected in a copper tube of narrow bore,

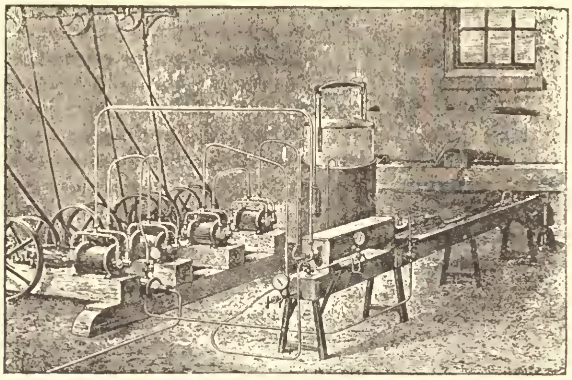

FIG. 3.—Pictet's Apparatus for Liquefaction of Gases.

connected at the one end with a manometer capable of indicating pressures up to 800 atmospheres, and with a fine steel stop-cock, and at the other with a very strong wrought-iron vessel in which the hydrogen is generated by heating a perfectly dry mixture of potassium formate with potassium hydroxide; these two substances enter into reaction in accordance with the equation $HCOOK + HOK = K_2CO_3 + H_2$, the hydrogen being evolved in a perfectly regular manner when the temperature is maintained at 225°. The dimensions of the condensation tube are—internal diameter ·001 metre, external diameter ·015 metre, length 4·16 metres; and the retort has a capacity of 1659 cubic centimetres. The charge introduced consisted of 500 grammes potassium hydroxide and 1251 grammes potassium formate. The condensation tube is surrounded with a wider tube containing condensed carbon dioxide or nitrous oxide; these tubes are enclosed in the lower box seen in the sketch. The upper box contains a tubular arrangement in which carbon dioxide or nitrous oxide from the gasholder is reduced to the liquid state. The pumps are such as are used in ice-making machines, one of each pair being an exhausting, the other a condensing pump; one pair of these pumps is employed in condensing and volatilizing the sulphur dioxide, and the other in condensing and volatilizing the carbon dioxide or nitrous oxide. Figs. 4 and 5 show the apparatus in vertical section and in plan.

In working the apparatus, in the first place liquid sulphur dioxide from the reservoir seen between the first pair of pumps is charged into the outer tube of the condenser in the upper box, and is caused rapidly to evaporate by the action of the exhausting pump in connexion with the tube, while the other pump serves to recondense it in the reservoir, which is a kind of tubular boiler provided with a cold water circulation. The temperature of the liquid sulphur dioxide is thus reduced to − 65° C.; on allowing the carbon dioxide or

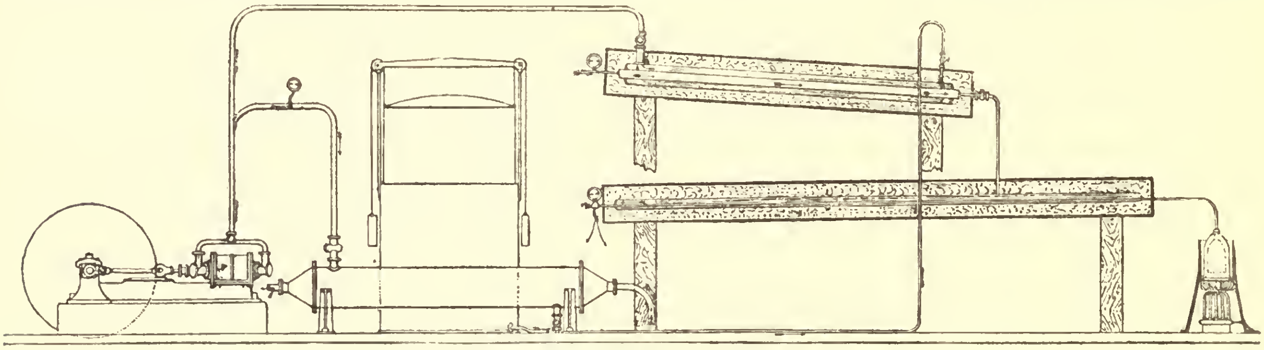

FIG 4.—Vertical Section of Pictet's Apparatus.

nitrous oxide to enter the inner tube of the condenser thus cooled, it begins to liquefy under a pressure of about 4 atmospheres, and the condensation of the whole of the gas is effected at a pressure of from 4 to 7 atmospheres, the temperature of the liquid sulphur dioxide fluctuating between − 65° and − 50°. The liquid carbon dioxide (or nitrous oxide) thus obtained is then allowed to pass into the tube surrounding the condensation tube, and by the action of the second exhausting pump it is caused to evaporate so quickly that it solidifies. The temperature may thus be reduced to − 120° or even − 140°.

In describing his first experiment with hydrogen with this apparatus, M. Pictet states that the pressure, having risen gradually during about 40 minutes, became stationary at about 650 atmospheres; on then opening the stop-cock, the orifice being illuminated by a powerful electric light, an opaque jet of a highly characteristic steel-blue tint was seen to issue forth. At the same moment, a sharp hissing noise like that produced on plunging a red-hot bar of iron into water was heard, and simultaneously a highly

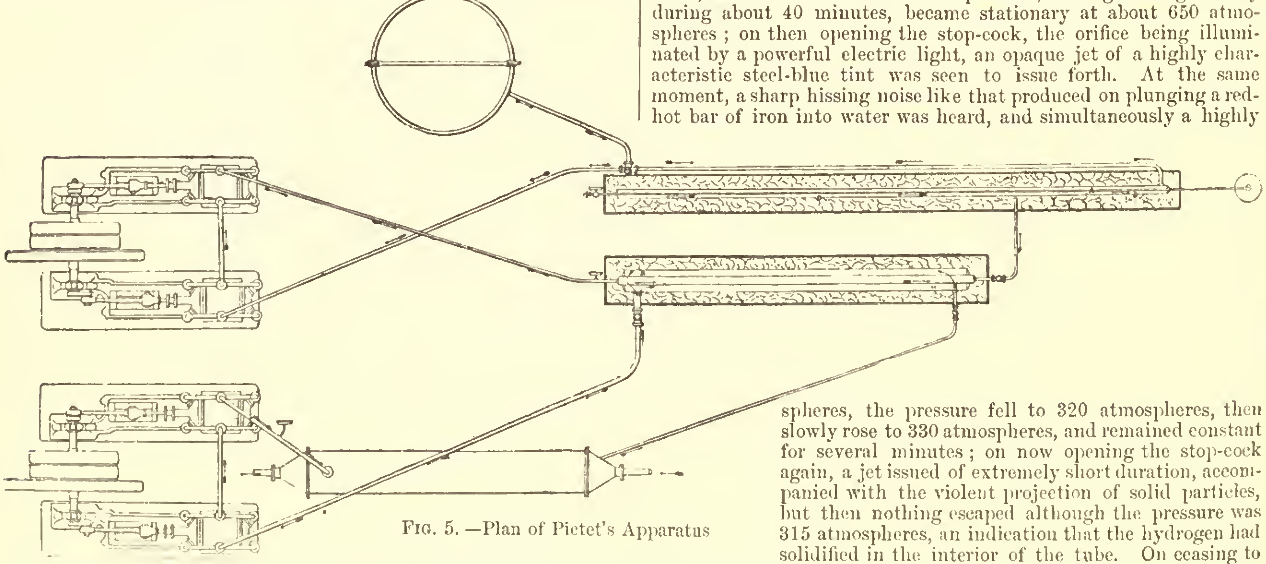

FIG. 5.—Plan of Pictet's Apparatus

characteristic rustling noise on the ground, recalling the sound of small seed falling. Moreover, the jet was not continuous as in the case of oxygen, but intermittent, each projection of matter being attended with the peculiar rustling noise alluded to; in fact, owing to the great reduction in temperature, due to the sudden volatilization of the liquid, portions became solidified in the tube. On closing the stop-cock after several seconds, the pressure being still 370 atmospheres, the pressure fell to 320 atmospheres, then slowly rose to 330 atmospheres, and remained constant for several minutes; on now opening the stop-cock again, a jet issued of extremely short duration, accompanied with the violent projection of solid particles, but then nothing escaped although the pressure was 315 atmospheres, an indication that the hydrogen had solidified in the interior of the tube. On ceasing to aspirate from the tube surrounding the condensation tube, and thus allowing the temperature of the latter to rise somewhat, discharges took place with increasing frequency, until after about a quarter of an hour the pressure fell to zero.

Pictet thus succeeded in liquefying and solidifying hydrogen on January 10th, 1878, Cailletet having demonstrated its liquefaction on December 30th previously.

HYDROMECHANICS

Historical Introduction.[1]

The word *Hydromechanics* is derived from the Greek ὑδρο-μηχανικά, meaning the mechanics of water and fluids in general. The science is divided into three branches:—*Hydrostatics*, which deals with the equilibrium of fluids; *Hydrodynamics*, which deals with the mathematical theory of the motion of fluids, neglecting the viscosity; and *Hydraulics*, in which the motion of water in pipes and canals is considered, and hydrodynamical questions of practical application are investigated.

The science of hydromechanics was cultivated with less success among the ancients than any other branch of mechanical philosophy. When the human mind had made considerable progress in the other departments of physical science, the doctrine of fluids had not begun to occupy the attention of philosophers; and, if we except a few propositions on the pressure and equilibrium of water, hydromechanics must be regarded as a modern science, which owes its existence and improvement to these great men who adorned the 17th and 18th centuries.

rchi-edes. Those general principles of hydrostatics which are to this day employed as the foundation of that part of the science were first given by Archimedes in his work Περὶ τῶν ὀχουμένων, or *De iis quæ vehuntur in humido*, about 250 B.C., and were afterwards applied to experiments by Marinus Ghetaldus in his *Promotus Archimedes* (1603). Archimedes maintained that each particle of a fluid mass, when in equilibrium, is equally pressed in every direction; and he inquired into the conditions according to which a solid body floating in a fluid should assume and preserve a position of equilibrium. We are also indebted to him for that ingenious hydrostatic process by which the purity of the precious metals can be ascertained, and for the screw engine which goes by his name.

ex-drian iool. In the Greek school at Alexandria, which flourished under the auspices of the Ptolemies, the first attempts were made at the construction of hydraulic machinery. About 120 B.C. the fountain of compression, the siphon, and the forcing pump were invented by Ctesibius and Hero; and, though these machines operated by the pressure of the air, yet their inventors had no distinct notions of the preliminary branches of pneumatical science. The siphon is a simple instrument; but the forcing pump is a complicated and abstruse invention, which could scarcely have been expected in the infancy of hydraulics. It was probably suggested to Ctesibius by the *Egyptian Wheel* or *Noria*, which was common at that time, and which was a kind of chain pump, consisting of a number of earthen pots carried round by a wheel. In some of these machines the pots have a valve in the bottom which enables them to descend without much resistance, and diminishes greatly the load upon the wheel; and, if we suppose that this valve was introduced so early as the time of Ctesibius, it is not difficult to perceive how such a machine might have led that philosopher to the invention of the forcing pump.

Notwithstanding these inventions of the Alexandrian school, its attention does not seem to have been directed to the motion of fluids. The first attempt to investigate this subject was made by Sextus Julius Frontinus, inspector of the public fountains at Rome in the reigns of Nerva and Trajan; and we may justly suppose that his work, entitled *De Aquæductibus Urbis Romæ Commentarius*, contains all the hydraulic knowledge of the ancients. After describing the nine [2] great Roman aqueducts, to which he himself added five more, and mentioning the dates of their erection, he considers the methods which were at that time employed for ascertaining the quantity of water discharged from ajutages, and the mode of distributing the waters of an aqueduct or a fountain. He justly remarks that the flow of water from an orifice depended not only on the magnitude of the orifice itself, but also on the height of the water in the reservoir; and that a pipe employed to carry off a portion of water from an aqueduct should, as circumstances required, have a position more or less inclined to the original direction of the current. But as he was unacquainted with the true law of the velocities of running water as depending upon the depth of the orifice, we can scarcely be surprised at the want of precision which appears in his results.

It has generally been supposed that the Romans were ignorant of the art of conducting and raising water by means of pipes; but it can scarcely be doubted, from the statement of Pliny and other authors, not only that they were acquainted with the hydrostatical principle, but that they actually used leaden pipes for the purpose. Pliny asserts that water will always rise to the height of its source, and he also adds that, in order to raise water up to an eminence, leaden pipes must be employed.[3]

Castelli and Torricelli, two of the disciples of Galileo, applied the discoveries of their master to the science of hydrodynamics. In 1628 Castelli published a small work, *Della Misura dell' acque correnti*, in which he gave a very satisfactory explanation of several phenomena in the motion of fluids in rivers and canals. But he committed a great paralogism in supposing the velocity of the water proportional to the depth of the orifice below the surface of the vessel. Torricelli, observing that in a jet where the water rushed through a small ajutage it rose to nearly the same height with the reservoir from which it was supplied, imagined that it ought to move with the same velocity as if it had fallen through that height by the force of gravity. And hence he deduced this beautiful and important proposition, that the velocities of fluids are as the square root of the head, allowing for the resistance of the air and the friction of the orifice. This theorem was published in 1643, at the end of his treatise *De Motu gravium Projectorum*. It was afterwards confirmed by the experiments of Raphael Magiotti on the quantities of water discharged from different ajutages under different pressures; and, though it is true only in small orifices, it gave a new turn to the science of hydraulics. Castelli. Torricelli.

After the death of the celebrated Pascal, who discovered the pressure of the atmosphere, a treatise on the equilibrium of fluids (*Sur l'Équilibre des Liqueurs*) was found among Pascal.

[1] This historical sketch of the subject is a revised abridgment of that written by David Buchanan, and prefixed to the article Hydrodynamics in the 8th edition of this work.

[2] These nine aqueducts delivered every day 14,000 quinaria, or about 50,000,000 cubic feet of water, or about 50 cubic feet for the daily consumption of each inhabitant, supposing the population of Rome to have been a million. From measurements of Frontinus at the close of the 1st century, the total length of channels of aqueducts was 285 Roman miles (Roman mile = 1618 English yards). The supply measured by Frontinus amounted to 13,470 quinaries,—outside Rome 3164, inside 10,306. Measured at the head the supply was 24,413 quinaries, the difference being due to waste, and to some of the channels having fallen into decay. Parker says:—"It has been computed by a French engineer that the supply to Rome was 332,306,624 gallons daily. If we assume the population at a million, the rate was 332 gallons daily per person. In our day we consider 40 gallons sufficient, and many think this excessive." Modern supply varies from 24 to 50 gallons per head per day.

his manuscripts, and was given to the public in 1663. In the hands of Pascal hydrostatics assumed the dignity of a science. The laws of the equilibrium of fluids were demonstrated in the most perspicuous and simple manner, and amply confirmed by experiments. The discovery of Torricelli, it may be supposed, would have incited Pascal to the study of hydraulics. But as he has not treated this subject in the work mentioned, it was probably composed before that discovery had been made public.

Mariotte. The theorem of Torricelli was employed by many succeeding writers, but particularly by the celebrated Mariotte, whose labours in this department of physics deserve to be recorded. His *Traité du Mouvement des Eaux*, which was published after his death in the year 1686, is founded on a great variety of well-conducted experiments on the motion of fluids, performed at Versailles and Chantilly. In the discussion of some points he has committed considerable mistakes. Others he has treated very superficially, and in none of his experiments does he seem to have attended to the diminution of efflux arising from the contraction of the fluid vein, when the orifice is merely a perforation in a thin plate; but he appears to have been the first who attempted to ascribe the discrepancy between theory and experiment to the retardation of the water's velocity arising from friction. His contemporary Guglielmini, who was inspector of the rivers and canals in the Milanese, had ascribed this diminution of velocity in rivers to transverse motions arising from inequalities in their bottom. But as Mariotte observed similar obstructions even in glass pipes, where no transverse currents could exist, the cause assigned by Guglielmini seemed destitute of foundation. The French philosopher, therefore, regarded these obstructions as the effects of friction. He supposes that the filaments of water which graze along the sides of the pipe lose a portion of their velocity; that the contiguous filaments, having on this account a greater velocity, rub upon the former, and suffer a diminution of their celerity; and that the other filaments are affected with similar retardations proportional to their distance from the axis of the pipe. In this way the medium velocity of the current may be diminished, and consequently the quantity of water discharged in a given time must, from the effects of friction, be considerably less than that which is computed from theory. Guglielmini was the first who attended to the motion of water in rivers and open canals (*La Misura dell' acque correnti*). Embracing the theorem of Torricelli, which had been confirmed by repeated experiments, Guglielmini concluded that each particle in the perpendicular section of a current has a tendency to move with the same velocity as if it issued from an orifice at the same depth from the surface. The consequences deducible from this theory of running waters are in every respect repugnant to experience, and it is really surprising that it should have been so hastily adopted by succeeding writers. Guglielmini himself was sufficiently sensible that his parabolic theory was contrary to fact, and endeavoured to reconcile them by supposing the motion of rivers to be obstructed by transverse currents arising from irregularities in their bed. The solution of this difficulty, as given by Mariotte, was more satisfactory, and was afterwards adopted by Guglielmini, who maintained also that the viscosity of water had a considerable share in retarding its motion.

Newton. The effects of friction and viscosity in diminishing the velocity of running water were noticed in the *Principia* of Sir Isaac Newton, who threw much light upon several branches of hydromechanics. At a time when the Cartesian system of vortices universally prevailed, this great man found it necessary to investigate that absurd hypothesis, and in the course of his investigations he showed that the velocity of any stratum of the vortex is an arithmetical mean between the velocities of the strata which enclose it; and from this it evidently follows that the velocity of a filament of water moving in a pipe is an arithmetical mean between the velocities of the filaments which surround it. Taking advantage of these results, it was afterwards shown by Pitot that the retardations arising from friction are inversely as the diameters of the pipes in which the fluid moves. The attention of Newton was also directed to the discharge of water from orifices in the bottom of vessels. He supposed a cylindrical vessel full of water to be perforated in its bottom with a small hole by which the water escaped, and the vessel to be supplied with water in such a manner that it always remained full at the same height. He then supposed this cylindrical column of water to be divided into two parts,—the first, which he calls the "cataract," being an hyperboloid generated by the revolution of an hyperbola of the fifth degree around the axis of the cylinder which should pass through the orifice, and the second the remainder of the water in the cylindrical vessel. He considered the horizontal strata of this hyperboloid as always in motion, while the remainder of the water was in a state of rest, and imagined that there was a kind of cataract in the middle of the fluid. When the results of this theory were compared with the quantity of water actually discharged, Newton concluded that the velocity with which the water issued from the orifice was equal to that which a falling body would receive by descending through half the height of water in the reservoir. This conclusion, however, is absolutely irreconcilable with the known fact that jets of water rise nearly to the same height as their reservoirs, and Newton seems to have been aware of this objection. In the second edition of his *Principia* accordingly, which appeared in 1714, he reconsidered his theory. He had discovered a contraction in the vein of fluid (*vena contracta*) which issued from the orifice, and found that, at the distance of about a diameter of the aperture, the section of the vein was contracted in the subduplicate ratio of two to one. He regarded, therefore, the section of the contracted vein as the true orifice from which the discharge of water ought to be deduced, and the velocity of the effluent water as due to the whole height of water in the reservoir; and by this means his theory became more conformable to the results of experience. This theory, however, is still liable to serious objections. The formation of a cataract is by no means agreeable to the laws of hydrostatics; for when a vessel is emptied by the efflux of water through an orifice in its bottom, all the particles of the fluid direct themselves toward this orifice, and therefore no part of it can be considered as in a state of repose.

The subject of the oscillation of waves, one of the most difficult in the science of hydrodynamics, was first investigated by Newton. In the forty-fourth proposition of the second book of his *Principia*, he has furnished us with a method of ascertaining the velocity of the waves of the sea, by observing the time in which they rise and fall. If the two vertical branches of a siphon, which communicate by means of a horizontal branch, are filled with a fluid of known density, the two fluid columns, when in a state of rest, will be in equilibrium and their surfaces horizontal. But if the one column is raised above the level of the other, and left to itself, it will descend below that level, and raise the other column above it, and, after a few oscillations, they will return to a state of repose. Newton occupied himself in determining the duration of these oscillations, or the length of a pendulum isochronous to their duration; and he found, by a simple process of reasoning, that, allowing for the effects of friction, the length of a synchronous pendulum is equal to one-half of the length of the siphon, that is, of the two vertical branches and the horizontal one, and hence he deduced the isochronism of these oscillations. From this Newton concluded that the velocity of waves formed on the surface of water, either by the wind or by a body thrown into it, was in the subduplicate ratio of their size. When their velocity, therefore, is measured, which can be easily done, the size of the waves will be determined by means of a pendulum which oscillates in the time that a wave takes to rise and fall.

ernoulli. Such was the state of hydrodynamics in 1738, when Daniel Bernoulli published his *Hydrodynamica, sive de Viribus et Motibus Fluidorum Commentarii.* The germ of Daniel Bernoulli's theory was first published in his memoir entitled *Theoria Nova de Motu Aquarum per Canales quocunque fluentes,* which he had communicated to the Academy of St Petersburg as early as 1726. His theory of the motion of fluids was founded on two suppositions, which appeared to him conformable to experience. He supposed that the surface of a fluid, contained in a vessel which is emptying itself by an orifice, remains always horizontal; and, if the fluid mass is conceived to be divided into an infinite number of horizontal strata of the same bulk, that these strata remain contiguous to each other, and that all their points descend vertically, with velocities inversely proportional to their breadth, or to the horizontal sections of the reservoir. In order to determine the motion of each stratum, he employed the principle of the *conservatio virium vivarum,* and obtained very elegant solutions. In the opinion of the Abbé Bossut, his work was one of the finest productions of mathematical genius. The uncertainty of the principle employed by Daniel Bernoulli, which has never been demonstrated in a general manner, deprived his results of that confidence which they would otherwise have deserved, and rendered it desirable to have a theory more certain, and depending solely on the fundamental laws of mechanics. Maclaurin and John Bernoulli, who were of this opinion, resolved the problem by more direct methods, the one in his *Fluxions,* published in 1742, and the other in his *Hydraulica nunc primum detecta, et demonstrata directe ex fundamentis pure mechanicis,* which forms the fourth volume of his works. The method employed by Maclaurin has been thought not sufficiently rigorous; and that of John Bernoulli is, in the opinion of Lagrange, defective in perspicuity and precision.

Alembert. The theory of Daniel Bernoulli was opposed also by the celebrated D'Alembert. When generalizing James Bernoulli's theory of pendulums he discovered a principle of dynamics so simple and general that it reduced the laws of the motions of bodies to that of their equilibrium. He applied this principle to the motion of fluids, and gave a specimen of its application at the end of his *Dynamics* in 1743. It was more fully developed in his *Traité des Fluides,* which was published in 1744, where he has resolved, in the most simple and elegant manner, all the problems which relate to the equilibrium and motion of fluids. He makes use of the very same suppositions as Daniel Bernoulli, though his calculus is established in a very different manner. He considers, at every instant, the actual motion of a stratum as composed of a motion which it had in the preceding instant and of a motion which it has lost. The laws of equilibrium between the motions lost furnish him with equations which represent the motion of the fluid. Although the science of hydrodynamics had then made considerable progress, yet it was chiefly founded on hypothesis. It remained a desideratum to express by equations the motion of a particle of the fluid in any assigned direction. These equations were found by D'Alembert from two principles,—that a rectangular canal, taken in a mass of fluid in equilibrium, is itself in equilibrium; and that a portion of the fluid, in passing from one place to another, preserves the same volume when the fluid is incompressible, or dilates itself according to a given law when the fluid is elastic. His very ingenious method was published in 1752, in his *Essai sur la Resistance des Fluides.* It was brought to perfection in his *Opuscules Mathématiques,* and was adopted by Euler.

Before the time of D'Alembert, it was the great object of philosophers to submit the motion of fluids to general formulæ, independent of all hypothesis. Their attempts, however, were altogether fruitless; for the method of fluxions, which produced such important changes in the physical sciences, was but a feeble auxiliary in the science of hydraulics. For the resolution of the questions concerning the motion of fluids, we are indebted to the method of partial differences, a new calculus, with which Euler enriched the sciences. This great discovery was first applied to the motion of water by D'Alembert, and enabled both him and Euler to represent the theory of fluids in formulæ restricted by no particular hypothesis.

The most successful labourer in the science of hydrodynamics was the Chevalier Dubuat, engineer in ordinary to the king of France. Following in the steps of the Abbé Bossut (*Nouvelles expériences sur la resistance des fluides,* 1777), he prosecuted the inquiries of that philosopher with uncommon ingenuity; and in the year 1786 he published, in two volumes, his *Principes d'Hydraulique,* which contains a satisfactory theory of the motion of fluids, founded solely upon experiments. Dubuat considered that if water were a perfect fluid, and the channels in which it flowed infinitely smooth, its motion would be continually accelerated, like that of bodies descending in an inclined plane. But as the motion of rivers is not continually accelerated, and soon arrives at a state of uniformity, it is evident that the viscosity of the water, and the friction of the channel in which it descends, must equal the accelerating force. Dubuat therefore assumes it as a proposition of fundamental importance that, when water flows in any channel or bed, the accelerating force which obliges it to move is equal to the sum of all the resistances which it meets with, whether they arise from its own viscosity or from the friction of its bed. This principle was employed by Dubuat in the first edition of his work, which appeared in 1779, but the theory contained in that edition was founded on the experiments of others. He soon saw, however, that a theory so new, and leading to results so different from the ordinary theory, should be founded on new experiments more direct than the former, and he was employed in the performance of these from 1780 to 1783. The experiments of Bossut having been made only on pipes of a moderate declivity, Dubuat found it necessary to supply this defect. He used declivities of every kind, and made his experiments upon channels from a line and a half in diameter to seven or eight square toises. Dubuat

The theory of running water was greatly advanced by the researches of Prony. From a collection of the best experiments by Couplet, Bossut, and Dubuat he selected eighty-two (fifty-one on the velocity of water in conduit pipes, and thirty-one on its velocity in open canals); and, discussing these on physical and mechanical principles, he succeeded in drawing up general formulæ, which afford a simple expression for the velocity of running water. Prony.

Eytelwein of Berlin published, in 1801, a valuable compendium of Hydraulics, entitled *Handbuch der Mechanik und der Hydraulik,* which contains an account of many new and valuable experiments made by himself. He investigates the subject of the discharge of water by compound pipes, the motions of jets, and their impulses against plane and oblique surfaces; and he shows theoretically that a water wheel will have its effect a maximum when its circumference moves with half the velocity of the stream. Eytelwein.

Mallet and Vici. A series of interesting hydraulic experiments was made at Rome in 1809 by Mallet and Vici. They found that a pipe whose gauge was five ounces French measure (or 0·03059 French kilolitres) furnished one-seventh more water than five pipes of one ounce, an effect arising from the velocity being diminished by friction in the ratio of the perimeters of the orifices as compared with their areas.

Hachette. Hachette, in the year 1816, presented to the National Institute a memoir containing the results of experiments which he had made on the spouting of fluids, and the discharge of vessels. The objects he had in view were to measure the contracted part of a fluid vein, to examine the phenomena attendant on additional tubes, and to investigate and describe the figure of the fluid vein, and the results which take place when different forms of orifices are employed. Hachette showed in the second part of his memoir that greater or lesser volumes of water will be discharged in the same time through tubes of different figures, the apertures in all having the same dimensions. He also gave several remarkable results respecting other fluids issuing out of orifices into air or a vacuum.

Investigations as to waves. Several very interesting experiments on the propagation of waves have been made by the brothers Weber[1] and by Bidone. Mr John Scott Russell performed a number of experiments on waves, which are described in the *Edinburgh Transactions*, vol. xiv., and in the *British Association Report* for 1837. The mathematical theory has been worked out by Green, Stokes, Rankine, and other mathematicians, but still offers an interesting field for the investigator. Stokes's Report of the British Association for 1846 on Recent Researches in Hydrodynamics gives an account of the subject as it existed at that date.

Bidone. In 1826 Bidone,[2] besides his experiments on waves, made a series on the velocity of running water at the hydraulic establishment of the university of Turin, and he published an account of them in 1829. After giving a description of his apparatus and method of experimenting, he gives the figures obtained from fluid veins, sections of which were taken at different distances from the orifice.

Poncelet. In the year 1827 Poncelet published a *Mémoire sur les Roues Hydrauliques à Aubes Courbes*, containing his experiments on the undershot wheel with curved palettes, which he had invented in the year 1824. The best undershot previous to the introduction of the Poncelet wheel never developed more than 0·25 of the work of the water, whereas this utilized 0·60 of that work, which is nearly equivalent to the maximum effect of the breast wheel. The principle on which the Poncelet wheel acts, and that which makes it utilize so much of the work of the water, is that the water is received by the curved floats without any shock, and is discharged finally with a small velocity. This undershot wheel is much used in France.

Fourneyron. Previous to the year 1827, the wheels required in the mills and manufactories of Germany and France were generally those which worked with the axis horizontal, or the tub and spoon wheels with the axis vertical; but in that year a young mechanician named Fourneyron introduced a wheel working with the axis vertical, yet wholly different from the latter kind. Fourneyron showed that in existing wheels with a vertical axis the water left the wheel with considerable velocity in the direction of the motion of the wheel, and thus carried away and wasted much of the energy of the fall. By the introduction of a series of fixed guide blades, which gave the water initially a backward velocity of rotation, the water left the wheel with a much smaller velocity of discharge. He thus invented the first complete turbine, a kind of water motor which has largely superseded the more cumbrous water wheels previously in use. Shortly after the invention was made public, Fourneyron was awarded the prize of 6000 francs which was offered by the Society for the Encouragement of National Industry.

Recent investigations. The most extensive experiments on the discharge of water from orifices are those made under the direction of the French Government by Poncelet and Lesbros (*Experiences Hydrauliques*, Paris, 1851). Boileau (*Traité de la mesure des eaux courantes*) has discussed these results and added experiments of his own. Bornemann has re-examined all these results with great care, and has been able to express in formulæ the variation of the coefficients of discharge in different conditions (*Civilingenieur*, 1880). Very valuable experiments leading to a modification of the usual formula for the discharge over weirs were made by Mr J. B. Francis (*Lowell Hydraulic Experiments*, Boston, Mass., 1855). Wiesbach also has made many experimental investigations of the discharge of fluids.

The friction of water investigated originally by Coulomb at slow speeds has been measured for higher speeds by Mr W. Froude, whose researches have very great value in the theory of ship resistance (*Report of Brit. Assoc.*, 1869).

The flow of air and steam from orifices has been measured by many experimenters from Young to Saint Venant. Mr Napier in some interesting experiments first pointed out that when the ratio of the pressures on the two sides of an orifice exceeded a certain limit the measured discharge was very different from that calculated by the accepted formulæ. Since then numerous experiments have been made, and the theory of the flow of elastic fluids has been discussed in numerous memoirs. The valuable investigations of Fliegner (*Civilingenieur*, 1878) deserve special mention.

