ENCYCLOPÆDIA BRITANNICA.

HIRING, in law, may be defined as a contract by which one man grants the use of a thing to another in return for a certain price. It corresponds to the *locatio-conductio* of Roman law. That contract was either a letting of a thing (*locatio-conductio rei*) or of labour (*locatio operarum*). The distinguishing feature of the contract was the price. Thus the contracts of *mutuum, commodatum, depositum,* and *mandatum,* which are all gratuitous contracts, become, if a price is fixed, cases of *locatio-conductio.* In modern English law the term can scarcely be said to be used in a strictly technical sense. The contracts which the Roman law grouped together under the head of *locatio-conductio*—such as those of landlord and tenant, master and servant, &c.—are not in English law treated as cases of hiring but as independent varieties of contract. Neither in law books nor in ordinary discourse could a tenant farmer be said to hire his land. Hiring would generally be applied to contracts in which the services of a man or the use of a thing are engaged for a short time.

HIRSCHAU, or HIRSAU, a village within the amt of Calw and the circle of Schwarzwald, Würtemberg, on the Nagold, is a station on the Pforzheim-Horb Railway, and has paper and other factories. Population 800. It owes its origin and its historical interest to the now ruinous Benedictine monastery in the neighbourhood, the Monasterium Hirsaugiense, at one period one of the most famous in Europe. It was founded in 830 or 832 by Count Erlafried of Calw, at the instigation of his son, Bishop Notting of Vercelli, who enriched it with, among other treasures, the body of St Aurelius. Its first occupants (838) were a colony of fifteen monks from Fulda, disciples of Hrabanus Maurus and Walafridus Strabus, headed by the abbot Liudebert. During about a century and a half, under the fostering care of the counts of Calw, it enjoyed great prosperity, and became an important seat of learning; but towards the end of the 10th century the ravages of the pestilence combined with the rapacity of its patrons, and the selfishness and immorality of its inmates, to bring it to the lowest ebb. After it had been desolate and in ruins for upwards of sixty years it was rebuilt in 1059, and under Abbot William "der Selige" (1069-1091) more than regained its former splendour. By his *Constitutiones Hirsaugienses,* a sort of new religious order, Ordo Hirsaugiensis, was formed, of which the rule was afterwards adopted by many monastic establishments throughout Germany, such as those of Blaubeuren, Erfurt, and Schaffhausen. The friend and correspondent of Pope Gregory VII., and of Anselm of Canterbury, he took active part in the politico-ecclesiastical controversies of his time; while a treatise from his pen, *De Musica et Tonis,* as well as the *Philosophicarum et astronomicarum institutionum libri III.,* bears witness to his interest in science and philosophy. About the end of the 12th century the material and moral welfare of Hirschau was again very perceptibly on the decline; and it never afterwards again rose into importance. In consequence of the Reformation it was secularized in 1558; in 1692 it was laid in ruins by the French. The *Chronicon Hirsaugiense,* or, as in the later edition it is called, *Annales Hirsaugienses* of Trithemius (Basel, 1559; St Gall, 1690), is, although containing much that is merely legendary, an important source of information, not only on the affairs of this monastery, but also on the early history of Germany. The *Codex Hirsaugiensis* was printed at Stuttgart in 1844. See Christmann, *Geschichte des Klosters Hirschau* (1782); Steck, *Das Kloster Hirschau* (1844); Wolff, "Joh. Trithemius u. die älteste Geschichte des Klosters Hirschau," in the *Württembergisches Jahrbuch* for 1863; and Helmsdörfer, *Forschungen zur Geschichte des Abts Wilhelm von Hirschau* (Göttingen, 1874).

HIRSCHBERG, the chief town of a circle in Prussian Silesia, government district of Liegnitz, is beautifully situated at the confluence of the Bober and Zacken, and on the Silesian mountain railway, 30 miles S.W. of Lauban by rail. It is the seat of a circle court and of a chamber of commerce. A great portion of its old walls still remains, and to the south of the town there are pleasant promenades. It possesses an Evangelical church, one of the six stipulated for in the agreement between Charles of Sweden and the emperor Joseph I. in 1707; four Catholic churches, one of which dates from the 14th century; a synagogue, an Evangelical gymnasium, a school of the middle grade, a female school of the higher grade, an orphanage, and an asylum. The town is the principal emporium of commerce in the Silesian mountains, and its industries include the carding and spinning of wool, and the manufacture of linen and cotton fabrics, Brabant lace, veils, artificial flowers, paper, Portland cement, porcelain, sealing-wax, blacking, chemicals, machines, fire-engines, champagne, and cider. There is also a lively trade in corn and agricultural produce. The town is celebrated for its romantic surroundings, including the Cavalierberg, from which there is a splendid view, the Hausberg, the Helicon, crowned by a small Doric temple, the Kreuzberg, with walks commanding beautiful views, and the Sattler ravine, over which there is a railway viaduct. The population in 1875 was 12,954.

Hirschberg was in existence in the 11th century, and obtained town rights in 1108 from Boleslaus III. of Poland. It withstood a siege by the Hussites in 1427, and an attack of the imperial troops in 1640. The foundation of its prosperity was laid in the 16th century by the introduction of the manufacture of linen and veils.

HIRTIUS, Aulus, one of Cæsar's chief supporters and most intimate friends. He was with him as *legatus* in Gaul. After the civil war broke out in 49 B.C., he seems to have been generally stationed in Rome to protect Cæsar's interests there. He was a personal friend of Cicero, and used his influence with Cæsar in behalf of the orator's brother and nephew. He was nominated along with Pansa by Cæsar for the consulship of 43 B.C.; and after the dictator's assassination in March 44, this honour made him for a short time one of the leading actors in that troubled time. The consuls supported the senatorial party against Antony, and led their armies into Umbria, where Antony was blockading Dec. Brutus in Mutina. On March 27th a double battle was fought: in the first Antony had the upper hand, and Pansa was mortally wounded; and in the second Hirtius completely defeated the enemy, but was himself killed in the subsequent assault on the enemy's camp. Hirtius was perhaps an author: the eighth book of Cæsar's commentaries on the Gallic war, which was certainly not written by Cæsar himself, is commonly attributed to him; and the accounts of the Alexandrian, African, and Spanish wars are perhaps also due to his pen.

HISPANIOLA. See Hayti.

HISSÁR, a British district belonging to the division of the same name,[1] in the lieutenant-governorship of the Punjab, India, lying between 28° 36′ and 29° 49′ N. lat., and between 75° 16′ and 76° 22′ E. long. It is bounded on the N. and N.W. by the Patiála state and a small portion of the British district of Sírsa, on the E. and S. by the territory of Jhínd and the British district of Rohtak, and on the W. by the deserts of Bíkaner. Area, 3539 square miles; population (1868), 484,681.

Hissár forms the western border district of the great Bíkaner desert, and consists for the most part of sandy plains dotted with shrub and brushwood, and broken by undulations towards the south, which rise into hills of rock like islands out of a sea of sand. The Ghaggar is its only river, whose supply is uncertain, depending much on the fall of rain in the lower Himálayas; its overflow in times of heavy rain is caught near Fatehábád and Murakhera by *jhíls*, which dry up in the hot season. A canal, known as the Western Jumna Canal, crosses the district from east to west, irrigating 54 villages. The soil is in places hard and clayey, and difficult to till; but when sufficiently irrigated it is highly productive. Old mosques and other buildings exist in parts of the district.

Rice is the staple crop of the district. In favourable seasons, cotton is extensively grown in lands irrigated by the Western Jumna Canal. In 1872–73, 1,431,541 acres were under tillage, out of an assessed area of 2,265,428 acres. Hissár produces a breed of milk-white oxen, 17 or 18 hands in height, which are in great request for the carriages of natives. The district has always been subject to famine. The first calamity of this kind of which we have authentic record was the famine of 1783; since then there have been several more or less serious failures of the crops.

The principal exports are oil-seeds, gram, grains, copper and brass utensils, hides, and a little cotton; the imports—salt, sugar, fine rice, cotton goods of English make, spices, and iron. The exports are double the imports in value. The rural manufactures comprise coarse cotton cloth, vessels made of prepared skins, and copper and brass vessels. The annual out-turn of rough saltpetre is estimated at 450 *maunds*. The trade of the district centres in Bhawáni, where nine lines of traffic converge. The main road, about 50 feet wide, unmetalled, traverses the district, passing through Hánsi and Hissár towns; fourteen other roads supply communication. The census of 1868 returned the population at 484,681 (males, 266,847; females, 217,834). The Hindus numbered 373,937; Mahometans, 102,928; Sikhs, 1812; and "others," 6004. There are three municipalities, viz., Bhawáni, 32,254; Hissár, 14,133; and Hánsi, 13,563. The district police numbered 396 men in 1872–73, and the municipal police 174. In the same year there were 50 schools, with 1729 scholars. The climate of Hissár is very dry; hot westerly winds blow from the middle of March till July. The average rainfall for the six years 1867–68 to 1872–73 was 14·57 inches. The principal diseases are fevers and small-pox. Cholera occasionally breaks out. Skin diseases also are common. Government dispensaries are situated at Bhawáni and Hánsi.

Prior to the Mahometan conquest, the semi-desert tract of which Hissár district now forms part was the retreat of Chauhán Rájputs. Towards the end of the 18th century, the Bhattís of Bhattíána gained ascendency after bloody struggles. To complete the ruin brought on by these conflicts, nature lent her aid in the great famine of 1783. Hissár passed nominally to the British in 1803, but they could not enforce order till 1810. Early in the mutiny of 1857 Hissár was wholly lost for a time to British rule, and all Europeans were either murdered or compelled to fly. The Bhattís rose under their hereditary chiefs, and the majority of the Mahometan population followed their example. Before Delhi had been recovered, the rebels were utterly routed.

Hissár, municipal town and administrative headquarters of the above district, 29° 9′ 51″ N. lat., 75° 45′ 55″ E. long.; population (1868), 14,133 (Hindus 9211, Mahometans 4805, Síkhs 34, Christians 83). The town is situated on the Western Jumna Canal, 102 miles W. of Delhi. It was founded in 1354 by the emperor Firoz Sháh, who constructed the canal to supply it with water; but this fell into decay during the last century, owing to the constant inroads of marauders. Hissár was almost completely depopulated during the famine of 1783, but was afterwards occupied by the adventurer George Thomas, who built a fort and collected inhabitants. It contains a cattle farm, both for commissariat purposes and for improving the breed of the province; attached is an estate of 43,287 acres for pasturage. There is an import trade in grain, *ghí*, sugar, oil, cotton, tobacco, and English piece goods. The municipal revenue in 1875–76 was £1229.

HISSAR, a state in Central Asia, lying between the meridians of 66° 30′ and 70° E. and the parallels of 39° 15′ and 37° N., and dependent on the amir of Bokhara. It forms that part of the basin of the Oxus which lies on the north side of the river, opposite the Afghan province of Balkh. The western prolongation of the Tian Shan, which divides the basin of the Zarafshan from that of the upper Oxus, after rising in one peak to a height of 12,300 feet, bifurcates in 67° 45′ E. long. Its two arms include between them the province of Shahr-i-Sabz, with the towns of Shahr Sabz, Kitab, Yakobagh, and Karchi. The main chain and the southern arm of its bifurcation, sometimes

[1] The division of Hissár is under a commissioner, and comprises the three districts of Hissár, Rohtak, and Sírsa. Area, 8478 square miles. Population (1868), 1,232,435

called Koh-i-tan, form the N. and N.W. boundaries of Hissar. On the W. it is wholly bounded by the desert; the Oxus limits it on the S. and S.E.; and the states of Karategin and Darwaz complete the boundary on the E. Until 1875 it was one of the least known tracts of Central Asia, but in that year a Russian expedition from Tashkend traversed and surveyed a great portion of it, and since then successive expeditions have explored various other portions, so that it is now very fairly known. Hissar is traversed from north to south by four important tributaries of the Oxus, viz., the Surkhab or Vakhsh, Kafirnihan, Surkhan, and Shirabad-Daria, which descend from the snowy mountains to the north and form a series of fertile valleys, disposed in a fan-shape, within which lie embosomed the principal towns of Hissar. The two chief roads by which Hissar is approached from Bokhara and Russian Turkestan lie through Karchi and Shahr-i-sabz respectively. Both these routes unite at Ak-roba, on the crest of the range between Khuzar and Baisun. There is also a difficult route, running through fine forests from Yakobagh across the mountains to Sarijui. A little way down the other side of the mountain chain between Khuzar and Derbend is situated the famous defile formerly called Kohluga (Mong. "Barrier") and the Iron Gate, but now styled Buzghol-khana or Goat's House. This pass is described by the Russians, who visited it and were vividly impressed with its solemnity, as a huge but narrow chasm in a transverse range, whose frowning rocks overhang and threaten to choke the tortuous and gloomy corridor (in places but 5 paces wide) affording the only exit from the valley. In ancient times it was a vantage point of much importance, and commanded the chief route between Turkestan and India. Hwen-Tsang, who passed through it in the 7th century on his way southward, states that there were then two folding doors or gates, cased with iron and hung with bells, placed across the pass. Clavijo, the Spanish ambassador to the court of Timur, heard of this when he passed through the defile 800 years after, but the gates had then disappeared. Derbend, the first inhabited place met with, is a poor village in the valley of the Shirabad-Daria, along which runs the road to the Oxus and to Afghanistan. Shirabad town itself is a place claiming great antiquity. It has a citadel and three rows of walls, and with its surrounding villages presents the aspect of a flourishing oasis. There are four ferries over the Oxus in the Shirabad chiefship or district, viz., Chushka-guzar (boar's ferry), Patta-kissar, Shur-ab, and Kara-kamir.

Baisun, a picturesque Uzbek town considered to be very healthy, lies on the road from Derbend to Hissar town. Emerging from the somewhat complex mountain mass which fills up this part of Hissar, the valley of the Surkhan is reached. This large river is formed by several affluents from the snowy range to the north, one of which, the Tupalan, formerly gave its name to the whole stream. The valley in its upper part is between 40 and 45 miles wide; the banks of the river are flat and reed-grown, and are frequented by wild hogs and a few tigers. The Surkhan valley is highly cultivated, especially in its upper portion, where the villages are crowded. It supplies Bokhara with corn and sheep, but its chief products are rice and flax. When Hissar was independent the valley of the Surkhan was always its political centre, the town of Hissar being simply an outlying fortress. Passing by four fortified towns, Dehinau, Sarijui, Regar, and Karatagh, all in the basin of the Surkhan, Hissar (=fort) claims notice. Its position at the entrance of the Pavi-dul-dul defile commanded the entrance into the fertile valleys of the Surkhan and Kafirnihan, just as Kubadian at the southern end of the latter stream defended them from the south. The famous bridge of Pul-i-sanghin (stone bridge, Tash-kepri in Turkish) lies on the road from Hissar and Kafirnihan to Baljuan and Kulab. It spans the Surkhab, which is here hemmed in between lofty and precipitous cliffs barely 30 paces apart. The bridge itself abuts on projecting rocks, and is ten paces wide. The next place of importance is Kulab, in the valley of the Kichi Surkhab, so called from the lakes or inundations near which it stands. The district is part of that once famous as Khotl. The town (which, strictly speaking, is the capital of Kulab district as distinct from Hissar) contains about 500 houses and a poor citadel, and from it there are roads to Badakhshan and Kurgan-tepe and Kubadian. These two lie in the valleys of the Vaksh (or Surkhab) and Kafirnihan respectively. Kulab produces wheat in great profusion, and gold is brought thither from the surrounding districts. Kubadian is a large, silk-producing town, and is surrounded with rice-fields. Formerly the two last-named valleys were densely peopled, and a series of settlements extended southward from Dehinau, from which town an arik or canal provided the city of Termez with water. Termez, or Termedh, was an ancient and important city on the Oxus. After being destroyed by Jenghiz Khan and lying for some time in ruins, it rose again into note in the following century, and when visited by Ibn Batuta, and later by Clavijo, it had grown again into a place of some importance. It is now a mass of ruins.

The population of the districts of Hissar and Kulab consists principally of Uzbeks and Tajiks, the former predominating, and, as in the valleys of the Sír and Zarafshán, gradually pushing the aboriginal Tajiks into the hills. East of Dushamba the Tajiks are the dominant race. On the banks of the Oxus there are some tribes of Baigush Turkmans who work at the ferries, drive sheep, and accompany caravans. Lyuli (gipsies), Jews, Hindus, and Afghans are also to be found in Hissar. But the Uzbeks are the most numerous, and their influence is so great that at Bokhara Hissar is known as Uzbekistan. The climate of the valleys of Hissar and Kulab is pleasant, as they are shut in by mountains to the north and open towards the Oxus to the south. Baisun (3410 feet) is the most elevated town. Hissar and Kulab produce in abundance all the cereals and garden plants indigenous to Central Asia. Cotton is grown in considerable quantities in the district of Shirabad, whence it is exported by way of Khuzar to Karshi. The difficulties of transport would prevent its being brought in any quantity from other places. Dehinau, Hissar, and Dushamba export corn and flax to Bokhara. From the vicinity of Khuzar is exported rock-salt, and sheep are brought to Bokhara and Karshi from all parts of Hissar district, as well as from Baljuan, Yurchi, and Afghanistan. A species of juniper, called archa, is used for timber. Salt is found at Bash-kurd, in the mountains of Hazret-Imam, and at other places. There are numerous brine springs in various quarters, indicating generally an inexhaustible supply of rock-salt. Auriferous sand has been discovered in the Vaksh, and the inhabitants wash the sands after the floods in spring. Merchandize is conveyed by means of camels, mules, and horses from Hissar to Karshi and Bokhara. Not a single waggon is to be found in the district, and the wooden *arba* is not even known there. Politically, Hissar now consists of seven sub-districts, governed by begs, Shirabad, Baisun, Dehinau, Yurchi, Hissar, Kurgan-tepe, and Kubadian; and Kulab of two, Baljuan and Kulab. The fact of the chief route between the Russian and British possessions in Asia lying through Hissar has served of late years to bring it into prominence, and will always invest it with a certain importance.

History.—Our knowledge of the history of Hissar is most fragmentary. In early written history this country was part of the Persian empire of the Achaemenidæ, and probably afterwards of the Græco-Bactrian kingdom, and then subject to the Eastern swarms who broke this up. In the time of the Sassanian kings of Persia it was under the Haiathalah, the Ephthalites or White Huns of the Greeks, subdued by the Turks in the early part of the 7th century, these soon to be displaced by the Mahometan power. Termedh, Kubadian, and Chagánián are named as places of importance by the Arab geographers of the 10th century; the last name was also applied territorially to a great part of the Hissar province, but is now obsolete. The country was successively subject to the Mongol Chagatai dynasty and to Timur and his successors; it afterwards became a cluster of Uzbek states of obscure history. Hissar was annexed by the amir of Bokhara in 1869–70, soon after the Russian occupation of Samarcand. (C. E. D. B.)

HISTOLOGY

I. Animal Histology.

ANIMAL HISTOLOGY (from ἱστός, a web or tissue, and λόγος, discourse) is the study of the minute structure of the tissues of animals. By a tissue is meant any part of an organism which has undergone special changes in structure in adaptation to the performance of special functions. These special changes are expressed by the general term "differentiation." In the lowest animal organisms, the whole of whose bodies are composed of the undifferentiated living substance termed "protoplasm," we find all its functions shared by every part of the organism. An amœba, for example, it is well known, is capable of finding, seizing, devouring, digesting, and assimilating food, has a special provision for collecting fluid and pumping it out of its body, respires by its whole surface, moves about apparently where it will, exhibits a sensibility to tactile impressions, and reacts in all probability to smell if not to sound and light,—in short, is capable of performing, although with the lowest possible amount of activity, almost every function which animals vastly higher in the scale of organization exhibit. But even in the amœba we cannot say certainly that there is no differentiation of its protoplasm. For a condensed portion—the nucleus—is set aside to initiate the reproductive function, and it is by means of the external and firmer layer (ectoplasm) that its movements are effected and its relations with the external world maintained, while the internal more fluid protoplasm (endoplasm) is concerned with the digestion of the food. Still there are simple organisms whose protoplasm is probably absolutely undifferentiated. On the other hand, there are other organisms which are also regarded as composed of simple protoplasm, and are constituted by a single cell, which nevertheless show a marked progress in the differentiation of portions of their substance apart altogether from the presence of a nucleus. Such differentiation in unicellular organisms generally takes the form of the production of a shell or "test," as in the *Foraminifera* and in *Noctiluca*, which subserves purely passive functions of sustentation or defence. It is not certain in such cases whether the structure thus produced is formed by the direct conversion of the protoplasm or by an exudation on the surface which subsequently hardens. But portions of the protoplasm may be set aside for the performance of *active* functions. We see this in its production in the form of locomotory organs, either temporary (pseudopodia) or permanent (cilia). But in neither of these can any actual change in the minute structure of the protoplasm be observed. A differentiation does, however, occur in one remarkable instance—the flagellum, namely, of the *Noctilucidæ* (fig. 1), which exhibits as definite a transverse striation as does the cross-striated or voluntary muscular tissue of the higher animals, in which structural peculiarity it is impossible not to infer a relation to its contractile functions; and similarly, in the *Vorticellidæ*, there is a differentiation of the protoplasm of the rapidly contractile stalk.

Whereas in the more highly organized unicellular animals portions of the single cell are thus set aside for the performance of special functions, and modified in structure accordingly, in multicellular animals, on the other hand, we find whole cells and sets of cells set apart and differentiated. It is to such modifications in sets of cells in multicellular organisms, rather than in portions of the protoplasm of a unicellular organism, that "histological differentiation" is commonly restricted; and each such set of cells, destined for the performance of a special function, and modified accordingly in structure, is denominated a "tissue."

The animal tissues may be classed under the four heads of *Epithelium*, *Connective Tissue*, *Muscular Tissue*, and *Nervous Tissue*.[1] Of these four classes of tissue the epithelium is the most primitive and least altered. In the development of the *Metazoa* the numerous embryonic cells which result from the division of the single cell—the ovum—tend in nearly every case to arrange themselves as a single layer surrounding a central cavity (unilaminar condition of the blastoderm), (fig. 2, A).[2] Presently a part of the wall of the hollow sphere becomes invaginated, so that, instead of a vesicle enclosed by but a single layer of cells, a cup (*Gastrula*, Haeckel), is produced (fig. 2, B), the wall of which is formed by two layers derived from the original single layer, and separated from one another by a narrow interval (which is all that remains of the original cavity of the vesicle) except at the orifice of the cup, where they are continuous (bilaminar condition of the blastoderm). At this part some cells become separated from one or both of

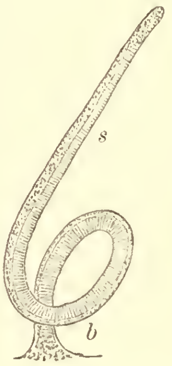

Fig. 1.

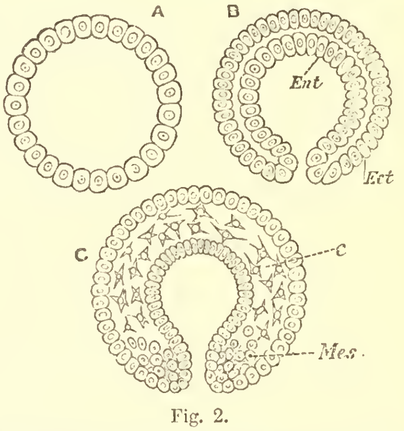

Fig. 2.

Fig. 1.—Flagellum of *Noctiluca miliaris* (highly magnified). *s*, transversely striated substance; *b*, base of attachment to body of animal.

Fig. 2.—Sections through the unilaminar (A), bilaminar (B), and trilaminar (C) conditions of the typical blastoderm. *Ect.*, ectoderm; *Ent.*, entoderm; *Mes.*, mesoderm; *c*, primitive connective tissue.

these two primary layers, and, extending in and occupying the cleft-like space which separates them, become a third layer of cells, which differs from those of the other two in not being arranged into a continuous membrane, and not, therefore, forming an epithelium (trilaminar condition of the blastoderm), (fig. 2, C). Now, of these three layers, the outer one, or ectoderm, and the inner one, or entoderm, give rise to all the epithelial tissues of the body. The nervous tissues are also derived from the ectoderm; whereas the connective and muscular tissues originate in the mesoderm or middle layer. In most of the *Cœlenterata*, however, the mesoderm is not developed at one part only of the embryo as in the higher *Metazoa*. In the hydroid polyps and *Medusæ* it never becomes completely distinct from the ectoderm and entoderm, although a jelly-like sustentacular substance may be formed to a greater or less extent between the two primary layers, and cells may pass into it from one of them, so that a kind of mesoderm is thus produced. In the *Medusæ*, also, the muscular function is performed by

[1] The characters of the several tissues and their varieties are best known as they occur in the Vertebrata, and a description of them will be found in the article on Anatomy.

[2] A layer of cells which thus forms a membrane by the union of the cells, with an inperceptible amount of intercellular cementing substance, would properly fall under the definition of the term epithelium, which was first applied by Ruysch to the cellular membrane covering the lips, and has ever since been used to designate membranes thus composed of cells alone.

cells which either still have their place in the general layer of the ectoderm or are but imperfectly separated from it; and here, again, the commencing separation does not occur at one part only, but over extensive tracts of the surface. Nevertheless these cells are modified in structure precisely in the same way as those which in higher animals are derived from the mesoderm. The nervous functions are also performed by cells and fibres, which, although they show those modifications of structure which in the higher animals are characteristic of nervous tissue, yet remain strictly confined to the ectoderm, and do not, as in the higher animals, penetrate into the mesoderm.

The Epithelial Tissues.—Although, as we have seen (see p. 4, note 2), the layers of cells which are first formed are layers of epithelium, and, therefore, the epithelial tissues are the first to be produced, nevertheless we find that they undergo less modification in structure than any of the other three classes of tissue. As before said, they invariably consist merely of cells cemented together by an imperceptible amount of intercellular substance,[1] and the cells themselves only show minor degrees of modification in shape and structure, at least as compared with the other tissues constituted mainly of cells, namely, the muscular and nervous.