A most valuable investigation of the flow of water in pipes and channels has been carried out with exceptional accuracy and on a very large scale by the late M. Darcy, and continued by his successor the late M. Bazin, at the expense of the French Government (*Recherches Hydrauliques*, Paris, 1866). The measurement of the flow in rivers has been extensively carried out, especially by German engineers. Harlacher's *Beiträge zur Hydrographie des Königreiches Böhmen* contains exceedingly valuable measurements of this kind, and a comparison of the experimental results with all the formulæ of flow which have been proposed. Messrs Humphreys and Abbott's gaugings of the Mississippi for the United States Government, Mr Gordon's gaugings of the Irrawaddi, and Captain Cunningham's experiments on the Ganges Canal may be referred to as having materially advanced hydraulic science.

The first adequate theory of turbines is that of Poncelet in the *Comptes Rendus de l'Academie de Paris*, 1838. Redtenbacher's *Theorie und Bau der Turbinen und Ventilatoren* (Mannheim, 1844) is the first complete treatise on the subject. Girard's turbine, which was of an entirely new type, was discussed in *Le Génie industrielle*, 1856–1857, and lately by Fink (*Civilingenieur*, 1880). Important experiments on turbines were made by Francis (*Lowell Hydraulic Experiments*, Boston, Mass., 1855).

General Principles.

Hydromechanics is the science of the equilibrium and motion of fluids, both elastic and non elastic. A fluid is defined to be a substance which yields continually to the slightest tangential stress; and, consequently, when the fluid has come to rest, the stress across any surface in the fluid must be normal to the surface.

The stress considered in hydromechanics is always a pressure, as fluids are in general capable of sustaining only a slight tension without disruption (see Capillary Action). The intensity of the pressure is measured, as in the subject of elasticity, by the number of units of force per unit of area.

[1] *Wellenlehre auf Experimente gegrundet*, Leipsic, 1825.
[2] *Turin Memoirs*, vol. xxv.

If an area a be pushed by P units of force, then the mean pressure p over the area a is $\frac{P}{a}$; or, if p be variable, then at any point $p = \text{lt}\frac{P}{a}$, a being any small area enclosing the point at which p is required, and P the number of units of force with which a is pushed.

The pressure across any surface being normal to the surface, it follows from the general equations of internal stress (see ELASTICITY) that at a point the pressure is the same in all directions about the point. This may be proved independently by considering the equilibrium of a tetrahedron ABCD. Let p, p' be the pressures on the faces ABC, BCD, and resolve the forces parallel to the edge AD; the face ABC will be pushed by a force $p \times$ area ABC, and the face BCD will be pushed by a force $p' \times$ area BCD; and the projections of the areas ABC, BCD on a plane perpendicular to AD being equal, it follows that $p = p'$.

If forces act throughout the fluid so that the pressure varies from one point to another, we must suppose the tetrahedron taken indefinitely small, and then the impressed forces, depending on the volume, may be neglected in comparison with the forces acting on the faces, which depend on the surface of the tetrahedron.

When fluids such as exist in nature are in motion, the stresses across any surfaces are no longer normal, but tangential stresses are called into play, the intensities of which depend upon the relative motion of the parts of the fluid; those tangential stresses are said to be due to the viscosity of the fluid.

The difference between a solid and a fluid is that in a solid the tangential stress must exceed a certain amount before permanent shearing takes place, otherwise the stress being removed the solid regains its shape; in a fluid the slightest tangential stress produces a permanent deformation, and if continued long enough will cause a complete change of form, however great the viscosity of the fluid may be.[1] But little progress has been made in the theory of the motion of viscous fluids, those cases which have been worked out mostly falling under the head of the practical subject of hydraulics. In the theoretical subject of hydrodynamics the motion of the so-called *perfect* fluids only is considered,—fluids in which no viscosity is supposed to exist, and in which therefore the pressure at a point is the same in all directions.

Fluids are divided into two classes, incompressible fluids called liquids, and compressible fluids called gases. The so-called incompressible fluids are in reality compressible, but the compressibility being small is neglected in ordinary problems.

The *compression* of a substance is defined to be the ratio of the diminution of the volume to the original volume; and the *compressibility* is defined to be the ratio of the compression to the pressure producing it. The *elasticity* or *resilience of volume* is the ratio of the pressure to the compression produced, and is therefore the reciprocal of the compressibility. Fluids, from the definition, possess only elasticity of volume; an elastic solid possesses in addition an elasticity of figure, called also the *rigidity*.

A table of the elasticities and compressibilities of liquids is given in Everett's *Units and Physical Constants*, expressed in C. G. S. units; for instance, at 8° C. the elasticity of water is $2{\cdot}08 \times 10^{10}$, and the compressibility per atmosphere is $4{\cdot}81 \times 10^{-5}$. The elasticity of water is also proved to exist, and can be determined from the velocity of sound in water; for instance, in water of density unity, the velocity is the square root of the elasticity, and therefore 144,000 centimetres per second, which agrees closely with the velocity determined by experiment.

[1] For examples of the difference between a soft solid and a very viscous fluid see Maxwell's *Heat*, chap. xxi.

Compressible fluids or gases are assumed to obey the two gaseous laws.

The first gaseous law, discovered by Boyle, and generally called Boyle's law, asserts that the pressure of a given quantity of a gas at a given temperature varies inversely as the volume, or directly as the density.

The *density* is defined to be the number of units of mass in the unit of volume, and the *specific volume* is the volume of the unit of mass. Hence Boyle's law asserts that the pressure of a gas at a given temperature varies as the density, or inversely as the specific volume.

Dalton generalized Boyle's law for a mixture of gases by enunciating the law that the pressure of a mixture of gases is the sum of the separate pressures each gas would have if it existed alone in the containing vessel.

If we suppose all the gases the same, we are led to Boyle's law, since, if a gramme of air in a centimetre cube produces a certain pressure, then two grammes will produce double the pressure, three grammes treble the pressure, and so on; hence the pressure varies as the density. This method of exhibiting Boyle's law is due to Rankine (Maxwell, *Heat*, p. 27).

The second gaseous law was discovered by Charles, but it generally goes by Gay-Lussac's name. It asserts that under constant pressure the volume of a given quantity of every gas increases by about $\frac{1}{273}$ of its volume at 0° C. for a rise of temperature of 1° C. Therefore, if v be the volume at τ° C. and v_0 the volume at 0° C., then

$$\frac{v}{v_0} = 1 + \frac{\tau}{273} = \frac{273 + \tau}{273}.$$

If we reckon temperature from −273° C., and put $273 + \tau = t$, then t is called the absolute temperature, and −273° C. is called the absolute zero; and the second gaseous law asserts that at a constant pressure the volume of a given quantity of gas is proportional to the absolute temperature.

Combined with Boyle's law, this leads to the result that

$$pv \propto t, = Rt \text{ suppose,}$$

where p is the pressure, v the specific volume, and t the absolute temperature; also, if ρ denote the density,

$$\rho = \frac{1}{v}, \text{ and } p = R\rho t.$$

To determine the numerical value of $\frac{pv}{t} = R$, in C.G.S. units, suppose at 80° C. a centimetre cube of air is ·001 of a gramme, the height of the barometer being 76 centimetres, and the numerical value of g to be 981; then

$$p = 981 \times 1342 \times 76 = 10^6 \text{ very nearly,}$$
$$t = 273 + 80 = 353,$$
$$v = 1.$$
$$\therefore \quad R = \frac{10^6}{353} = 2833.$$

If the temperature is kept constant, then, an increment of pressure dp producing a compression $-\frac{dv}{v}$, the elasticity of volume

$$= -v\frac{dp}{dv} = \rho\frac{dp}{d\rho} = p;$$

and therefore at a constant temperature the elasticity is equal to the pressure.

Professor Maxwell (*Heat*, p. 171) has proved from first principles that the ratio of the elasticity of volume when no heat escapes is to the elasticity at constant temperature as the specific heat at constant pressure to the specific heat at constant volume.

Consequently if γ denotes the ratio of the specific heat at constant pressure to the specific heat at constant volume, and if the gas be compressed and no heat allowed to escape, then

$$-v\frac{dp}{dv} = \gamma p,$$

or

$$\frac{dp}{p} + \gamma\frac{dv}{v} = 0,$$

or

$$pv^\gamma = \text{constant}.$$

Consequently, if p, p' be the pressures, v, v' the specific volumes, ρ, ρ' the densities, and t, t' the absolute temperatures at two different states of a gas, when no heat has been allowed to escape, then

$$\frac{p}{p_1}=\left(\frac{v'}{v}\right)^{\gamma}=\left(\frac{\rho}{\rho'}\right)^{\gamma}=\left(\frac{t}{t'}\right)^{\frac{\gamma}{\gamma-1}};$$

since

$$\frac{pv}{p'v'}=\frac{t}{t'}.$$

The value of γ for air is about 1·4; for instance, the velocity of sound is $\sqrt{\frac{dp}{d\rho}}=\sqrt{\gamma\frac{p}{\rho}}$; and, for dry air at τ° C.,

$$\frac{p}{\rho}=7\cdot8376\times10^{8}\left(1+\frac{\tau}{273}\right);$$

and therefore the velocity of sound in centimetres per second

$$=33240\sqrt{\left(1+\frac{\tau}{273}\right)}=33240+60\tau,\text{ nearly.}$$

We have defined the *density* of a substance to be the number of units of mass in the unit of volume; for instance, with English units the density is the number of pounds in a cubic foot, and the density of water would be 62·5, a cubic foot of water being 1000 oz. But the densities of substances are generally tabulated relatively to water, and the old-fashioned name for the density relative to water was *specific gravity*. With French units of the centimetre and the gramme, a centimetre cube of water being a gramme, the density of water is unity.

PART I.—HYDROSTATICS.

Hydrostatics is the science of the equilibrium of fluids. When a fluid has come to rest there can be no tangential stress, and consequently the stress across any surface is normal to the surface, and therefore the same in all directions about a point. We shall begin with a few elementary propositions about the equilibrium of liquids like water under gravity, and afterwards proceed to the consideration of the equilibrium of any fluid under any forces.

Prop. I. The pressure is the same at all points in a horizontal plane of a liquid at rest under gravity.

For, taking any two points in the same horizontal plane, and joining them, and describing about the joining line as axis an indefinitely thin cylinder, then, since the weight and the pressures on the sides of the cylinder are normal to the axis of the cylinder, resolving parallel to the axis of the cylinder, the pressures on the ends must be equal for equilibrum, and must therefore be of equal intensity.

Corollary.—It follows that the free surface must be a horizontal plane, supposing the pressure uniform over it, and gravity to act in parallel vertical lines.

That the free surface is a plane is verified experimentally by the fact that objects are seen by reflexion at the surface undisturbed as in a plane mirror; and that it is a horizontal plane is verified by the fact that a plumb line and its image by reflexion at the surface always appear in the same straight line.

Prop. II. The pressure at any point of a liquid at rest under gravity is proportional to the depth.

For, let P (fig. 1) be any point at a depth $AP=z$ in the liquid, and about AP as axis describe a cylinder, of sectional area α suppose. Then, considering the equilibrium of the liquid in this cylinder, and resolving vertically, the pressure, p suppose, at P acting over the area α must balance the weight of the liquid in the cylinder, neglecting the atmospheric pressure, and therefore

$$p\alpha=\rho z\alpha,$$

or

$$p=\rho z,$$

ρ denoting the weight of the liquid per unit of volume.

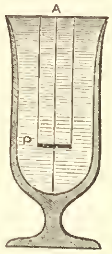

Fig. 1.

In practical hydrostatics the gravitation measure of forces is employed, and p the pressure is generally estimated in lb per square inch, and then, an inch being the unit of length, z is given in inches, and ρ is the number of pounds to a cubic inch of the liquid considered.

Thus with water, taking a cubic foot of water to be 62·4 lb,

$$p=\frac{62\cdot4}{1728}z=0\cdot036\times z.$$

If, however, z be measured in feet and p in lb per square inch,

$$p=\frac{62\cdot4}{144}z=0\cdot433\times z.$$

Consequently the head of each foot of water produces a pressure of 0·433 lb to the square inch.

With the French metric system of units, a centimetre cube of water is one gramme, and therefore with the centimetre as the unit of length and gramme as unit of weight, using gravitation units of force, $\rho=1$, and $p=z$.

Even if the point C considered (fig. 2) should not be vertically below the actual free surface, it still follows that the pressure at C is proportional to the depth below the free surface. For the pressure at C is equal to the pressure at D in the same horizontal plane, and this is proportional to the depth DE, that is, to the depth CF.

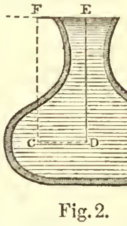

Fig. 2.

If the atmospheric pressure ϖ be taken into account, then

$$p=\varpi+\rho z,$$

and generally, at different depths z and z',

$$p-p'=\rho(z-z');$$

or the difference of the pressures at any two points of a liquid at rest under gravity is proportional to the difference of the depths.

Corollary.—It follows from this that a liquid rises to the same level in a series of communicating vessels (fig. 3), since the fluid must have one horizontal plane as the free surface.

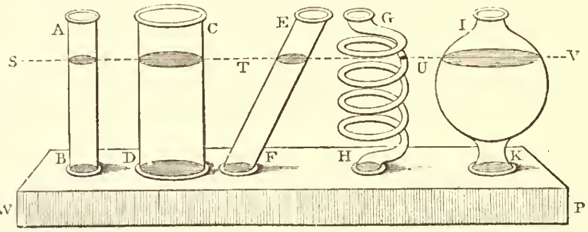

Fig. 3.

If liquids of different densities ρ and ρ' be poured into the two branches of a bent tube, the heights of the free surfaces above the plane of separation will be inversely as the densities. For the pressure at the level of the common surface being constant, and in one case due to a height h of liquid of density ρ and in the other case to a height h' of liquid of density ρ', therefore

$$\rho h=\rho' h',$$

or

$$h:h'=\rho':\rho.$$

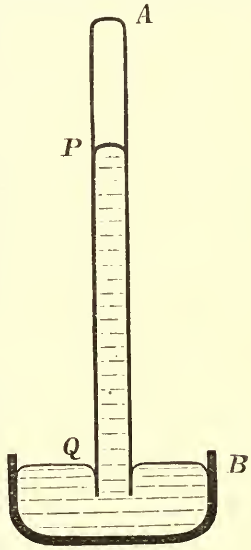

Fig. 4.

The barometer (fig. 4) is in reality an instrument of this character, for a column of mercury, of density σ and height h suppose, supports a column of air, which is of density ρ suppose, and, if homogeneous, would reach to a height H. Hence the pressure at the level of the common surface

$$p=\sigma h=\rho H,$$

estimated in gravitation measure.

If the tube AB should not be exactly vertical, then h must be taken to denote the vertical distance between the level of the mercury at P and Q, which becomes difficult to estimate at sea when the ship is rolling.

When h is observed the temperature must also be observed; for at the same pressure the coefficient of linear expansion of h is the coefficient of cubical expansion of mercury. For, if the density of mercury were halved, the height h would be doubled, and so on in any proportion.

H is called the pressure height (Everett, *Units and Physical Constants*). For dry air at 0° C.,

$$H = 7{\cdot}988 \times 10^5 \text{ centimetres.}$$

Prop. III. To find the pressure on the bottom of a vessel of any form containing liquid, the bottom of the vessel being supposed a horizontal plane.

The pressure at any point of the base being the same and due to the depth below the free surface, whatever be the shape of the sides of the vessel, as in fig. 5, it follows that the pressure on the base AB is equal to the weight of the liquid contained in an imaginary cylinder, traced out by vertical lines round the base AB reaching to the surface.

In order to illustrate this, let there be four vessels A, B, C, D (fig. 6), having bottoms all of the same area, and closed by plates E, F, G, H, of the same weight. Let the plates also be kept in their places by means of strings passing over pulleys and supporting equal weights w, w', w'', w'''. The weights will measure the vertical forces acting on the plates, *i.e.*, the bases of the vessels. It will be found that water must be poured into each vessel to the same height to cause the plates to descend. The same will be the case whatever be the shapes of the vessels, and the extreme cases of a very large base acted upon by the pressure of water in a very contracted vessel, and of a very small area kept closed by a very small weight when the vessel is very much enlarged above, constitute what used to be called the *hydrostatic paradox*. Another kind of hydrostatic paradox is the hydraulic press, where water, pumped in with small exertion by a forcing pump of which the plunger is of small diameter, causes a second plunger of very much greater diameter to rise and produce a very great pressure.

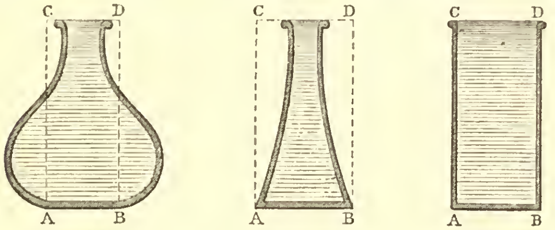

Fig. 5.

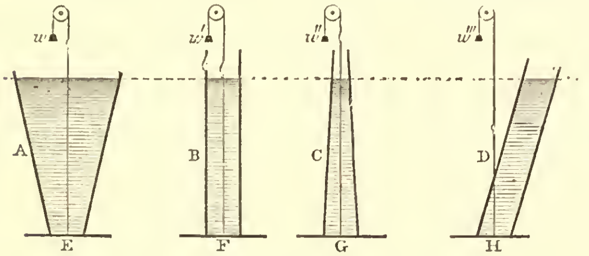

Fig. 6.

Prop. IV. (*Archimedes's Principle*).—The resultant pressure of a fluid on a body immersed in it acts vertically upwards through the centre of gravity, and is equal to the weight of the displaced liquid.

For, suppose the body removed and its place filled up with fluid as it would be at rest, and imagine for clearness this fluid solidified. The fluid pressures which act upon this solidified fluid are the same as before, and since the fluid is in equilibrium under its own weight and the fluid pressures, the resultant of the fluid pressures must be a single vertical force equal to the weight of the displaced liquid, and acting upwards through the centre of gravity of the displaced liquid.

Corollary.—If a body float at rest in fluid, the weight of the body must be equal to the weight of the displaced fluid, and the C.G.s of the body and displaced fluid must be in the same vertical line. For instance, the weight of water displaced by a ship is equal to the weight of the whole ship, masts, rigging and all. When a balloon is at rest in the air, the weight of the balloon is equal to the weight of air displaced.

Archimedes's principle is employed to determine the densities of bodies; for, if w be the weight of a body weighed in a balance in air (strictly speaking *in vacuo*), and if w' be its apparent weight when immersed in water, then $w - w'$, the resultant upward pressure of the water, is equal to the weight of water displaced, and the density relative to water is therefore

$$\frac{w}{w - w'}.$$

In very accurate weighings the weight of air displaced must be taken into account, the real weight of a body being its apparent weight in air plus the weight of air displaced. Thus, if in air a pound of lead and a pound of feathers balance in a pair of scales, if placed under a receiver and the air exhausted the feathers would preponderate.

The densities of liquids and solids are also determined by hydrometers, for a description of which consult the article HYDROMETER.

The numerical measure of the density of a substance being the quotient of the number of units of mass (or weight) by the number of units of volume, it follows that in a mixture of fluids the density of the mixture is the quotient of the number of units of mass in the component fluids by the volume of the mixture.

The volume of the mixture will in general be the sum of the volumes of the component fluids, except in some cases where the fluids combine chemically with each other. If equal volumes of the component fluids be taken, the density of the mixture will therefore be the arithmetical mean of the densities of the component fluids; but if equal weights be taken, the density of the mixture will be the harmonical mean of the densities of the component fluids, no change of volume being supposed to take place.

Prop. V. To find the resultant vertical and horizontal pressures on one side of a portion of a surface immersed in fluid at rest under gravity.

The resultant vertical pressure is the weight of the superincumbent fluid contained by vertical lines drawn round the bounding curve of the surface to the free surface. If, however, the free surface does not extend over the surface, we must suppose it made to do so by filling up the empty space with fluid. The line of action of the resultant vertical pressure passes through the centre of gravity of this superincumbent fluid.

The resultant horizontal pressure in any direction is equal to the resultant pressure on the plane area traced out on a plane perpendicular to the given horizontal direction by horizontal lines drawn through the bounding line of the surface in the given direction; this plane area is called the orthogonal projection of the surface on a plane perpendicular to the given direction. For, resolving in the given direction the weight of the enclosed liquid and the pressures on the cylindrical surface traced out by the horizontal lines acting in a direction at right angles, the horizontal components of the pressures on the ends balance, which proves the proposition. The line of action of this horizontal pressure passes through the centre of pressure of the plane area (*vide* "Centre of Pressure").

If a plane area be immersed in homogeneous liquid at rest under gravity, the resultant force acting on one side of the area will be the product of the area and the pressure at the centre of gravity of the area.

For, dA denoting an element of the area, and z its depth, the resultant pressure

$$= \int \rho z dA = \rho \bar{z} A$$

which proves the proposition.

General Equations of Equilibrium of any Fluid at rest under any Forces.

If we take any arbitrary origin O, and three rectangular axes of reference Ox, Oy, Oz, then, if p be the pressure, ρ the density, and X, Y, Z the components of the impressed force per unit of mass at the point xyz, the equilibrium of the fluid in any closed surface S requires, resolving parallel to the axis of x,

$$\iint lp dS = \iiint \rho X dx dy dz,$$

the integrations extending respectively over the surface and through the volume of the space S, and l, m, n denoting the direction-cosines of the outward drawn normal at the surface element dS.

But by Green's transformation

$$\iint lp dS = \iiint \frac{dp}{dx} dx dy dz,$$

and therefore
$$\iiint \frac{dp}{dx} dx dy dz = \iiint \rho X dx dy dz,$$

leading to the differential relation

$$\frac{dp}{dx} = \rho X.$$

Similarly,
$$\frac{dp}{dy} = \rho Y, \quad \frac{dp}{dz} = \rho Z.$$

The three equations of equilibrium obtained by taking moments about the axis will be found to be satisfied identically.

Hence the space variation of the pressure in any direction is equal to the resolved force per unit of volume in that direction. The resultant force is therefore in the direction of the greatest space variation of the pressure, that is, normal to the surface of equal pressure; and the lines of force must therefore be capable of being cut orthogonally by a system of surfaces, which will be the surfaces of equal pressure.

If we neglect changes of temperature, then, the density at any point being a function of the pressure, it follows that surfaces of equal pressure are also surfaces of equal density, and therefore $\frac{1}{\rho}\frac{dp}{dx}$, $\frac{1}{\rho}\frac{dp}{dy}$, $\frac{1}{\rho}\frac{dp}{dz}$ are the partial differential coefficients with respect to x,y,z of some function P of x,y,z such that $P=\int\frac{dp}{\rho}$; and therefore also X,Y,Z must be the partial differential coefficients of some function $-V$, called the potential, such that the force in any direction is rate of diminution of V in that direction, and the conditions of equilibrium $\frac{1}{\rho}\frac{dp}{dx}=X$, &c., are equivalent to

$$\frac{dP}{dx}+\frac{dV}{dx}=0\,,\quad \frac{dP}{dy}+\frac{dV}{dy}=0\,,\quad \frac{dP}{dz}+\frac{dV}{dz}=0\,;$$

or

$$P+V=\text{constant}.$$

If the temperature be variable, then the surfaces of equal pressure and density need not be coincident; but, since the pressure is a function of the density and temperature only, it follows that the surfaces of equal temperature and of equal density must intersect in curves which lie on surfaces of equal pressure.

As an example of the use of the general equations, take the simplest case of a homogeneous liquid at rest under gravity; then, the axis of z being directed vertically downwards, the equations become

$$\frac{1}{\rho}\frac{dp}{dx}=0\,,\quad \frac{1}{\rho}\frac{dp}{dy}=0\,,\quad \frac{1}{\rho}\frac{dp}{dz}=g\,,$$

and therefore $p=\varpi+g\rho z$, ϖ being the pressure at the level of the origin.

We are here employing a new unit of force—the absolute unit—which is defined as the force which causes unit acceleration in the unit of mass. With the same units of length, time, and mass, the gravitation unit of force is g times the absolute unit of force; for instance, in the equations $p=\rho z$, and $p=g\rho z$, the p in the first equation is measured in gravitation units of force per unit of area, and in the second equation in absolute units of force per unit of area.

Again, suppose the density to vary as any power of the depth, and put

$$\rho=\mu z^n\,;$$

then

$$\frac{dp}{dz}=g\rho=g\mu z^n\,;$$

and

$$p=\varpi+\frac{g\mu}{n+1}z^{n+1}.$$

If the fluid be elastic, and the temperature uniform, $p=k\rho$, and

$$\frac{1}{\rho}\frac{dp}{dz}=\frac{k}{p}\frac{dp}{dz}=g\,;$$

and integrating,

$$\log\frac{p}{\varpi}=\frac{gz}{k}\,;$$

$$p=\varpi e^{\frac{gz}{k}}\,;$$

$$\rho=\frac{\varpi}{k}e^{\frac{gz}{k}}.$$

Consequently, as we go up in the air, if the temperature be uniform, as the heights increase in arithmetical progression, the pressures and densities diminish in geometrical progression.

If H denote the pressure height, then

$$p=k\rho=g\rho H\,,$$

and therefore

$$H=\frac{k}{g}\,;$$

and if p_1, p_2 denote the pressures at levels z_1, z_2, then

$$\frac{p_1}{p_2}=e^{\frac{z_1-z_2}{H}}\,,$$

or

$$z_1-z_2=H\log\frac{p_1}{p_2}\,,$$

$$=H\times 2{\cdot}3026\log_{10}\frac{p_1}{p_2}.$$

For dry air at 0° C., taking H = 26,000 feet,

$$z_1-z_2=60{,}000\log_{10}\frac{p_1}{p_2}\ \text{nearly.}$$

—(Maxwell, *Heat*, chap. xiv.)

The Figure of the Earth.

Suppose a fluid mass arranged under the gravitation of its parts in concentric spherical strata, the density increasing towards the centre for stability of equilibrium, and ρ being the density at a distance k from the centre. If we suppose this mass to be rotating without relative motion of its parts about an axis, and to be slightly disturbed in consequence of the rotation from the spherical arrangement of the strata, we can gain an idea of the figure of the earth on the hypothesis of original fluidity.

If ω be the angular velocity, we must suppose a disturbing function, whose potential is $\frac{1}{2}\omega^2r^2\sin^2\theta$, added to the gravitation potential, θ being the angular distance from the axis of revolution and of figure. Denoting the zonal surface harmonic of the second degree $\frac{3}{2}\mu^2-\frac{1}{2}$, where $\mu=\cos\theta$, by Q_2, the disturbing function may be written

$$\tfrac{1}{3}\omega^2r^2(1-Q_2)\,;$$

and we shall assume in consequence that the disturbance of each stratum from the spherical form is also a zonal harmonic of the second degree, so that when disturbed the equation of a stratum will be

$$r=k(1-\tfrac{2}{3}\epsilon Q_2)\,;$$

and ϵ, which is the ratio of the difference of the equatorial and polar axes to the mean axis, is called the ellipticity of the stratum.

The gravitation potential of a homogeneous spheroid of density ρ, and bounded by

$$r=k(1-\tfrac{2}{3}\epsilon Q_2),$$

is the same as that of a homogeneous sphere of radius k and density ρ, and of a distribution of matter on the sphere of radius k, of surface density $-\frac{2}{3}k\epsilon Q_2\rho$, neglecting ϵ^2.

Therefore, for an internal point the potential is

$$2\pi\rho k^2-\tfrac{2}{3}\pi\rho r^2-\tfrac{8}{15}\pi\rho\epsilon r^2Q_2\,;$$

and for an external point the potential is

$$\tfrac{4}{3}\pi\rho\frac{k^3}{r}-\tfrac{8}{15}\pi\rho\frac{k^5\epsilon}{r^3}Q_2.$$

Therefore, for the shell of density ρ, enclosed by the stratum

$$r=k(1-\tfrac{2}{3}\epsilon Q_2)$$

and the consecutive stratum, the potential dU

$$=4\pi\rho k\,dk-\tfrac{8}{15}\pi\rho\frac{d\epsilon}{dk}r^2Q_2dk$$

for an internal point, and

$$=4\pi\rho\frac{k^2}{r}-\tfrac{8}{15}\pi\rho\frac{d}{dk}(k^5\epsilon)\frac{1}{r^3}Q_2dk$$

for an external point; and, therefore, for any point in the interior of the whole mass on the stratum

$$r=k(1-\tfrac{2}{3}\epsilon Q_2),$$

$$U=4\pi\int_k^K\rho k\,dk-\tfrac{8}{15}\pi r^2Q_2\int_k^K\rho\frac{d\epsilon}{dk}dk+\frac{M}{r}-\tfrac{8}{15}\pi\frac{Q_2}{r^3}\int_0^k\rho\frac{d}{dk}(k^5\epsilon)dk\,,$$

M denoting the mass enclosed by the stratum of mean radius k, and K being the mean radius of the exterior stratum. Neglecting ϵ^2,

$$U=4\pi\int_k^K\rho k\,dk-\tfrac{8}{15}\pi k^2Q_2\int_k^K\rho\frac{d\epsilon}{dk}dk$$
$$+\frac{M}{k}\left(1+\tfrac{2}{3}\epsilon Q_2\right)-\tfrac{8}{15}\pi\frac{Q_2}{k^3}\int_0^k\rho\frac{d}{dk}(k^5\epsilon)dk.$$

The equation of equilibrium is, since the force in any direction is the rate of *increase* of the gravitation potential,

$$\int\frac{dp}{\rho}-U-\tfrac{1}{3}\omega^2r^2(1-Q_2)=\text{constant}\,;$$

and, supposing surfaces of equal pressure to be also surfaces of equal density, we must have to our order of approximation

$$U+\tfrac{1}{3}\omega^2k^2(1-Q_2)=\text{constant},$$

over a surface of equal density, or, equating to zero the coefficient of Q_2,

$$\frac{M\epsilon}{k}-\tfrac{4}{5}\pi k^2\int_k^K\rho\frac{d\epsilon}{dk}dk-\tfrac{4}{5}\frac{\pi}{k^3}\int_0^k\rho\frac{d}{dk}(k^5\epsilon)dk+\tfrac{1}{2}\omega^2k^2=0.$$

Dividing by k^2, and differentiating with respect to k, ω^2 disappears, and we obtain

$$k^3\frac{d\,.\,M\epsilon}{dk}-3k^2M\epsilon-4\pi\rho k^5\epsilon+4\pi\int_0^k\rho\frac{d}{dk}(k^5\epsilon)dk=0\,;$$

and, differentiating again with respect to k,

$$k^3\frac{d^2\,.\,M\epsilon}{dk^2}-6kM\epsilon-4\pi k^5\epsilon\frac{d\rho}{dk}=0\,,$$

or

$$k^2\frac{d^2\,.\,M\epsilon}{dk^2}-\left(6+\frac{4\pi k^4}{M}\frac{d\rho}{dk}\right)M\epsilon=0\,;$$

a differential equation of the second order to determine $M\epsilon$, and therefore ϵ, provided we know what function ρ and therefore M is of k.

Properly speaking, from the elasticities of the substances of the various strata we should know the relation between the pressure and the density, and then from the conditions of equilibrium of the strata when undisturbed and in this spherical shape we could determine what function ρ is of k,—the pressure and density at a stratum with our approximations being the same in the undisturbed and disturbed states; and therefore

$$\frac{1}{\rho}\frac{dp}{dk}=-\frac{M}{k^2}.$$

Laplace, on the assumption that the cubical elasticity is double the pressure, and therefore the pressure proportional to the square of the density, has integrated the differential equation for the ellipticity,—his assumption amounting to putting

$$\frac{4\pi k^2}{M}\frac{d\rho}{dk}=-q^2, \text{ a constant.}$$

More generally, to make the equation for the ellipticity integrable, we may put

$$\frac{4\pi k^4}{M}\frac{d\rho}{dk}=-\left(\frac{k}{a}\right)^n,$$

where a and n are constants, the negative sign being taken because $\frac{d\rho}{dk}$ is negative for stability. This assumption reduces the differential equations for ρ, M, and $M\epsilon$ to equations reducible to Bessel's differential equation, and therefore ρ, M, and ϵ can be expressed by Bessel's functions.

Laplace's assumption amounts to putting $n=2$, and then the Bessel's functions which occur are of the order $\frac{1}{2}$, $\frac{3}{2}$, and $\frac{5}{2}$.

Then $\rho=\sigma\frac{\sin qk}{qk}$, where σ is the density at the centre of the earth, and therefore

$$M=\frac{4\pi\sigma}{q^3}(\sin qk-qk\cos qk),$$

and $$\epsilon=\frac{5\omega^2}{8\pi\sigma}\,\frac{\sin a-a\cos a}{\frac{2}{a^3}\sin^2 a-\frac{1}{a^2}\sin a\cos a-\frac{1}{a}}\cdot\frac{\left(\frac{3}{q^2k^2}-1\right)\sin qk-\frac{3}{qk}\cos qk}{\sin qk-qk\cos qk},$$

where $a=qK$, and the value of q must be determined from the condition that the mean density of the earth is twice the density at the surface.

Centre of Pressure.

When a plane area is exposed to fluid pressure on one side, the resultant force experienced by the area is a single force perpendicular to the area, the sum of all the separate pressures, and acts through a definite point called the *centre of pressure*.

If p be the pressure at the point xy, the axes being taken in the plane of the area, then the resultant force

$$R=\iint p\,dxdy,$$

and, if $\bar{x}$, $\bar{y}$ denote the coordinates of the centre of pressure,

$$\bar{x}=\frac{\iint xp\,dxdy}{\iint p\,dxdy},\quad \bar{y}=\frac{\iint yp\,dxdy}{\iint p\,dxdy}.$$

The centre of pressure is therefore the C.G. of the plane area, supposed a lamina of variable density p. If p is uniform, the centre of pressure is obviously the C.G. of the area.

For a homogeneous liquid at rest under gravity, p is proportional to the depth below the surface, that is, proportional to the perpendicular distances from the line of intersection of the plane of the area with the free surface of the liquid. If the equation of this line be

$$x\cos\alpha+y\sin\alpha-p=0,$$

then $$\bar{x}=\frac{\iint x(p-x\cos\alpha-y\sin\alpha)dxdy}{\iint(p-x\cos\alpha-y\sin\alpha)dxdy},$$

$$\bar{y}=\frac{\iint y(p-x\cos\alpha-y\sin\alpha)dxdy}{\iint(p-x\cos\alpha-y\sin\alpha)dxdy}.$$

If the origin be taken at the centre of gravity of the area, and if the axes be the principal axes of the area, then

$$\iint dxdy=A, \text{ the area},$$

$$\iint xdxdy=0,\ \iint ydxdy=0,\ \iint xydxdy=0$$

and $$\iint y^2dxdy=Aa^2,\ \iint x^2dxdy=Ab^2;$$

a and b being the semi-axes of the momental ellipse of the area. Therefore

$$\bar{x}=-\frac{a^2}{p}\cos\alpha,\ \bar{y}=-\frac{b^2}{p}\sin\alpha;$$

and therefore the centre of pressure is the antipole of the line of intersection with the free surface, with respect to the momental ellipse.

The centre of pressure of a rectangular area, with a side in the free surface, is at $\frac{2}{3}$ of the depth of the lower side; of a triangle with vertex in the free surface and base horizontal is $\frac{3}{4}$ of the depth of the base; of a triangle with base in the surface is $\frac{1}{2}$ the depth of the vertex.

Metacentre.

We have found from Archimedes's principle the conditions of equilibrium of a floating body, and we must now examine whether the equilibrium is stable or unstable.

Let ACB (fig. 7) represent the cross section of a floating body, like a ship, and let G be the C.G. of the body, and H that of the liquid displaced, supposed homogeneous. Let the body be turned through a small angle in the plane of the paper, whose circular measure is θ, so that the volume of liquid displaced remains the same. Then, if W denote the weight of the body, and therefore also of the liquid displaced, the resultant force due to the liquid on the body in the displaced position is a vertical force W acting vertically upwards through H′, the new C.G. of the displaced liquid.

In order that the volume displaced may remain unaltered, it is necessary that the line of intersection of the two planes of flotation AB and DE should pass through the C.G. of the area of the curve of flotation. For dA denoting an element of the area A of flotation, and x its distance from the line of intersection of the planes AB and DE, the element of volume traced out by dA when the body is displaced being $\theta x dA$, we must have

$$\int\theta x dA=0,$$

or $$\int x dA=0;$$

which proves that the line of intersection of the planes of AB and DE passes through the C.G. of the area of flotation.

The force W acting upwards through H′ is therefore equivalent to an equal force W acting upwards through H, and a couple, due to the moment of the weight of AOD upwards and BOE downwards, the moment of which is therefore, in gravitation units,

$$\rho\int\theta x^2 dA=\rho\theta Ak^2,$$

k denoting the radius of gyration of the area A about the line whose projection on the plane is O.

Since HH′ is the arc of a curve, such that the tangent at H is

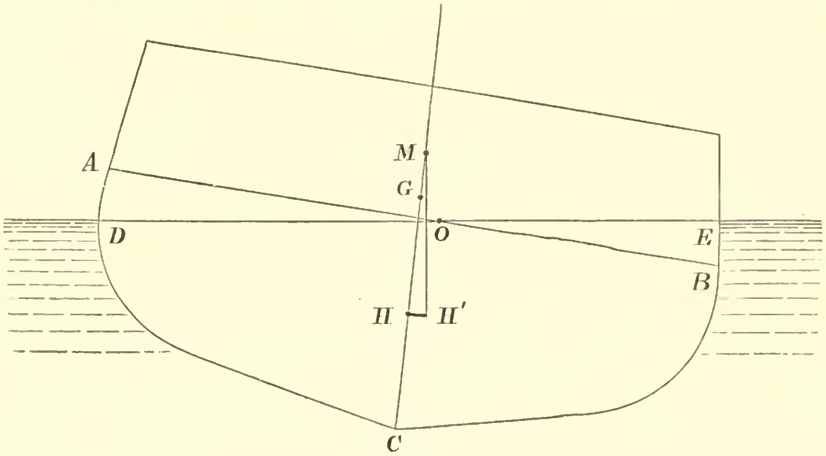

Fig. 7

parallel to AB, therefore HH′ is ultimately a straight line perpendicular to GH, and

$$W\ .\ HH'=\rho\theta Ak^2,$$

or $$HH'=\theta\frac{\rho Ak^2}{W}=\theta\frac{Ak^2}{V}$$

if V be the volume of liquid displaced.

If H′M be drawn vertically upwards to meet HG in M, then M is ultimately the centre of curvature of the locus of H in the body, and is called the metacentre, and

$$HM=\mathrm{lt}\frac{HH'}{\theta}=\frac{Ak^2}{V}.$$

If M lies above G, the fluid pressure tends to restore the body to its position of equilibrium, and the equilibrium is therefore stable; but if M lies below G the equilibrium is unstable.

Generally we see that, if planes be drawn cutting off constant volumes from a solid, the principal radii of curvature of the locus of H, the centre of gravity of the volume cut off, will be $\frac{Ak_1^2}{V}$ and $\frac{Ak_2^2}{V}$, where V is the volume cut off, A the area of the cutting plane intercepted by the surfaces, and k_1, k_2 the principal radii of gyration of this area about the centre of gravity of the area. The vertical through H′ will intersect HG only when the plane of displacement is a plane of symmetry, that is, if it is perpendicular to k_1 or k_2.

Generally for finite displacements in a plane the locus of M will be the evolute of the curve which is the intersection of the plane with the locus of H.

The surface the locus of H is called the surface of buoyancy, and the surface which is the envelope of the planes of flotation is called the surface of flotation.

If r_1, r_2 be the principal radii of curvature of the surface of buoyancy, then

$$r_1 = \frac{Ak_1^2}{V} = \frac{I_1}{V}\ ;\ r_2 = \frac{Ak_2^2}{V} = \frac{I_2}{V}.$$

If R_1, R_2 be the principal radii of gyration of the surface of flotation, Mons. E. Leclert has proved that

$$R_1 = \frac{dI_1}{dV} = r_1 + \frac{Vdr_1}{dV},\ R_2 = \frac{dI_2}{dV} = r_2 + \frac{Vdr_2}{dV}.$$ [1]

For small oscillations, if we suppose the liquid pressure the same as if the liquid were at rest, the body oscillates as if the surface of buoyancy moved upon a horizontal plane.

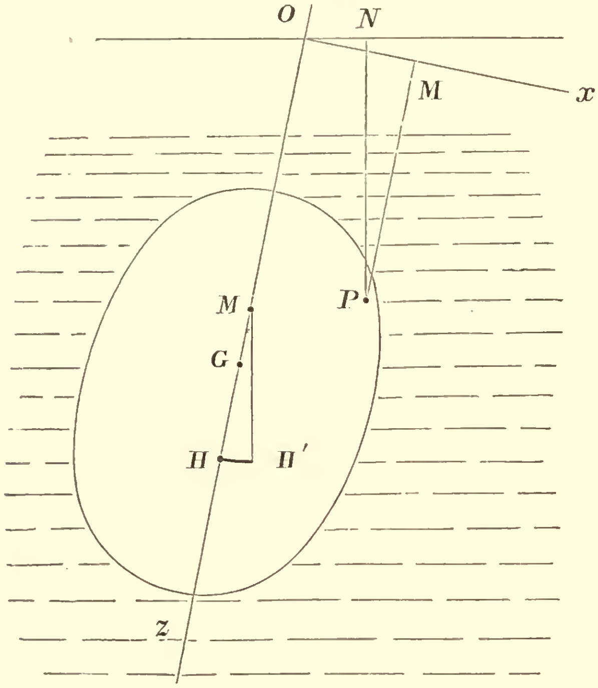

Fig. 8.

Next, suppose a body completely immersed in heterogeneous liquid, which must for equilibrium be arranged in horizontal strata of equal density, and suppose $\rho = f(z)$ the density of the liquid at any depth z; let G be the centre of gravity of the body and H that of the liquid displaced (fig. 8). When the body is in equilibrium, we must have G and H in the same vertical line, and

$$\iiint \rho\, dxdydz = W,$$

the weight of the liquid displaced, using gravitation units of force again.

Suppose the axes of coordinates fixed in the body, and take GM as the axis of z; suppose the body turned through a small angle θ about the axis Oy, and let H′ be the centre of gravity of the displaced liquid in the new position. The density of the liquid displaced at a point P, whose coordinates are x, y, z, is now

$$\begin{aligned} f(\text{NP}) &= f(z\cos\theta + x\sin\theta) \\ &= f(z + x\theta) \\ &= f(z) + \theta x f'(z), \end{aligned}$$

neglecting θ^2; and, to the same order of approximation,

$$\text{HH}' = \frac{\iiint x\{f(z) + \theta x f'(z)\}\, dxdydz}{W} = \theta \frac{\iiint x^2 f'(z)\, dxdydz}{W},$$

since

$$\iiint x f(z)\, dxdydz = 0,$$

H lying in the axis of z.

If the vertical through H′ meet Oz in M, M is called the metacentre, and is the centre of curvature of the locus of H, and

$$\text{HM} = \frac{\text{HH}''}{\theta} = \frac{\iiint x^2 f'(z)\, dxdydz}{W} = \frac{\int Ak^2 \frac{d\rho}{dz}\, dz}{W},$$

if Ak^2 denote the moment of inertia of a horizontal plane section of the body at a depth z, about the line of intersection with the plane of yz.

We have here supposed that H′ lies in the plane of xz; but this will only be true for two directions of displacement.

In general for any displacement, if $\bar{x}$, $\bar{y}$, $\bar{z}$ be the coordinates of H′,

$$\bar{y} = \frac{\iiint y\{f(z) + \theta x f'(z)\}\, dxdydz}{W} = \theta \frac{\iiint xy f'(z)\, dxdydz}{W};$$

and therefore $\bar{y} = 0$, only when the axis of y is a principal axis of the body, supposed of density $\frac{d\rho}{dz}$.

When ρ is discontinuous, as in the case of the body floating in homogeneous fluid, then the integral $\int Ak^2 d\rho$ will have a term $Ak^2\rho$, due to the discontinuity at the surface, and the rest of the integral will vanish, because $\frac{d\rho}{dz} = 0$.

For a body floating wholly immersed in two liquids, the upper of uniform density ρ' and the lower of uniform density ρ,

$$\text{HM} = \frac{(\rho - \rho')Ak^2}{W}.$$

Tension of Flexible Surfaces exposed to Pressure.

In hydrostatics it is usual to determine the circumferential and longitudinal tension produced in a thin circular cylinder, due to uniform internal pressure, and also to determine the tension of a spherical surface, like a soap-bubble, due to the excess of the internal pressure over the atmospheric pressure.

Let r be the internal radius of the cylinder, c the thickness (supposed small), p the internal pressure, and t, t' the circumferential and longitudinal tension per unit of area caused by the pressure p.

If we suppose the cylinder divided into two halves by a diametral plane, and consider the equilibrium of unit length of either half under the resultant of the fluid pressure over the half-cylinder and the tensions at the ends of the diameters, the resultant of the tensions must balance the resultant of the fluid pressures, which is the resultant pressure on the diametral plane, since the resultant of the uniform pressure on a closed surface is zero. Therefore

$$2tc = 2pr;$$

or

$$\frac{t}{p} = \frac{r}{c}.$$

To determine the longitudinal tension t', consider that the resultant pressure on the end of the cylinder, which is $p.\pi r^2$, is balanced by the resultant of the tensions round a circumferential seam, which is $t'c.2\pi r$; and therefore

$$2\pi t'cr = \pi pr^2;$$

or

$$\frac{t'}{p} = \frac{1}{2}\frac{r}{c};$$

and therefore

$$t' = \tfrac{1}{2}t.$$

Thus in a boiler, half an inch thick, and 3 feet in diameter, a pressure of 150 lb to the square inch makes $t = 5400$, $t' = 2700$.

For a sphere of internal radius r, and small thickness c, supposing it divided by a diametral plane, then the resultant tension round the circumference, $tc.\ 2\pi r$, must balance the resultant fluid pressure $p.\pi r^2$, supposing p the excess of the internal over the external pressure; and therefore

$$2\pi tcr = \pi pr^2;$$

or

$$\frac{t}{p} = \frac{1}{2}\frac{r}{c}.$$

In the experiment with the Magdeburg hemispheres, where two hemispheres were joined by an air-tight joint and the air say half exhausted, then, with a pound and inch as units, $p = 7\cdot5$, supposing 15 the atmospheric pressure; and if the diameter of the hemispheres be 3 feet, then $r = 18$; and the force required to separate the hemispheres would be

$$\pi \times 18^2 \times 7\cdot5 = 7634 \text{ lb}.$$

The tension of flexible surfaces is considered more fully in the article CAPILLARY ACTION.

[1] Drawings of the curves of buoyancy and of flotation, and of the metacentric curves, are given in the plates of illustration of a paper on the "Calculation of the Stability of Ships," by W. H. White and W. John, read before the Institution of Naval Architects, March 1871.

PART II.—HYDRODYNAMICS.

In considering the motion of fluids we shall suppose them non-viscous, so that whatever be the state of motion, the stress across any section is normal to the section, and therefore the stress is a pressure and the same in all directions about a point, as in Hydrostatics.

Two methods are employed in hydrodynamics, called the Eulerian and Lagrangian, although both are due to Euler; in the Eulerian we fix our attention on particular points of space, and observe the changes of pressure, density, and velocity which take place there, and in the Lagrangian we follow a particle of fluid and observe its changes. The first may be called the statistical and the second the historical method, according to Prof. J. C. Maxwell. The Eulerian method is generally employed except where the fluid has a moving boundary.

The Eulerian Form of the Equations of Motion.

The first equation to be established is the equation of continuity, which expresses the fact that the increase of matter inside a fixed surface is due to the flow of fluid across the surface into the interior, supposing there are no hypothetical sources or sinks in the interior of the surface.

Lemma.—The quantity of fluid, estimated in units of mass, which flows across a plane area in a given time is equal to the product of the area, the density, the time, and the resolved part of the velocity perpendicular to the area.

Fig. 9.

For if q be the velocity, the quantity of fluid which flows across the area A in the time t will form an oblique cylinder of length qt, with its generating lines in the direction of motion (fig. 9). If θ denote the angle between the normal to the area and the velocity, the mass of the cylinder

$$=A\rho t q \cos\theta,$$

which is therefore the flux across the area A in the time t.

Generally, if S denote any fixed surface, M the mass of the fluid inside it, and θ the angle which the normal drawn outwards at any point of the surface makes with the velocity q at that point, then

$\frac{dM}{dt}$ = rate of increase of quantity of fluid inside the surface per unit of time

= flux across the surface per unit of time

$$= -\int \rho q \cos\theta\, dS;$$

or
$$\frac{dM}{dt}+\int\rho q\cos\theta\, dS=0 \quad . \quad . \quad . \quad . \quad . \quad (1),$$

the integral equation of continuity.

In the Eulerian equations of motion u, v, w are taken to denote the components of the velocity q parallel to the coordinate axes at the point xyz at the time t; u, v, w are therefore functions of x, y, z, t the independent variables, and d is used to denote partial differentiation with respect to these four independent variables.

To transfer the integral equation into the differential equation of continuity, we require Green's transformation, namely,

$$\iiint\left(\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}\right)dxdydz=\iint(l\xi+m\eta+n\zeta)dS\,;$$

or, individually,

$$\iiint\frac{d\xi}{dx}dxdydz=\iint l\xi dS,\ \iiint\frac{d\eta}{dy}dxdydz=\iint m\eta dS,$$

$$\iiint\frac{d\zeta}{dz}dxdydz=\iint n\zeta dS\,;$$

where the integrations extend respectively through the volume and over the surface of a closed space S; l,m,n denote the direction-cosines of the outward drawn normal at the surface element dS, and ξ, η, ζ are continuous functions of x, y, z.

The integral equation of continuity may now be written

$$\iiint\frac{d\rho}{dt}dxdxdy+\iint(l\rho u+m\rho v+n\rho w)dS=0,$$

which by Green's transformation becomes

$$\iiint\left(\frac{d\rho}{dt}+\frac{d\rho u}{dx}+\frac{d\rho v}{dy}+\frac{d\rho w}{dz}\right)dxdydz=0,$$

leading to the differential equation of continuity

$$\frac{d\rho}{dt}+\frac{d\rho u}{dx}+\frac{d\rho v}{dy}+\frac{d\rho w}{dz}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

It is customary to establish the differential equation of continuity immediately by considering the fluid which enters and leaves an infinitesimal parallelepiped, whose edges are dx, dy, dz, in the time dt, but this requires us to suppose in succession each of the elements dx, dy, dz, though infinitesimal, to be infinite compared with the other two, and with the infinitesimal element of time dt; this violation of the principles of the differential calculus is avoided by establishing the equation in its integral form first.

We shall establish the equations of motion in a similar way by considering the rate of increase of momentum in a fixed direction of the fluid inside the surface, and equating it to the momentum generated by the forces acting throughout the space S and by the pressures acting at the surface S.

Taking the fixed direction parallel to the axis of x, the rate of increase of momentum in that direction per unit of time, due to the fluid which crosses the surface, is

$$\iint(l\rho u^2+m\rho uv+n\rho uw)dS\,,$$

which by Green's transformation

$$=\iiint\left(\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}\right)dxdydz\,;$$

and, adding this to the rate of increase of momentum per unit of time of the fluid inside the surface

$$\iiint\frac{d\rho u}{dt}\,dxdydz,$$

we obtain, as the total rate of increase of momentum per unit of time of the fluid which fills the space S,

$$\iiint\left(\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}\right)dxdydz$$

in the direction of the axis of x.

The rate of generation of momentum in this direction by the forces of components X, Y, Z per unit of mass in the interior is

$$\iiint\rho X dxdydz,$$

and by the pressures at the surface is

$$-\int lp dS\,,$$

which by Green's transformation is equal to

$$-\iiint\frac{dp}{dx}\,dxdydz\,;$$

and therefore

$$\iiint\left(\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho ur}{dy}+\frac{d\rho uw}{dz}\right)dxdydz$$

$$=\iiint\left(\rho X-\frac{dp}{dx}\right)\,dydxdz\,;$$

leading to the differential equation of motion

$$\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}=\rho X-\frac{dp}{dx} \quad . \quad . \quad . \quad (3);$$

with two similar equations in y and z.

These equations may be slightly simplified; for

$$\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}$$

$$=\rho\left(\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}\right)$$

$$+u\left(\frac{d\rho}{dt}+\frac{d\rho u}{dx}+\frac{d\rho v}{dy}+\frac{d\rho w}{dz}\right),$$

which reduces to the first line, the second line vanishing in consequence of the equation of continuity; and therefore the equations of motion may be written

$$\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}=X-\frac{1}{\rho}\frac{dp}{dx} \quad . \quad . \quad . \quad (4);$$

with the two similar equations

$$\frac{dv}{dt}+u\frac{dv}{dx}+v\frac{dv}{dy}+w\frac{dv}{dz}=Y-\frac{1}{\rho}\frac{dp}{dy} \quad . \quad . \quad . \quad (5),$$

$$\frac{dw}{dt}+u\frac{dw}{dx}+v\frac{dw}{dy}+w\frac{dw}{dz}=Z-\frac{1}{\rho}\frac{dp}{dz} \quad . \quad . \quad . \quad (6).$$

As a rule these equations are established immediately by determining the component accelerations of the fluid particle which is at xyz at the instant of time t considered, and saying that these accelerations reversed, combined with the impressed forces per unit of mass, will form a system in equilibrium according to D'Alembert's principle.

To determine the component accelerations, suppose F any function of x, y, z, t, and determine the rate of change of F per unit of time for a moving particle; denoting this change by $\frac{DF}{dt}$, we have

$$\frac{DF}{dt} = \text{lt}\,\frac{F(x+u\delta t,\ y+v\delta t,\ z+w\delta t,\ t+\delta t) - F(x,y,z,t)}{\delta t}$$

$$= \frac{dF}{dt} + u\frac{dF}{dx} + v\frac{dF}{dy} + w\frac{dF}{dz},$$

so that

$$\frac{D}{dt} = \frac{d}{dt} + u\frac{d}{dx} + v\frac{d}{dy} + w\frac{d}{dz}.$$

$\frac{D}{dt}$ is called particle differentiation, because we follow the rate of change of the particle as it leaves the point xyz; but $\frac{dF}{dt}$, $\frac{dF}{dx}$, $\frac{dF}{dy}$, $\frac{dF}{dz}$ are the rates of change of F at the time t at the point xyz, fixed in space. Consequently the component accelerations parallel to the axes of coordinates of a particle of fluid are

$$\frac{du}{dt} + u\frac{du}{dx} + v\frac{du}{dy} + w\frac{du}{dz},$$

$$\frac{dv}{dt} + u\frac{dv}{dx} + v\frac{dv}{dy} + w\frac{dv}{dz},$$

$$\frac{dw}{dt} + u\frac{dw}{dx} + v\frac{dw}{dy} + w\frac{dw}{dz},$$

leading to the equations of motion last established.

If $F(x,y,z,t)=0$ be the equation of a surface containing always the same particles of fluid, it follows from the preceding that

$$\frac{DF}{dt} = 0,$$

or

$$\frac{dF}{dt} + u\frac{dF}{dx} + v\frac{dF}{dy} + w\frac{dF}{dz} = 0 \quad . \quad . \quad . \quad . \quad . \quad (7).$$

This is called the differential equation of the bounding surface, as particles of fluid once in the bounding surface always remain in it.

To integrate the equations of motion (4), (5), and (6), suppose the impressed forces due to a potential V, such that the force in any direction is the rate of diminution of V in that direction, then

$$X = -\frac{dV}{dx}, \quad Y = -\frac{dV}{dy}, \quad Z = -\frac{dV}{dz};$$

and putting

$$\frac{dw}{dy} - \frac{dv}{dz} = 2\xi, \quad \frac{du}{dz} - \frac{dw}{dx} = 2\eta, \quad \frac{dv}{dx} - \frac{du}{dy} = 2\zeta,$$

the equations may be written

$$\frac{du}{dt} - 2v\zeta + 2w\eta + \frac{dR}{dx} = 0 \quad . \quad . \quad . \quad . \quad . \quad (8),$$

$$\frac{dv}{dt} - 2w\xi + 2u\zeta + \frac{dR}{dy} = 0 \quad . \quad . \quad . \quad . \quad . \quad (9)$$

$$\frac{dw}{dt} - 2u\eta + 2v\xi + \frac{dR}{dz} = 0 \quad . \quad . \quad . \quad . \quad (10),$$

where

$$R = \int\frac{dp}{\rho} + V + \frac{1}{2}q^2,$$

and $q^2 = u^2 + v^2 + w^2$ (Lamb, *Motion of Fluids*, Appendix D; also *Proc. London Math. Society*, vol. ix.).

A *stream line* is defined to be the actual path of a particle, and a *line of flow* to be a line such that the tangent at every point is in the direction of the velocity at the point; the stream lines and lines of flow are coincident only when the motion is steady; and when the motion is irrotational, the lines of flow are orthogonal to the surfaces obtained by equating the velocity function to a constant.

A *vortex line* is defined to be a line whose tangent at any point is in the direction of the resultant ω of the component angular velocities ξ, η, ζ at that point; and ω is called the *spin* (Clifford, *Kinematic*).

ξ, η, ζ are called the components of molecular rotation (or spin) at xyz, for a reason to be explained afterwards; and when they vanish the motion is said to be irrotational, and a function ϕ exists, called the velocity function, such that

$$u = \frac{d\phi}{dx}, \quad v = \frac{d\phi}{dy}, \quad w = \frac{d\phi}{dz};$$

and, generally, the velocity in any direction is then the space variation of ϕ.

When the motion is irrotational, equations (8), (9), and (10) become

$$\frac{d^2\phi}{dxdt} + \frac{dR}{dx} = 0, \quad \frac{d^2\phi}{dydt} + \frac{dR}{dy} = 0, \quad \frac{d^2\phi}{dzdt} + \frac{dR}{dz} = 0;$$

and therefore

$$\frac{d\phi}{dt} + R = H,$$

or

$$\int\frac{dp}{\rho} + V + \frac{1}{2}q^2 + \frac{d\phi}{dt} = H,$$

a constant throughout the fluid, which may, however, be a function of the time.

If, however, the motion be steady, that is, if the velocity at any point of space does not change with the time, then

$$\frac{du}{dt} = 0, \quad \frac{dv}{dt} = 0, \quad \frac{dw}{dt} = 0,$$

and the equations become

$$\frac{dR}{dx} - 2v\zeta + 2w\eta = 0,$$

$$\frac{dR}{dy} - 2w\xi + 2u\zeta = 0,$$

$$\frac{dR}{dz} - 2u\eta + 2v\xi = 0;$$

so that

$$u\frac{dR}{dx} + v\frac{dR}{dy} + w\frac{dR}{dz} = 0;$$

$$\xi\frac{dR}{dx} + \eta\frac{dR}{dy} + \zeta\frac{dR}{dz} = 0;$$

and therefore the surface R, = constant, contains both stream lines and vortex lines; and therefore

$$\int\frac{dp}{\rho} + V + \tfrac{1}{2}q^2 = \text{constant} \quad . \quad . \quad . \quad . \quad . \quad (11)$$

along a stream line, and along a vortex line; and if the motion is irrotational, the constant is the same for all the space filled with the fluid; for then

$$\frac{dR}{dx} = 0, \quad \frac{dR}{dy} = 0, \quad \frac{dR}{dz} = 0.$$

Taking the axis of x for an instant in the direction of the normal to the surface R = constant, then $u=0$ and $\xi=0$, and (8), (9), and (10), if the motion is steady, reduce to $\frac{dR}{dn} = 2v\zeta - 2w\eta = 2q\omega \sin\theta$, where θ is the angle between the stream and the vortex line.

It is sometimes convenient to use moving axes of coordinates in Hydrodynamics, and the equations of motion then become

$$\frac{du}{dt} - v\omega_3 + w\omega_2 + (u + y\omega_3 - z\omega_2)\frac{du}{dx} + (v + z\omega_1 - x\omega_3)\frac{du}{dy}$$
$$+ (w + x\omega_2 - y\omega_1)\frac{du}{dz} = X - \frac{1}{\rho}\frac{dp}{dx},$$

with two similar equations; ω_1, ω_2, ω_3 denoting the component angular velocities of the moving axes, and u, v, w the components of the velocity of the fluid in space at the point xyz at the time t parallel to the axes.