Modifications in Shape of Epithelial Cells.—The cells of this tissue may be either elongated and set like palisades over the surface which they cover, in which case they are termed "columnar" (fig. 3), or they may be flattened out over the surface, and they then appear as thin "scales"; and every variation in shape is met with between these two extremes. In any case where they form a single layer, since the cells are set closely together, the mutual apposition of neighbouring cells produces a flattening of the opposed sides, so that, when the epithelium is looked at from the surface, the cells have a polygonal outline, and collectively present the appearance of a mosaic pavement (fig. 4). In

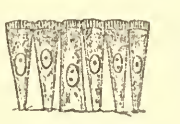

Fig. 3.

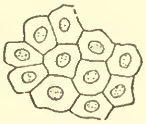

Fig. 4.

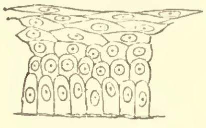

Fig. 5.

FIG. 3.—Columnar epithelium cells.
FIG. 4.—Mosaic appearance of epithelium.
FIG. 5.—Stratified epithelium.

certain cases, especially where there is liability to abrasion of the surface which they cover, the epithelial cells are disposed in two, three, or more superimposed layers (fig. 5), and then the cells of the different layers may vary much in size, shape, and consistence. Such an epithelium is termed "stratified."

It frequently happens that the layer of epithelium which covers a surface is prolonged into depressions, which may be quite simple or may be ramified either slightly or in the most complex manner. The epithelial cells which line such depressions may resemble those of the surface upon which the depression opens, or they may become more or less modified in size, shape, and other particulars, and constitute themselves into a distinct variety of epithelial tissue. Since depressions like those just mentioned are generally for the purpose of forming some special secretion, and are termed *glands*, and since this secretion is elaborated by the agency of the epithelial cells which line the gland, any such special variety of epithelium is termed a "glandular" or "secreting" epithelium.

Modifications in Structure.—The modifications in structure which the cells of epithelial tissue undergo are comparatively slight. One of the most common is the conversion of the external layer of the protoplasm of the cell into a firm membrane, generally of a horny nature, but this membrane is seldom sharply marked off from the substance of the cell, as is the case with the cellulose membrane of the vegetable cell. It becomes formed, moreover, to a very different extent in different cells, according to the function which the particular epithelium has to perform; where, for example, the epithelium is almost purely a protective covering, as in the stratified scaly epithelia, a considerable part, or even the whole thickness of many of the epithelial cells, is thus transformed; but where, on the other hand, the cells have to play an active part in yielding a secretion to moisten the surface, or in protruding a portion of their protoplasm in the form of vibratile cilia to produce currents over the surface, or to move the organism through the water, we find little, if any, of such conversion of the superficial cell-substance. What little there may be is confined to the attached surfaces of the cell, or if there is any such covering on the free surface, it is penetrated by pores which allow of a communication between the protoplasm of the cell and the external medium.

Another common modification of structure which epithelial cells exhibit is the existence of vibratile cilia at the free surface (fig. 6). This, again, is especially frequent with cells of a columnar shape, but it may occur in any. The cilia appear to be protrusions of the more active external protoplasm of the cell, which are in most cases incapable of being again withdrawn, and are in all probability modified in minute structure, although they are always so small that such modification, if it exists, escapes detection even with the employment of the highest powers of the microscope. At their base, however, the cilia are certainly continuous with the unaltered protoplasm of the cell. This may be

Fig. 6.

Fig. 7.

Fig. 8.

Fig. 9.

FIG. 6.—A ciliated epithelium cell.
FIG. 7.—A striated epithelium cell.
FIG. 8.—A ciliated cell with one large cilium.
FIG. 9.—Sense-epithelium cell of *Aurelia*.

seen even where the cilia are small and spring in a bunch from the free surface of the cell, but much better in those kinds of ciliated epithelium in which but a single large cilium is connected to each columnar cell (fig. 8).

Many epithelial cells, especially those of secreting glands, show a differentiation of their protoplasm in the form of fine striæ or rods which pass from the attached border of the cell towards the free end (fig. 7). Cells thus modified are found in the ducts of the salivary glands, in the alveoli of the pancreas, and in the convoluted tubules of the kidney in Vertebrata.

One of the most remarkable modifications which epithelium cells exhibit is found in the organs of special sense. This is the presence of a fine filamentous process or processes springing from the free surface of the epithelium cells, and resembling in their appearance long cilia, but not spontaneously vibratile (fig. 9). Moreover, the cells in question,

[1] Exceptions to this general rule are seen in the layer of cells which underlies the chitinous cuticula of annelids (Claparède), and in the enamel organ of the developing teeth of vertebrates (Kölliker), where the cells, although epithelial, are ramified and united by their branches into a network; and, in a far less degree, in many of the lower cells of a stratified epithelium, where it can be seen with a high power that the edges and surfaces of the cells are provided with numerous short projections which are applied to those on adjacent cells.

which are generally of an elongated columnar form, commonly branch out at their detached end into fine processes which appear to become connected with nerve-fibres. Cells of this character occur even so low in the *Metazoa* as the *Medusæ*, in connexion with the nerve-epithelium to be afterwards mentioned. And, indeed, in many cases where cells of this character enter into the constitution of the sense organs, it is probably most consistent with their true nature to regard them as detached portions of nervous tissue, which also in every case is originally of an epithelial nature.

Modifications in the Cell Contents.—Another chief modification which the cells of an epithelial tissue may undergo consists in the accumulation within the cells of various chemical substances, which may be either taken in bodily as such, or may be formed in the cell from other substances which are supplied to it by the blood. The substances that are thus accumulated and formed within the cells of an epithelium are of very various nature, as, for example, the constituents of special secretions (fig. 10), mucin, pigment, fatty globules, uric acid, &c., &c. These several substances are tolerably constant in an epithelium of the same kind—thus, mucin is a very frequent constituent of columnar epithelium, and in glands which have the same function in different animals, the same substances are found in the epithelium cells of the gland.

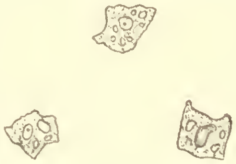

FIG. 10.—Epithelium cells of renal organ of mollusc containing crystals of uric acid. (Boll.)

Exudation from Epithelium Cells. Formation of Cuticular Structures.—In many invertebrates the epithelium which covers the surface of the body, and sometimes also that which lines a part of the alimentary canal, forms an exudation which is generally soft at first, but may afterwards harden into a horny consistency, or may be rendered still harder and at the same time more brittle by impregnation with earthy salts. Any such structure is termed a cuticular formation. It may be composed of a single thin layer, or a number of layers may be superimposed, so that a "shell" of considerable thickness is thus formed. The chitinous or calcareous covering which forms the exoskeleton in many molluscs, arthropods, annelids, and *Hydrozoa* is of this nature. On the other hand, the firm skeletons of sponges, *Actinozoa*, and *Echinodermata* are formed by deposition in the connective tissue.

The Connective Tissues.—The connective tissues are characterized by the great development of intercellular substance in comparison with the cells; indeed in those animals in which connective tissue may first of all be said to appear, there is an entire absence of cellular elements properly belonging to the tissue. This is the case in many of the *Cœlenterata*, in which the connective tissue is represented merely by a layer, more or less thick, of hyaline substance, which undoubtedly performs a sustentacular function, in addition to connecting together the epithelial layers of the ectoderm and entoderm.

The intercellular or ground substance almost invariably takes a prominent part in the formation of connective tissue. It is of a semi-fluid nature, and often contains in addition to albumen a certain amount of mucin. In most cases the cells of the connective tissue separate themselves from the primary layers before the formation of this ground substance; indeed the mesoderm is at first chiefly formed of these cells. The stages of development are as follows. The mesodermic cells, which are at first in apposition, become separated from one another by the accumulation of intercellular substance, but at the same time maintain a connexion with one another throughout the tissue by their branching cell-processes (see fig. 2, C, *c*). Presently, in the production of ordinary connective tissue, fibres of two kinds make their appearance in the intercellular substance, and to all appearance independent of the cells. Those of the one kind (fig. 11, A) are highly elastic and refracting, not easily affected by reagents, stain deeply with magenta, run singly, always branch, and become united with neighbouring fibres so as to form a network throughout the tissue; those of the other kind (fig. 11, B) are excessively fine and indistinct, never run singly but always in bundles, and generally with a wavy course, are readily affected by reagents, and, in vertebrates, yield gelatin on boiling. In the various kinds of connective tissue the relative proportion of these two kinds of fibres to one another and to the cellular elements of the tissue varies. Thus in the so-called elastic tissue of the Vertebrata the elastic fibres greatly preponderate; in tendinous tissue, on the other hand, they are scarcely to be found, and the ground is almost wholly occupied by the white fibres. It may happen that the intercellular substance is so completely occupied by the fibres as to be entirely obscured, but its presence may be always recognized in consequence of the property which it possesses of reducing silver from its salts when exposed to the light. In certain cases the intercellular substance becomes hardened by the deposit within it either of a substance termed chondrin, which confers upon it the well-known toughness and elasticity of cartilage, or by a deposit of earthy salts imparting to it the firmness of bone. These several changes in the intercellular substance are accompanied by special modifications in the form and relations of the cells (by whose agency they are in all probability effected). In comparatively rare cases the intercellular substance which is found occupying the meshes of the network formed by the branched cells of the developing connective tissue may disappear entirely, and the meshes may be occupied either by blood or by the lymph or plasma of the blood (spleen and lymphatic glands of vertebrates).

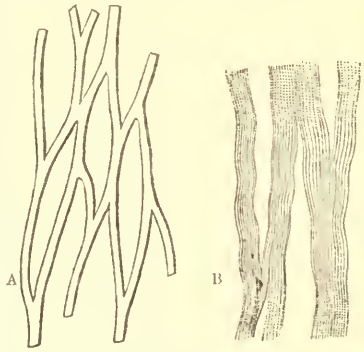

Fig. 11.

It frequently happens that the connective tissue presents the consistence of jelly, and this is generally ascribed to the characters of the intercellular substance. It may, however, be due in many cases to the entanglement of fluid in the meshes of the fibres, and not to a gelatinization of the ground substance. This is shown by the fact that the fluid may be drained from out the meshes by means of filter paper. And the possibility of the formation of a jelly in this manner is evidenced in the coagulation of lymph, where the apparently solid gelatinous clot is a tangled meshwork of fine filaments enclosing fluid.

The connective tissues of invertebrates are, on the whole, similar to those of the vertebrate; at the same time it must be admitted that there are not unimportant differences in chemical constitution, such as the absence of a substance yielding gelatin, and the absence for the most part of mucin, both of which are characteristic constituents of vertebrate connective tissue. On the other hand the anatomical characters of the elements, both cells and fibres, are in most cases sufficiently well marked to be recognizable.

In the sponges the bulk of the animal is made up of a jelly which, when examined under the microscope, is found to consist of large branched cells (fig. 12) connected together by their processes into a network. The meshes of this are occupied by clear intercellular substance within which the calcareous or horny matter which forms the skeleton is deposited.

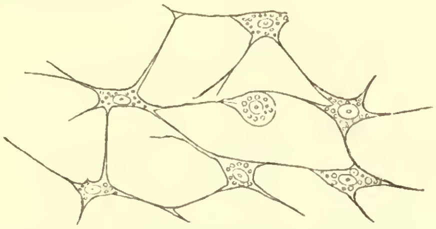

FIG. 12.—Connective tissue of sponge. (F. E. Schulze.)

When the development of the sponge is traced it is found that the first part of the tissue to be seen is the clear intermediate substance, and the skeletal spicules begin to appear in this before the cellular elements. These wander subsequently into it from one of the primary layers. There can be no doubt that this jelly-like tissue of the sponge represents a primitive form of connective tissue, although, so far as has at present been ascertained, no fibres are developed in it.

In the *Cœlenterata*, as in the sponges, the connective tissue makes its first appearance in the form of a clear intermediate substance, which may be so small in amount as to be almost imperceptible, or so large in amount as to form the main bulk of the organism. In the former case, as in the developing sponge, there is an entire absence of both fibres and cells, whereas in the latter case both kinds of elements are found. The fibres are the more constant, and are of the elastic kind (fig. 13); they have for the most part a direction across the thickness of the tissue stretching from entoderm to ectoderm, branching and uniting with their neighbours to form the characteristic network which, enclosing watery fluid in its meshes, produces the jelly-like consistence of the tissue. Fibres of the white variety are also found as low down in the *Metazoa* as the *Cœlenterata*. In some of the acraspedote *Medusæ* they occur in the form of bundles of indistinct wavy fibres situated near the surface of the jelly, and in the *Actiniæ* similar fibres are found forming membranes which bear a strong resemblance to some of the forms of membranous connective tissue of the Vertebrata (fig. 14). As before

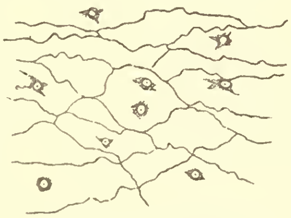

FIG. 13.—Cells and elastic fibres from connective tissue of *Aurelia*.

FIG. 14.—Fibres and cells of connective tissue of an *Actinia*. (Kölliker.)

mentioned, in the lower forms of *Cœlenterata* cells are entirely absent from their jelly-like connective tissue, but in the higher forms scattered cells (fig. 13) of indeterminate shape and position, but generally in the neighbourhood of the entoderm, begin to make their appearance. Some of these cells are amœboid, but others become fixed, and arranged in a network which pervades the jelly.

We see then that the cells, the intercellular substance, the white fibres, and the elastic fibres of the vertebrate connective tissue are represented in these low forms of the *Metazoa* in a perfectly recognizable manner. It is not surprising, therefore, to find in all the higher classes of the Invertebrata that similar elements characterize the connective tissue, although there are undoubtedly certain modifications and exceptions. The most noteworthy modifications occur in the chemical constitution of the ground substance and of the fibres. Thus, as before mentioned, there is for the most part an absence of the gelatin-yielding substance of the vertebrate connective tissue. On the other hand, the intercellular substance may become infiltrated with chemical principles unknown in vertebrate histology, as in the tunic of the *Tunicata*, where cellulose is found.[1] There are modifications also in the appearance of the connective tissue fibres which are often accompanied by modifications in the chemical constitution. For example, in the *Arthropoda* the tissue often undergoes extensive chitinization, and the fibres in it present a straight, stiff appearance, very unlike the soft, wavy look which is exhibited by the fibrous tissue of the Vertebrata.

Although the ramified cell may be looked upon as on the whole the most characteristic form of cell met with in connective tissue, and although this is the first modification in shape which the rounded embryonic cells of the developing vertebrate connective tissue take on, nevertheless it gives place in many parts both in invertebrates as well as vertebrates to other forms. One of the commonest of these is the flat cell, and we almost invariably find cells of this description lying on or in connective tissue membranes, and lining cavities which may have become formed in the connective tissue. In the latter case the flat cells may be and most commonly are spread over the whole inner surface of the cavity which they line, and assume the appearance of a pavement epithelium. Such cells, which are termed epithelioid (or by some endothelial), are found lining the body cavity and the vascular canals and heart (where these exist) of all invertebrates just as they do the similar cavities and canals in vertebrates, and they are derived like the rest of the cells of the connective tissue from the mesoderm, and therefore only indirectly from the primary blastodermic layers. But in the holothurians, and some other animals, the cells in question are derived directly from the entoderm.

In the *Mollusca* (fig 15) a peculiar type of connective tissue cell makes its appearance in addition to the rounded, the ramified, and the flattened forms. This takes the

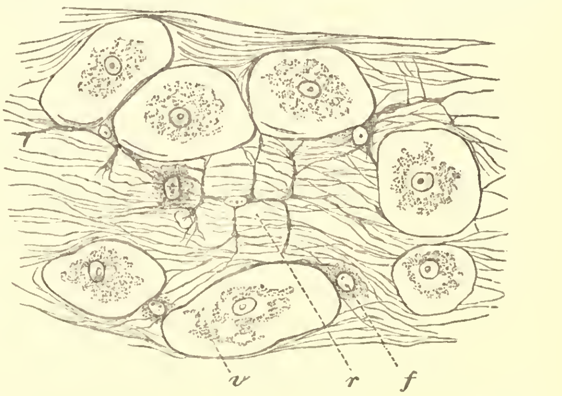

FIG. 15.—Connective tissue of slug. *r*, ramified cell; *f*, flattened cell; *v*, vesicular cell. The fibres in the ground substance are also indicated.

shape of a large clear, vesicular, double-contoured cell-body (*v*) with a relatively small nucleus. Cells of this character are in some cases only to be found scattered here and there in the tissues, but in others they are closely collected masses, and by their aggregation confer an almost cartilaginous consistency upon the tissue. This is

[1] This tunic seems, however, from its development to be an epithelial structure, although resembling in many respects connective tissue.

not due, however, to the accumulation of chondrin—the chemical principle of the cartilage of vertebrates—in intercellular substance. But a true cartilage is met with in some of the higher molluscs (*Cephalopoda*), in which there is a considerable amount of intercellular substance, and the only difference, as compared with ordinary cartilage of most vertebrates, is that the cells are much ramified (as in some fishes).

Bone, or osseous connective tissue, as the word is understood in vertebrate histology, is not met with anywhere amongst the Invertebrata, and this is less to be wondered at since it does not make its appearance even in some of the lowest of the Vertebrata. But hard structures of various kinds serve to supply the place of bone as a sustentacular tissue, and these may be developed either within the connective tissue, so as to form an internal hard skeleton, or on the exterior of the body, so as to form an external skeleton or shell. When external the shell is an epithelial structure, or at least is produced by the formative activity of the epithelium which covers the surface of the body. An internal hard skeleton may either coexist with an external, or the one may be found to the exclusion of the other.

In the cœlenterates the internal skeleton when found is generally deposited in the jelly-like intercellular substance in the form of separate spicules, which subsequently are cemented together by a further deposit of calcareous matter into a continuous skeleton. In the sponges the calcareous spicules often project from the jelly into the external medium, but it is probable that they are covered by an extension of the superficial flattened cells which they seem to pierce; the separate calcareous spicules are in some cases united by calcareous matter, in others by horny substance, or the spicules may be altogether absent and the horny framework constitute the whole skeleton. There is no evidence to show that these calcareous and horny deposits are formed by the direct agency of the cells of the jelly-like tissue. On the contrary, the fact that the spicules make their appearance in the jelly-like substance which accumulates between the two primary layers before there is any trace of cells to be seen in it is a fact pointing in the opposite direction.

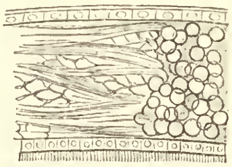

Fig. 16.—Section of the shell of *Echinus*, partly decalcified by acid. (Leydig.) The connective tissue bundles are seen on the left; some are cut transversely; on the right they are obscured by the calcareous globules (*c*). Above and below is seen a layer of epithelium (*e*, *é*).

In the echinids amongst *Echinodermata* the shell is formed by a dense deposit of calcareous substance (fig. 16) in the fibrous connective tissue of the integument, but is not of the nature of bone, as has been sometimes supposed. In other echinoderms the deposition is more scanty, and in some (*Holothuria*) it may merely take the form of isolated spicules, which often present curious shapes.

The Muscular Tissues of Animals.—In the Vertebrata three kinds of muscular tissue are met with—the plain or involuntary, the cross-striped or voluntary, and the cardiac or heart muscle. Undoubtedly the last-named is to be regarded as a transitional form between the other two, for it combines some of the characters of each. This is especially well seen in the lower vertebrates, in which the muscular fibres of the heart (fig. 17) consist of long, tapering, uninuclear cells, in form resembling the plain contractile fibre-cells, but differing from these and resembling the multinucleated voluntary muscular fibres in exhibiting distinct transverse striations. Although these three kinds of muscular tissue thus differ from one another in this respect, they agree in one important character. Whether transversely striated or not, they all exhibit a distinct longitudinal striation of their substance, which is probably indicatory of a polarity which the protoplasm of the cell has assumed at the same time with the faculty of becoming rapidly shortened in the direction of its length and coincidently with the loss of the power of contracting in other directions. Moreover, this longitudinal striation is generally associated with the property of double refraction, which is exhibited to a marked degree by all kinds of muscular tissue.

Fig. 17.—Muscular fibre of Frog's heart.

The voluntary muscular fibres are those in which the protoplasm of the original cell has undergone most differentiation. If we trace their development we find that they originate from mesodermic cells which become elongated in one direction, the nucleus undergoing a corresponding change in shape, and soon becoming multiplied; we next find the external layer of the protoplasm becoming altered and converted into muscular substance, which exhibits from the first both a longitudinal and a transverse striation. The change in question gradually extends inwards, so as to involve more and more of the protoplasm. Up to this time we can distinguish (fig. 18) in the muscular fibre a medullary part composed of unaltered protoplasm, with nuclei, and a cortical part composed of differentiated muscle-substance. Subsequently the nuclei leave their central situation, and either become scattered through the muscular substance or come to lie entirely at the surface. There is always a little of the unaltered protoplasm to be found with each nucleus.

Fig. 18.—Part of developing muscular fibre of a mammal.

In the plain muscular fibres, and in the cardiac muscular fibres, the nucleus does not multiply, and it maintains its central situation. The differentiation of the cell-protoplasm into muscle-substance begins at the periphery and extends towards the centre in the cells which constitute the heart-muscle as in the voluntary muscle, and it is probable that the same is the case in the plain muscular cells.

The muscular fibres of the Invertebrata very closely resemble those of vertebrates. In most cases the differentiation of the muscular substance is not so complete as in the voluntary muscles of vertebrates and especially of mammals, but there is a striking exception in the *Arthropoda*, and especially in insects, where in conformity with the greater muscular activity they possess we find far better marked structural features. On this account the muscles of insects have been especially carefully studied with a view to the elucidation of the structure of muscle generally.

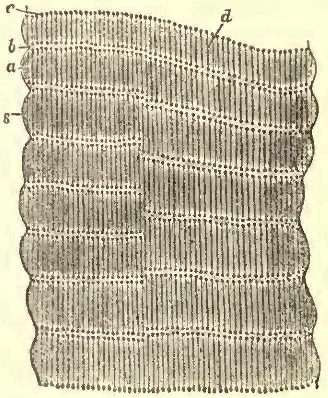

Fig. 19.—Living muscle of Water-beetle (*Dytiscus marginalis*), highly magnified. *s*, sarcolemma; *a*, dim stripe; *b*, bright stripe; *c*, rows of dots in bright stripe, which are seen to be the knobbed heads of *d*, muscle rods.

With a sufficiently high power a voluntary muscular fibre of an insect (fig. 19) is seen to be composed of an external structureless membrane,—the sarcolemma,—a central strand of nucleated protoplasm, and a semi-fluid substance—the proper muscular substance—lying between these and forming almost the whole of the fibre. This proper muscular substance is composed of a clear doubly-refracting material, in which are embedded a number of minute rod-shaped particles, which are so arranged side by side and end to end as to cause the muscular substance to present both a transversely and a longitudinally striated appearance. Sometimes (as in the fibre shown in the figure) the substance of each muscle rod is partly collected into a swelling or knob at either end, and these knobs so act singly and collectively upon the light which passes through the muscular substance as to cause a brighter appearance in their neighbourhood. In this way bright bands seem to cross the muscular substance alternating with the dimmer intermediate portions, and the appearance of transverse striation is much intensified. This is still more the case when the muscle contracts, for the contraction is accompanied by an accumulation of the substance of the rods towards their ends, and an apparent blending of these into a dark transverse band or rather a series of dark transverse bands, which, reflecting from their surfaces the light which is passing through the muscle, cause the whole of the substance between them to appear much brighter than they are themselves. There are other muscular fibres in the insect which present an entirely different appearance. In these (fig. 20) the fibres, which are very fine, are wholly made up of alternating bands of dark and light substance. They are far less like the voluntary muscular fibres of mammals than are the others, and there are no rod-like structures to be seen in them.

FIG. 20.—Fibre of wing-muscle of an insect.

We find muscular tissue, like the other tissues, appearing already in the lowest of the *Metazoa*. In sponges the orifices of the water canals are in many cases capable of being closed partially or wholly when the organism is irritated. The researches of F. E. Schulze have shown that these orifices are encircled by long fusiform cells which appear to be modifications of some of the ordinary ramified cells of the jelly-like tissue. The substance of these cells seems to be undifferentiated, and it cannot be conclusively affirmed that they are of muscular nature, but at least they seem to subserve the function of muscular tissue. But in the very next division—the *Hydromedusæ*—the muscular cells are already so much differentiated as to exhibit both longitudinal and transverse striation. Thus many of the cells which form the muscular layer of the sub-umbrella of the *Medusæ* are long fusiform cells (fig 21, A) with an elongated nucleus in the centre, and gradually tapering ends, and their substance is striated, as just remarked, both transversely and longitudinally. Sometimes there is a considerable amount of unaltered protoplasm in the middle of the fibre around the nucleus (fig 21, B), and this nucleated protoplasm may then project between the epithelial cells

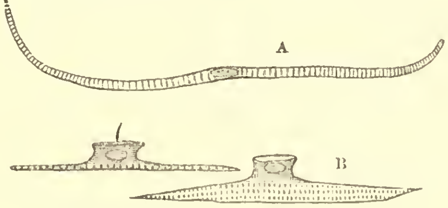

FIG. 21.—Muscular cells of Jelly-fish. (Hertwig.)

of the ectoderm. In every case the muscular fibres are in close contiguity with the attached ends of the ectodermal epithelium, and are with justice reckoned as a part of the ectoderm. In the higher cœlenterates the muscular tissue tends to lose its connexion with the ectoderm and to become embedded in the jelly-like mesoderm, but the connexion is not wholly lost in any. In *Hydra*, on the other hand, the muscular tissue is represented only by simple longitudinal fibres, which are either direct prolongations of the tapering ends of some of the ectoderm cells (Kleinenberg) or are embedded in the enlarged attached end of the cells (Kölliker, Korotneff). In other invertebrates the muscular tissue is nearly always in the form of long cylindrical or flattened, tapering or uniform, uninucleated, longitudinally-striated fibres, which may possess a membrane, and a central strand of undifferentiated protoplasm (fig. 22, B). In some cases a transverse striation may be detected (fig. 22, A), but more commonly the muscular fibres, especially in echinoderms, worms, and molluscs, exhibit a peculiar double oblique striation (fig. 23), so that an appearance of intercrossing lines is thereby produced. The obliquely striated fibres seem to take the place, in many of these comparatively sluggish animals, of the more active, transversely striated tissues. With the exception of the appearance mentioned, they resemble the plain muscular fibres in structure, but they are capable of more energetic contraction than the latter.