For if q denote the component velocity of the particle xyz at the time t in a direction fixed in space whose direction-cosines are l, m, n, then

$$q = lu + mv + nw;$$

and in the infinitesimal element of time dt the coordinates of the particle will have become

$$x + (u + y\omega_3 - z\omega_2)dt, \ y + (v + z\omega_1 - x\omega_3)dt, \ z + (w + x\omega_2 - y\omega_1)dt;$$

so that

$$\frac{Dq}{dt} = \frac{dl}{dt}u + \frac{dm}{dt}v + \frac{dn}{dt}w$$
$$+ l\left\{\frac{du}{dt} + (u + y\omega_3 - z\omega_2)\frac{du}{dx} + (v + z\omega_1 - x\omega_3)\frac{du}{dy} + (w + x\omega_2 - y\omega_1)\frac{du}{dz}\right\}$$
$$+ m\left\{\frac{dv}{dt} + (u + y\omega_3 - z\omega_2)\frac{dv}{dx} + (v + z\omega_1 - x\omega_3)\frac{dv}{dy} + (w + x\omega_2 - y\omega_1)\frac{dv}{dz}\right\}$$
$$+ n\left\{\frac{dw}{dt} + (u + y\omega_3 - z\omega_2)\frac{dw}{dx} + (v + z\omega_1 - x\omega_3)\frac{dw}{dy} + (w + z\omega_2 - y\omega_1)\frac{dw}{dz}\right\}.$$

But, since l, m, n are the direction-cosines of a line fixed in space,

$$\frac{dl}{dt} = m\omega_3 - n\omega_2, \quad \frac{dm}{dt} = n\omega_1 - l\omega_3, \quad \frac{dn}{dt} = l\omega_2 - m\omega_1;$$

$$\therefore \frac{Dq}{dt} = l\left\{\frac{du}{dt} - v\omega_3 + w\omega_2 + (u + y\omega_3 - z\omega_2)\frac{du}{dx} + (v + z\omega_1 - x\omega_3)\frac{du}{dy}\right.$$
$$\left. + (w + x\omega_2 - y\omega_1)\frac{du}{dz}\right\}$$
$$+ m\left\{\frac{dv}{dt} - w\omega_1 + u\omega_3 + (u + y\omega_3 - z\omega_2)\frac{dv}{dx} + (v + z\omega_1 - x\omega_3)\frac{dv}{dy}\right.$$
$$\left. + (w + x\omega_2 - y\omega_1)\frac{dv}{dz}\right\}$$
$$+ n\left\{\frac{dw}{dt} - u\omega_2 + v\omega_1 + (u + y\omega_3 - z\omega_2)\frac{dw}{dx} + (v + z\omega_1 - x\omega_3)\frac{dw}{dy}\right.$$
$$\left. + (w + x\omega_2 - y\omega_1)\frac{dw}{dz}\right\}$$
$$= l\left(X - \frac{1}{\rho}\frac{dp}{dx}\right) + m\left(Y - \frac{1}{\rho}\frac{dp}{dy}\right) + n\left(Z - \frac{1}{\rho}\frac{dp}{dz}\right)$$

for all values of l, m, n, leading to the equations of motion.

As an example of the use of moving axes in hydrodynamics, consider the liquid filling the ellipsoidal case

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1;$$

and first suppose the liquid to be frozen, and to have component angular velocities ξ, η, ζ about the axes, then

$$u=-y\zeta+z\eta,\ v=-z\xi+x\zeta,\ w=-x\eta+y\xi.$$

If the liquid now be suddenly melted, and additional component angular velocities Ω_1, Ω_2, Ω_3 communicated to the ellipsoid about the axes, then (*vide infra*)

$$u=-y\zeta+z\eta+\frac{c^2-a^2}{c^2+a^2}\Omega_2 z+\frac{a^2-b^2}{a^2+b^2}\Omega_3 y,$$

$$v=-z\xi+x\zeta+\frac{a^2-b^2}{a^2+b^2}\Omega_3 x+\frac{b^2-c^2}{b^2+c^2}\Omega_1 z,$$

$$w=-x\eta+y\xi+\frac{b^2-c^2}{b^2+c^2}\Omega_1 y+\frac{c^2-a^2}{c^2+a^2}\Omega_2 x;$$

and if U, V, W denote the component velocities of the liquid relative to the axes,

$$U=u+y\omega_3-z\omega_2=\frac{2a^2}{a^2+b^2}\Omega_3 y-\frac{2a^2}{c^2+a^2}\Omega_2 z,$$

$$V=v+z\omega_1-x\omega_3=\frac{2b^2}{b^2+c^2}\Omega_1 z-\frac{2b^2}{a^2+b^2}\Omega_3 x,$$

$$W=w+x\omega_2-y\omega_1=\frac{2c^2}{c^2+a^2}\Omega_2 x-\frac{2c^2}{b^2+c^2}\Omega_1 y,$$

since $\omega_1=\Omega_1+\xi,\ \omega_2=\Omega_2+\eta,\ \omega_3=\Omega_3+\zeta,$

ω_1, ω_2, ω_3 being the component angular velocities of the axes.

We see that

$$U\frac{x}{w}+V\frac{y}{b^2}+W\frac{z}{c^2}=0,$$

so that a liquid particle always remains on a similar ellipsoid.

The hydrodynamical equations with moving axes, taking into account the mutual gravitation of the liquid, are

$$\frac{1}{\rho}\frac{dp}{dx}+Ax+\frac{du}{dt}-v\omega_3+w\omega_2+U\frac{du}{dx}+V\frac{du}{dy}+W\frac{du}{dz}=0 \quad (1),$$

$$\frac{1}{\rho}\frac{dp}{dy}+By+\frac{dv}{dt}-w\omega_1+u\omega_3+U\frac{dv}{dx}+V\frac{dv}{dy}+W\frac{dv}{dz}=0 \quad (2),$$

$$\frac{1}{\rho}\frac{dp}{dz}+Cz+\frac{dw}{dt}-u\omega_2+v\omega_1+U\frac{dw}{dx}+V\frac{dw}{dy}+W\frac{dw}{dz}=0 \quad (3);$$

where

$$A=\tfrac{3}{2}M\int_0^\infty\frac{d\lambda}{(a^2+\lambda)P},$$

$$B=\tfrac{3}{2}M\int_0^\infty\frac{d\lambda}{(b^2+\lambda)P},$$

$$C=\tfrac{3}{2}M\int_0^\infty\frac{d\lambda}{(c^2+\lambda)P},$$

and $P^2=(a^2+\lambda)(b^2+\lambda)(c^2+\lambda).$

With the above values of u, v, w, U, V, W, the hydrodynamical equations are of the form

$$\frac{1}{\rho}\frac{dp}{dx}+Ax+\alpha x+hy+gz=0,$$

$$\frac{1}{\rho}\frac{dp}{dy}+By+hx+\beta y+fz=0,$$

$$\frac{1}{\rho}\frac{dp}{dx}+Cz+gx+fy+\gamma z=0.$$

The component accelerations in space of the liquid particle at xyz parallel to the axes are therefore

$$\alpha x+hy+gz,\ hx+\beta y+fz,\ gx+fy+\gamma z;$$

and by the dynamical equations the rates of change of angular momentum about the coordinate axes are zero, and therefore

$$\Sigma m\left\{(gx+fy+\gamma z)y-(hx+\beta y+fz)z\right\}=0;$$

or $f\Sigma m(y^2-z^2)=0,$

or $f(b^2-c^2)=0;$

and therefore $f=0;$

and similarly g and h vanish.

Therefore the hydrodynamical equations become

$$\frac{1}{\rho}\frac{dp}{dx}+(A+\alpha)x=0,$$

$$\frac{1}{\rho}\frac{dp}{dy}+(B+\beta)y=0,$$

$$\frac{1}{\rho}\frac{dp}{dz}+(C+\gamma)z=0;$$

where

$$\alpha=\frac{4c^2(c^2-a^2)}{(c^2+a^2)^2}\Omega_2^2-\left(\frac{c^2-a^2}{c^2+a^2}\Omega_2-\eta\right)^2$$
$$-\frac{4b^2(a^2-b^2)}{(a^2+b^2)^2}\Omega_3^2-\left(\frac{a^2-b^2}{a^2+b^2}\Omega_3+\zeta\right)^2,$$

$$\beta=\frac{4a^2(a^2-b^2)}{(a^2+b^2)^2}\Omega_3^2-\left(\frac{a^2-b^2}{a^2+b^2}\Omega_3-\zeta\right)^2$$
$$-\frac{4c^2(b^2-c^2)}{(b^2+c^2)^2}\Omega_1^2-\left(\frac{b^2-c^2}{b^2+c^2}\Omega_1+\xi\right)^2,$$

$$\gamma=\frac{4b^2(b^2-c^2)}{(b^2+c^2)^2}\Omega_1^2-\left(\frac{b^2-c^2}{b^2+c^2}\Omega_1-\xi\right)^2$$
$$-\frac{4a^2(c^2-a^2)}{(c^2+a^2)^2}\Omega_2^2-\left(\frac{c^2-a^2}{c^2+a^2}\Omega_2+\eta\right)^2.$$

Therefore, integrating,

$$\frac{p}{\rho}+\tfrac{1}{2}\left\{(A+\alpha)x^2+(B+\beta)y^2+(C+\gamma)z^2\right\}=\text{constant};$$

and therefore the surfaces of equal pressure are the similar and co-axial quadrics

$$(A+\alpha)x^2+(B+\beta)y^2+(C+\gamma)z^2=\text{constant}.$$

If we can make α, β, γ constant, and $(A+\alpha)a^2=(B+\beta)b^2=C+\gamma)c^2$, the surfaces of equal pressure are similar to the external case, which can therefore be removed without affecting the motion.

This is the case when the axis of revolution is a principal axis; and, supposing it the axis of z, then

$$\Omega_1=0,\ \Omega_2=0,\ \xi=0,\ \eta=0.$$

If in addition we put $\Omega_3=0$, or $\omega_3=\zeta$, we obtain the solution of the particular case considered by Jacobi, of a liquid ellipsoid of three unequal axes, rotating about its least axis in relative equilibrium; or, putting $a=b$, we obtain Maclaurin's solution of the equilibrium of a rotating spheroid (*Cam. Phil. Soc. Proc.*, iii.).

Equation (11) is called Bernoulli's equation, and for homogeneous liquids under gravity is a very useful principle in hydraulics; the equation may be established from first principles by considering the energy which enters and leaves a certain portion of a tube of flow. (Lamb, *Motion of Fluids*, p. 23).

If homogeneous liquid be drawn off from a vessel, so large that the motion of the free surface may be neglected, then Bernoulli's equation becomes, P being the atmospheric pressure and h the height of the free surface,

$$\frac{p}{\rho}+gz+\tfrac{1}{2}q^2=\frac{P}{\rho}+gh;$$

and in particular, for a jet issuing into the atmosphere, where $p=P$,

$$\tfrac{1}{2}q^2=g(h-z);$$

or the velocity is due to the depth below the free surface. This is Torricelli's theorem (*De Motu gravium Projectorum*, 1643).

If we suppose fluid to escape according to this law from a large closed vessel in which the pressure is p where the motion is insensible, and neglect the variations of velocity due to variations of level, p being sufficiently great, then

$$\tfrac{1}{2}q^2=\frac{p-P}{\rho};\ \text{or } q=\sqrt{\left(2\frac{p-P}{\rho}\right)}.$$

If A be the sectional area of the jet (at the *vena contracta*), the quantity of fluid which escapes per unit of time is

$$A\rho q=A\sqrt{\{2\rho(p-P)\}};$$

the momentum per unit of time is

$$A\rho q^2=2A(p-P);$$

and the energy per unit of time is

$$\tfrac{1}{2}A\rho q^3=A(p-P)^{\frac{3}{2}}\sqrt{\frac{2}{\rho}}.$$

Suppose, for instance, two equal pipes leading one from the steam space and the other from the water space of a steam boiler at a pressure p, and suppose Torricelli's theorem to hold for the rate of efflux of the steam and water, then, if σ denote the density of steam, and ρ the density of water,

(1) $\dfrac{\text{The velocity of steam jet}}{\text{The velocity of water jet}}=\sqrt{\dfrac{\rho}{\sigma}}$,

(2) $\dfrac{\text{The quantity of steam jet}}{\text{The quantity of water jet}}=\sqrt{\dfrac{\sigma}{\rho}}$,

(3) $\dfrac{\text{The momentum of steam jet}}{\text{The momentum of water jet}}=1$,

(4) $\dfrac{\text{The energy of steam jet}}{\text{The energy of water jet}}=\sqrt{\dfrac{\rho}{\sigma}}$.

For instance, with steam at 8 atmospheres, or 120 lb to the square inch,

$$\sqrt{\frac{\rho}{\sigma}}=15\text{ nearly}.$$

—(Rankine, *Steam Engine*, appendix).

These principles assumed enable us to give a general explanation of the working of Giffard's injector. For, if the steam jet and water jet be directed at each other, with a small interval between, the superior energy and equal momentum of the steam jet will overcome the water jet, and the steam will flow back into the boiler. But the steam jet, without losing its momentum, is capable of being mixed with water to such an extent as to become a condensed water jet, moving with the velocity of the water jet, and still entering the boiler, a valve preventing the reversal of the motion. Consequently, the amount of water carried into the boiler per unit of time will theoretically be at most the difference between the quantities which would escape by the water and the steam jets, and therefore

$$=A\sqrt{(p-P)}(\sqrt{2\rho}-\sqrt{2\sigma})\ ;$$

and the efficiency of the injector, that is, the ratio of the water pumped in to the quantity of steam used, will be

$$\sqrt{\frac{\rho}{\sigma}}-1,$$

the efficiency of a pump being $\frac{\rho}{\sigma}$.

With C.G.S. units, and a pressure of 8 atmospheres, for instance,

$$p-P=7\times10^6 \text{ very nearly}, \quad \sqrt{\frac{\rho}{\sigma}}=15, \text{ and } \rho=1.$$

Therefore, if the diameter of the nozzles of the injector be d centimetres, the delivery in grammes per second

$$=\tfrac{1}{4}\pi d^2\sqrt{14}\cdot10^3(1-\sqrt{\tfrac{1}{15}})$$
$$=2180d^2\ ;$$

and since 1 gallon is 4541 cubic centimetres, the delivery in gallons per minute

$$=\frac{2180\times60}{4541}d^2$$
$$=28\cdot78d^2 \text{ nearly}.$$

The Lagrangian Form of the Equations.

Here the independent variables which define a particle are the time t, and a, b, c, the initial values of the coordinates x, y, z of a particle of fluid (or else functions of the initial coordinates, but it is best to consider a, b, c as the initial coordinates themselves).

Here x, y, z do not refer to a fixed point in space, but are the variable coordinates of a fluid particle, and are functions of a, b, c, t, the independent variables; and consequently

$$u=\frac{dx}{dt},\quad v=\frac{dy}{dt},\quad w=\frac{dz}{dt}\ ;$$

and the component accelerations of the fluid particle are

$$\frac{du}{dt},\ \frac{dv}{dt},\ \frac{dw}{dt}.$$

Consequently the equations of motion, assuming the existence of the potential V, and putting $P=\int\frac{dp}{\rho}$, and $P+V=Q$, ar

$$\frac{dQ}{dx}+\frac{du}{dt}=0,\quad \frac{dQ}{dy}+\frac{dv}{dt}=0,\quad \frac{dQ}{dz}+\frac{dw}{dt}=0\ ;$$

or multiplying by $\frac{dx}{da}$, $\frac{dy}{da}$, $\frac{dz}{da}$, and adding,

$$\frac{dQ}{da}+\frac{du}{dt}\frac{dx}{da}+\frac{dv}{dt}\frac{dy}{da}+\frac{dw}{dt}\frac{dz}{da}=0 \quad . \quad . \quad . \quad (1);$$

with two similar equations

$$\frac{dQ}{db}+\frac{du}{dt}\frac{dx}{db}+\frac{dv}{dt}\frac{dy}{db}+\frac{dw}{dt}\frac{dz}{db}=0 \quad . \quad . \quad . \quad (2),$$

$$\frac{dQ}{dc}+\frac{du}{dt}\frac{dx}{dc}+\frac{dv}{dt}\frac{dy}{dc}+\frac{dw}{dt}\frac{dz}{dc}=0 \quad . \quad . \quad . \quad (3).$$

Since the elementary parallelepiped whose edges were initially da, db, dc, becomes strained into a parallepiped of volume

$$\frac{d(x,y,z)}{d(a,b,c)}da\,db\,dc$$

therefore the equation of continuity is

$$\rho\frac{d(x,y,z)}{d(a,b,c)}=\rho_0,$$

or, if the fluid be a homogeneous liquid,

$$\frac{d(x,y,z)}{d(a,b,c)}=1.$$

When a, b, c are not the coordinates of a point actually occupied by the fluid particle, this equation of continuity must be replaced by

$$\frac{d}{dt}\left\{\rho\frac{d(x,y,z)}{d(a,b,c)}\right\}=0.$$

Cauchy's Integrals of Lagrange's Equations.

Eliminating Q by differentiation between (2) and (3)

$$\frac{d^2u}{dtdb}\frac{dx}{dc}-\frac{d^2u}{dtdc}\frac{dx}{db}+\frac{d^2v}{dtdb}\frac{dy}{dc}-\frac{d^2v}{dtdc}\frac{dy}{db}+\frac{d^2w}{dtdb}\frac{dz}{dc}-\frac{d^2w}{dtdc}\frac{dz}{db}=0\ ;$$

and integrating with respect to t,

$$\frac{du}{db}\frac{dx}{dc}-\frac{du}{dc}\frac{dx}{db}+\frac{dv}{db}\frac{dy}{dc}-\frac{dv}{dc}\frac{dy}{db}+\frac{dw}{db}\frac{dz}{dc}-\frac{dw}{dc}\frac{dz}{db}=\frac{dw_0}{db}-\frac{dv_0}{dc},$$

u_0, v_0, w_0 being the initial values of u, v, w, and a, b, c the initial values of x, y, z. Now

$$\frac{du}{da}=\frac{du}{dx}\frac{dx}{da}+\frac{du}{dy}\frac{dy}{da}+\frac{du}{dz}\frac{dz}{da},$$

and therefore

$$\left(\frac{dw}{dy}-\frac{dv}{dz}\right)\frac{d(y,z)}{d(b,c)}+\left(\frac{du}{dz}-\frac{dw}{dx}\right)\frac{d(z,x)}{d(b,c)}+\left(\frac{dv}{dx}-\frac{du}{dy}\right)\frac{d(x,y)}{d(b,c)}=\frac{dw_0}{db}-\frac{dv_0}{dc}\ ;$$

or putting

$$\frac{dw}{dy}-\frac{dv}{dz}=2\xi,\quad \frac{du}{dz}-\frac{dw}{dx}=2\eta,\quad \frac{dv}{dx}-\frac{du}{dy}=2\zeta,$$

$$\xi\frac{d(y,z)}{d(b,c)}+\eta\frac{d(z,x)}{d(b,c)}+\zeta\frac{d(x,y)}{d(b,c)}=\xi_0\ ;$$

with two similar equations

$$\xi\frac{d(y,z)}{d(c,a)}+\eta\frac{d(z,x)}{d(c,a)}+\zeta\frac{d(x,y)}{d(c,a)}=\eta_0,$$

$$\xi\frac{d(y,z)}{d(a,b)}+\eta\frac{d(z,x)}{d(a,b)}+\zeta\frac{d(x,y)}{d(a,b)}=\zeta_0.$$

Therefore

$$J\xi=\xi_0\frac{dx}{da}+\eta_0\frac{dx}{db}+\zeta_0\frac{dx}{dc},$$

$$J\eta=\xi_0\frac{dy}{da}+\eta_0\frac{dy}{db}+\zeta_0\frac{dy}{dc},$$

$$J\zeta=\xi_0\frac{dz}{da}+\eta_0\frac{dz}{db}+\zeta_0\frac{dz}{dc},$$

where

$$J=\frac{d(x,y,z)}{d(a,b,c)}\ ;$$

or, since $J=\frac{\rho_0}{\rho}$, therefore

$$\frac{\xi}{\rho}=\frac{\xi_0}{\rho_0}\frac{dx}{da}+\frac{\eta_0}{\rho_0}\frac{dx}{db}+\frac{\zeta_0}{\rho_0}\frac{dx}{dc} \quad . \quad . \quad . \quad . \quad . \quad (4),$$

$$\frac{\eta}{\rho}=\frac{\xi_0}{\rho_0}\frac{dy}{da}+\frac{\eta_0}{\rho_0}\frac{dy}{db}+\frac{\zeta_0}{\rho_0}\frac{dy}{dc} \quad . \quad . \quad . \quad . \quad . \quad (5),$$

$$\frac{\zeta}{\rho}=\frac{\xi_0}{\rho_0}\frac{dz}{da}+\frac{\eta_0}{\rho_0}\frac{dz}{db}+\frac{\zeta_0}{\rho_0}\frac{dz}{dc} \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Consequently if ξ,η,ζ are ever zero they are always zero, and then

$$u=\frac{d\phi}{dx},\quad v=\frac{d\phi}{dy},\quad w=\frac{d\phi}{dz},$$

and a velocity function ϕ exists.

For instance, if motion be generated from rest in a non-viscous fluid under forces due to a potential, a velocity function always exists, and the discovery of this velocity function for different cases is one of the chief problems to be solved in hydrodynamics.

A good example of the use of the Lagrangian equations of motion is given by the state of wave motion in deep water invented by Rankine; he puts

$$x=\alpha+ce^{-\frac{\beta}{c}}\sin\left(\omega t+\frac{\alpha}{c}\right),$$

$$y=\beta+ce^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right)\ ;$$

and therefore the coordinates of a particle are given in terms of t and α and β.

But α and β are not the initial coordinates of a particle; for putting $t=0$, then the coordinates are

$$a=\alpha+ce^{-\frac{\beta}{c}}\sin\frac{\alpha}{c},$$

$$b=\beta+ce^{-\frac{\beta}{c}}\cos\frac{\alpha}{c}.$$

Therefore

$$\frac{d(x,y)}{d(\alpha,\beta)}=1-e^{-2\frac{\beta}{c}},$$

and

$$\frac{d(a,b)}{d(\alpha,\beta)}=1-e^{-2\frac{\beta}{c}}\ ;$$

therefore

$$\frac{d(x,y)}{d(a,b)}=1\ ;$$

and the equation of continuity is satisfied.

Cauchy's integrals reduce to the single equation

$$\zeta\frac{d(x,y)}{d(a,b)}=\zeta_0,$$

or

$$\zeta=\zeta_0,$$

where

$$2\zeta_0=\frac{dv_0}{da}-\frac{du_0}{db},$$

and therefore

$$2\zeta_0\frac{d(a,b)}{d(\alpha,\beta)}=\frac{d(v_0,b)}{d(\alpha,\beta)}-\frac{d(u_0,a)}{d(\beta,\alpha)}.$$

Now

$$u=\frac{dx}{dt}=c\omega e^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right),$$

$$\frac{dy}{dt}=-c\omega e^{-\frac{\beta}{c}}\sin\left(\omega t+\frac{\alpha}{c}\right);$$

therefore

$$u_0=c\omega e^{-\frac{\beta}{c}}\cos\frac{\alpha}{c},\quad v_0=-c\omega e^{-\frac{\beta}{c}}\sin\frac{\alpha}{c};$$

and

$$2\zeta_0\frac{d(a,b)}{d(\alpha,\beta)}=2\omega e^{-\frac{\beta}{c}};$$

therefore

$$\zeta=\zeta_0=\frac{e^{-\frac{\beta}{c}}}{1-e^{-2\frac{\beta}{c}}}\omega=\frac{\omega}{2\sinh\frac{\beta}{c}}:$$

and the motion cannot therefore have been generated from rest by natural forces; the fluid must have been created with the proper amount of spin at every point.

We have

$$\frac{du}{dt}=-c\omega^2e^{-\frac{\beta}{c}}\sin\left(\omega t+\frac{\alpha}{c}\right),$$

$$\frac{dv}{dt}=-c\omega^2e^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right);$$

and therefore the dynamical equations (1) and (2) become

$$\frac{dQ}{d\alpha}-c\omega^2e^{-\frac{\beta}{c}}\sin\left(\omega t+\frac{\alpha}{c}\right)=0,$$

$$\frac{dQ}{d\beta}-c\omega^2e^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right)+c\omega^2e^{-2\frac{\beta}{c}}=0;$$

and therefore the integral of these two equations is

$$Q+c^2\omega^2e^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right)-\tfrac{1}{2}c^2\omega^2e^{-2\frac{\beta}{c}}=H,\ \text{a constant.}$$

Now

$$Q=\int\frac{dp}{\rho}+V,\ =\frac{p}{\rho}-gy,$$

$$=\frac{p}{\rho}-g\beta-gce^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right);$$

and therefore

$$\frac{p}{\rho}-g\beta+c(c\omega^2-g)e^{-\frac{\beta}{c}}\cos\left(\omega t+\frac{\alpha}{c}\right)-\tfrac{1}{2}c^2\omega^2e^{-2\frac{\beta}{c}}=H.$$

A free surface is possible if

$$c\omega^2=g,$$

and then

$$\frac{p}{\rho}=g\beta+\tfrac{1}{2}c^2\omega^2e^{-2\frac{\beta}{c}}+H,$$

and the pressure at a particle is constant.

The wave length $\lambda=2\pi c$; and the velocity of propagation

$$c\omega=\sqrt{gc}=\sqrt{\frac{g\lambda}{2\pi}}.$$

The surfaces of equal pressure are trochoids, obtained by rolling a circle of radius c on the under side of a line at a depth $\beta-c$, the distance of the carried point from the centre being $ce^{-\frac{\beta}{c}}$.

Irrotational Motion.

If liquid originally at rest be contained in a singly-connected space, then forces due to a singly-valued function V are not capable of setting up any motion in the liquid, and any motion must be due to the motion of the bounding surface.

For, ϕ denoting the velocity function, by Green's theorem the kinetic energy

$$T=\tfrac{1}{2}\rho\iiint\left\{\left(\frac{d\phi}{dx}\right)^2+\left(\frac{d\phi}{dy}\right)^2+\left(\frac{d\phi}{dz}\right)^2\right\}dxdydz$$

$$=\tfrac{1}{2}\rho\iint\phi\frac{d\phi}{dn}dS;$$

and therefore, if $\frac{d\phi}{dn}=0$, then $T=0$, and therefore

$$\left(\frac{d\phi}{dx}\right)^2+\left(\frac{d\phi}{dy}\right)^2+\left(\frac{d\phi}{dz}\right)^2=0,$$

or

$$\frac{d\phi}{dx}=0,\ \frac{d\phi}{dy}=0,\ \frac{d\phi}{dz}=0.$$

If we suppose the actual motion at any instant to have been instantaneously generated from rest by the application of proper impulses at the bounding surface, then, since no natural forces can act impulsively throughout the liquid, the equations of impulse are

$$\frac{1}{\rho}\frac{d\varpi}{dx}=-u,\ \frac{1}{\rho}\frac{d\varpi}{dy}=-v,\ \frac{1}{\rho}\frac{d\varpi}{dz}=-w,$$

ϖ denoting the impulsive pressure at any point of the liquid; and therefore, if ϕ denote the velocity function, we can put

$$\phi=-\frac{\varpi}{\rho}.$$

Since the work done by an impulse is the product of the impulse into half the sum of the initial and final velocities, we see how it is that the kinetic energy of the liquid

$$=-\frac{1}{2}\iint\varpi\frac{d\phi}{dn}dS$$

$$=\frac{1}{2}\rho\iint\phi\frac{d\phi}{dn}dS.$$

Also the kinetic energy acquired thus due to the velocity function ϕ will be less than the kinetic energy of any other motion, wholly or partially rotational, but satisfying the equation of continuity, and the condition at the boundary that the normal velocity of the liquid is the normal velocity of the boundary.

For, if u_1, v_1, w_1 be the velocities at any point of this new motion, and T_1 the whole kinetic energy,

$$T_1-T=\tfrac{1}{2}\rho\iiint(u_1^2-u^2+v_1^2-v^2+w_1^2-w^2)dxdydz$$

$$=\tfrac{1}{2}\rho\iiint\left\{(u_1-u)^2+(v_1-v)^2+(w_1-w)^2\right\}dxdydz$$

$$+\rho\iiint\left\{u(u_1-u)+v(v_1-v)+w(w_1-w)\right\}dxdydz.$$

But

$$\iiint\left\{u(u_1-u)+v(v_1-v)+w(w_1-w)\right\}dxdydz$$

$$=\iiint\left\{\frac{d\phi}{dx}(u_1-u)+\frac{d\phi}{dy}(v_1-v)+\frac{d\phi}{dz}(w_1-w)\right\}dxdydz$$

$$=\iint\phi\left\{l(u_1-u)+m(v_1-v)+n(w_1-w)\right\}dS$$

$$-\iiint\phi\left\{\frac{d}{dx}(u_1-u)+\frac{d}{dy}(v_1-v)+\frac{d}{dz}(w_1-w)\right\}dxdydz$$

$$=0.$$

Then

$$T_1-T=\tfrac{1}{2}\rho\iiint\left\{(u_1-u)^2+(v_1-v)^2+(w_1-w)^2\right\}dxdydz,$$

a positive quantity; and therefore T_1 is always greater than T, a theorem due to Sir W. Thomson. If, however, ϕ be multiply-valued, and the space occupied by the liquid multiply-connected, we can have circulation existing in the different circuits of the space even when the bounding surface is at rest, and the motion may still be differentially irrotational, and any motion of the bounding surface will not affect these circulations. For instance, we may have $\phi=\frac{m}{2\pi}\tan^{-1}\frac{y}{x}$, and the liquid circulating in any ring-shaped surface, whose axis of figure is the axis of z.

To find the kinetic energy of a liquid in a multiply-connected space, the motion being differentially irrotational, but circulations existing in the circuits, the space occupied by the liquid must be rendered acyclic by barriers, which may be supposed to be membranes, moving with the velocity of the liquid; and then, if k be the cyclic constant of the value of ϕ in any circuit, we must suppose the value of ϕ on one side of the membrane to exceed the value of ϕ on the other side by k, so that the integral $\iint\phi\frac{d\phi}{dn}dS$ over the membrane must be replaced by $k\iint\frac{d\phi}{dn}dS$; so that to the term $\frac{1}{2}\rho\iint\phi\frac{d\phi}{dn}$ over the outside surface must be added a number of terms of the form $\frac{1}{2}\rho k\iint\frac{d\phi}{dn}dS$, to express the energy due to the circulation in the circuits; and the condition of continuity shows that $\iint\frac{d\phi}{dn}dS$ over one of these membranes which render a circuit acyclic is independent of the form of the membrane.

On Flow, Circulation, and Vortex Motion.

The line integral of the tangential velocity $\int\left(u\frac{dx}{ds}+v\frac{dy}{ds}+w\frac{dz}{ds}\right)ds$ or $\int(udx+vdy+wdz)$, from one point to another of a curve, is called the *flow* along the curve from the initial to the final point; and, if the curve be closed, the line integral round the curve is called the *circulation* in the curve.

If a velocity function ϕ exist, then the flow $=\int d\phi=\phi_2-\phi_1$, where ϕ_1 and ϕ_2 are the initial and final values of ϕ; and therefore the flow is independent of the curve for all mutually reconcilable curves; and the circulation in any closed curve, capable of being reduced to a point without leaving space for which ϕ is single-valued, is zero.

If through every point of a small closed curve the vortex lines be drawn, a tube is obtained and the fluid contained is called a *vortex filament*.