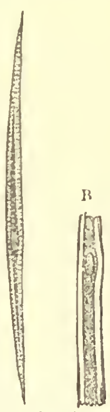

FIG. 22.—Muscular fibres of molluscs.

The Nervous Tissues of Animals.—The nervous tissue of vertebrates is composed firstly of cells—the nerve-cells or ganglion-cells,—and secondly of nerve-fibres. Most of the nerve-fibres possess a sheath formed of nucleated cells wrapped around the fibre, and in this sheath a peculiar white fatty so-called medullary substance is accumulated in some fibres, so that they are distinguished from the others as the white or medullated fibres. There is reason to believe that every nerve-fibre is connected with at least one nerve-cell, and conversely, that every nerve-cell is connected directly or indirectly with one or more nerve-fibres. Nerve-cells are generally comparatively large solid-looking corpuscles, with a relatively large nucleus and nucleolus, and every developed nerve-cell has either one or two or a greater number of processes, which may or may not be ramified. It is certain that from many nerve-cells one process of the cell passes into and becomes a nerve-fibre.[1] Nerve-cells are always traversed by exquisitely fine fibrils,—nerve-fibrils,—and these pass out from the cell into its processes. Apart from any sheath which it may possess, a nerve-fibre is composed of one or more nerve-fibrils, which are embedded in a soft interfibrillar substance. The nervous tissue of vertebrates is developed from that part of the ectoderm which occupies the middle of the dorsal surface of the embryo. In the bird and mammal the epithelial cells in this situation become cut off from the general ectoderm by the formation of a groove which subsequently closes over and forms a canal—the neural canal. The innermost ectoderm cells (fig. 24, B) which form the wall of this canal acquire cilia at the end which is turned towards the cavity, while the other end of each cell is prolonged into branching processes which collectively form a network amongst the deeper lying cells of the wall. The latter multiply considerably, and moreover groups of them grow out from the sides of the neural canal as the roots of the nerves. The nerve-fibres themselves seem to be formed either by the outgrowth of undivided processes from these cells of the neural canal, or by the junction of one elongated

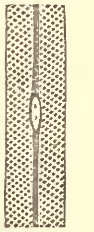

FIG. 23.—Part of an obliquely striated muscular fibre. (From Schwalbe.)

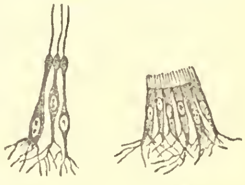

FIG. 24.—Nerve-epithelium cells—A, of *Medusa*; B, from central canal of spinal cord of vertebrate.

[1] The term nerve-fibre is here employed to denote the essential part of the nerve, corresponding to the "axis-cylinder" of vertebrate histology

cell with others. At any rate the fibres are to be looked upon as outgrowths or prolongations of nerve-cells. But some of the outgrowths of the nerve-cells, instead of passing into nerve-fibres, become ramified, and eventually break up into fine twigs, each of which is occupied by a nerve-fibril, and these form by their interlacement a network which joins that of the branched processes of the ciliated epithelium.

With the exception of the formation of the medullary substance in the sheath, the nervous tissue of the invertebrate *Metazoa* agrees precisely, so far as the minute structure is concerned, with that of vertebrates. The lowest forms in which nervous structures have been found are the *Medusæ*. In these the tissue exhibits itself under two modifications. The first of these is a so-called nerve epithelium (fig. 24, A), consisting of a portion of the ciliated ectoderm, the cells of which are prolonged at their attached ends into fine ramified fibres which interlace with one another and form a network of nerve-fibrils underneath the epithelium. This form seems to correspond with the ciliated epithelium of the vertebrate neural canal. The second modification occurs in certain cells of the ectoderm, which have become sunken singly here and there below the general epithelium of the surface, and between it and the muscular layer of the sub-umbrella. These cells become enlarged, and their nucleus takes on the characteristic appearance of the nucleus of a nerve-cell. Then generally from opposite ends of the cell (fig. 25) two processes grow out into long fibres,

FIG 25. Nerve cell and fibre of a Jelly-fish (*Aurelia*).

which exhibit all the features of the nerve-fibres of higher animals, and may even possess a nucleated sheath. These fibres, which may be branched or unbranched, seem to be applied to the substance of the muscular fibres, and in all probability serve to convey impulses to the muscle. There can be no doubt of the correspondence of these cells and fibres with the nerve-cells and nerve-fibre prolongations of the Vertebrata. In other invertebrates the nervous tissue is not only more localized than in the *Cœlenterata*, but the original ectodermal epithelium cells from which it is derived become much more extensively developed into well-characterized nerve-cells and nerve-fibres, and tend moreover to be completely separated from the rest of the ectoderm and embedded in the mesoderm. But they are never originally developed in common with connective-tissue cells, as are the cells which form the muscular tissue. (E. A. S.)

II. VEGETABLE HISTOLOGY.

By Vegetable Histology is meant the study by means of the microscope of the texture, web, or tissue of which plants are composed. It may be considered as synonymous with the minute anatomy of plants, and embraces the study of all those points of structure and development requiring the use of the microscope for their elucidation. Histology is, therefore, a modern science of observation and experiment, and it dates its origin from the time when magnifying glasses were first applied to the scrutiny of the organs of plants. All advances in histology have been preceded by some important improvement either in the construction of lenses and microscopes, or by the invention of some new method of research and application of new reagents. In order to prosecute the study of vegetable histology, it is necessary to understand thoroughly the construction and use of the microscope, to be able to manipulate well and dexterously employ the various cutting and other instruments required, and, lastly, to be able to use the numerous reagents now so important in assisting to unravel the more difficult tissues.

Nature of the Vegetable Cell.—If a small portion of the contents of the fertilized embryo-sac of the *Phaseolus multiflorus* (scarlet-runner, or French bean) be examined in a drop of water on a slide, it is seen to consist of protoplasm with a number of small free cells, in different stages of development, floating in it. These cells consist of little rounded masses of protoplasm with a single contour line; they have the protoplasm more or less granular; and each contains a rounded solid body, the nucleus, usually with a small spot, the nucleolus. Other cells in the preparation have a distinct wall with a double contour line, these being older and more fully developed. In examining the cells it is usually best not to employ pure water, but to use instead a solution of sugar or gum (1 part to 50 or 100 of water). Strasburger recommends, for examining the contents of the embryo-sac in phanerogams, a 3 per cent. solution of sugar, to which is added on the slide one drop of a 1 per cent. solution of osmic acid. Absolute alcohol may also be used for fixing the protoplasm in a nearly unaltered state. A longitudinal section of the growing end of the root of *Fritillaria imperialis* will exhibit the different stages of development of tissue cells. Near the apex the cells are more or less hexagonal in shape, and have a marked wall with a more or less distinct double contour. Inside the cell-wall, and in close contact with it, is the protoplasm, a densely granular soft inelastic mass, consisting of a mixture of albuminoids, and having in the centre a round and relatively very large solid nucleus, with one or two nucleoli. In both *Phaseolus* and *Fritillaria*, as the cell enlarges, clear spaces, called vacuoles, but filled with cell-sap, that is, water with substances in solution, appear in the protoplasm of the cell. In some algæ contractile vacuoles are met with. The ordinary vacuoles rapidly increase in number and enlarge, separating the protoplasm into two parts—one in close contact with the wall of the cell, the other forming strings of varying size and thickness separating the vacuoles. Presently the vacuoles all coalesce and form a central cell-sap cavity, the protoplasm forming a completely closed sac inside the cell-wall. The nucleus remains imbedded in the protoplasm, and is pushed to one side, appearing as if in contact with the wall. The vacuoled condition of the protoplasm may be considered as representing the cell at its state of greatest activity: the central cell-sap cavity is usually seen in tissue-cells, as in *Fritillaria*, and may be taken to indicate a condition of diminished activity. Further changes take place in tissue cells. The protoplasm with its nucleus may disappear and the cell-sap remain, or even the cell-sap itself may disappear sooner or later, and the dry cell-walls, as those of cork, be left. The conditions here described in *Fritillaria* may be taken as typical of all young tissue cells.

Natur the ce

The protoplasm is the essential part of the cell, and by it all the other parts are formed, as well as all the substances, such as chlorophyll and starch, that are contained in cells. When the cell contains protoplasm it can grow, multiply, and elaborate new chemical compounds; when the protoplasm disappears it ceases to perform any of these functions, and passively acts as a protection to deeper cells, or permits certain physical processes to take place, as the transport of water through the walls. The substance of the protoplasm seems to consist of a mixture of various albuminoids, and probably of other nitrogenous compounds. It is a more or less granular, soft, inelastic substance, never a true fluid, but varying in consistence in accordance with the quantity of water it contains.

Proto-plasm.

The chemical reactions of protoplasm are those of albumen. It contracts when substances are applied to it which remove some of the water, as glycerin and alcohol. It contracts when heat is applied, a temperature of between 50° and 60° C. completely altering the texture of protoplasm containing a normal quantity of

Chemi of reactio

water. Where the protoplasm contains little water and is very dense, as in some seeds, a higher temperature produces little or no change. A violet colour is given to the protoplasm of young cells by the application first of a concentrated solution of copper sulphate, next washing the preparation carefully to remove all free traces of the copper solution and then applying a solution of caustic potash. Iodine gives a brown colour, sugar solution and sulphuric acid a red; and dilute caustic potash dissolves protoplasm or renders it perfectly transparent. Carmine and other colouring matters do not colour living protoplasm, but impart a brilliant stain to it when dead.

Protoplasm is usually separable into two parts, an inner portion, endoplasm, more or less granular, and an outer more dense layer, the ectoplasm or primordial utricle, which is quite free from granules. A similar layer surrounds the protoplasm of the nucleus.

ove-
ents.

The living protoplasm exhibits movements either when inside a cell-wall or when the protoplasm is free and in the condition of a wall-less or primordial cell. The constant changes in protoplasm must be always accompanied by movements, but these are usually too small to be visible, and it is only in a few cases that the amplitude of the movements renders them visible. The movements are of four kinds, and are distinguished as rotation, circulation, amœboid, and ciliary.

The first is the movement of rotation, as in *Vallisneria* and *Anacharis*, where the whole protoplasmic sac rotates in the interior of the cell. The second is circulation, where portions only of the protoplasm move as indicated by the circulation of the granules hither and thither in the mass, as in the cells of the hairs of *Tradescantia* and the stinging hairs of the nettle. In the third or amœboid movement whole masses of protoplasm not enclosed in walls change their form and position like the *amœba* or white blood corpuscle. These movements have been noticed in the amœboid and plasmodium stage of the *Myxomycetes* or gelatinous fungi. Lastly, a movement of small masses of protoplasm destitute of walls, and having parts of the ectoplasm prolonged to form one, two, or more vibratile cilia is not unfrequent in the zoospores, swarmspores, and spermatozoids of cryptogamic plants. All these movements are dependent on and much influenced by varying external conditions, as light, heat, presence or absence of oxygen, &c.

ell-
all.

The cell-wall is a thin, elastic, transparent and colourless membrane, destitute of visible openings (except in some cells of *Sphagnum* and in bordered pits), but easily permeated by water and gas. It consists of the carbohydrate cellulose ($C_6H_{10}O_5$), isomeric with starch, and in young cells it is present in an almost pure state. During the growth of the cell the protoplasm furnishes material for the increase of the wall in size and thickness, and usually during growth of the wall various chemical and physical changes occur in it.

The increase in the size of the cell is rarely quite regular or general, except in free cells as pollen grains and spores; usually the growth is more or less limited to definite parts of the wall, and the increase in size is accompanied by a marked change in form. Intercalar growth at a ring-like zone on the cell-wall is seen in the genus *Œdogonium*, while growth at the apex of the cell is not uncommon in many unicellular algæ and in hairs, as well as in the peculiar cells (the hyphæ) of fungi.

Growth at several points on the surface of a cell gives rise to the stellate forms seen in the pith of *Juncus*, and a similar but more limited growth is the cause of the "tyloses," or cellular filling-up of vessels seen in many stems, vine, &c. The growth of the cell-wall in thickness may be general or local. Usually it is local, and is either internal (centripetal) or external (centrifugal). Local thickening gives rise to the production of peculiar markings depending on the different optical effects produced by the thickened and unthickened parts. Pitted markings are very common, rounded or variously shaped portions of the wall being left unthickened, while the form of the pits, and their special arrangement, either irregularly scattered or spirally placed, give a characteristic appearance to the walls of the cells. Pits are often elongated, and when very much elongated, and extending the whole width of the cell, form scalariform markings, as seen in ferns. When pits are very narrow, cylindrical, deep, and branching, they form canals. Bordered pits, in which the pit is surrounded by a border, occur in the pines. In other cells the thickening assumes the appearance of rings, spirals, or reticulations, which sometimes become detached from the walls. In some instances, as in the wood of the lime and yew, two kinds of marking occur in one cell. Peculiar modifications of internal thickening are seen in the root-hairs of *Marchantia*, in the cells with cystolithes in the leaf of the india rubber, and in the pith of *Ricinus*, &c. External thickening is seen on the surface (cuticle of the epidermis) of the plant or on free cells, as pollen grains, spores, &c., and produces peculiar and characteristic markings in various plants. By the alternation of more and less watery layers the cell-wall becomes marked by concentric lines or striæ, as if the wall was built up of layers or strata formed one inside the other, which, however, is not the case. A longitudinal striation assuming a ring-like or spiral direction is also met with on the walls of many wood and bast cells, and is, like the stratification just mentioned, due to alternations of more and less watery layers in the cell-wall. The inner layer in the interior of the cell and next the contents is always a dense layer rich in cellulose and with little water, a fact at once negativing the incrustation theory. Stratification can be readily seen in transverse sections of the bast fibres in the leaf of *Hoya*, or the bast of the stems of many *Asclepiadaceæ*; and the longitudinal striation may be seen in the same fibres when dried, or in the dry wood cells of many conifers, as in *Pinus sylvestris*.