By analogy with the spin of a rigid body the component spin of the fluid in any plane at any point is defined as the circulation round any infinitesimal area in the plane enclosing the point divided by twice the area. For in a rigid body, rotating about the axis of x with angular velocity ξ suppose, the circulation round a curve in the plane of yz is

$$\int\omega\left(x\frac{dy}{ds}-y\frac{dx}{ds}\right)ds$$

$=\omega$ times twice the area of the curve.

Now if, in the fluid at the point xyz, we take the circulation round the elementary area $dydz$, it is equal to

$$vdy+\left(w+\frac{dw}{dy}dy\right)dz-\left(v+\frac{dv}{dz}\right)dz-wdz$$
$$=\left(\frac{dw}{dy}-\frac{dv}{dz}\right)dydz,$$

and therefore the component spin in the plane yz is $\frac{1}{2}\left(\frac{dw}{dy}-\frac{dv}{dz}\right)$, which we have denoted by ξ. Similarly the component spins in the planes of zx and xy are $\frac{1}{2}\left(\frac{du}{dz}-\frac{dw}{dx}\right)=\eta$ and $\frac{1}{2}\left(\frac{dv}{dx}-\frac{du}{dy}\right)=\zeta$ respectively.

Since the circulation round any triangular area is the sum of the circulations round the projections of the area on the coordinate planes, the composition of the component spins ξ, η, ζ is according to the vector law. Hence in any infinitesimal part of the fluid the circulation is zero round every small plane curve passing through a certain line, the resultant axis of spin of ξ, η, ζ at that point of the fluid. Consequently the circulation round any closed curve drawn on the surface of a vortex filament is zero; and therefore, if at any two points of a vortex filament we draw the cross sections ABC, A′B′C′, joined by the line AA′, then, since the flow in AA′ in the complete circuit ABCAA′B′C′A′A is taken in opposite directions, the resultant flow in AA′ vanishes, and therefore the circulations in ABC, A′B′C′, estimated in the same direction, are equal. This is expressed by saying that, at all points of a vortex filament, $\omega\alpha$ is constant, where α is the sectional area of the filament, and ω the spin (Clifford, *Kinematic*, Book iii.).

So far the theorems about vortex motion are kinematical; but, introducing Euler's equation of motion

$$\frac{\mathrm{D}u}{dt}+\frac{d\mathrm{Q}}{dx}=0,\ \frac{\mathrm{D}v}{dt}+\frac{d\mathrm{Q}}{dy}=0,\ \frac{\mathrm{D}w}{dt}+\frac{d\mathrm{Q}}{dz}=0,$$

where
$$\mathrm{Q}=\int\frac{dp}{\rho}+\mathrm{V},$$

then
$$\frac{\mathrm{D}}{dt}(udx+vdy+wdz)$$
$$=u\frac{\mathrm{D}dx}{dt}+v\frac{\mathrm{D}dy}{dt}+w\frac{\mathrm{D}dz}{dt}+\frac{\mathrm{D}u}{dt}dx+\frac{\mathrm{D}v}{dt}dy+\frac{\mathrm{D}w}{dt}dz$$
$$=udu+vdv+wdw-\frac{d\mathrm{Q}}{dx}dx-\frac{d\mathrm{Q}}{dy}dy-\frac{d\mathrm{Q}}{dz}dz$$
$$=\tfrac{1}{2}dq^2-d\mathrm{Q};$$

and therefore, by integration round a closed curve,

$$\frac{\mathrm{D}}{dt}\int(udx+vdy+wdz)=0;$$

and therefore the circulation in any circuit composed of the same fluid particles is constant, and, if the motion is differentially irrotational, is zero round all reconcilable paths.

The circulation round any small plane curve passing through the axis of spin at any point being always zero, it follows conversely that a vortex filament is always composed of the same fluid particles; and, since the circulation round any cross section is constant for different times, it follows from the previous kinematical propositions that $\alpha\omega$ is constant for all the time, and the same at all points of a vortex filament.

Professor Clifford (*Proc. London Mathematical Society*, vol. ix.) has given a simple quaternion proof of the theorem—To determine the velocity at any point of a fluid, when the spin is given.

If σ denote the velocity and ω the spin at any point, then

$$2\omega=\mathrm{V}\nabla\sigma;$$

also, if k denote the cubical expansion,

$$k=-\mathrm{S}\nabla\sigma.$$

Hence the quaternion q or $-k+2\omega$ is simply $\nabla\sigma$; consequently the problem to be solved is to determine σ from the equation

$$q=\nabla\sigma,$$

q being given.

Operating by ∇,

$$\nabla q=\nabla^2\sigma;$$

therefore σ is the potential of ∇q; and therefore

$$\sigma_a=\tfrac{1}{4\pi}\int\frac{\nabla q_b\,dv_b}{\mathrm{D}_{ab}},$$

where σ_a means the value of σ at the point a, dv_b means an element of volume at the point b, and D_{ab} the distance between the points a, b.

Returning to Euler's equations of motion,

$$\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}+\frac{d\mathrm{Q}}{dx}=0,$$

. . . .

and eliminating Q,

$$\frac{\mathrm{D}\xi}{dt}-\xi\frac{du}{dx}-\eta\frac{dv}{dx}-\zeta\frac{dw}{dx}+\xi\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)=0;$$

and, since by the equation of continuity

$$\frac{1}{\rho}\frac{\mathrm{D}\rho}{dt}+\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0,$$

therefore

$$\frac{\mathrm{D}}{dt}\left(\frac{\xi}{\rho}\right)=\frac{\xi}{\rho}\frac{du}{dx}+\frac{\eta}{\rho}\frac{dv}{dx}+\frac{\zeta}{\rho}\frac{dw}{dx};$$

and similarly

$$\frac{\mathrm{D}}{dt}\left(\frac{\eta}{\rho}\right)=\frac{\xi}{\rho}\frac{du}{dy}+\frac{\eta}{\rho}\frac{dv}{dy}+\frac{\zeta}{\rho}\frac{dw}{dy},$$
$$\frac{\mathrm{D}}{dt}\left(\frac{\zeta}{\rho}\right)=\frac{\xi}{\rho}\frac{du}{dz}+\frac{\eta}{\rho}\frac{dv}{dz}+\frac{\zeta}{\rho}\frac{dw}{dz}.$$

These equations, first given by Professor Stokes for homogeneous liquid, were generalized for any fluid by Professor Nanson, *Messenger of Mathematics*, 1873. They may also be obtained immediately by the differentiation of Cauchy's integrals (4), (5), and (6), given above.

Plane Vortex Motion.

When a series of straight vertical vortices (called columnar vortices by Sir W. Thomson) are present in homogeneous liquid, bounded by two horizontal planes, we can determine the motion of any vortex by supposing it due to the remaining vortices.

A single vortex will remain at rest, and cause a velocity at any point perpendicular to the plane through the point and the vortex inversely as the distance from the vortex.

If m denote the strength of the vortex, *i.e.*, the circulation in any circuit enclosing the vortex once, then the velocity at a distance r from the vortex will be $\frac{m}{2\pi r}$, and the current function ψ will be $\frac{m}{2\pi}\log r$, and the velocity function ϕ will be $\frac{m}{2\pi}\theta$, where θ is the angle between any fixed plane and the plane through the vortex and the point.

The surface of equal pressure under gravity will be of the form

$$(x^2+y^2)(z-a)=\frac{m^2}{4\pi^2g},$$

the axis of the vortex being the axis of z.

When there are more than one vortex present, each vortex moving with the velocity due to the other vortices will describe the curve whose equation is

$$\Sigma\frac{m}{2\pi}\log r=\text{constant},$$

where m is the strength of one of the remaining vortices, and r the distance between it and the vortex whose motion is considered; this equation may also be written

$$\Pi r^m=\text{constant}.$$

When the liquid is bounded by a vertical cylindrical surface, the motion of a vortex may be determined as due to a series of vortices considered as images of the original vortex, and so arranged as to make the velocity across the boundary zero at every point of the boundary.

When the boundaries are plane surfaces, the images are the optical images by reflexion of the original vortex, considered as positive or negative, according as formed by an even or odd number of reflexions.

Thus the curve described by a vortex inside the angle bounded by the planes $\theta = \pm\frac{\pi}{2n}$ is the Cotes's spiral

$$r \cos n\theta = C,$$

and inside the space bounded by the planes $x=0$, $x=a$, $y=0$, $y=b$ is

$$\cot^2 \text{am}\left(K\frac{x}{a}, k\right) + \cot^2 \text{am}\left(K'\frac{y}{b}, k'\right) = \text{constant},$$

where

$$\frac{K}{K'} = \frac{a}{b}$$

(*Quarterly Journal of Mathematics*, vol. xv.).

A single vortex of strength m in a circular cylinder of radius a at a distance c from the centre will move with the velocity due to an image of strength $-m$ at a distance $\frac{a^2}{c}$ from the centre, and therefore describe a circle of radius c with velocity

$$\frac{m}{2\pi}\frac{a}{\frac{a^2}{c} - c} = \frac{m}{2\pi}\cdot\frac{c}{a^2 - c^2},$$

and therefore in the periodic time $\frac{4\pi^2}{m}(a^2 - c^2)$.

A single circular vortex in infinite fluid will move with a certain velocity in the direction of its axis ("Vortex Motion," *Trans. R.S.E.*, 1869; "Vortex Motion," Helmholtz, *Crelle*, 1858); and, if another equal circular vortex be projected coaxially after the first, the motion of the first must be compounded with that due to the second. Consequently the first vortex will dilate and move slower till the second vortex passes through it, when it will contract and move faster till it passes through the second, and so on. This can be verified experimentally with smoke rings projected from the same circular hole, or with half vortex rings, formed on the surface of water by drawing a semi-circular blade a short distance through the water.

The motion of a vortex ring projected perpendicularly against a plane boundary will be determined by compounding it with the motion due to an equal and opposite vortex ring, its optical image in the wall. The vortex ring will therefore spread out and move more slowly in the direction of its axis as it approaches the wall; at the same time the molecular rotation, being inversely proportional to the cross section of the vortex, will be seen to increase.

Plane Motion of Liquids.

When the velocity of the fluid is always parallel to a fixed plane, we take this plane as the plane of xy, and then $w=0$, and u and v are functions of x and y, and the stream lines are plane curves.

Considering only the cases where the fluid is incompressible, the equation of continuity becomes

$$\frac{du}{dx} + \frac{dv}{dy} = 0,$$

and therefore a function ψ exists, called the stream function, such that

$$u = -\frac{d\psi}{dy}, \quad v = \frac{d\psi}{dx};$$

and ψ = constant is the equation of a line of flow.

The spin at any point

$$\zeta = \frac{1}{2}\left(\frac{dv}{dx} - \frac{du}{dy}\right)$$

$$= \frac{1}{2}\left(\frac{d^2\psi}{dx^2} + \frac{d^2\psi}{dy^2}\right).$$

If the motion is irrotational, then $\zeta = 0$, and a velocity function ϕ exists such that

$$u = \frac{d\phi}{dx} = -\frac{d\psi}{dy},$$

$$v = \frac{d\phi}{dy} = +\frac{d\psi}{dx};$$

therefore ψ and ϕ are conjugate functions of x and y, and

$$\psi + i\phi = f(x + iy).$$

By assigning particular values to this function, Helmholtz and Kirchhoff have discovered the solution of various problems of discontinuous plane liquid motion, an account of which is given in Lamb's *Motion of Fluids*.

The kinetic energy of the liquid bounded by two planes perpendicular to the axis of z at unit distance is

$$T = \frac{1}{2}\rho\iint\left\{\left(\frac{d\phi}{dx}\right)^2 + \left(\frac{d\phi}{dy}\right)^2\right\}dxdy$$

$$= \frac{1}{2}\rho\iint\left\{\left(\frac{d\psi}{dx}\right)^2 + \left(\frac{d\psi}{dy}\right)^2\right\}dxdy$$

$$= \frac{1}{2}\rho\int\phi\frac{d\phi}{dn}ds = \frac{1}{2}\rho\int\psi\frac{d\psi}{dn}ds,$$

when $\frac{d\phi}{dn}$, $\frac{d\psi}{dn}$ are the rates of change of ϕ and ψ in the direction of the outward drawn normal to the bounding curve at the element ds.

Since $\frac{d\psi}{dn} = \frac{d\phi}{ds}$, $\frac{d\phi}{dn} = -\frac{d\psi}{ds}$,

therefore $T = -\frac{1}{2}\rho\int\phi d\psi = \frac{1}{2}\rho\int\psi d\phi.$

We can interchange ϕ and ψ, and make ϕ the stream function and ψ the velocity function; thus from any given irrotational motion in two dimensions another may be derived by turning the velocity through a right angle without altering its magnitude.

For instance, if the axis of z be a line source of delivery m, then, since the flow across any cylinder of radius r is m, the velocity must be $\frac{m}{2\pi r}$; and therefore

$$\phi = \frac{m}{2\pi}\log r, \text{ and } \psi = \frac{m}{2\pi}\theta;$$

where θ is the angle made by a plane through the axis of z and the point with a fixed plane.

If the values of ϕ and ψ be interchanged, we obtain a vortex round the axis of z, of strength m.

Plane Motion in a Liquid due to the Motion of Rigid Cylinders perpendicular to their Axes.

Suppose a rigid cylindrical surface moving in the direction of the axis of x with velocity V, and other fixed rigid cylindrical surfaces to be present in the liquid, which is supposed for simplicity to be bounded also by two fixed planes perpendicular to the axis of z at unit distance from each other, the generating lines of the cylinders being supposed parallel to the axis of z; then at all points of the boundary of the moving surface

$$-\frac{d\psi}{ds} = \text{normal velocity of fluid}$$

$$= \text{velocity of boundary normal to itself}$$

$$= V\frac{dy}{ds};$$

and therefore $\psi = -Vy + \text{constant}$; and at all points of the fixed surfaces $\frac{d\psi}{ds} = 0$, and therefore ψ = constant.

We must therefore discover a function ψ which satisfies the equation

$$\frac{d^2\psi}{dx^2} + \frac{d^2\psi}{dy^2} = 0,$$

and is equal to a constant round a fixed boundary, and equal to $-Vy + \text{constant}$ round a moving boundary, moving with velocity V in the direction of the axis of x; and ϕ, the conjugate function, can then easily be written down.

Ex. 1. The moving cylinder a circular cylinder of radius a, and the fixed cylinder a circular cylinder of radius b, both having the axis of z as axis. Then

$$\psi = -Va\sin\theta\frac{\frac{b^2}{r} - r}{\frac{b^2}{a} - a}$$

$$= -V\frac{a^2}{b^2 - a^2}\left(\frac{b^2}{r} - r\right)\sin\theta,$$

and therefore

$$\phi = -V\frac{a^2}{b^2 - a^2}\left(\frac{b^2}{r} + r\right)\cos\theta.$$

If ϕ' denote the velocity function of liquid filling the cylinder $r=a$,

$$\phi' = Vr\cos\theta,$$

and therefore, when $r=a$,

$$\frac{\phi}{\phi'} = -\frac{b^2 + a^2}{b^2 - a^2}.$$

In determining the kinetic energy of the liquid intermediate to the cylinders, $\frac{d\phi}{dr} = 0$ when $r=b$; and when $r=a$, $\frac{d\phi}{dr} = \frac{d\phi'}{dr}$; and therefore the kinetic energy of the liquid intermediate to the cylinders is $\frac{b^2 + a^2}{b^2 - a^2}$ of the kinetic energy of the liquid filling the cylinder $r=a$. Consequently, if the cylinder $r=a$ be moved, the inertia to be overcome will be its own inertia, together with the inertia of a mass of a liquid $\frac{b^2+a^2}{b^2-a^2}$ times the volume of the cylinder; this is called the effective inertia of the cylinder.

In particular, if $b=\infty$, the effective inertia is the mass of the cylinder, increased by a mass of liquid of equal volume with the cylinder; and then

$$\psi=-V\frac{a^2}{r}\sin\theta,\quad \phi=-V\frac{a^2}{r}\cos\theta,$$

so that

$$\psi+i\phi=\frac{Va^2}{i(x+iy)}.$$

Ex. 2. The moving cylinder an elliptic cylinder, and the fixed cylinder a confocal elliptic cylinder.

Using elliptic coordinates ξ, η, such that $c\cosh\eta$, $c\sinh\eta$ are the semi-axes of the confocal ellipse, $c\cos\xi$, $c\sin\xi$ of the confocal hyperbola passing through a point, $2c$ being the distance between the foci; then $x=c\cosh\eta\cos\xi$, $y=c\sinh\eta\sin\xi$; and if $\eta=\alpha$ is the equation of the moving ellipse, $\eta=\beta$ of the fixed ellipse, then

$$\psi=-Vc\sinh\alpha\frac{\sinh(\beta-\eta)}{\sinh(\beta-\alpha)}\sin\xi$$

satisfies the conditions that

(i) $$\frac{d^2\psi}{d\xi^2}+\frac{d^2\psi}{d\eta^2}=0,$$

(ii) $\psi=-Vc\sinh\alpha\sin\xi=-Vy$, when $\eta=\alpha$,

(iii) $\psi=0$, when $\eta=\beta$.

Therefore the conjugate function

$$\phi=Vc\sinh\alpha\frac{\cosh(\beta-\eta)}{\sinh(\beta-\alpha)}\cos\xi;$$

so that

$$\psi+i\phi=Vc\frac{\sinh\alpha}{\sinh(\beta-\alpha)}\cos(\xi+i\eta-i\beta).$$

If ϕ' denote the velocity function of the liquid filling the elliptic cylinder $\eta=\alpha$, then

$$\phi'=Vx=Vc\cosh\eta\cos\xi;$$

and round the ellipse $\eta=\alpha$,

$$\frac{\phi}{\phi'}=\frac{\tanh\alpha}{\tanh(\beta-\alpha)};$$

while $\frac{d\phi}{dn}$ is the same for each, and $\frac{d\phi}{dn}$ vanishes when $\eta=\beta$; therefore the kinetic energy of the liquid between $\eta=\alpha$ and $\eta=\beta$ is $\frac{\tanh\alpha}{\tanh(\beta-\alpha)}$ of the kinetic energy of the liquid inside $\eta=\alpha$, which is

$$\tfrac{1}{2}\pi\rho V^2c^2\sinh\alpha\cosh\alpha.$$

Hence the mass of the cylinder $\eta=\alpha$ must be increased by $\frac{\tanh\alpha}{\tanh(\beta-\alpha)}$ times the mass of an equal volume of liquid to give the effective inertia for motion in the direction of the major axis, the space between the cylinder $\eta=\alpha$ and a fixed cylinder $\eta=\beta$ being filled with liquid.

Similarly for motion parallel to the minor axis,

$$\psi=Vc\cosh\alpha\frac{\sinh(\beta-\eta)}{\sinh(\beta-\alpha)}\cos\xi,$$

$$\phi=Vc\cosh\alpha\frac{\cosh(\beta-\eta)}{\sinh(\beta-\alpha)}\sin\xi$$

(*Quarterly Journal of Mathematics*, vol. xvi.).

Ex. 3. When the moving and fixed cylinders are any two circular cylinders, not co-axial, the limiting points are taken as the foci of reference; and, supposing $2c$ the distance between them, and ξ, η the dipolar system of coordinates, we have

$$x=c\frac{\sinh\eta}{\cosh\eta-\cos\xi},\quad y=c\frac{\sin\xi}{\cosh\eta-\cos\xi},$$

and then $$\eta=\frac{1}{2}\log\frac{(x+c)^2+y^2}{(x-c)^2+y^2},$$

$$\xi=\tan^{-1}\frac{y}{x-c}-\tan^{-1}\frac{y}{x+c};$$

so that $\xi=$constant is the equation of a circle passing through the two limiting points, and $\eta=$constant is the equation of an orthogonal circle.

If $\eta=\alpha$ be the moving cylinder, moving in the direction of the axis of x (the line of centres) with velocity V, and if $\eta=\beta$ be the fixed cylinder, we must make

$$\psi=-Vc\frac{\sinh\alpha}{\cosh\alpha-\cos\xi}+\text{constant},$$

when $\eta=\alpha$; $\psi=0$ when $\eta=\beta$; and $\frac{d^2\psi}{d\xi^2}+\frac{d^2\psi}{d\eta^2}=0$ in the intervening space.[1]

[1] For various expressions for ψ, consult the articles by Mr W. M. Hicks in the *Quarterly Journal of Mathematics*, vol. xvi

Now, expanding,

$$\frac{\sinh\alpha}{\cosh\alpha-\cos\xi}=1+2\sum_{n=1}^{n=\infty}e^{-n\alpha}\cos n\xi,$$

and therefore

$$\psi=-2Vc\sum_{n=1}^{n=\infty}e^{-n\alpha}\frac{\sinh n(\eta-\beta)}{\sinh n(\alpha-\beta)}\cos n\xi,$$

and $$\phi=2Vc\sum e^{-n\alpha}\frac{\cosh n(\eta-\beta)}{\sinh n(\alpha-\beta)}\sin n\xi.$$

Similarly for a velocity V of the cylinder $\eta=\alpha$ perpendicular to the line of centres, the cylinder $\eta=\beta$ being fixed,

$$\psi=2Vc\sum e^{-n\alpha}\frac{\sinh n(\eta-\beta)}{\sinh n(\alpha-\beta)}\sin n\xi,$$

$$\phi=2Vc\sum e^{-n\alpha}\frac{\cosh n(\eta-\beta)}{\sinh n(\alpha-\beta)}\cos n\xi.$$

Next, suppose a rigid cylindrical surface to be rotating about the axis of z with angular velocity ω; we must have $-\frac{d\psi}{ds}=$ velocity of boundary normal to itself

$$=-\omega x\frac{dx}{ds}-\omega y\frac{dy}{ds},$$

and therefore $\psi=\frac{1}{2}\omega(x^2+y^2)+$constant, at all points of the moving boundary, and $\psi=$constant, at all points of a fixed cylindrical boundary.

Ex. 4. Take the two elliptic cylinders of Ex. 2, and suppose the cylinder $\eta=\alpha$ to be rotating with angular velocity ω, and the cylinder $\eta=\beta$ to be fixed; since

$$x^2+y^2=\tfrac{1}{2}c^2(\cosh 2\eta+\cos 2\xi),$$

if we put

$$\psi=\tfrac{1}{4}\omega c^2\frac{\sinh 2(\beta-\eta)}{\sinh 2(\beta-\alpha)}\cos 2\xi,$$

then (i) when $\eta=\alpha$, $\psi=\frac{1}{4}\omega c^2\cos 2\xi$
$=\frac{1}{2}\omega(x^2+y^2)+$constant;

(ii) when $\eta=\beta$, $\psi=0$;

(iii) $$\frac{d^2\psi}{d\xi^2}+\frac{d^2\psi}{d\eta^2}=0;$$

and therefore ψ satisfies the required conditions.

Then $$\phi=-\tfrac{1}{4}\omega c^2\frac{\cosh 2(\beta-\eta)}{\sinh 2(\beta-\alpha)}\sin 2\xi,$$

and from the value of the kinetic energy of the intermediate liquid the instantaneous value of the effective moment of inertia can be inferred.

If the cylinder $\eta=\beta$ be also rotating with angular velocity ω, the cylinders will remain confocal, and the values of ψ and ϕ will not change; then

$$\psi=\tfrac{1}{4}\omega c^2\frac{\sinh 2(\eta-\alpha)+\sinh 2(\beta-\eta)}{\sinh 2(\beta-\alpha)}\cos 2\xi$$

$$=\tfrac{1}{4}\omega c^2\frac{\cosh(2\eta-\alpha-\beta)}{\cosh(\beta-\alpha)}\cos 2\xi;$$

and $$\phi=\tfrac{1}{4}\omega c^2\frac{\sinh(2\eta-\alpha-\beta)}{\cosh(\beta-\alpha)}\sin 2\xi.$$

To find the kinetic energy of the liquid, since

$$\int\phi\frac{d\phi}{dn}ds=-\int\phi\frac{d\psi}{ds}ds$$

$$=-\int\phi\frac{d\psi}{d\xi}d\xi=\int\phi\frac{d\phi}{d\eta}d\xi,$$

therefore $$T=\tfrac{1}{2}\rho\int\phi\frac{d\phi}{d\eta}d\xi;$$

and when $\eta=\alpha$, and $\eta=\beta$,

$$\phi\frac{d\phi}{d\eta}=\tfrac{1}{4}\omega^2c^4\tanh(\beta-\alpha)\sin^2 2\xi;$$

therefore $$T=\tfrac{1}{8}\rho\omega^2c^4\tanh(\beta-\alpha)\int_0^{2\pi}\sin^2 2\xi d\xi$$

$$=\tfrac{1}{8}\pi\rho\omega^2c^4\tanh(\beta-\alpha);$$

and, if k denote the effective radius of gyration of the liquid,

$$T=\tfrac{1}{2}\pi\rho\omega^2c^2k^2(\sinh\beta\cosh\beta-\sinh\alpha\cosh\alpha);$$

therefore $$k^2=\tfrac{1}{4}c^2\frac{\tanh(\beta-\alpha)}{\sinh\beta\cosh\beta-\sinh\alpha\cosh\alpha}$$

$$=\tfrac{1}{4}c^4\frac{ab_1-a_1b}{(aa_1-bb_1)(a_1b_1-ab)},$$

where a_1, b_1 are the semi-axes of the ellipse $\eta=\beta$, and a, b of the ellipse $\eta=\alpha$.

Ex. 5. Suppose a sector, bounded by $r=a$ and $\theta=\pm\alpha$, rotating about the axis with angular velocity ω; we must put

$$\psi = \tfrac{1}{2}\omega r^2 \frac{\cos 2\theta}{\cos 2\alpha} + \sum_{n=0}^{n=\infty} A_{2n+1}\left(\frac{r}{a}\right)^{(2n+1)\frac{\pi}{2\alpha}} \cos(2n+1)\frac{\pi\theta}{2\alpha},$$

which satisfies the conditions $\nabla^2\psi = 0$, and $\psi = \frac{1}{2}\omega r^2$ when $\theta = \pm\alpha$; in order that $\psi = \frac{1}{2}\omega r^2$ when $r = a$, we must have

$$\sum_{n=0}^{n=\infty} A_{2n+1} \cos(2n+1)\frac{\pi\theta}{2\alpha} = \tfrac{1}{2}\omega a^2\left(1 - \frac{\cos 2\theta}{\cos 2\alpha}\right),$$

and therefore, by Fourier's theorem,

$$A_{2n+1} = \omega a^2(-1)^{n+1}\left\{\frac{1}{(2n+1)\pi - 4\alpha} - \frac{2}{(2n+1)\pi} + \frac{1}{(2n+1)\pi + 4\alpha}\right\}.$$

When all the cylinders present rotate, as if rigidly connected, about the axis of z with angular velocity ω at any instant, then $\psi = \frac{1}{2}\omega(x^2+y^2)$ + constant round the boundary of every cylinder; and if we put $\chi = \psi - \frac{1}{2}\omega(x^2+y^2)$, then χ is the stream function of the relative motion, relative to the cylinders, and satisfies the conditions $\frac{d^2\chi}{dx^2} + \frac{d^2\chi}{dy^2} = -2\omega$ at every point of the liquid, and χ = constant round the boundaries.

Since χ involves ω as a factor, which is a function of t only, it follows that $\frac{\chi}{\omega}$ = constant is the equation of a *stream line* of the relative motion, and any alteration in ω does not affect the shape of the relative stream lines, the liquid being frictionless, and the motion generated from rest.

Ex. 6. Put

$$\chi = -\omega \frac{\frac{x^2}{a^2} + \frac{y^2}{b^2}}{\frac{1}{a^2} + \frac{1}{b^2}};$$

then

$$\frac{d^2\chi}{dx^2} + \frac{d^2\chi}{dy^2} = -2\omega;$$

and the relative stream lines are similar ellipses.

Then

$$\psi = \chi + \frac{1}{2}\omega(x^2+y^2)$$

$$\frac{1}{2}\omega\frac{a^2-b^2}{a^2+b^2}(x^2-y^2);$$

and therefore

$$\phi = \omega\frac{a^2-b^2}{a^2+b^2}xy,$$

for the motion between two similar elliptic cylinders, rotating with angular velocity ω.

The velocity of any liquid particle is $\frac{a^2-b^2}{a^2+b^2}$ of what it would be if rigidly connected to the cylinders; hence the effective radius of gyration of the liquid is $\frac{a^2-b^2}{a^2+b^2}$ of the radius of gyration of the homogenous rigid body occupying the space.

Ex. 7. Put

$$\chi = -\tfrac{1}{2}\frac{\omega}{a^2+b^2}\{\sqrt{2}(x^2-y^2) + x^2 + y^2 - a^2\}\{\sqrt{2}(x^2-y^2) - x^2 - y^2 + b^2\};$$

then $\nabla^2\chi = -2\omega$, and $\chi = 0$, when

$$\sqrt{2}(x^2-y^2) + x^2 + y^2 - a^2 = 0,$$
$$\sqrt{2}(x^2-y^2) - x^2 - y^2 + b^2 = 0,$$

which may therefore be taken as boundaries of the liquid. This problem is due to Mr Ferrers.

Again put

$$\chi = \tfrac{1}{2}\frac{\omega}{a^2+b^2}\{2x(x-y) - a^2\}\{2y(x+y) - b^2\};$$

then $\nabla^2\chi = -2\omega$, and the hyperbolas

$$2x(x-y) - a^2 = 0,\ 2y(x+y) - b^2 = 0$$

may be taken as boundaries, but these hyperbolas are only the previous ones turned through a quarter of a right angle.

Ex. 8. When the liquid fills a rectangular cylinder bounded by $x = \pm a$, and $y = \pm b$ the conditions

$$\frac{d^2\chi}{dx^2} + \frac{d^2\chi}{dy^2} = -2\omega,$$

and

$$u = -\frac{d\chi}{dy} = 0 \text{ when } x = \pm a,$$

$$v = \frac{d\chi}{dx} = 0 \text{ when } y = \pm b,$$

are satisfied by putting

$$\frac{du}{dy} = -\frac{d^2\chi}{dy^2} = \frac{4\omega}{\pi}\tan^{-1}\frac{k\,\mathrm{cn}\left(K\frac{x}{a}, k\right)}{k'\mathrm{cn}\left(K'\frac{y}{b}, k'\right)}$$

$$\frac{dv}{dx} = \frac{d^2\chi}{dx^2} = -\frac{4\omega}{\pi}\tan^{-1}\frac{k'\mathrm{cn}\left(K'\frac{y}{b}, k'\right)}{k\,\mathrm{cn}\left(K\frac{x}{a}, k\right)},$$

where

$$\frac{K}{K'} = \frac{a}{b}$$

(*Quarterly Journal of Mathematics*, vol. xv.).

In fact, if

$$\psi = \omega\frac{16}{\pi^3}a^2\sum_{i=0}^{i=\infty}(-1)^i\frac{\cosh(2i+1)\frac{\pi y}{2a}\cos(2i+1)\frac{\pi x}{2a}}{(2i+1)^3\cosh(2i+1)\frac{\pi b}{2a}}$$

$$+\omega\frac{16}{\pi^3}b^2\sum_{i=0}^{i=\infty}(-1)^i\frac{\cosh(2i+1)\frac{\pi x}{2b}\cos(2i+1)\frac{\pi y}{2b}}{(2i+1)^3\cosh(2i+1)\frac{\pi a}{2b}},$$

then

(1) $\frac{d^2\psi}{dx^2} + \frac{d^2\psi}{dy^2} = 0$;

(2) $\psi = \frac{1}{2}\omega(b^2 - y^2)$ when $x = \pm a$;

(3) $\psi = \frac{1}{2}\omega(a^2 - x^2)$ when $y = \pm b$;

and therefore ψ satisfies the required conditions, and is therefore the value of ψ required.

Ex. 9. Consider liquid filling the interior of a cylinder, whose cross section is an equilateral triangle of altitude h, and let α, β, γ denote the perpendicular distances of a point in the interior from the sides. If we put

$$\chi = 2\omega\frac{\alpha\beta\gamma}{h},$$

then

$$\frac{d^2\chi}{dx^2} + \frac{d^2\chi}{dy^2} = -2\omega,$$

and χ is the stream function of the relative motion, supposing the cylinder rotating with angular velocity ω.

Therefore the cubic $\alpha\beta\gamma$ = constant is the equation of the path of a liquid particle relative to the cylinder, when it is moved in any manner; and also for the cylinder bounded by $\alpha\beta\gamma = c_1$ and $\alpha\beta\gamma = c_2$.[1]

We have supposed the liquid motion to have been generated from rest by the motion of the moving cylinders, but we might also have supposed the liquid to have been of infinite extent, and streaming past the cylinders as fixed obstacles; in that case, the stream function of the relative motion $\chi = \psi + Vy$, and χ satisfies the relations

$$\frac{d^2\chi}{dx^2} + \frac{d^2\chi}{dy^2} = 0,$$

and χ = constant, the equation of a stream line, and therefore also of a boundary; also at infinity

$$\frac{d\chi}{dx} = 0,\ \frac{d\chi}{dy} = V.$$

For instance, if in liquid, moving with velocity $-V$ parallel to the axis of x, the fixed circular cylinder $r = a$ be introduced, then

$$\chi = -V\frac{a^2}{r}\sin\theta + Vy$$
$$= V\left(r - \frac{a^2}{r}\right)\sin\theta.$$

If the elliptic cylinder $\eta = \alpha$ be introduced, then, since $\beta = \infty$,

$$\chi = Vy - Vc\sinh\alpha\frac{\sinh\eta - \cosh\eta}{\sinh\alpha - \cosh\alpha}\sin\xi$$
$$= Vc\sinh\eta\sin\xi - Vc\sinh\alpha\, e^{-\eta+\alpha}\sin\xi$$
$$= Vce^{\alpha}\sinh(\eta-\alpha)\sin\xi$$
$$= V(a+b)\sinh(\eta-\alpha)\sin\xi.$$

If the axis of z be horizontal, and the liquid supposed of infinite extent, and originally at rest, then a circular cylinder of density σ, projected in any manner perpendicular to its length, will describe a parabola with vertical acceleration $\frac{\sigma-\rho}{\sigma+\rho}g$.

If, however, previously to projection, a vortex exist in the liquid, co-axial with the cylinder and of strength m, then any motion of the cylinder will not affect the circulation of the liquid round the cylinder due to the vortex, and inequalities of pressure round the cylinder will arise from the vortex motion.

Lord Rayleigh has shown (*Messenger of Mathematics*, vol. vii.) that, if no forces act, the cylinder will describe a circle in the same direction as the circulation of the vortex in the periodic time $\frac{\pi}{\omega}\frac{\sigma+\rho}{\rho}$, where the circulation of the vortex is $2\pi a^2\omega$, a being the radius of the cylinder.

If the axis of the cylinder be horizontal, and the influence of the boundaries of the liquid neglected, then the cylinder will describe a trochoid, and for a particular velocity of projection can be made to describe a horizontal straight line (*Messenger of Mathematics*, vol. ix. p. 113).

[1] For the analogy between the motion of a liquid in a cylinder and the torsion of an elastic bar, pointed out by St Venant, consult Thomson and Tait's *Natural Philosophy*, § 704.

On the Motion of a Solid through a Liquid.

If we take an origin O, and axes Ox, Oy, Oz fixed in the body, then, if u, v, w, p, q, r denote the component linear and angular velocities of the body at any instant, the velocity function

$$\phi = u\psi_1 + v\psi_2 + w\psi_3 + p\chi_1 + q\chi_2 + r\chi_3,$$

where the ψ's and χ's are functions of x, y, z, depending only upon the shape of the body.

To determine ψ_1, we may suppose the velocity u only to exist, and thus ψ_1 must satisfy the conditions—

(i) $\nabla^2\psi_1 = 0$;

(ii) $\frac{d\psi_1}{dn} = l$, the cosine of the angle between the normal to the surface and the axis of x, at the surface of the moving body ;

(iii) $\frac{d\psi_1}{dn} = 0$, over a fixed surface.

Similarly for ψ_2 and ψ_3.

To determine χ_1, we may suppose the velocity p only to exist, and and then, l, m, n being the direction-cosines of the normal to the surface, χ_1 satisfies the conditions—

(i) $\nabla^2\chi_1 = 0$;

(ii) $\frac{d\chi_1}{dn} = ny - mz$ at the surface of the moving body ;

(iii) $\frac{d\chi_1}{dn} = 0$ at a fixed surface.

Similarly for χ_2 and χ_3.

For a cavity filled with liquid in the interior of a moving body, since the liquid moves as if solid when the moving body has a motion of translation only, therefore

$$\psi_1 = x \;,\; \psi_2 = y \;,\; \psi_3 = z.$$

The only cases practically solved are those where the bounding surfaces are similar or confocal surfaces of the second degree.

Ex. 1. Consider the space between the ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ and a similar and similarly situated ellipsoid rigidly connected with it ; then obviously $\chi_1 = \frac{b^2 - c^2}{b^2 + c^2} yz$, as for plane motion ; and therefore

$$\phi = ux + vy + wz + p\,\frac{b^2 - c^2}{b^2 + c^2}\,yz + q\,\frac{c^2 - a^2}{c^2 + a^2}\,zx + r\,\frac{a^2 - b^2}{a^2 + b^2}\,xy.$$

The liquid filling this space will behave therefore like a body of equal mass, and of principal radii of gyration $\frac{b^2 - c^2}{b^2 + c^2}$, $\frac{c^2 - a^2}{c^2 + a^2}$, $\frac{a^2 - b^2}{a^2 + b^2}$ of the radii of gyration if the liquid were solidified.

Ex. 2. Consider the liquid filling the space between the ellipsoids

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \quad . \quad . \quad . \quad . \quad (1)$$

and

$$\frac{x^2}{a_1^2} + \frac{y^2}{b_1^2} + \frac{z^2}{c_1^2} = 1 \,. \quad . \quad . \quad . \quad (2),$$

the ellipsoids being confocal, such that

$$a_1^2 = a^2 + \lambda_1,\; b_1^2 = b^2 + \lambda_1,\; c_1^2 = c^2 + \lambda_1.$$

Put $A = \int_\lambda^\infty \frac{d\lambda}{(a^2 + \lambda)P}$, $B = \int_\lambda^\infty \frac{d\lambda}{(b^2 + \lambda)P}$, $C = \int_\lambda^\infty \frac{d\lambda}{(c^2 + \lambda)P}$

where $P^2 = (a^2 + \lambda)(b^2 + \lambda)(c^2 + \lambda)$,

and
$$\frac{x^2}{a^2 + \lambda} + \frac{y^2}{b^2 + \lambda} + \frac{z^2}{c^2 + \lambda} = 1 \quad . \quad . \quad . \quad . \quad . \quad (3),$$

so that $a^2 + \lambda$, $b^2 + \lambda$, $c^2 + \lambda$ are the squares of the semi-axis of the confocal ellipsoid passing through xyz. Then

$$A + B + C = \frac{2}{P} \;;$$

also, if p be the length of the perpendicular from the centre on the tangent plane to (3),

$$p^2 = (a^2 + \lambda)l^2 + (b^2 + \lambda)m^2 + (c^2 + \lambda)n^2,$$

and therefore
$$\frac{d\lambda}{dp} = 2p = \frac{d\lambda}{dn} \,.$$

Suppose the ellipsoid (1) moving with velocity u, and the ellipsoid (2) fixed, then ψ_1 can be made to satisfy the required conditions by putting

$$\psi_1 = Mx + NAx \,,$$

where M and N are constants.

For
$$\nabla^2\psi_1 = 0,$$

and
$$\begin{aligned} \frac{d\psi_1}{dn} &= M\frac{dx}{dn} + NA\frac{dx}{dn} + N\frac{dA}{dn}x \\ &= Ml + NAl - \frac{2px}{(a^2 + \lambda)P}N \\ &= \left(M + NA - 2\frac{N}{P}\right)l \\ &= \{M - N(B + C)\}\, l \,. \end{aligned}$$

Consequently, when $\lambda = 0$, we must have

$$M - N(B_0 + C_0) = 1,$$

and when $\lambda = \lambda_1$,

$$M - N(B_1 + C_1) = 0 \,,$$

where A_0, B_0, C_0 are the values of A, B, C, when $\lambda = 0$, and A_1, B_1, C_1 when $\lambda = \lambda_1$.

Hence

$$N = -\frac{1}{B_0 + C_0 - B_1 - C_1} \,,$$

$$M = -\frac{B_1 + C_1}{B_0 + C_0 - B_1 - C_1} \;;$$

and
$$\psi = -\frac{A + B_1 + C_1}{B_0 + C_0 - B_1 - C_1}x \,.$$

Similarly

$$\psi_2 = -\frac{A_1 + B + C_1}{C_0 + A_0 - C_1 - A_1}y \,,$$

$$\psi_3 = -\frac{A_1 + B_1 + C}{A_0 + B_0 - A_1 - B_1}z \,.$$

If the inner ellipsoid had been fixed and the outer moved, we should have had

$$\psi_1 = \frac{A + B_0 + C_0}{B_0 + C_0 - B_1 - C_1}x \,,$$

$$\psi_2 = \frac{A_0 + B + C_0}{C_0 + A_0 - C_1 - A_1}y \,,$$

$$\psi_3 = \frac{A_0 + B_0 + C}{A_0 + B_0 - A_1 - B_1}z \,.$$

Next suppose the outer ellipsoid fixed, and the inner to have the angular velocity p ; then χ_1 can be made to satisfy the required conditions by putting

$$\chi_1 = Myz + N(B - C)yz \,,$$

where M and N are constants.

For then $\nabla^2\chi_1 = 0$, and

$$\begin{aligned} \frac{d\chi_1}{dn} &= \{M + N(B - C)\}\left(\frac{dy}{dn}z + y\frac{dz}{dn}\right) + N\left(\frac{dB}{dn} - \frac{dC}{dn}\right)yz \,, \\ &= \{M + N(B - C)\}\left(\frac{py}{b^2 + \lambda}z + y\frac{pz}{c^2 + \lambda}\right) - N\left(\frac{1}{b^2 + \lambda} - \frac{1}{c^2 + \lambda}\right)\frac{2pyz}{P} \\ &= \left[\{M + N(B - C)\}\left(\frac{1}{b^2 + \lambda} + \frac{1}{c^2 + \lambda}\right)\right. \\ &\qquad \left. - N(A + B + C)\left(\frac{1}{b^2 + \lambda} - \frac{1}{c^2 + \lambda}\right)\right]pyz \,, \end{aligned}$$

which when $\lambda = 0$ must

$$= ny - mz = \frac{pz}{c^2}y - \frac{py}{b^2}z = \left(\frac{1}{c^2} - \frac{1}{b^2}\right)pyz \,,$$

and when $\lambda = \lambda_1$ must $= 0$.

Therefore M and N must be determined from the equations

$$\{M + N(B_0 - C_0)\}\left(\frac{1}{b^2} + \frac{1}{c^2}\right) - N(A_0 + B_0 + C_0)\left(\frac{1}{b^2} - \frac{1}{c^2}\right) = \frac{1}{c^2} - \frac{1}{b^2} \,,$$

and

$$\{M + N(B_1 - C_1)\}\left(\frac{1}{b_1^2} + \frac{1}{c_1^2}\right) - N(A_1 + B_1 + C_1)\left(\frac{1}{b_1^2} - \frac{1}{c_1^2}\right) = 0 \,.$$

Similarly χ_2 and χ_3 can be determined, and also χ_1, χ_2, and χ_3 when the inner ellipsoid is fixed and the outer moved with given angular velocities.

When the outer ellipsoid is indefinitely great, then A_1, B_1, C_1 are zero, as also is M. Then

$$N = \frac{\frac{1}{c^2} - \frac{1}{b^2}}{(B_0 - C_0)\left(\frac{1}{b^2} + \frac{1}{c^2}\right) - (A_0 + B_0 + C_0)\left(\frac{1}{b^2} - \frac{1}{c^2}\right)} \,,$$

and
$$\chi_1 = N(B - C)yz.$$

To find the effective inertia of the inner ellipsoid, when the outer ellipsoid is fixed, and first for motion parallel to the axis of x ; when $\lambda = \lambda_1$, $\frac{d\psi_1}{dn} = 0$; but when $\lambda = 0$, $\frac{d\psi_1}{dn} = l$, and the ψ_1 for the liquid in the interspace is $-\frac{A_0 + B_1 + C_1}{B_0 + C_0 - B_1 - C_1}$ of the ψ_1 for the liquid filling the inner ellipsoid ; and hence, since the kinetic energy $= \frac{1}{2}\rho\int\phi\frac{d\phi}{dn}dS$, it follows that the kinetic energy of the liquid in the interspace is $\frac{A_0 + B_1 + C_1}{B_0 + C_0 - B_1 - C_1}$ of the liquid filling the interior ellipsoid for motion parallel to the axis of x, and therefore the effective inertia parallel to the axis of x is

$$\tfrac{4}{3}\pi\rho abc\frac{A_0+B_1+C_1}{B_0+C_0-B_1-C_1};$$

with similar expressions for the effective inertia parallel to the axes of y and z.

If the outer ellipsoid be indefinitely large, then the effective inertia of the liquid parallel to the axis of x (since $A_1=B_1=C_1=0$)

$$=\tfrac{4}{3}\pi\rho abc\frac{A_0}{B_0+C_0},$$

which, in the case of the sphere, is half the effective inertia of the liquid inside the sphere, since in the sphere $A_0=B_0=C_0$.

For a rotation about the axis of x of the inner ellipsoid, it follows in the same way that the effective inertia of the liquid in the interspace is to the effective inertia of the liquid filling the inner ellipsoid in the ratio of the χ's of the two motions, which, supposing the outer ellipsoid indefinitely large,

$$\frac{\left(\frac{1}{c^2}-\frac{1}{b^2}\right)(B_0-C_0)}{\left(\frac{1}{c^2}+\frac{1}{b^2}\right)(B_0-C_0)-(A_0+B_0+C_0)\left(\frac{1}{b^2}-\frac{1}{c^2}\right)}\cdot\frac{b^2+c^2}{b^2-c^2}$$
$$=\frac{(B_0-C_0)(b^2+c^2)}{(B_0-C_0)(b^2+c^2)+(A_0+B_0+C_0)(b^2-c^2)};$$

and therefore the effective moment of inertia of the liquid about the axis of x

$$=\tfrac{4}{15}\pi\rho abc\frac{(B_0-C_0)(b^2-c^2)^2}{(B_0-C_0)(b^2+c^2)+(A_0+B_0+C_0)(b^2-c^2)},$$

with similar expressions for the effective moment of inertia about the other axes.

Ex. 3. In the case of two spheres and the liquid between, the χ's are all zero, and, if the spheres be instantaneously concentric,

$$\psi_1=\frac{a^3}{a^3-a_1^3}\left\{x+\frac{a_1^3x}{2(x^2+y^2+z^2)^{\frac{3}{2}}}\right\}$$
$$=\frac{a^3}{a^3-a_1^3}\left(r+\frac{a_1^3}{2r^2}\right)l,$$

supposing a the radius of the moving, and a_1 that of the fixed sphere.

This is a particular case of the confocal ellipsoids, when $a=b=c$. For then

$$\psi_1=-\frac{A+2A_1}{2(A_0-A_1)}x,$$

and
$$A=\int_\lambda^\infty\frac{d\lambda}{(a^2+\lambda)^{\frac{5}{2}}}=\tfrac{2}{3}\frac{1}{(a^2+\lambda)^{\frac{3}{2}}}=\frac{2}{3r^3}.$$

Therefore

$$\psi_1=-\frac{\frac{1}{r^3}+\frac{2}{a_1^3}}{2\left(\frac{1}{a^3}-\frac{1}{a_1^3}\right)}x=\frac{a^3}{a^3-a_1^3}\left(x+\frac{a_1^3x}{2r^3}\right).$$

When the spheres are not concentric, expressions for the effective inertias have been obtained by the method of images by Mr W. M. Hicks (*Philosophical Transactions*, 1880).

The image of a source at P of strength μ outside a sphere is a source inside the sphere of strength $\frac{a\mu}{OP}$ at a distance $\frac{a^2}{OP}$ from the centre, a being the radius of the sphere, and a line sink reaching from the image to the centre of line strength $-\frac{\mu}{a}$; this combination will be found to produce no flow across the surface of the sphere.

Again for a source P of strength μ inside the sphere, the images will be a source of strength $\frac{a\mu}{OP}$ at the inverse point of P, that is, at a distance $\frac{a^2}{OP}$ from the centre, and a line sink $-\frac{\mu}{a}$ thence to infinity.

In order that there should be no flow across the spherical boundary, another sink of equal strength must exist inside the sphere, and the infinite parts of the line sinks will then cancel.

The determination of the ψ's and χ's is a kinematical problem, as yet solved only for the cases we have mentioned, and the discovery of the solution of fresh problems is at present engaging the attention of mathematicians.

But supposing them determined for the motion of a body through liquid, then T, the kinetic energy of the body and the liquid, will be a quadratic function of u, v, w, p, q, r; so that we may put

$$2T=c_{11}u^2+c_{22}v^2+c_{33}w^2+c_{44}p^2+c_{55}q^2+c_{66}r^2$$
$$+2c_{23}vw+\ .\ .\ .\ .\ +2c_{56}qr+\ .\ .\ .\ .\ +2c_{14}up+\ .\ .\ .\ .$$

in all twenty-one terms; and, in order to determine the c's, we may suppose all the velocities except one or two to vanish, and then we see that

$$c_{11}=M+\rho\iint l\psi_1 dS,\ .\ .\ .\ .$$

where M is the mass of the body,

$$c_{44}=A+\rho\iint\chi_1(ny-mz)dS,\ .\ .\ .\ .$$

where A is the moment of inertia of the body about the axis of x; these are obtained by supposing all to vanish except u or p.

If we suppose all to vanish except v and w, we find

$$\phi=\psi_2v+\psi_3w,$$

and
$$2T=\rho\iint\phi\frac{d\phi}{dn}dS+M(v^2+w^2)$$
$$=c_{22}v^2+c_{33}w^2+\rho vw\iint\left(\psi_2\frac{d\psi_3}{dn}+\psi_3\frac{d\psi_2}{dn}\right)dS,$$

or
$$c_{23}=\tfrac{1}{2}\rho\iint\left(\psi_2\frac{d\psi_3}{dn}+\psi_3\frac{d\psi_2}{dn}\right)dS$$
$$=\rho\iint\psi_2\frac{d\psi_3}{dn}dS=\rho\iint\psi_3\frac{d\psi_2}{dn}dS$$
$$=\rho\iint\psi_2 n dS=\rho\iint\psi_3 m dS.$$

Similarly the other coefficients may be determined (Kirchhoff, *Vorlesungen über Mathematische Physik*, p. 240).

In particular cases of symmetry, the coefficients of the products of u, v, w, p, q, r can be made to vanish by a proper choice of axes; and in the case of the ellipsoid, the only case for which the coefficients have as yet been determined,

$$c_{11}=M+4\pi\rho abc\frac{A_0}{B_0+C_0}$$

. . . .

$$c_{44}=A+\tfrac{4}{15}\pi\rho abc\frac{(B_0-C_0)(b^2-c^2)^2}{(B_0-C_0)(b^2+c^2)+(A_0+B_0+C_0)(b^2-c^2)},$$

. . . .

while c_{12}, . . . vanish, the origin O being at the centre of the ellipsoid, and the axes of the ellipsoid its principal axes.

In the case of a sphere of mean density σ, projected in infinite liquid of density ρ, and subject to gravity, the sphere will describe a parabola, with vertical acceleration $\frac{\sigma-\rho}{\sigma+\frac{1}{2}\rho}g$.

Having expressed T now as a quadratic function of u, v, w, p, q, r, the coefficients being functions of the shape but independent of the position and orientation of the body, the Hamiltonian equations of motion lead to the equations

$$\frac{d}{dt}\left(\frac{dT}{du}\right)-r\frac{dT}{dv}+q\frac{dT}{dw}=X.$$

. . . .

$$\frac{d}{dt}\left(\frac{dT}{dp}\right)-r\frac{dT}{dq}+q\frac{dT}{dr}-w\frac{dT}{dv}+v\frac{dT}{dw}=L.$$

. . . .

For if P denote the resultant linear impulse in the direction, *fixed in space*, whose direction-cosines are l, m, n, then

$$P=l\frac{dT}{du}+m\frac{dT}{dv}+n\frac{dT}{dw};$$

and, differentiating with respect to the time, since

$$\frac{dl}{dt}=mr-nq,\quad\frac{dm}{dt}=np-rl,\quad\frac{dn}{dt}=lq-mp,$$

$$\therefore\quad\frac{dP}{dt}=l\left\{\frac{d}{dt}\left(\frac{dT}{du}\right)-r\frac{dT}{dv}+q\frac{dT}{dw}\right\}$$
$$+m\left\{\frac{d}{dt}\left(\frac{dT}{dv}\right)-p\frac{dT}{dw}+r\frac{dT}{du}\right\}$$
$$+n\left\{\frac{d}{dt}\left(\frac{dT}{dw}\right)-q\frac{dT}{du}+p\frac{dT}{dv}\right\}$$
$$=lX+mY+nZ,$$

for all values of l, m, n.

Again, taking a fixed origin, and supposing G the impulsive couple about a straight line through the origin fixed in space whose direction-cosines are l, m, n;

$$G=l\left(\frac{dT}{dp}+y\frac{dT}{dw}-z\frac{dT}{dv}\right)$$
$$+m\left(\frac{dT}{dq}+z\frac{dT}{du}-x\frac{dT}{dw}\right)$$
$$+n\left(\frac{dT}{dr}+x\frac{dT}{dv}-y\frac{dT}{du}\right),$$

where x, y, z are the coordinates of the centre of the body.

Differentiating with respect to the time, and supposing afterwards that the centre of the body and the fixed origin are coincident, then, since $\frac{dx}{dt}=u$, $\frac{dy}{dt}=v$, $\frac{dz}{dt}=w$, but $x=0$, $y=0$, $z=0$,

$$\begin{aligned}\frac{dG}{dt}&=l\left\{\frac{d}{dt}\left(\frac{dT}{dp}\right)-r\frac{dT}{dq}+q\frac{dT}{dr}-w\frac{dT}{dv}+v\frac{dT}{dw}\right\}\\&+m\left\{\frac{d}{dt}\left(\frac{dT}{dq}\right)-p\frac{dT}{dr}+r\frac{dT}{dp}-u\frac{dT}{dw}+w\frac{T}{du}\right\}\\&+n\left\{\frac{d}{dt}\left(\frac{dT}{dr}\right)-q\frac{dT}{dp}+p\frac{dT}{dq}-v\frac{dT}{du}+u\frac{dT}{dv}\right\}\\&=lL+mM+nN,\end{aligned}$$

for all values of l, m, n.

If no external forces act, then three integrals of the equations of motion are

(1) $T=\text{constant}$;

(2) $\left(\frac{dT}{du}\right)^2+\left(\frac{dT}{dv}\right)^2+\left(\frac{dT}{dw}\right)^2=\text{constant}$;

(3) $\frac{dT}{du}\frac{dT}{dp}+\frac{dT}{dv}\frac{dT}{dq}+\frac{dT}{dw}\frac{dT}{dr}=\text{constant}$;

expressing the fact that the energy is constant, and also the force and couple constituents of the resultant impulse.

For a body like an ellipsoid, using single suffixes,

$$T=\tfrac{1}{2}(c_1u^2+c_2v^2+c_3w^2+c_4p^2+c_5q^2+c_6r^2);$$

and the integration of the equations of motion under no forces leads to hyperelliptic and double θ functions (Weber, *Mathematische Annalen*, vol. xiv.).

The equations of motion become

$$c_1\frac{du}{dt}-c_2vr+c_3wq=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

$$c_2\frac{dv}{dt}-c_3wp+c_1ur=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

$$c_3\frac{dw}{dt}-c_1uq+c_2rp=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3);$$

$$c_4\frac{dp}{dt}-(c_5-c_6)qr-(c_2-c_3)vw=0 \quad . \quad . \quad (4),$$

$$c_5\frac{dq}{dt}-(c_6-c_4)rp-(c_3-c_1)wu=0 \quad . \quad . \quad (5),$$

$$c_6\frac{dr}{dt}-(c_4-c_5)pq-(c_1-c_2)uv=0 \quad . \quad . \quad (6).$$

Multiplying the equations by u, v, w, p, q, r, and adding,

$$c_1u\frac{du}{dt}+c_2v\frac{dv}{dt}+c_3w\frac{dw}{dt}+c_4p\frac{dp}{dt}+c_5q\frac{dq}{dt}+c_6r\frac{dr}{dt}=0,$$

or $\tfrac{1}{2}(c_1u^2+c_2v^2+c_3w^2+c_4p^2+c_5q^2+c_6r^2)=T$, a constant . . (7).

Multiply (1) by c_1u, (2) by c_2v, and (3) by c_3w, and add; then

$$c_1^2u\frac{du}{dt}+c_2^2v\frac{dv}{dt}+c_3^2w\frac{dw}{dt}=0,$$

and $$c_1^2u^2+c_2^2v^2+c_3^2w^2=F^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

F being a constant, the resultant linear impulse of the motion.

Again, multiplying the equations (1 to 6) by c_4p, c_5q, c_6r, c_1u, c_2v, c_3w, adding and integrating,

$$c_1c_4up+c_2c_5vq+c_3c_6wr=G, \text{ a constant} \quad . \quad . \quad . \quad (9).$$

Equations (4), (5), (6) show that the body is acted upon by component couples about the principal axes $(c_2-c_3)vw$, $(c_3-c_1)wu$, $(c_1-c_2)uv$, the principal moments of inertia being supposed to be c_4, c_5, c_6.

If the body be of revolution, $c_1=c_2$ and $c_4=c_5$, the motion can be expressed by elliptic functions. For equation (6) shows that r is constant, and equation (3) becomes

$$c_3^2\left(\frac{dw}{dt}\right)^2=c_1^2(uq-vp)^2=c_1^2\left\{(u^2+v^2)(p^2+q^2)-(up+vq)^2\right\}$$

$$=\frac{1}{c_4}(F^2-c_3^2w^2)\left\{2T-\frac{F^2}{c_1}-c_6r^2-\frac{c_3}{c_1}(c_1-c_3)w^2\right\}-\frac{(G-c_3c_6wr)^2}{c_4^2} \quad . \quad . (10),$$

a biquadratic function of w, and therefore w is an elliptic function of t, the time.

Put $u=s\cos f$, $v=-s\sin f$; then from (1) and (2)

$$c_1s^2\frac{df}{dt}=c_1(\dot{u}v-u\dot{v})=c_1rs^2-c_3(up+vq)w$$

or $$\frac{df}{dt}=r-\frac{c_3}{c_1}\frac{up+vq}{u^2+v^2}w;$$

a rational function of w; and therefore f is expressed in terms of the time by elliptic integrals of the third kind.

Again, put $p=\sigma\cos g$, $q=-\sigma\sin g$; then from (4) and (5)

$$c_4\sigma^2\frac{dg}{dt}=c_4(\dot{p}q-p\dot{q})=(c_4-c_6)\sigma^2r+(c_1-c_3)(up+vq)w;$$

or $$\frac{dg}{dt}=\left(1-\frac{c_6}{c_4}\right)r+\frac{c_1-c_3}{c_4}\frac{up+vq}{p^2+q^2}w,$$

a rational function of w; and therefore g is expressed in terms of the time by elliptic integrals of the third kind.

In a state of steady motion, w is constant, and $\frac{df}{dt}=\frac{dg}{dt}$; also $up+vq=s\sigma$; and therefore

$$\frac{c_6}{c_4}\frac{r}{w}=\frac{c_3}{c_1}\frac{\sigma}{s}+\frac{c_1-c_3}{c_4}\frac{s}{\sigma};$$

and we must therefore have

$$\frac{r^2}{w^2}>4\frac{c_3}{c_1}(c_1-c_3)\frac{c_4}{c_6^2}$$

for the roots of this quadratic in $s:\sigma$ to be real.

If we employ the Lagrangian coordinates x, y, z, θ, ϕ, ψ, and take OZ in the direction of the resultant linear impulse F, then

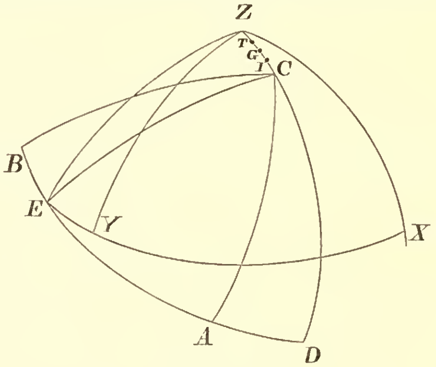

Fig. 10.

(fig. 10) the eye being supposed at O the centre of the sphere,

$c_1u=$ component momentum in direction $OA=-F\sin\theta\cos\phi$,
$c_1v=$,, ,, $OB=F\sin\theta\sin\phi$,
$c_3w=$,, ,, $OC=F\cos\theta$;

and therefore equation (10) gives $\cos\theta$ as an elliptic function of t.

Since

$$p=\sin\phi\dot{\theta}-\sin\theta\cos\phi\dot{\psi},$$
$$q=\cos\phi\dot{\theta}+\sin\theta\sin\phi\dot{\psi},$$

equation (9) becomes

$$c_4\sin^2\theta\dot{\psi}+c_6r\cos\theta=G \quad . \quad . \quad . \quad . \quad . \quad . \quad (11);$$

or $$\frac{d\psi}{dt}=\frac{G-c_6r\cos\theta}{c_4\sin^2\theta}$$

$$=\frac{1}{2}\frac{G-c_6r}{c_4}\frac{1}{1-\cos\theta}+\frac{1}{2}\frac{G+c_6r}{c_4}\frac{1}{1+\cos\theta};$$

and therefore ψ will consist of elliptic integrals of the third kind.