The walls of young cells consist almost exclusively of pure cellulose, which is coloured blue by Schultz's solution[1] or by iodine and sulphuric acid, and is dissolved by strong sulphuric acid and by ammoniacal solution of cupric oxide. Iodine solution alone gives no reaction, or more generally a brown tint; rarely the wall gives a blue reaction, as in the asci of some lichens or in the cells of the cotyledons of *Tamarindus indica*. The cell-walls of most fungi do not give a blue reaction with iodine and sulphuric acid, forming the modification generally known as fungus cellulose. During growth changes occur in the nature of the wall, different strata often having different chemical and physical properties. The three most important changes in the cell-wall are (1) the suberous or corky change, the cell-wall wholly or partially becoming cuticularized or converted into cork; (2) the ligneous or woody change, the walls being converted into wood; and (3) the gelatinous change, as seen in many algæ, where the cell-wall swells up enormously by the imbibition of water, and assumes a clear gelatinous appearance. These changes may occur separately, the whole wall being more or less completely changed; or a part remains composed of cellulose; or, in other cases, two or more of these changes may coexist in the same cell-wall.

Reactions of cellulose.

Changes in cell-wall.

The following reagents are useful in distinguishing the different changes. Schultz's solution gives a blue with starch and cellulose, and a yellow-brown with wood and cork. If the cork-cells are previously boiled in caustic potash, and the wood cells touched with nitric acid, the blue reaction may be got with sulphuric acid and iodine. Sulphuric acid dissolves wood cells, but does not touch cork cells. Ammoniacal solution of cupric oxide does not dissolve cork, causes wood to swell up and to become blue, and deeply colours mucilaginous walls. Boiling caustic potash ultimately dissolves cork. Cold caustic potash at first causes it to swell up and become yellow, and when slowly heated the colour deepens and the texture becomes granular.[2] Chlorate of potash and nitric acid (Schultz's macerating fluid) ultimately dissolves cork, like caustic potash, but does not affect wood. When cork-cells are slowly warmed in this mixture the walls of the cork-cells become very distinct, the other cells being very transparent, and, if washed and treated with alcohol and then with ether, they become perfectly transparent. Chromic acid renders cork distinct by rendering other tissues transparent. Bichromate of potash dissolves cork. The following reactions are given by Zacharias for cell-walls which are coloured brown by Schultz's solution in the rhizome of *Acorus Calamus*.[3] Sulphate of aniline and hydrochlorate of aniline, even when the cells are previously treated with hydrochloric acid, give no reaction, but colour the walls of vessels of a golden yellow. An aqueous solution of aniline blue gives no reaction, while an alcoholic solution of aniline red colours the walls of vessels and oil-glands. The red colour is

---

[1] *Schultz's Solution.*—1 ounce of fused chloride of zinc is dissolved in ½ fluid ounce of water; then add iodine 3 grains, and iodide of potassium 6 grains, dissolved together in the smallest possible quantity of water. Or dissolve granulated zinc in hydrochloric acid, and evaporate in contact with metallic zinc until a thick syrup is formed. Add iodide of potassium to saturation, then a little iodine, and if necessary dilute with water.

[2] For this and other reactions see Höhnel, *Ueber den Kork und verkorkte Gewebe überhaupt*, p. 16.

[3] "Ueber Secret-Behälter mit verkorkten Membranen," *Bot. Zeitung*, 1879, p. 619.

best seen when thin slices of the rhizome are placed for a few days in the solution, and then dried and observed under water. The addition of caustic potash causes the colour to disappear, but it reappears on washing away the potash. The walls of vessels become coloured blue-violet by addition of hydrochlorate of phenole, and also when use is made of alcoholic solution of cherry-wood and concentrated hydrochloric acid (Höhnel's xylophilin reaction).

Mineral matters in cell-walls.

Mineral matters are often deposited in cell-walls. Calcium carbonate occurs rarely, calcium oxalate frequently, and silica is the commonest of all. Calcium carbonate forms the cystolithes of *Ficus* and of the *Acanthaceæ*, crystals or masses of crystals imbedded in the cell-wall but projecting into the cavity although surrounded by the substance of the wall. In corallines and many algæ, as also in the *Charas*, carbonate of lime is abundant in the cell-walls. Calcium oxalate crystals occur in the cell-walls of many plants, in other cases forming small granules. The crystals of calcium carbonate are soluble in acetic acid, while those of oxalate are not, although soluble in dilute nitric and hydrochloric acids. Silica is abundant in the *Diatomaceæ* and also in the cells of many of the higher plants (*Equisetum*, grasses, beech, &c.).

Products of desorganization or degradation of the cell-wall occur in the form of gum, gum-resins, or resins, examples of which may be seen in the cherry, gum-arabic, gum-tragacanth, myrrh, &c. Gum-arabic consists of arabin, gum-tragacanth of bassorin, and cherry-gum is a mixture of the two. These substances, when formed, are apparently of no further use to the plant, and are produced by the destruction or desorganization of the cell-walls, as portions of the cell-wall can be distinctly traced when gum-tragacanth is examined microscopically.

Molecular structure of cell-wall.

Cell-walls, as those of the wood of Conifers, bast-cells, and cells of ivory nut, and starch granules, are found when examined by polarized light to be doubly refracting. By an elaborate series of researches Nägeli concluded that these structures were made up of crystalline doubly refracting particles or micellæ, each consisting of numerous atoms and impermeable by water, although each of the micellæ is surrounded by a thinner or thicker layer of water. The water may increase or diminish within certain limits without destroying the structure; or under certain conditions as by the application of certain reagents (strong acids and alkalies, ammoniacal solution of cupric oxide), the texture can be destroyed by the swelling up of the part. The water between the micellæ may be removed by drying, when the micellæ themselves come into contact, as the presence of air would destroy the transparency of the membrane. This peculiar molecular composition of the wall at once explains the striation and stratification observed in it, and also enables us to understand growth and nutrition by the intussusception of new particles in the water space between the micellæ.[1]

Certain substances are formed by the protoplasm and separate from it in the form of granules or crystal-like bodies. The most important of these substances are chlorophyll and starch, the less important are aleurone grains and crystalloids.

Chlorophyll.

Chlorophyll or leaf-green is the green colouring matter of plants, and is met with most frequently in the leaves and young stems. The colouring matter is always united with the protoplasm, usually to definite rounded masses, the chlorophyll granules or corpuscles, readily distinguishable from the general protoplasmic mass of the cell in which they are imbedded. Chlorophyll granules never occur separate from the protoplasm of the cell. In a few instances the whole of the protoplasmic mass, with the exception of the ectoplasm, is uniformly coloured green as in *Pleurococcus* and other low algæ; while in other plants the protoplasmic base for the colouring matter is star-like (*Zygnema*), in plates or lamellæ (*Closterium* and *Mesocarpus*), or spiral, as in *Spirogyra*. The chlorophyll grains of the vast majority of plants are rounded corpuscles of varying size with a slightly denser external layer, and frequently containing vacuoles or small starch granules. They grow in size and divide, the grain elongating and being cut into two by the formation of a gradually deepening circular groove. These changes may be seen in the prothallus of a fern or the leaf of a moss. The granules are produced by the aggregation of protoplasmic particles, so as to form a sharply-defined spherical mass. At first these are colourless or of a yellow tinge, and become green by the formation of the colouring matter, the chlorophyll, when exposed to the light, as it is only in a few rare cases, as in the cotyledons of pines and in ferns, that the colouring matter is formed independently of light.

The colouring matter can be removed by means of alcohol, ether, benzole, chloroform, and other solvents, the protoplasmic mass remaining behind unchanged in size and appearance, except in so far that it is now colourless. The solution thus obtained is of a dark green colour by transmitted light, and blood-red by reflected light. Its spectrum shows seven absorption bands, the strongest being between the lines B and C of the solar spectrum. Many modifications of chlorophyll exist in plants, and it also undergoes changes in colour during the ripening of fruits or in the corollas of certain flowers. The chief modifications are—etiolin, in blanched parts of plants; anthoxanthin, in yellow granules of many flowers; xanthophyll, yellow granules in leaves in autumn; the green colouring matter of red sea-weeds; phycoerythrin, the red colouring matter of red sea-weeds; the phycochrome of nostoc, &c.; and the brown colour of diatoms and fucoids.

Starch

Starch occurs in granules of varying size and form, and during the growth of the granule it is always in relation to the protoplasm of the cell. The granules are oval, lenticular, polyhedral, or bone-shaped, as may be seen in the potato, wheat, and maize, and in the milk-sap of certain exotic *Euphorbias* respectively. Each grain usually exhibits a central or lateral spot, the hilum, and a series of concentric striæ, caused like the striation and stratification of the cell-wall by the alternation of more and less watery layers. Sometimes the starch granule has two or more hila, the compound grains, which often separate into their several parts.

Starch has the same chemical composition as cellulose, $C_6H_{10}O_5$, and differs from cellulose in being coloured blue directly by a dilute solution of iodine. Schacht's solution contains 1 grain of iodine and 3 grains of iodide of potassium dissolved in 1 ounce of distilled water; but an aqueous solution of iodine answers quite well. Two substances are generally recognized in the starch grain —(1) granulose, coloured blue by iodine and forming by far the greater part of the granule, and (2) starch cellulose, not coloured blue and only forming a sort of skeleton to the grain. Starch is one of the most widely distributed substances in plants, being absent from comparatively few except the fungi.

Oil globules occur not unfrequently in the protoplasm of plants; and in a few instances they occur in chlorophyll granules. Oil is easily distinguished by its reactions with ether, and by its optical properties.

Crystalloids, globoids and aleurone grains.

Occasionally portions of the protoplasm assume a crystal-like appearance, resembling cubes, octohedra, tetrahedra, &c. These portions are known as crystalloids or protein crystals. They give the ordinary reactions of protoplasm, and differ from crystals in their power of swelling up and changing their angles in certain solutions, as in caustic potash. Crystalloids occur frequently in the cells of the tuber of the potato, in fatty seeds, in red algæ, in petals of many flowers (*Viola tricolor*), and in some fruits. Usually the crystalloids occur in fatty seeds, as in the castor oil and brazil nut, in the interior of rounded grains of albuminoids, the aleurone or protein grains, along with little rounded bodies called globoids consisting of a combination of magnesia and lime with phosphoric acid. In other instances aleurone grains without crystalloids are met with, as in *Cynoglossum*. The aleurone grains are usually soluble in water, and are, therefore, best examined microscopically in strong glycerin, in iodine dissolved in glycerin, or in a solution of corrosive sublimate in alcohol. Aleurone grains form when the seed is nearly ripe, the crystalloids and globoids appearing earlier.

Cell-sap

The cell-sap consists of water with different substances in solution, the substances varying in different cells, and also changing in the same cell from time to time during growth. It saturates the whole wall and protoplasm, and collects in the vacuoles and cell-sap cavity.

The most important substances in the cell-sap are inulin, sugar, tannin, and colouring matters, while the calcium oxalate usually crystallizes out, and forms visible crystals in the cell, or in the wall as already described. Inulin can be separated, in the form of sphærocrystals, by the action of alcohol or glycerin, from the tissues of many of the *Compositæ*, dahlia, sunflower, &c. By keeping the tissue long in absolute alcohol the crystals grow to a large size, and occupy more than one cell. Sugar in solution in the cell-sap may be grape or cane sugar, and can be rendered visible by the copper test, or by the action of glycerin. Glycerin forms drop-like spheres with sugar and inulin; these are very highly refracting and easily

[1] See Nägeli and Schwendener, *Das Mikroskop* (2d ed.), p. 299 *sq.*; and Dippel, *Das Mikroskop*, vol. i. p. 409 *sq.*

distinguished in the cell. When these spheres are of syrup they quickly disappear, no trace remaining in a few minutes, while, as Kraus (*Bot. Zeitung*, 1877, p. 329) has shown, if the substance be inulin the formation of sphærocrystals rapidly occurs. Hesperidin may be obtained from the unripe fruit of orange, &c., in the form of sphærocrystals when treated with alcohol.

Tannin is present in the cells of many plants, and may be seen, when water is applied to the section, in the bark of the oak or birch in the form of fine granules which soon dissolve. A bluish black or greenish colour or precipitate is produced by the action of salt of iron, and a dark red-brown with bichromate of potash. Colouring matter (anthocyan) gives red and blue colours to flowers and a red colour to stems and leaves, and is dissolved in the cell-sap. Lastly, calcium oxalate, which is formed in plants by the metastasis of nutrient matters during growth, is got rid of in many parts of plants, or rendered harmless in others, by crystallizing out, either as large crystals, prismatic or octohedral, or in masses of small crystals, or in the form of long needle-like crystals or raphides belonging to the trimetric system. The two forms differ only in the quantity of water of crystallization present: the raphides have two equivalents, the prisms six of water.

ell formation.