Equations (4), (5), (6) show that the body is acted upon at every instant by a couple whose axis is OE, of magnitude

$$=\frac{c_3}{c_1}(c_1-c_3)w^2\tan\theta,$$

c_4 being supposed to be the equatorial moment of inertia of the body.

If OT be the direction of motion of O, then OT lies in the plane ZOC, and

$$\tan COT=\frac{c_3}{c_1}\tan\theta.$$

We may determine the steady motion from elementary reasoning; for if OG be the axis of the resultant angular momentum (also lying in the plane ZOC) making an angle β with OC, and if μ be the constant value of $\dot{\psi}$, then

$$G\mu\sin(\theta-\beta)=\text{impressed couple}$$
$$=\frac{c_3}{c_1}(c_1-c_3)w^2\tan\theta.$$

But $$G\cos\beta=c_6r,\ G\sin\beta=-c_4p;$$

and $$p=-\mu\sin\theta;$$

therefore $$\tan\beta=\frac{c_4\mu}{c_6r}\sin\theta;$$

and if γ be the angle made by the axis of instantaneous rotation with OC, $\tan\gamma=\frac{\mu}{r}\sin\theta$.

Therefore

$$G\mu \sin(\theta-\beta) = c_6 r\mu \frac{\sin(\theta-\beta)}{\cos\beta}$$
$$= c_6 r\mu(\sin\theta - \cos\theta\tan\beta)$$
$$= c_6 r\mu \sin\theta - c_4\mu^2 \sin\theta\cos\theta$$
$$= \frac{c_3}{c_1}(c_1-c_3)w^2 \tan\theta\,;$$

and, dropping the factor $\sin\theta$,

$$c_4\cos\theta\mu^2 - c_6 r\mu + \frac{c_3}{c_1}(c_1-c_3)\frac{w^2}{\cos\theta} = 0,$$

a quadratic equation in μ, the condition for steady motion.

The least admissible value of r in order that the roots should be real is given by

$$c_6{}^2 r^2 = 4\frac{c_3}{c_1}(c_1-c_3)c_4 w^2,$$

or

$$r^2 = 4\frac{c_3}{c_1}(c_1-c_3)\frac{c_4}{c_6{}^2}w^2.$$

In an oblate solid of revolution c_1-c_3 is negative, and the roots of the quadratic in μ are always real for all values of r. In a prolate solid c_1-c_3 is positive, and a certain spin r is required to keep the motion stable.

An interesting application is to determine the proper amount of rifling of a gun. The following table has been calculated, from the formulæ given below, by Captain J. P. Cundill, R.A., and the results appear to agree very fairly with what is observed in practice.

Table calculated for Stability of Rotation of Projectiles.

Length of projectile in calibres $= \frac{c}{a}$	Value of $\alpha-\gamma$.	Minimum twist at muzzle of gun requisite to give stability of rotation = 1 turn in n calibres.

Suppose the rifling at the muzzle makes one turn in n calibres, and $2a$ is the calibre and β the angle of the rifling; then

$$\tan\beta = \frac{\pi}{n} = \frac{ar}{w} = 2\sqrt{\left\{\frac{c_3}{c_1}(c_1-c_3)\frac{c_4}{c_6{}^2}\right\}}.$$

If W = weight of shot, and W′ = weight of air displaced, then

$$c_1 = W + W'\alpha,\ c_3 = W + W'\gamma,$$
$$c_4 = Wk_1{}^2 + W'k_1'{}^2\alpha',\ c_6 = Wk^2,$$

where k_1, k are the radii of gyration of the shot about an equatorial diameter and the axis, and k_1' of the air displaced, supposed rigidified, about an equatorial axis; and then α, γ, α' will be certain quantities depending only upon the external shape of the projectile, supposing the surrounding medium frictionless and incompressible.

When, as in practice, the fraction $\frac{W'}{W}$ is so small that its square may be neglected,

$$\tan^2\beta = \frac{\pi^2}{n^2} = 4\frac{c_3}{c_1}(c_1-c_3)\frac{a^2c_4}{c_6{}^2}$$
$$= 4\frac{W+W'\gamma}{W+W'\alpha}W'(\alpha-\gamma)a^2\frac{Wk_1{}^2+W'k_1'{}^2\alpha'}{W^2k^4}$$
$$= 4\frac{W'}{W}(\alpha-\gamma)\frac{a^2k_1{}^2}{k_4}\frac{1+\frac{W'}{W}\gamma}{1+\frac{W'}{W}\alpha}\left(1+\frac{W'}{W}\frac{k_1'{}^2}{k_1{}^2}\alpha'\right)$$
$$= 4\frac{W'}{W}(\alpha-\gamma)\frac{a^2k_1{}^2}{k^4}$$

+ higher powers of $\frac{W'}{W}$ which are neglected.

The only body for which α, γ, and α' have as yet been determined is the ellipsoid; and in the case of a prolate spheroid of semi-axes a and c,

$$\alpha = \frac{A}{A+C},\ \gamma = \frac{C}{2A},$$
$$\alpha' = \frac{(C-A)(c^2-a^2)^2}{\left\{(C-A)(c^2-a^2)+(2A+C)(c^2+a^2)\right\}(c^2+a^2)}$$

where

$$A = \int_0^\infty \frac{d\lambda}{(a^2+\lambda)^2(c^2+\lambda)^{\frac{1}{2}}}$$
$$= \frac{c}{a^2(c^2-a^2)} - \frac{1}{2(c^2-a^2)^{\frac{3}{2}}}\log_e\frac{c+\sqrt{(c^2-a^2)}}{c-\sqrt{(c^2-a^2)}},$$
$$C = \int_0^\infty \frac{d\lambda}{(a^2+\lambda)(c^2+\lambda)^{\frac{3}{2}}},$$
$$= \frac{1}{(c^2-a^2)^{\frac{3}{2}}}\log_e\frac{c+\sqrt{(c^2-a^2)}}{c-\sqrt{(c^2-a^2)}} - \frac{2}{c(c^2-a^2)};$$

and therefore $2A + C = \frac{2}{a^2c}$.

Wave Motion in Liquids.

First consider plane waves propagated in the direction of the axis of x in liquid of depth h, the undisturbed surface being taken as the plane of xy and the axis of z drawn vertically upwards.

The equation of continuity, supposing a velocity function ϕ to exist, being

$$\frac{d^2\phi}{dx^2} + \frac{d^2\phi}{dz^2} = 0,$$

we must first seek a solution of this equation, involving a periodic term of the form $\sin(mx-nt)$, where $m = \frac{2\pi}{\lambda}$, $n = \frac{2\pi V}{\lambda}$, λ being the wave length and V the velocity of propagation of the waves.

If we put $\phi = f(z)\sin(mx-nt)$, then

$$\frac{d^2f}{dz^2} - m^2f = 0,$$

the solution of which, under the condition that $\frac{d\phi}{dz} = 0$ when $z = -h$, is

$$f(z) = A\cosh m(z+h),$$

and therefore

$$\phi = A\cosh m(z+h)\sin(mx-nt).$$

We must now endeavour to make the free surface a surface of equal pressure, and in order to do this we must suppose A small enough for its square to be neglected; and therefore the square of the velocity is to be neglected too.

The dynamical equation then becomes

$$\frac{p}{\rho} + gz + \frac{d\phi}{dt} = H, \text{ a constant};$$

and at the surface where $z = 0$, $\frac{Dp}{dt} = 0$, and $\frac{dz}{dt}$ may be put $= \frac{d\phi}{dz}$,

therefore $g\frac{d\phi}{dz} + \frac{d^2\phi}{dt^2} = 0$, when $z = 0$.

Therefore

$$Amg\sinh mh - n^2A\cosh mh = 0,$$

or

$$n^2 = mg\tanh mh,$$

or

$$V^2 = \frac{g\lambda}{2\pi}\tanh\frac{2\pi h}{\lambda}.$$

If the depth h be very great compared with the wave length λ, then neglecting the square of $\frac{\lambda}{h}$,

$$V^2 = \frac{g\lambda}{2\pi}.$$

If the depth h be very small compared with the wave length λ, then, neglecting the square of $\frac{h}{\lambda}$,

$$V^2 = gh.$$

Next consider the more general case of wave motion propagated in the direction of the axis of x at the common surface $z=0$ of two liquids, the lower of density ρ and bounded below by the fixed plane $z = -h$, and the upper of density ρ' and bounded by the fixed plane $z = h'$, and suppose U and U′ the mean velocities of currents in the liquids making angles α and α' with the axis of x; suppose in addition there is a surface tension T at the common surface of the liquids.

Denoting the velocity functions by ϕ and ϕ',

$$\phi = \mathrm{U}\cos\alpha\,.\,x + \mathrm{U}\sin\alpha\,.\,y + \mathrm{A}\cosh m(z+h)\cos(mx-nt)$$

$$\phi' = \mathrm{U}'\cos\alpha'\,.\,x + \mathrm{U}'\sin\alpha'\,.\,y + \mathrm{A}'\cosh m(z-h')\cos(mx-nt)\;;$$

then ϕ and ϕ' satisfy the equations of continuity, and the conditions that $\frac{d\phi}{dz}=0$ when $z=-h$, and $\frac{d\phi'}{dz}=0$ when $z=h'$.

Supposing the equation of the moving surface of separation to be $z=b\sin(mx-nt)$, then the direction of motion of each liquid, relative to the moving surface of separation, must be a tangent to the surface, and therefore, when $z=0$,

$$\frac{\frac{d\phi}{dz}}{\frac{d\phi}{dx}-\mathrm{V}} = \frac{\frac{d\phi'}{dz}}{\frac{d\phi'}{dx}-\mathrm{V}} = \frac{dz}{dx}\;;$$

or, neglecting A^2 and A'^2,

$$\frac{\mathrm{A}\sinh mh}{\mathrm{U}\cos\alpha - \mathrm{V}} = \frac{-\mathrm{A}'\sinh mh'}{\mathrm{U}'\cos\alpha' - \mathrm{V}} = b,$$

dividing out by the common factor $m\cos(mx-nt)$, and therefore

$$\phi = \mathrm{U}\cos\alpha\,.\,x + \mathrm{U}\sin\alpha\,.\,y + (\mathrm{U}\cos\alpha - \mathrm{V})b\frac{\cosh m(z+h)}{\sinh mh}\cos(mx-nt),$$

$$\phi' = \mathrm{U}'\cos\alpha'.x + \mathrm{U}'\sin\alpha'.y - (\mathrm{U}'\cos\alpha' - \mathrm{V})b\frac{\cosh m(z-h')}{\sinh mh'}\cos(mx-nt).$$

The dynamical equations are

$$p + g\rho z + \rho\frac{d\phi}{dt} + \tfrac{1}{2}\rho q^2 = \mathrm{H},$$

$$p' + g\rho' z + \rho'\frac{d\phi'}{dt} + \tfrac{1}{2}\rho' q'^2 = \mathrm{H}'\;;$$

and at the surface of separation, where $z=0$, we must have

$$p - p' = -\mathrm{T}\frac{d^2z}{dx^2} = m^2\mathrm{T}b\sin(mx-nt)$$

$$= \mathrm{H} - \mathrm{H}' - g(\rho-\rho')b\sin(mx-nt)$$
$$-\rho(\mathrm{U}\cos\alpha - \mathrm{V})\coth mh\,.\,nb\sin(mx-nt)$$
$$-\rho'(\mathrm{U}'\cos\alpha' - \mathrm{V})\coth mh'\,.\,nb\sin(mx-nt)$$
$$-\tfrac{1}{2}\rho\left\{\mathrm{U}\cos\alpha - (\mathrm{U}\cos\alpha - \mathrm{V})\coth mh\,.\,mb\sin(mx-nt)\right\}^2$$
$$-\tfrac{1}{2}\rho\mathrm{U}^2\sin^2\alpha - \tfrac{1}{2}\rho(\mathrm{U}\cos\alpha - \mathrm{V})^2m^2b^2\cos^2(mx-nt)$$
$$+\tfrac{1}{2}\rho'\left\{\mathrm{U}'\cos\alpha' + (\mathrm{U}'\cos\alpha' - \mathrm{V}')\coth mh'\,.\,mb\sin(mx-nt)\right\}^2$$
$$+\tfrac{1}{2}\rho'\mathrm{U}'^2\sin^2\alpha' + \tfrac{1}{2}\rho'(\mathrm{U}'\cos\alpha' - \mathrm{V})^2m^2b^2\cos^2(mx-nt)\;;$$

and neglecting b^2 and equating to zero the coefficient of $\sin(mx-nt)$,

$$m^2\mathrm{T} + g(\rho-\rho') - (\mathrm{U}\cos\alpha - \mathrm{V})(m\mathrm{U}\cos\alpha - n)\rho\coth mh$$
$$-(\mathrm{U}'\cos\alpha' - \mathrm{V})(m\mathrm{U}'\cos\alpha' - n)\rho'\coth mh' = 0,$$

which, since $\frac{n}{m}=\mathrm{V}$, reduces to

$$m^2\mathrm{T} + g(\rho-\rho') - m(\mathrm{U}\cos\alpha - \mathrm{V})^2\rho\coth mh$$
$$-m(\mathrm{U}'\cos\alpha' - \mathrm{V})^2\rho'\coth mh' = 0,$$

or, since $m=\frac{2\pi}{\lambda}$,

$$\frac{4\pi^2}{\lambda^2}\mathrm{T} = \frac{2\pi}{\lambda}\left\{(\mathrm{U}\cos\alpha - \mathrm{V})^2\rho\coth\frac{2\pi h}{\lambda} + (\mathrm{U}'\cos\alpha' - \mathrm{V})^2\rho'\coth\frac{2\pi h'}{\lambda}\right\}$$
$$-g(\rho-\rho') = 0.$$

If $\mathrm{U}=0$, $\mathrm{U}'=0$, $\rho'=0$, we find

$$\mathrm{V}^2 = \left(\frac{g\lambda}{2\pi} + \frac{2\pi\mathrm{T}}{\lambda\rho}\right)\tanh\frac{2\pi h}{\lambda},$$

as at first, if $\mathrm{T}=0$.

A discussion of the different cases that can arise is given by Lord Rayleigh in his papers on the "Instability of Jets" published in the *Proceedings of the Royal Society* and of the *London Mathematical Society*; also in a paper by Sir W. Thomson in the *Phil. Mag.*, 1871.

In the last-mentioned paper an interesting application of the above equations is made to determine the ripples produced by wind blowing over the surface of still water.

Put $\mathrm{U}=0$, $h=\infty$, $h'=\infty$;

then $m^2\mathrm{T} + g(\rho-\rho') - m\mathrm{V}^2\rho - m(\mathrm{U}'-\mathrm{V})^2\rho' = 0.$

If W be the velocity of propagation of waves of the same length with no wind, then

$$m^2\mathrm{T} + g(\rho-\rho') - m\mathrm{W}^2(\rho+\rho') = 0\;;$$

or

$$\mathrm{W}^2 = \frac{g}{m}\frac{\rho-\rho'}{\rho+\rho'} + \frac{m\mathrm{T}}{\rho+\rho'}\;;$$

the minimum value of which for different values of m is given by

$$\mathrm{W}^2 = 2\sqrt{(g\mathrm{T})}\frac{\sqrt{(\rho-\rho')}}{\rho+\rho'},$$

and then

$$m^2 = \frac{g}{\mathrm{T}}(\rho-\rho')\;.$$

But

$$\mathrm{V}^2\rho + (\mathrm{U}'-\mathrm{V})^2\rho' = \mathrm{W}^2(\rho+\rho)$$

and therefore

$$\mathrm{V} = \frac{\rho'}{\rho+\rho'}\mathrm{U}' \pm \sqrt{\left\{\mathrm{W}^2 - \frac{\rho\rho'}{(\rho+\rho')^2}\mathrm{U}'^2\right\}}\;;$$

giving the velocities of propagation of waves with and against the wind.

The least value of U'^2 is less than $\frac{(\rho+\rho')^2}{\rho\rho'}$ times the least value of W^2, and is therefore

$$2\sqrt{(g\mathrm{T})}\frac{\rho+\rho'}{\rho\rho'}\sqrt{(\rho-\rho')}\;.$$

If the wind be blowing with a velocity greater than this minimum value of U′, the surface of the water as a plane level surface becomes unstable, and ripples are produced.

With C. G. S. units, $g=981$, $\mathrm{T}=81$, $\rho=1$, $\rho'=\cdot0012759$, and then the minimum value of U′ is about 664, equivalent to about 14·8 miles an hour. This velocity is of course much greater than what is required to ruffle the surface of water in reality, the discrepancy being due to the viscosity of the air.

In the case of standing waves in a circular tank, cylindrical coordinates r, θ, z being used, where

$$x = r\cos\theta,\quad y = r\sin\theta,$$

the equation of continuity becomes

$$\frac{d^2\phi}{dr^2} + \frac{1}{r}\frac{d\phi}{dr} + \frac{1}{r^2}\frac{d^2\phi}{d\theta^2} + \frac{d^2\phi}{dz^2} = 0\;.$$

If the liquid be of depth h, we must put

$$\phi = \phi_1\cosh k(z+h)\cos 2\pi nt,$$

where n is the number of oscillations per second, and then

$$\frac{d^2\phi_1}{dr^2} + \frac{1}{r}\frac{d\phi_1}{dr} + \frac{1}{r^2}\frac{d^2\phi_1}{d\theta^2} + k^2\phi_1 = 0\;.$$

If we put $\phi_1 = \psi\cos m\theta$, then

$$\frac{d^2\psi}{dr^2} + \frac{1}{r}\frac{d\psi}{dr} + \left(k^2 - \frac{m^2}{r^2}\right)\psi = 0\;,$$

Bessel's differential equation; and therefore

$$\psi = \mathrm{AJ}_m(kr),$$

and

$$\phi = \mathrm{AJ}_m(kr)\cos m\theta\cosh k(z+h)\cos 2\pi nt\;;$$

and k must be determined from the condition that

$$\frac{d\phi}{dr} = 0,\ \text{when } r=a\;;$$

or

$$\mathrm{J}'_m(ka) = 0\;.$$

At the free surface

$$g\frac{d\phi}{dz} + \frac{d^2\phi}{dt^2} = 0\;,$$

or

$$gk\sinh kh - 4\pi^2n^2\cosh kh = 0,$$

or

$$n^2 = \frac{gk}{4\pi^2}\tanh kh.$$

For circular waves, $m=0$, and the roots of $\mathrm{J}'_0(ka)=0$, are

$$ka = 3{\cdot}832,\ 7{\cdot}016,\ 10{\cdot}173,\ 13{\cdot}323,\ \ldots\ldots$$

(Rayleigh, *Sound*, p. 274).

When the tank is limited by the radial plane $\theta=0$, then the slowest oscillation corresponds to $m=\frac{1}{2}$, and then

$$\mathrm{J}_{\frac{1}{2}}(kr) = \frac{\sin kr}{\sqrt{kr}},$$

and

$$\mathrm{J}'_{\frac{1}{2}}(ka) = \sqrt{\frac{k}{a}}\left(\cos ka - \frac{\sin ka}{ka}\right) = 0\;,$$

gives

$$\tan ka = ka,$$

and therefore

$$\frac{ka}{\pi} = 1{\cdot}4303$$

(Rayleigh, *Sound*, p. 279).

When the tank is bounded by the radial planes $\theta=0$, $\theta=\frac{2}{3}\pi$, the slowest oscillation corresponds to $m=\frac{3}{2}$, and then

$$\mathrm{J}_{\frac{3}{2}}(kr) = \frac{1}{\sqrt{kr}}\left(\frac{\sin kr}{kr} - \cos kr\right),$$

and the equation $\mathrm{J}'(ka)=0$ leads to

$$\tan ka = \frac{3ka}{2k^2a^2-3}\;.$$

For the discussion of the free oscillations of an ocean of uniform depth, covering a central nucleus, under the gravitation of the parts, and the surface tension at this free surface, consult Lamb's *Motion of Fluids*, p. 196, and Lord Rayleigh's papers in the *Proceedings of the London Mathematical Society*.

The propagation of plane waves of longitudinal displacement in air, and the notes produced by open and closed pipes, have been considered under the heading ACOUSTICS.

When the air is limited by special surfaces, the problem of its vibrations is worked out by Lord Rayleigh in the *Proceedings of the London Mathematical Society*, 1872.

A list of references to the memoirs and treatises on the subject will be found at the end of Lamb's *Motion of Fluids*. (A. G. G.)

PART III.—HYDRAULICS.

I. THE DATA OF HYDRAULICS.

[*Units.*—Except where other units are given, the units throughout this article are feet, pounds, pounds per sq. ft., feet per second.]

1. *Properties of Fluids.*—The fluids to which the laws of practical hydraulics relate are substances the parts of which possess very great mobility, or which offer a very small resistance to distortion independently of inertia. Under the general heading Hydromechanics a fluid is defined to be a substance which yields continually to the slightest tangential stress, and hence in a fluid at rest there can be no tangential stress. But, further, in fluids such as water, air, steam, &c., to which the present division of the article relates, the tangential stresses that are called into action between contiguous portions during distortion or change of figure are always small compared with the weight, inertia, pressure, &c., which produce the visible motions it is the object of hydraulics to estimate. On the other hand, while a fluid passes easily from one form to another, it opposes considerable resistance to change of volume.

It is easily deduced from the absence or smallness of the tangential stress that contiguous portions of fluid act on each other with a pressure which is exactly or very nearly normal to the interface which separates them. The stress must be a pressure, not a tension, or the parts would separate. Further, at any point in a fluid the pressure in all directions must be the same; or, in other words, the pressure on any small element of surface is independent of the orientation of the surface.

2. Fluids are divided into liquids, or incompressible fluids, and gases, or compressible fluids. Very great changes of pressure change the volume of liquids only by a small amount, and if the pressure on them is reduced to zero they do not sensibly dilate. In gases or compressible fluids the volume alters sensibly for small changes of pressure, and if the pressure is indefinitely diminished they dilate without limit.

In ordinary Hydraulics, liquids are treated as absolutely incompressible. In dealing with gases the changes of volume which accompany changes of pressure must be taken into account.

3. Viscous fluids are those in which change of form under a continued stress proceeds gradually and increases indefinitely. A very viscous fluid opposes great resistance to change of form in a short time, and yet may be deformed considerably by a small stress acting for a long period. A block of pitch is more easily splintered than indented by a hammer, but under the action of the mere weight of its parts acting for a long enough time it flattens out and flows like a liquid.

All actual fluids are viscous. They oppose a resistance to the relative motion of their parts. This resistance diminishes with the velocity of the relative motion, and becomes zero in a fluid the parts of which are relatively at rest. When the relative motion of different parts of a fluid is small, the viscosity may be neglected without introducing important errors. On the other hand, where there is considerable relative motion, the viscosity may be expected to have an influence too great to be neglected.

Measurement of Viscosity. Coefficient of Viscosity.—Suppose the plane *ab*, fig. 11, of area ω, to move with the velocity V relatively to the surface *cd* and parallel to it. Let the space between be filled with liquid. The layers of liquid in contact with *ab* and *cd* adhere to them. The intermediate layers all offering an equal resistance to shearing or distortion, the rectangle of fluid *abcd* will take the form of the parallelogram *a′b′cd*. Further, the resistance to the motion of *ab* may be expressed in the form

$$R = \kappa\omega V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where κ is a coefficient the nature of which remains to be determined.

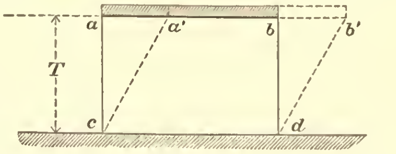

Fig. 11.

If we suppose the liquid between *ab* and *cd* divided into layers as shown in fig. 12, it will be clear that the stress R acts, at each dividing face, forwards in the direction of motion if we consider the upper layer, backwards if we consider the lower layer. Now suppose the original thickness of the layer T increased to nT; if the bounding plane in its new position has the velocity nV, the shearing at each dividing face will be exactly the same as before, and the resistance must therefore be the same. Hence,

$$R = \kappa'\omega\,(nV) \quad . \quad . \quad (2).$$

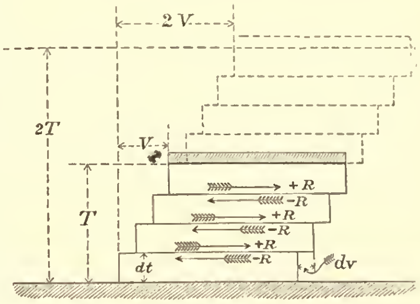

Fig. 12.

But equations (1) and (2) may both be expressed in one equation if κ and κ' are replaced by a constant varying inversely as the thickness of the layer. Putting $\kappa = \frac{\mu}{T}$, $\kappa' = \frac{\mu}{nT}$,

$$R = \mu\omega\frac{V}{T};$$

or, for an indefinitely thin layer,

$$R = \mu\omega\frac{dV}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

an expression first proposed by Navier. The coefficient μ is termed the coefficient of viscosity.

According to Maxwell, the value of μ for air at $\theta°$ Fahr. in pounds, when the velocities are expressed in feet per second, is

$$\mu = 0{\cdot}000\,000\,025\,6(461° + \theta);$$

that is, the coefficient of viscosity is proportional to the absolute temperature and independent of the pressure.

The value of μ for water at 77° Fahr. is, according to Helmholtz and Piotrowski,

$$\mu = 0{\cdot}000\,001\,91,$$

the units being the same as before. For water μ decreases rapidly with increase of temperature.

4. When a fluid flows in a very regular manner, as for instance when it flows in a capillary tube, the velocities vary gradually at any moment from one point of the fluid to a neighbouring point. The layer adjacent to the sides of the tube adheres to it and is at rest. The layers more interior than this slide on each other. But the resistance developed by these regular movements is very small. If in large pipes and open channels there were a similar regularity of movement, the neighbouring filaments would acquire, especially near the sides, very great relative velocities. Boussinesq has shown that the central filament in a semicircular canal of 1 metre radius, and inclined at a slope of only 0·0001, would have a velocity of 187 metres per second,[1] the layer next the boundary remaining at rest. But before such a difference of velocity can arise, the motion of the fluid becomes much more complicated. Volumes of fluid are detached continually from the boundaries, and, revolving, form eddies traversing the fluid in all directions, and sliding with finite relative velocities against those surrounding them. These slidings develop resistances, incomparably greater than the viscous resistance due to movements varying continuously from point to point. The movements which produce the phenomena commonly ascribed to fluid friction must be regarded as rapidly or even suddenly varying from one point to another. The internal resistances to the motion of the fluid do not depend

[1] *Journal de M. Liouville*, t. xiii., 1868; *Mémoires de l'Académie des Sciences de l'Institut de France*, t. xxiii., xxiv., 1877.

on the general velocities of translation at different points of the fluid (or what M. Boussinesq terms the mean local velocities), but rather on the intensity at each point of the eddying agitation. The problems of hydraulics are therefore much more complicated than problems in which a regular motion of the fluid is assumed, hindered by the viscosity of the fluid.

Relation of Pressure, Density, and Temperature of Liquids.

5. *Density of Water.*—Water at ordinary temperature and pressure contains 62·4 lb per cubic foot, or 1000 kilogrammes per cubic metre. The density or weight per unit of volume will be designated by G. River and spring water is not sensibly denser than pure water, being at most 1-100000th heavier. Sea-water may be taken at 64 lb per cubic foot.

6. *Compressibility of Liquids.*—The most accurate experiments show that liquids are sensibly compressed by very great pressures, and that up to a pressure of 65 atmospheres, or about 1000 lb per square inch, the compression is proportional to the pressure. The chief results of experiment are given in the following table. Let V_1 be the volume of a liquid in cubic feet under a pressure p_1 lb per square foot, and V_2 its volume under a pressure p_2. Then the cubical compression is

$$\frac{V_2 - V_1}{V_1},$$

and the ratio of the increase of pressure $p_2 - p_1$ to the cubical compression is sensibly constant. That is, $\frac{(p_2-p_1)V_1}{V_2-V_1}$ is constant. This constant is termed the elasticity of volume, and is denoted by k (Thomson). With the notation of the differential calculus,

$$k = \frac{dp}{-\frac{dV}{V}} = -V\frac{dp}{dV}.$$

Elasticity of Volume of Liquids.

	Canton.	Oerstedt.	Colladon and Sturm.	Regnault.

Alcohol.....	32,060,000	...	23,100,000	...

According to the experiments of Grassi, the compressibility of water diminishes as the temperature increases, while that of ether, alcohol, and chloroform is increased.

7. *Change of Volume and Density of Water with Change of Temperature.*—Although the change of volume of water with change of temperature is so small that it may generally be neglected in ordinary hydraulic calculations, yet it should be noted that there is a change of volume which should be allowed for in very exact calculations. The values of ρ in the following short table, which gives data enough for hydraulic purposes, are taken from Professor Everett's *System of Units.*

Density of Water at Different Temperatures.

The weight per cubic foot has been calculated from the values of ρ, on the assumption that a cubic foot of water at 39·2° Fahr. is 62·425 lb. For ordinary calculations in hydraulics, the density of water (which will in future be designated by the symbol G) will be taken at 62·4 lb per cubic foot, which is its density at 53° Fahr. It may be noted also that ice at 32° Fahr. contains 57·2 lb per cubic foot. The values of ρ are the densities in grammes per cubic centimetre.

8. *Pressure Column. Free Surface Level.*—Suppose a small vertical pipe introduced into a liquid at any point P (fig. 13). Then the liquid will rise in the pipe to a level OO, such that the pressure due to the column in the pipe exactly balances the pressure on its mouth. If the fluid is in motion the mouth of the pipe must be supposed accurately parallel to the direction of motion, or the impact of the liquid at the mouth of the pipe will have an influence on the height of the column. If this condition is complied with, the height h of the column is a measure of the pressure at the point P. Let ω be the area of section of the pipe, h the height of the pressure column, p the intensity of pressure at P; then

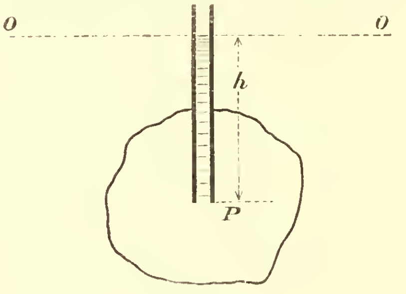

Fig. 13.

$$p\omega = Gh\omega \text{ lb},$$

$$\frac{p}{G} = h;$$

that is, h is the height due to the pressure at p. The level OO will be termed the free surface level corresponding to the pressure at P.

Relation of Pressure, Temperature, and Density of Gases.

9. *Relation of Pressure, Volume, Temperature, and Density in Compressible Fluids.*—Certain problems on the flow of air and steam are so similar to those relating to the flow of water that they are conveniently treated together. It is necessary, therefore, to state as briefly as possible the properties of compressible fluids so far as knowledge of them is requisite in the solution of these problems. Air may be taken as a type of these fluids, and the numerical data here given will relate to air.

Relation of Pressure and Volume at Constant Temperature.—At constant temperature the product of the pressure p and volume V of a given quantity of air is a constant (Boyle's law).

Let p_0 be mean atmospheric pressure (2116·8 lb per square foot), V_0 the volume of 1 lb of air at 32° Fahr. under the pressure p_0. Then

$$p_0 V_0 = 26214 \quad \ldots\ldots \quad (1).$$

If G_0 is the weight per cubic foot of air in the same conditions,

$$G_0 = \frac{1}{V_0} = \frac{2116·8}{26214} = ·08075 \quad \ldots\ldots \quad (2).$$

For any other pressure p, at which the volume of 1 lb is V and the weight per cubic foot is G, the temperature being 32° Fahr.,

$$pV = \frac{p}{G} = 26214; \quad \text{or } G = \frac{p}{26214} \quad \ldots\ldots \quad (3).$$

Change of Pressure or Volume by Change of Temperature.—Let p_0, V_0, G_0, as before be the pressure, the volume of a pound in cubic feet, and the weight of a cubic foot in pounds, at 32° Fahr. Let p, V, G be the same quantities at a temperature t (measured strictly by the air thermometer, the degrees of which differ a little from those of a mercurial thermometer). Then, by experiment,

$$pV = p_0 V_0 \frac{460·6 + t}{460·6 + 32} = p_0 V_0 \frac{\tau}{\tau_0} \quad \ldots\ldots \quad (4),$$

where τ, τ_0 are the temperatures t and 32° reckoned from the absolute zero, which is −460·6° Fahr.;

$$\frac{p}{G} = \frac{p_0}{G_0} \cdot \frac{\tau}{\tau_0} \quad \ldots\ldots \quad (4a);$$

$$G = \frac{p}{p_0} \cdot \frac{\tau_0 G_0}{\tau} \quad \ldots\ldots \quad (5).$$

If $p_0 = 2116·8$, $G_0 = ·08075$, $\tau_0 = 460·6 + 32 = 492·6$, then

$$\frac{p}{G} = 53·2\tau \quad \ldots\ldots \quad (5a).$$

II. KINEMATICS OF FLUIDS.

10. Moving fluids as commonly observed are conveniently classified thus:—

(1) *Streams* are moving masses of indefinite length, completely or incompletely bounded laterally by solid boundaries. When the solid boundaries are complete, the flow is said to take place in a pipe. When the solid boundary is incomplete and leaves the upper surface of the fluid free, it is termed a stream bed or channel or canal.

(2) A stream bounded laterally by differently moving fluid of the same kind is termed a *current*.

(3) A *jet* is a stream bounded by fluid of a different kind.

(4) An *eddy*, *vortex*, or *whirlpool* is a mass of fluid the particles of which are moving circularly or spirally.

(5) In a stream we may often regard the particles as flowing along definite paths in space. A chain of particles following each other along such a constant path may be termed a fluid filament or elementary stream.

11. *Steady and Unsteady, Uniform and Varying, Motion.*—There are two quite distinct ways of treating hydrodynamical questions. We may either fix attention on a given mass of fluid and consider its changes of position and energy under the action of the stresses to which it is subjected, or we may have regard to a given fixed portion of space and consider the volume and energy of the fluid entering and leaving that space.

If, in following a given path *ab* (fig. 14), a mass of water *a* has a constant velocity, the motion is said to be uniform. The kinetic energy of the mass *a* remains unchanged. If the velocity varies from point to point of the path, the motion is called varying motion. If at a given point *a* in space, the particles of water always arrive with the same velocity and in the same direction, during any given time, then the motion is termed steady motion. On the contrary, if at the point *a* the velocity or direction varies from moment to moment the motion is termed unsteady. Steady motion is sometimes termed permanent motion. A river which excavates its own bed is in unsteady motion so long as the slope and form of the bed is changing. It, however, tends always towards a condition in which the bed ceases to change, and it is then said to have reached a condition of permanent regime. No river probably is in absolutely permanent regime, except perhaps in rocky channels. In other cases the bed is scoured more or less during the rise of a flood, and silted again during the subsidence of the flood. But while many streams of a torrential character change the condition of their bed often and to a large extent, in others the changes are comparatively small and not easily observed.

Fig. 14.

As a stream approaches a condition which would be strictly defined as one of steady motion, its regime becomes permanent. Hence steady motion and permanent regime are sometimes used as meaning the same thing. The one, however, is a definite term applicable to the motion of the water, the other a less definite term applicable in strictness only to the condition of the stream bed.

12. *Theoretical Notions on the Motion of Water.*—The actual motion of the particles of water is in most cases very complex. To simplify hydrodynamic problems, simpler modes of motion are assumed, and the results of theory so obtained are compared experimentally with the actual motions.

Motion in Plane Layers.—The simplest kind of motion in a stream is one in which the particles initially situated in any plane cross section of the stream continue to be found in plane cross sections during the subsequent motion. Thus, if the particles in a thin plane layer *ab* (fig. 15) are found again in a thin plane layer *a'b'* after any interval of time, the motion is said to be motion in plane layers. In such motion the internal work in deforming the layer may usually be disregarded, and the resistance to the motion is confined to the circumference.

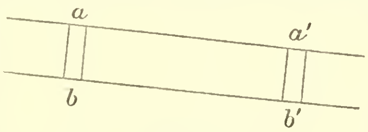

Fig. 15.

Laminar Motion.—In the case of streams having solid boundaries, it is observed that the central parts move faster than the lateral parts. To take account of these differences of velocity, the stream may be conceived to be divided into thin laminae, having cross sections somewhat similar to the solid boundary of the stream, and sliding on each other. The different laminae can then be treated as having differing velocities according to any law either observed or deduced from their mutual friction. A much closer approximation to the real motion of ordinary streams is thus obtained.

Stream Line Motion.—In the preceding hypothesis, all the particles in each lamina have the same velocity at any given cross section of the stream. If this assumption is abandoned, the cross section of the stream must be supposed divided into indefinitely small areas, each representing the section of a fluid filament. Then these filaments may have any law of variation of velocity assigned to them. If the motion is steady motion these fluid filaments (or as they are then termed *stream lines*) will have fixed positions in space.

Periodic Unsteady Motion.—In ordinary streams with rough boundaries, it is observed that at any given point the velocity varies from moment to moment in magnitude and direction, but that the average velocity for a sensible period (say for 5 or 10 minutes) varies very little either in magnitude or velocity. It has hence been conceived that the variations of direction and magnitude of the velocity are periodic, and that, if for each point of the stream the mean velocity and direction of motion were substituted for the actual more or less varying motions, the motion of the stream might be treated as steady stream line or steady laminar motion.

13. *Volume of Flow.*—Let A (fig. 16) be any ideal plane surface, of area ω, in a stream, normal to the direction of motion, and let V

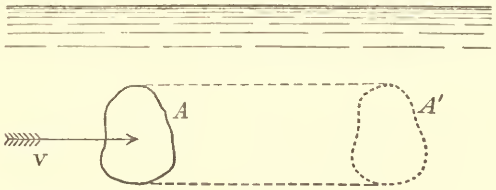

Fig. 16.

be the velocity of the fluid. Then the volume flowing through the surface A in unit time is

$$Q = \omega V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Thus, if the motion is rectilinear, all the particles at any instant in the surface A will be found after one second in a similar surface A', at a distance V, and as each particle is followed by a continuous thread of other particles, the volume of flow is the right prism AA' having a base ω and length V.

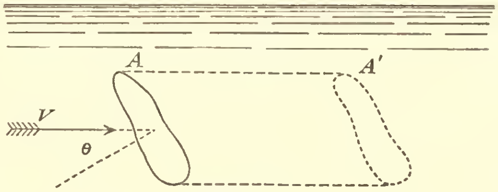

Fig. 17.

If the direction of motion makes an angle θ with the normal to the surface, the volume of flow is represented by an oblique prism AA' (fig. 17), and in that case

$$Q = \omega V \cos \theta \, .$$

If the velocity varies at different points of the surface, let the surface be divided into very small portions, for each of which the velocity may be regarded as constant. If $d\omega$ is the area and v, or $v \cos \theta$, the normal velocity for this element of the surface, the volume of flow is

$$Q = \int v d\omega, \text{ or } \int v \cos \theta \, d\omega \, ,$$

as the case may be.

14. *Principle of Continuity.*—If we consider any completely bounded fixed space in a moving liquid initially and finally filled continuously with liquid, the inflow must be equal to the outflow. Expressing the inflow with a positive and the outflow with a negative sign, and estimating the volume of flow Q for all the boundaries,

$$\Sigma Q = 0 \, .$$

In general the space will remain filled with fluid if the pressure at every point remains positive. There will be a break of continuity, if at any point the pressure becomes negative, indicating that the stress at that point is tensile. In the case of ordinary water this statement requires modification. Water contains a variable amount of air in solution, often about one-twentieth of its volume. This air is disengaged and breaks the continuity of the liquid, if the pressure falls below a point corresponding to its tension. It is for this reason that pumps will not draw water to the full height due to atmospheric pressure.

Application of the Principle of Continuity to the case of a Stream.—If A_1, A_2 are the areas of two normal cross sections of a stream and V_1, V_2 are the velocities of the stream at those sections, then, from the principle of continuity,

$$V_1A_1 = V_2A_2 ;$$
$$\frac{V_1}{V_2} = \frac{A_2}{A_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2);$$

that is, the normal velocities are inversely as the areas of the cross sections. This is true of the mean velocities, if at each section the velocity of the stream varies. In a river of varying slope the velocity varies with the slope. It is easy therefore to see that in parts of large cross section the slope is smaller than in parts of small cross section.

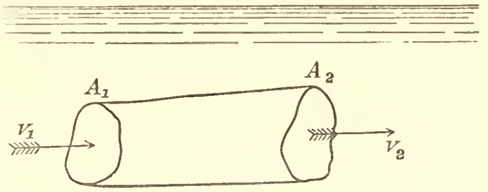

Fig. 18.

If we conceive a space in a liquid bounded by normal sections at A_1, A_2 and between A_1, A_2 by stream lines (fig. 18), then, as there is no flow across the stream lines,

$$\frac{V_1}{V_2} = \frac{A_2}{A_1},$$

as in a stream with rigid boundaries.

In the case of compressible fluids the variation of volume due to the difference of pressure at the two sections must be taken into account. If the motion is steady the weight of fluid between two cross sections of a stream must remain constant. Hence the weight flowing in must be the same as the weight flowing out. Let p_1, p_2 be the pressures, v_1, v_2 the velocities, G_1, G_2 the weight per cubic foot of fluid, at cross sections of a stream of areas A_1, A_2. The volumes of inflow and outflow are

$$A_1v_1 \text{ and } A_2v_2 ,$$

and, if the weights of these are the same,

$$G_1A_1v_1 = G_2A_2v_2 ;$$

and hence, from (5*a*) § 9, if the temperature is constant,

$$p_1A_1v_1 = p_2A_2v_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

III. PHENOMENA OF THE DISCHARGE OF LIQUIDS FROM ORIFICES AS ASCERTAINABLE BY EXPERIMENTS.

15. When a liquid issues vertically from a small orifice, it forms a jet which rises nearly to the level of the free surface of the liquid in the vessel from which it flows. The difference of level h_r (fig. 19) is so small that it may be at once suspected to be due either to air resistance on the surface of the jet or to the viscosity of the liquid or to friction against the sides of the orifice. Neglecting for the moment this small quantity, we may infer, from the elevation of the jet, that each molecule on leaving the orifice possessed the velocity required to lift it against gravity to the height h. From ordinary dynamics, the relation between the velocity and height of projection is given by the equation

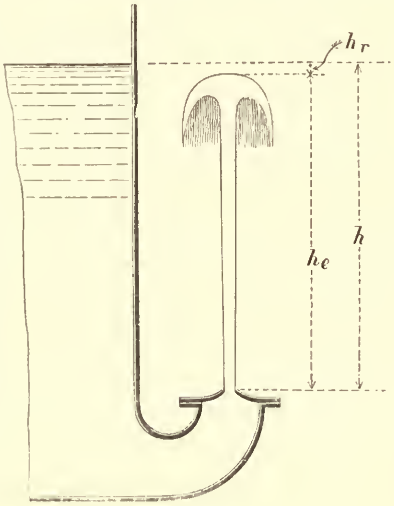

Fig. 19.

$$v = \sqrt{2gh} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

As this velocity is nearly reached in the flow from well-formed orifices, it is sometimes called the theoretical velocity of discharge. This relation was first obtained by Torricelli.

If the orifice is of a suitable conoidal form, the water issues in filaments normal to the plane of the orifice. Let ω be the area of the orifice, then the discharge per second must be, from eq. (1),

$$Q = \omega v = \omega\sqrt{2gh} \text{ nearly} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

This is often termed the theoretical discharge.

Use of the term Head in Hydraulics.—The term *head* is an old millwright's term, and meant primarily the height through which a mass of water descended in actuating a hydraulic machine. Since the water in fig. 19 descends through a height h to the orifice, we may say there are h feet of head above the orifice. Still more generally any mass of liquid h feet above a horizontal plane may be said to have h feet of elevation head relatively to that datum plane. Further, since the pressure p at the orifice which produces outflow is connected with h by the relation $\frac{p}{G} = h$, the quantity $\frac{p}{G}$ may be termed the pressure head at the orifice. Lastly, the velocity v is connected with h by the relation $\frac{v^2}{2g} = h$, so that $\frac{v^2}{2g}$ may be termed the head due to the velocity v.

16. *Coefficients of Velocity and Resistance.*—As the actual velocity of discharge differs from $\sqrt{2gh}$ by a small quantity, let the actual velocity

$$= v_a = c_v\sqrt{2gh} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

where c_v is a coefficient to be determined by experiment, called the *coefficient of velocity*. This coefficient is found to be tolerably constant for different heads with well-formed simple orifices, and it very often has the value 0·97.

The difference between the velocity of discharge and the velocity due to the head may be reckoned in another way. The total height h causing outflow consists of two parts,—one part h_e expended in producing the velocity of outflow, another h_r in overcoming the resistances due to viscosity and friction. Let

$$h_r = c_rh_e ,$$

where c_r is a coefficient determined by experiment, and called the *coefficient of resistance* of the orifice. It is tolerably constant for different heads with well-formed orifices. Then

$$v_a = \sqrt{2gh_e} = \sqrt{2g\frac{h}{1+c_r}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

The relation between c_v and c_r for any orifice is easily found:—

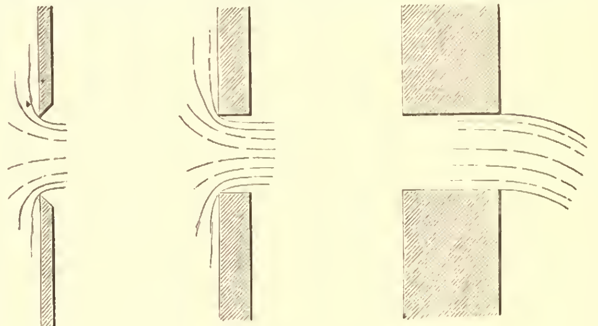
$$v_a = c_v\sqrt{2gh} = \sqrt{2g\frac{h}{1+c_r}} .$$

$$c_v = \sqrt{\frac{1}{1+c_r}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

$$c_r = \frac{1}{c_v^2} - 1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5a).$$

Thus if $c_v = 0·97$, then $c_r = 0·0628$. That is, for such an orifice about 6¼ per cent. of the head is expended in overcoming frictional resistances to flow.

Coefficient of Contraction—Sharp-edged Orifices in Plane Surfaces.—When a jet issues from an aperture in a vessel, it may either spring clear from the inner edge of the orifice as at *a* or *b* (fig. 20), or it may adhere to the sides of the orifice as at *c*. The former condition will be found if the orifice is bevelled outwards as at *a*, so as to be sharp edged, and it will also occur generally for a prismatic aperture like *b*, provided the thickness of the vessel round the aperture is less than the diameter of the jet. But if the thickness is greater the condition shown at *c* will occur.



a *b* *c*

Fig. 20.

When the discharge takes place as at *a* or *b*, the section of the jet is smaller than the section of the orifice. This is due to the formation of the jet from filaments converging to the orifice in all directions inside the vessel. The inertia of the filaments opposes sudden change of direction of motion at the edge of the orifice, and the convergence continues for a distance of about half the diameter of the orifice beyond it. Let ω be the area of the orifice, and $c_c\omega$ the area of the jet at the point where convergence ceases; then c_c is a coefficient to be determined experimentally for each kind of orifice, called the *coefficient of contraction*. When the orifice is a sharp-edged orifice in a plane surface, the value of c_c is on the average 0·64, or the section of the jet is very nearly five-eighths of the area of the orifice.

Coefficient of Discharge.—In applying the general formula $Q = \omega v$ to a stream, it is assumed that the filaments have a common velocity v normal to the section ω. But if the jet contracts, it is at the contracted section of the jet that the direction of motion is normal to a transverse section of the jet. Hence the actual discharge when contraction occurs is

$$Q_a = c_v v \times c_c \omega = c_c c_v \omega \sqrt{2gh},$$

or simply, if $c = c_v\, c_c$,

$$Q_a = c\omega\sqrt{2gh},$$

where c is called the *coefficient of discharge*. Thus for a sharp-edged plane orifice $c = 0{\cdot}97 \times 0{\cdot}64 = 0{\cdot}62$.

17. *Experimental determination of c_v, c_c, and c.*—The coefficient of contraction c_c is directly determined by measuring the dimensions of the jet. For this purpose fixed screws of fine pitch (fig. 21) are convenient. These are set to touch the jet, and then the distance between them can be measured at leisure.

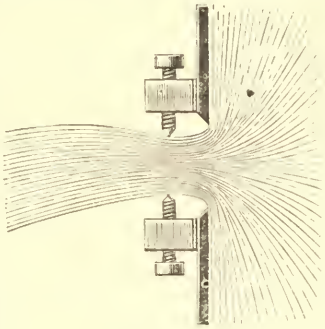


Fig. 21

The coefficient of velocity is determined directly by measuring the parabolic path of a horizontal jet.

Let OX, OY (fig. 22) be horizontal and vertical axes, the origin being at the orifice. Let h be the head, and x, y the coordinates of a point A on the parabolic path of the jet. If v_a

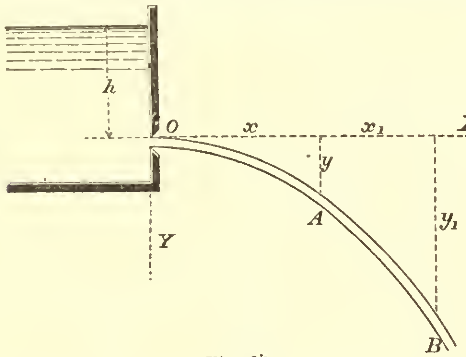

Fig. 22.

is the velocity at the orifice, and t the time in which a particle moves from O to A, then

$$x = v_a t\,;\quad y = \tfrac{1}{2}gt^2.$$

Eliminating t,

$$v_a = \sqrt{\frac{gx^2}{2y}}.$$

Then

$$c_v = \frac{v_a}{\sqrt{2gh}} = \sqrt{\frac{x^2}{4yh}}.$$

If the jet is not initially horizontal, let OB (fig. 23) be any horizontal datum line, and let the vertical distances OC, AD, BE be

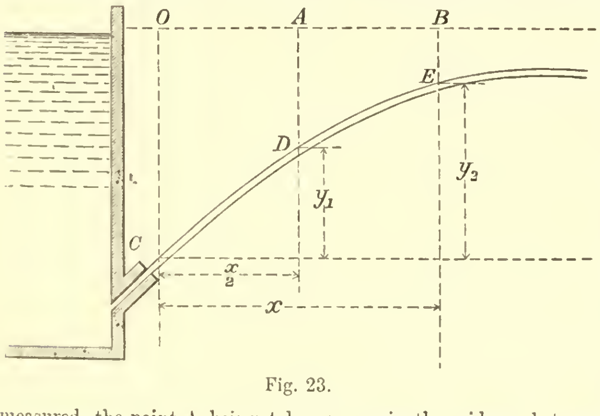

Fig. 23.

measured, the point A being taken conveniently midway between O and B. Then

$$y_1 = \mathrm{OC} - \mathrm{AD}, \text{ and } y_2 = \mathrm{OC} - \mathrm{BE}.$$

Let α be the inclination of the jet at C to the horizontal, so that $v_a \cos\alpha$ is its horizontal and $v_a \sin\alpha$ its vertical velocity at that point. If t is the time in which a particle moves from C to D, then

$$\frac{x}{2} = v_a \cos\alpha\, t,$$

$$y_1 = v_a \sin\alpha\, t - \frac{gt^2}{2}.$$

Eliminating t,

$$y_1 = \frac{x}{2}\tan\alpha - \frac{gx^2}{8v_a^2}(1 + \tan^2\alpha).$$

Similarly,

$$y_2 = x\tan\alpha - \frac{gx^2}{2v_a^2}(1 + \tan^2\alpha).$$

Hence

$$\tan\alpha = \frac{4y_1 - y_2}{x},$$

$$v_a = \sqrt{\frac{g\{x^2 + (4y_1 - y_2)^2\}}{4(2y_1 - y_2)}},$$

$$c_v = \frac{v_a}{\sqrt{2gh}} = \sqrt{\frac{x^2 + (4y_1 - y_2)^2}{8h(2y_1 - y_2)}},$$

where for h is to be put the depth of C below the free water surface.

The coefficient of discharge is determined independently, by measuring the discharge in a gauging tank for a given time. Then, if Q is the measured volume discharged in one second,

$$c = \frac{Q}{\omega\sqrt{2gh}}.$$

18. *Coefficients for Bellmouths and Bellmouthed Orifices.*—If an orifice is furnished with a mouthpiece exactly of the form of the contracted vein, then the whole of the contraction occurs within the mouthpiece, and if the area of the orifice is measured at the smaller end, c_c must be put $= 1$. It is often desirable to bellmouth the ends of pipes, to avoid the loss of head which occurs if this is not done; and such a bellmouth may also have the form of the contracted jet. Fig. 24 shows the proportions of such a bellmouth

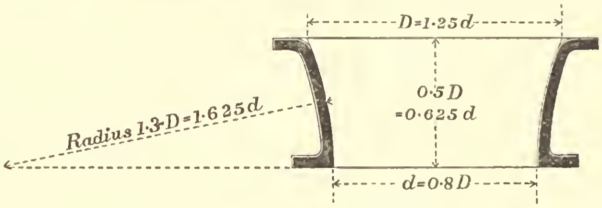

Fig. 24.

or bellmouthed orifice, which approximates to the form of the contracted jet sufficiently for any practical purpose.

For such an orifice Weisbach has found the following values of the coefficients with different heads.

Head over orifice, in feet $= h$	·66	1·64	11·48	55 77	337·93
Coefficient of velocity $= c_v$..	·959	·967	·975	·994	·994
Coefficient of resistance $= c_r$	·087	·069	·052	·012	·012

As there is no contraction after the jet issues from the orifice, $c_c = 1$, $c = c_v$; and therefore

$$Q = c_v\omega\sqrt{2gh} = \omega\sqrt{2g\frac{h}{1 + c_r}}.$$

19. *Coefficients for Sharp-edged or virtually Sharp-edged Orifices.*—The coefficient of velocity for sharp-edged orifices of different areas and under different heads is not very accurately determined. Its mean value is about 0·96.

The coefficient of contraction is also dependent on circumstances the relative influence of which is not so perfectly known as is desirable. Its mean value for well-placed orifices in a plane surface is 0·64. For conditions similar in other respects, the contraction is less (that is, the area of the stream is greater) the smaller the orifice and the less the head. If the surface surrounding the orifice is not plane, the coefficient is greater for a surface convex to the interior of the reservoir and less for a concave surface. The thickening of the edges of the orifice modifies the contraction in a slight degree, and if a border or rim is placed round part of the edge of the orifice, and projects inwards or outwards, the coefficient is very considerably altered, and the contraction is then termed incomplete. If the orifice is placed in a contracted part of the vessel so that the water approaches the orifice with considerable velocity, the coefficient is increased, and the contraction is said to be imperfect.

The coefficient of discharge has been determined for sharp-edged orifices under a great variety of conditions. Its mean value, taking the values of c_v and c_c given above, is 0·62.

For circular orifices, sharp-edged and with complete and perfect contraction, Weisbach found the following values:—

Coefficients of Discharge for Sharp-edged Circular Orifices.

Diameter of Orifice in Inches.	Coefficient of Discharge = c.	
	Head 2 ft.	Head 0·8 ft.
0·4	0·628	0·637
0·8	·621	·629
1·2	·614	·622
1·6	·607	·614

The following table, compiled by Mr Fanning (*Treatise on Water Supply Engineering*), gives values for rectangular orifices in vertical plane surfaces, the head being measured, not immediately over the orifice, where the surface is depressed, but to the still-water surface at some distance from the orifice. The values were obtained by graphic interpolation, all the most reliable experiments being plotted and curves drawn so as to average the discrepancies.

Coefficients of Discharge for Rectangular Orifices, Sharp-edged, in Vertical Plane Surfaces.

20. *Orifices with Edges of Sensible Thickness.*—When the edges of the orifice are not bevelled outwards, but have a sensible thickness, the coefficient of discharge is somewhat altered. The following table gives values of the coefficient of discharge for the arrangements of the orifice shown in vertical section at P, Q, R (fig. 25). The plan of all the orifices is shown at S. The planks forming the orifice and sluice were each 2 inches thick, and the orifices were all 24 inches wide. The heads were measured immediately over the orifice. The formula above becomes, in this case,

$$Q = cb(H-h)\sqrt{2g\frac{H+h}{2}}.$$

Table of Coefficients of Discharge for Rectangular Vertical Orifices in Fig. 25.

Head h above upper edge of Orifice in ft.	Height of Orifice, $H-h$, in feet.

21. *Partially Suppressed Contraction.*—Since the contraction of the jet is due to the convergence towards the orifice of the issuing streams, it will be diminished if for any portion of the edge of the orifice the convergence is prevented. Thus, if an internal rim or border is applied to part of the edge of the orifice (fig. 26), the convergence for so much of the edge is suppressed. For such cases Bidone found the following empirical formulæ applicable:—

For rectangular orifices,

$$c_c = 0·62\left(1 + 0·152\frac{n}{p}\right);$$

and for circular orifices,

$$c_c = 0·62\left(1 + 0·128\frac{n}{p}\right);$$

where n is the length of the edge of the orifice over which the border extends, and p is the whole length of edge or perimeter of the orifice.

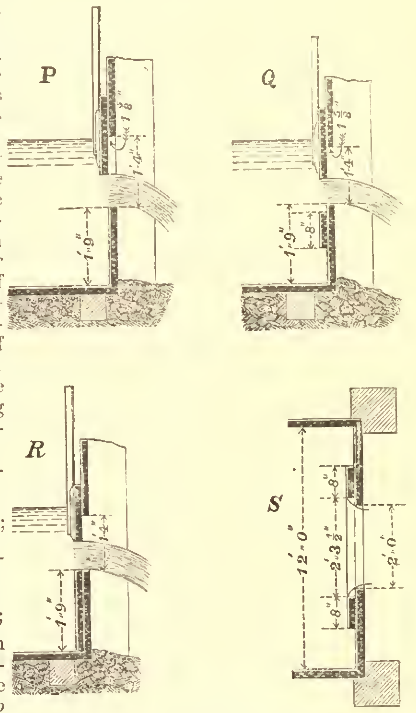

Fig. 25.

The following are the values of c_c, when the border extends over ¼, ½, or ¾ of the whole perimeter:—

$\frac{n}{p}$	c_c Rectangular Orifices.	c_c Circular Orifices.
0·25	0·643	·640
0·50	0·667	·660
0·75	0·691	·680

For larger values of $\frac{n}{p}$ the formulæ are not applicable. Bornemann has shown, however, that these formulæ for suppressed contraction are not reliable.

22. *Imperfect Contraction.*—If the sides of the vessel approach near to the edge of the orifice, they interfere with the convergence of the streams to which the contraction is due, and the contraction is then modified. It is generally stated that the influence of the sides begins to be felt if their distance from the edge of the orifice is less than 2·7 times the corresponding width of the orifice. The coefficients of contraction for this case are imperfectly known.

23. *Orifices Furnished with Channels of Discharge.*—These external borders to an orifice also modify the contraction.

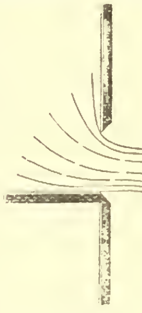

Fig. 26.

The following coefficients of discharge were obtained with openings 8 inches wide, and small in proportion to the channel of approach (fig. 27, A, B, C).

$h_2 - h_1$ in feet.		h_1 in feet.								
		·0656	·164	·328	·656	1·640	3·28	4·92	6·56	9·84

24. *Inversion of the Jet.*—When a jet issues from a horizontal orifice, or is of small size compared with the head, it presents no marked peculiarity of form. But if the orifice is in a vertical surface, and if its dimensions are not small compared with the head, it undergoes a series of singular changes of form after leaving the orifice. These were first investigated by Bidone; subsequently Magnus measured jets from different orifices; and lately Lord Rayleigh (*Proc. Roy. Soc.*, xxix. 71) has investigated them anew.

Fig. 28 shows some remarkable forms, the upper row giving the shape of the orifices, and the others sections of the jet. The jet first contracts as described above, in consequence of the convergence

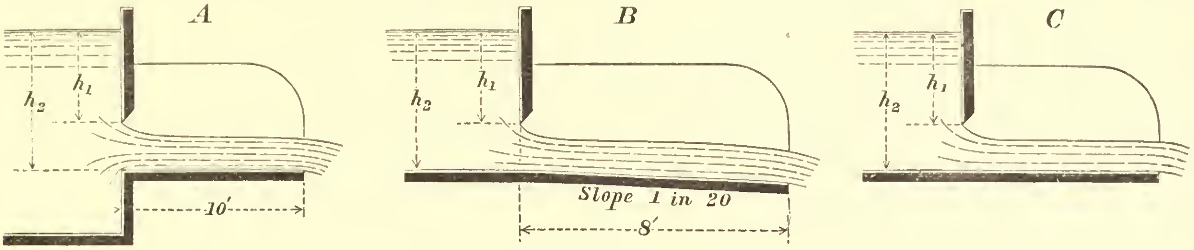

Fig. 27.