Cytogenesis.—The enlargement of organs of plants is not only accompanied by an increase in the size of the individual cells, but new cells are also formed in the part, these new cells, which are at first small, soon enlarging to their full dimensions. Usually the formation of a new cell takes place by the division of the protoplasm of a pre-existing cell, the mother-cell, into two portions of equal or unequal size, the daughter-cells. These daughter-cells in turn enlarge, and may each become the mother-cells of new daughter-cells. In this way by cell-division the vegetative cells of plants are increased in number. The process of reproduction in plants is invariably associated with the formation of a new cell or cells, and in general the process is very different from that of division, there being often a diminution in the number of cells, instead of an increase.

Four types of Cytogenesis may be distinguished:—(1) Rejuvenescence; (2) Conjugation; (3) Free-cell formation; and (4) Division.

ejuvenescence.

In rejuvenescence, the whole protoplasm of the mother-cell undergoes contraction and rounding; water is eliminated, and an entire rearrangement of the molecules of the protoplasm may be noticed by changes in the contents. As a result of these changes one new daughter-cell is formed from the entire protoplasm of the mother-cell. Rejuvenescence is observed in the formation of the swarm-spores, non-sexual reproductive organs, of some algæ, such as *Œdogonium* and *Vaucheria*, as also in the formation of single spermatozoids. The egg-cell of many algæ and fungi, as well as of the vascular cryptogams, is formed by rejuvenescence, the only difference being that here the daughter-cell remains inside the wall of the mother-cell until fertilization, when it forms a wall and begins to divide.

onjugation.

Conjugation consists in the union of two, rarely more, masses of protoplasm, nearly or quite similar in size and appearance, to form a single new daughter-cell, which then becomes surrounded by a wall and forms a zygospore. The union of the two masses is always accompanied by rounding and contraction of the masses and a complete molecular rearrangement of the protoplasm. Conjugation is seen in the group of the *Conjugatæ* among the algæ, and also in the *Zygomycetes* and *Myxomycetes* among the fungi. In all cases conjugation is a reproductive process. The conjugation in the *Myxomycetes* is very peculiar, the numerous small masses of protoplasm (the myxoamœbæ) fusing into a naked mass of protoplasm (the plasmodium).

'ree-cell ormation.

Free-cell formation consists of the formation of several (rarely one) cells from and in the protoplasm of the mother-cell, the whole of the protoplasm not going to form daughter-cells. Free-cell formation may be typically observed in the formation of the ascospores of the *Ascomycetes*. The nucleus of the large mother-cell or ascus disappears, and two new ones form, which again and again divide, thus forming eight, each nucleus forming the centre of a new mass of protoplasm, which at length becomes surrounded by a wall. In other cases many new masses of protoplasm form after the disappearance of the nucleus of the mother-cell; and these new masses develop a wall and a nucleus, or very rarely no nucleus forms. The endosperm in the embryo-sac of *Phaseolus* and other phanerogams is formed by free-cell formation, the cells after attaining a certain size fusing together and forming a tissue, the individual cells of which divide. In some fungi, *Peronospora*, *Cystopus*, &c., only one daughter-cell is formed in the protoplasm of the mother-cell.

ivision.

The last variety is cell-division, the whole of the protoplasm of the mother-cell going to form two, rarely more, daughter-cells. The process may be observed in the cells of *Spirogyra*, in the cells of the hairs of *Tradescantia*, or in the cells near the growing points of the roots or stems of plants. *Spirogyra* and *Tradescantia* may be observed in a hanging drop of fluid,—water in the case of *Spirogyra*, a dilute sugar solution (1 per cent.) in the other. In *Spirogyra* a ring-like groove forms round the protoplasm in the centre of the cell, gradually deepening until the nucleus divides, and the two portions of protoplasm become separate. As the separation of the protoplasm goes on, the wall forms a ring-like projection of cellulose, which gradually extends inwards until only a small central hole is left; this soon fills up, and the mother-cell is separated into the two daughter-cells.

Cell-division can be seen in the hairs of the young stamen of *Tradescantia virginica*. A small unopened bud about one-fifth of an inch long is recommended by Strasburger.[1] The entire stamens are removed, and one, with the small hairs attached, is to be placed in the 1 per cent. sugar solution in a hanging drop. The cover glass on the under side of which the hairs are arranged must be very thin, to permit of observation with an immersion object-glass magnifying about 600 diameters. The cell-division in the last three cells of the hair can be readily observed, as well as the peculiar behaviour of the nucleus, its solution, and the formation of the barrel-like body "Kerntonne." These and other changes, which had been fully described by Strasburger (*Ueber Zellbildung und Zelltheilung*) in *Spirogyra* and other cells from specimens hardened and fixed in absolute alcohol, can be seen in the living cell of *Tradescantia*.

In the pollen of monocotyledons and the tissue cells of many dicotyledons, as in the pith and epidermis, the division of the cell differs slightly from that seen in *Spirogyra*. The nucleus of the mother-cell divides into two sister nuclei, and the protoplasm separates into two portions, the wall forming at once as a plate stretching right across the mother-cell and cutting it into two daughter-cells. The process of division can rarely be observed in living cells; hence it is necessary to make use of specimens killed during the process of division by immersion in absolute alcohol, or in a 1 per cent. solution of osmic acid.

Special modifications of the process of cell-division may be observed in yeast (*Saccharomyces*), in the formation of styloconidia as in *Penicillium*, and of the basidiospores of the *Basidiomycetes*, as also in *Œdogonium*, in the sporangia of *Saprolegnia*, and in the spores of the higher cryptogams. In yeast a portion of the cell-wall enlarges in a sac-like manner, and into it a portion of the protoplasm of the mother-cell passes, thus forming two daughter-cells of very different sizes; when the smaller cell is full-grown a wall separates the two, and they become detached. In *Penicillium*, and in the formation of basidiospores, a very similar process is seen. In *Œdogonium* division of the cells is preceded by the formation of the curious cap-like structures at the apex of the cell due to local intercalar growth of the wall.[2] In *Saprolegnia* the protoplasm of the mother-cell divides into a large number of daughter-cells, which are liberated as ciliated swarm-spores, and afterwards form a cell-wall. Lastly, in the spores of the higher cryptogams the division of the mother-cell into four daughter-cells is observed.

Tissues true and false.

Union of Cells to form Tissues.—Cells are usually united together to form an aggregate governed by some common law of growth. Such an aggregate of cells is called a tissue. Tissues are formed in different ways, and in accordance with their mode of formation are distinguished as true and false. A true tissue is formed by cell-division. In the young growing part of the plant the young active cells are all capable of dividing, a transverse wall cutting the mother-cell into two daughter-cells, the process being repeated for some time. In this way the tissues of the higher plant are formed, either originally from a single cell (apical cell) at the apex of the part, or from several cells (initial cells) situated at the growing point. In some of the lower plants false tissues are formed, rarely in some of the higher ones. The first mode of formation of a false tissue is noticed in some of the algæ, as in *Pediastrum* and in *Hydrodictyon*, as well as in the formation of the endosperm in the embryo-sac of many plants, as in *Phaseolus*, *Gnetum*, &c. Here the cells are at first separate and distinct, but these loose cells become aggregated together, often, as in *Pediastrum* and *Hydrodictyon*, to form a beautiful and regular figure. In such instances the wall separating two cavities is a double structure formed by the union of two distinct walls. In the endosperm of the higher plants, when the false

[2] Fully described by Strasburger, *Ueber Zellbildung und Zelltheilung* (2d ed.), p. 73.

tissue is formed, the cells divide in the ordinary way, and at length give rise to a true tissue, as different modes of cytogenesis may occur in the same plant, either in different parts or at different times. The second mode of formation of a false tissue is seen in the fungi and lichens, in the peculiar hyphæ tissue so characteristic of these plants. The cells form long narrow rows or filaments, which branch and interlace, producing a network of interlacing fibres, but without the walls becoming fused firmly together as in *Pediastrum*. In some cases the hyphæ cells swell up and come into such close contact by mutual pressure that they form a tissue so like ordinary cell-tissue that it has been denominated pseudo-parenchyma. This variety of tissue occurs commonly in the higher fungi, as in the mushroom.

Mode of union of cells.

Cells are united in various ways, the modes of union being often very characteristic of certain of the lower groups of plants, although the same modes of union repeat themselves in the higher plants. The following are the chief varieties. (1) Cell-rows have the cells united by their ends to form a long filament, formed by the repeated division of the cells. Examples of cell-rows are seen in *Spirogyra*, *Conferva*, *Œdogonium*, the hyphæ of fungi, the moniliform hairs in *Tradescantia*, and in many others; not unfrequently these cells branch in various ways. Cell-fusions or vessels are cell-rows occurring in the higher plants, but having the transverse walls separating the original cells either partially or completely absorbed. They occur in the fibro-vascular bundles of plants, both in the wood and in the bast. Laticiferous vessels are examples of branching and anastomosing cell-rows. (2) Cell-surfaces have the cells united to form a single layer, and are thus in contact by the ends and sides, having an upper and under (rarely only one) free surface. Examples are afforded by some of the sea-weeds, as *Ulva*, and by the leaves of liverworts. In the higher plants cell-surfaces occur not unfrequently, as in the epidermis, a layer of distinct cells, free on one surface, but in contact with other cells below. Many flat, scale-like hairs are also cell-surfaces, as well as the thin plates of cells separating the remarkable air spaces in the petioles of *Nuphar* and *Musa*. (3) Cell-bundles are bands or bundles of similar cells either occurring separately or running through the other tissues of plants, and when doing so easily recognized in a transverse section of the part, as the bast-bundles in the stem of flax. Other examples occur among the red sea-weeds, and in the bundles of sclerenchyma in the stems of ferns. (4) Cell-groups are small masses of similar cells, either forming the families or colonies (cœnobia) of many thallophytes, as *Chroococcus*, *Glœocapsa*, *Pandorina*, &c., or forming the curious groups of sclerenchyma producing the gritty particles in the pulp of the pear or the hard masses in cork. (5) Cell-masses are formed when the cells are united in all directions of space, the whole not having necessarily any definite external shape. Examples are numerous, but we may cite the tissues of large fungi, the ground tissue of the higher plants, and the pulp and hard endocarps of fleshy fruits. (6) Lastly, separate cells occur, either distinguished from the cells in the neighbourhood by their peculiar form and development (idioblasts), or the originally united cells separate themselves, as in pollen-grains and spores, and form eremoblasts.

Prosenchymatous and parenchymatous cells.

By the form and connexions of the cells aggregations of cells may be described as parenchymatous tissue and prosenchymatous tissue, both these forms occurring very commonly in plants, and usually shortly designated by botanists parenchyma and prosenchyma. Parenchymatous cells are usually thin-walled, and have a correspondingly large cavity; their length is generally not very much greater than their breadth, the form frequently being rounded or polyhedral; the walls are broad and flat, the cells, if elongated, not having pointed and overlapping ends. At the places where neighbouring cell-walls meet triangular or quadrangular intercellular spaces are formed, by splitting of the wall during rapid growth. Sometimes these spaces are very minute, in other cases they are largely developed, and if irregular growth of the wall occurs a very loose form of parenchyma may be produced, as in the pith of *Juncus*. In other cases tolerably large intercellular spaces occur, as in the spongy parenchyma of the mesophyll of leaves. In prosenchyma the individual cells are greatly elongated and fibre-like, the walls are very thick, and the cavity small or even nearly obliterated; the ends of the cells are elongated, pointed, and overlapping those above and below; and lastly, no intercellular spaces are developed. Wood-fibres and bast-fibres are examples of prosenchyma; the young cells of stem or root, and the tissues of pith, leaves, flowers, and many fruits, of parenchyma.

Meristem and permanent tissue.

By the power possessed by the cells in a tissue of dividing and forming new cells such a tissue is distinguished as meristem or the formative tissue of plants, all the other tissues being permanent tissues, or incapable of further enlargement by the formation of new cells. Meristem is observed forming the whole of the tissue of the young embryo plant, as also the whole tissue at the apex of a stem and root. All the other tissues of the plant are formed by the gradual differentiation of the originally similar cells of the meristem. Generally meristem tissue differentiates into special layers, each capable of forming cells which will ultimately form some definite portion of permanent tissue, not necessarily of the same value, however, in different groups of plants. The meristem of the embryo and of young stems and roots is distinguished as primary meristem, because occasionally a zone of cells forms in the permanent tissue having the characters of meristem, and secondary meristem, which either originates from the permanent tissue or is partly connected with the primary meristem. The cork-cambium or phellogen in the cortical tissues of dicotyledons is a layer of secondary meristem, while the cambium layer between the wood and bast portion of the bundle is partly (the fascicular cambium) derived from the primary meristem (the procambium) of the fibro-vascular bundle.

Walls of tissue cells.

Walls of Tissue-Cells.—The cell-wall separating the contiguous cavities of two young cells appears as a simple homogeneous plate or lamella of pure cellulose, giving the usual reaction with Schultz's solution and iodine and sulphuric acid. As the tissue grows older and the wall thickens, it apparently separates into distinct layers having different chemical and physical properties, so that in some cases it appears as if each cavity had its own special wall separated from the neighbouring wall by a thin or thick layer of material, to which the older botanists gave the name of intercellular substance. The thickening layers usually exhibit a well-marked stratification, the strata often differing in chemical composition, as in pine-wood, in the bast of laburnum, or in the epidermis of *Viscum*, *Ephedra*, *Nerium Oleander*, &c. The application of Schultz's solution usually brings out the differences very well. In a few instances the middle lamella becomes gelatinous, and swells up enormously in water. Examples are afforded by the stems of many algæ, and by the endosperm of *Ceratonia*, where the so-called intercellular substance separates the cell-cavities widely one from the other. The middle lamella or intercellular substance and the thickening layers in the stratified cell-wall vary much in composition, but generally it is found that the incrusting layers are soluble in sulphuric acid, while the middle lamella is dissolved by nitric acid and chlorate of potash. These two substances, just mentioned under the name of Schultz's maceration process, are constantly employed to separate cells from their connexions, as the markings in the thickening layers are not injured by the solution of the middle lamella in the chlorate of potash and nitric acid.

Classification of Tissues.—In classifying vegetable tissues it is necessary first to distinguish the different kinds of tissue depending on the characters of the individual elements composing it, and, secondly, to consider the various grouping of these kinds or species into systems more or less homogeneous and obeying certain common laws of growth. It is necessary to distinguish the kinds of tissue, because different kinds may occur in the same system, and it is further necessary to distinguish the systems, because the same form of cell may be repeated in different systems or in different parts of the same system and yet be of very different morphological and physiological value. In classifying the different kinds of tissue we shall follow De Bary (*Vergleichende Anatomie der Vegetationsorgane der Phanerogamen und Farne*), and in the systems we shall adopt the threefold divisions of Sachs (*Lehrbuch der Botanik*), now generally used.

I. Kinds of Tissue.
- (A.) *Meristem Tissue.*

II. Systems of Tissues.
- (A.) *Epidermal or Limitary System.*
- (B.) *Fibro-vascular System.*
- (C.) *Ground System.*

Primary meristem. (A.) *Meristem Tissue.*—Primary meristem can be observed in the embryo in its young stages, and at the apex of the stem and root. In the embryo at an early stage, as described by Hanstein (*Botanische Abhandlungen*, i.), the meristem becomes separable into three zones, differing in the appearance and arrangement of the cells and in the mode of dividing. Dermatogen, periblem, plerome. These zones were called by Hanstein (1) dermatogen, or primary epidermis; (2) the plerome or central series of more elongated cells with marked longitudinal division of the cells; and (3) a series between the plerome and dermatogen, dividing more or less irregularly or transversely, the periblem. These three zones remain distinctly marked at the apex of the stem, and in *Hippuris* the three can be easily seen, while as the stem elongates new cells continually form, the initial cells or cell, as there may be one or more for each zone. Usually the dermatogen layer is the most constant in angiospermous plants, the separation into periblem and plerome being sometimes a little obscure. In the root a fourth zone of meristem has to be distinguished, called by Janczewski the calyptrogen layer, from which the calyptra, pileorhiza, or root-cap is formed. Various modifications of the arrangement of the different layers in the meristem of roots have been described. Very rarely, as in *Hydrocharis* and in *Pistia*, four distinct layers are formed Calyptrogen. —the plerome, periblem, dermatogen, and calyptrogen. In *Cucurbita*, *Pisum*, and a few others there is a common mass of meristem at the apex, from which the others are all differentiated. In *Zea Mays* and most monocotyledons two distinct zones are seen, the plerome and the calyptrogen, while between them a short distance from the apex the initial layer forms, which separates into the periblem and dermatogen. In *Fagopyrum* and most dicotyledons the plerome and periblem are sharply separated, but the periblem above the apex of the plerome passes into a common layer with the initial cells of the dermatogen and calyptra, the dermocalyptrogen. In gymnosperms the root possesses a sharply-defined plerome with a periblem mantle, in *Thuja* formed by from 12 to 14 regular concentric layers; there is no trace either of a calyptrogen or dermatogen layer, the outer cells of the periblem serving as a calyptra. In the stems of gymnosperms the condition of the layers is somewhat intermediate between those formed in the angiosperms and lycopods. In *Araucaria* and *Dammara* the dermatogen, periblem, and plerome are separate and distinct, but in *Abietineæ* and in *Cycas* they run into a common initial group, and it is only at some distance from the apex that in the *Abietineæ* the separation becomes very marked, and in *Cycas* only slightly marked. In lycopods the end of the stem shows a series of cells, the initial group from which the periblem and dermatogen (or the external layer representing it) arise. Further down the initial cells of the plerome are developed from the side of the periblem. In the root of lycopods the arrangement of the layers is exactly the same as in *Hydrocharis* and *Pistia*. In the *Ligulatæ* and the remaining *Pteridophyta* there is a single cell at the apex of root and stem which divides into two. The one daughter-cell forms the new apical cell, the other is the segment cell. The segment cell divides still further, and forms a meristem from which at a later stage zones corresponding more or less accurately to dermatogen, periblem, and plerome are produced. In the roots a segment is cut off in front of the apical cell, which is the first cell of the calyptra, and from which, by repeated divisions, that structure arises.

Secondary meristem is intimately connected with the secondary circumferential growth of stems and roots in gymnosperms and dicotyledons. Secondary meristem. One of the zones of secondary meristem arising from permanent cells is the cork-cambium or phellogen layer, which is described under the epidermal system of tissues. The other example of secondary meristem is the cambium layer separating the wood and bast in the stems and roots of gymnosperms and dicotyledons.

When the fibro-vascular bundles first appear, either in the periblem or plerome, the cells become distinguishable by Procambium. their form and arrangement, and as the cells are still in the condition of meristem, the term procambium has been given to the whole. The cells of the procambium are gradually converted into permanent tissue, generally changing their appearance completely, although in some cases the change is but slight, the cells being *cambiform* and hardly differentiated into the two parts of the fibro-vascular bundle, the wood and bast, to be described under the fibro-vascular tissues. In some plants all the procambium is converted into permanent tissue, while in others a small zone between the wood and bast remains in the condition of meristem. If the bundles are separate, secondary meristem forms in the ground tissue between the bundles, bridging over the space between the bundles, but uniting so as to form the cambium-ring, Cambium ring. which consists of fascicular cambium in the bundle, derived from the procambium, and interfascicular cambium, a secondary meristem formed in the ground tissue. It is by the growth of this cambium ring that the secondary circumferential growth, so marked in our ordinary forest trees, takes place.

(B.) *Permanent Tissue.*—It will be sufficient to give only Permanent tissue. a general sketch of the seven kinds of tissue described by De Bary, and to refer for full details to his *Vergleichende Anatomie* above mentioned.

1. *Cell-tissue* is permanent tissue, the cells of which are little if Cell-tissue. at all altered in form and appearance from their meristem stage. In some cases the cells are short, in others elongated. The wall may be thin, and enclose the protoplasm and other contents, the chlorophyll, starch, sugar, inulin, &c. In others the wall is thick and changed in composition. As varieties of cell-tissue De Bary includes (1) epidermis and its appendages, equivalent to the epidermal system of Sachs, and to be considered below; (2) cork, parenchymatous cells chemically altered, and forming usually a part of the secondary epidermal system; and (3) parenchyma proper, all the cell-tissue inside the epidermis and cork cells, a division almost but not quite equivalent to the ground tissue of Sachs.

2. *Sclerenchyma.*—De Bary includes under the name of scleren- Sclerenchyma. chyma all the hard thickened cells of plants, whether long or short, which have become greatly thickened, and whose cavity is nearly if not quite obliterated,—the cell-contents also, as a consequence, having entirely disappeared, or left only slight traces. In this state these cells act in conveying water through their walls, and also serve to give rigidity to the plant, forming the mechanical system of Schwendener. Two forms are distinguished: (1) the short sclerenchymatous cells, and (2) long sclerenchymatous fibres. Of the former, examples are met with in the flesh of the pear, in the root-tubers of *Dahlia*, in the rhizome of *Dentaria*, the pith of *Hoya carnosa*, and

many others. Such cells are rare in monocotyledons, and the typical form (like the cells in the pear) does not occur in cryptogams. A variety of the short cells is described under the name of stegmata. The long sclerenchymatous fibres are pointed, with overlapping ends, and occur commonly in dicotyledons. They are either simple or branched. The best examples are the bast fibres of the fibro-vascular bundles, and the libriform fibres of the secondary wood. The wall of the sclerenchym fibre often exhibits peculiar split-like pitted markings (*Pteris aquilina*). Not unfrequently the sclerenchym fibres have numerous small crystals of calcic oxalate imbedded in the wall, a very beautiful example of which is afforded by *Welwitschia mirabilis*. Sometimes the cavity in the interior of the fibre is divided by transverse partitions forming chambered fibres, as seen in the bast of the vine, *Platanus*, *Tamarix*, &c.

lands. 3. *Gland Cells.*—Gum, resin, ethereal oils, balsam, and gum-resins are usually met with in peculiar elongated cells, which develop from special meristem-cells. Sometimes they are isolated, in other cases they occur in rows; they are considered by De Bary as a special kind of tissue, the cells being at once distinguished from the others in the neighbourhood by their contents. In many ways these gland-cells exhibit intermediate transition forms to laticiferous tubes on the one hand, and to intercellular spaces containing special secretions on the other. De Bary distinguishes four varieties. (*a.*) Cells with the cavity nearly filled with raphides or with single crystals or groups of crystals, *e.g.*, *Aloe*, *Scilla*, and many monocotyledons, as also many dicotyledons. Groups of crystals occur in petiole of aroids, pith of *Ricinus*, and others, large crystals in leaves of *Citrus*, and in the bast of *Acer*, *Robinia*, *Ulmus*, *Berberis*, &c. (*b.*) Cells with the cavity filled with mucilaginous and gummy substances, root of *Symphytum*, *Orchis* tubers, and in the parenchyma of *Malvaceæ*, *Tiliaceæ*, *Ulmaceæ*, &c. (*c.*) Cells containing resin or gum-resin. Two modifications occur, the cells being either short or long, and frequently, as Zacharias (*Bot. Zeit.*, 1879, p. 167) has pointed out, the walls are corky. Short cells occur in *Acorus*, *Canella*, *Zingiberaceæ*, &c., while long ones occur with milk-like juice, the laticiferous cells of some authors. As examples De Bary gives *Allium*, aroids, *Musaceæ*, *Convolvulaceæ*, *Sapotaceæ*, *Sambucus*, *Acer*, and doubtfully *Sanguinaria*, *Glaucium*, &c. (*d.*) Cells containing tannin, occurring in rhizocarps, ferns, monocotyledons, and dicotyledons.

Vessels nd essel- ike ells. 4. *Tracheal Tissue.*—Under this head De Bary distinguishes all those cells which become more or less lignified, and in which the thickening of the wall assumes the form of spirals, rings, reticulations, or pits, and which as soon as these markings are formed either lose their contents completely and become filled with air, or contain clear watery fluid. Usually these form long cell-fusions, the vessels of plants, or else they form elongated or shorter cells not united into a vessel. The former are the vessels, the latter the tracheides. The markings in the two forms correspond, and there are intermediate varieties. The markings are spiral, annular, reticulated, pitted, and trabeculate (juniper and lycopod), with the varieties of bordered pits and scalariform markings. Short tracheides form the velamen or outer modification of the epidermis of the aerial orchid roots, also the outer tissue of the stem of *Sphagnum*. In *Nelumbrium speciosum* the tracheides are 12 centimetres long. Many of the structures usually called vessels are tracheides. Large vessels frequently exhibit tyloses or cells filling up the cavity of the vessel. They have been observed in many monocotyledons and dicotyledons, both in stems and roots, and in herbaceous as well as in woody plants.

ieve- ubes. 5. *Sieve-tubes.*—These resemble vessels in being elongated cylindrical or prismatic cells joined in long rows, the individual cells always remaining distinctly marked. The transverse wall separating the two cavities becomes perforated at the unthickened parts, forming the sieve-plate perforated by the sieve-pores. The contents of the sieve-tubes are colourless and transparent, and the wall is coated with a thin layer of protoplasm-like substance, not unfrequently with small starch granules. Sieve-tubes form a special part of the bast of plants, and are met with in pteridophytes, gymnosperms, and angiosperms, exhibiting occasionally in different groups slight structural differences.

Iilk- earing ubes. 6. *Laticiferous Tubes* are tubes containing the peculiar milky sap or latex occurring in special groups of plants. These run through the plant usually for very long distances, and when a portion is injured the milk-sap flows out at the opening. The walls are always soft, of pure cellulose, and readily giving the characteristic reaction with iodine and sulphuric acid. The tubes contain no protoplasm and nucleus; but a quantity of a rarely watery, usually milky juice, occasionally, however, orange or yellow, and sometimes containing peculiar starch granules. The tubes are either simple or segmented. Segmented tubes occur in *Cichoraceæ*, *Campanulaceæ*, *Lobeliaceæ*, *Papayaceæ*, many *Papaveraceæ*, as *Papaver*, *Argemone*, and *Chelidonium*, but not in *Glaucium* or *Sanguinaria*, many aroids, and *Musaceæ*. Simple tubes are met with in *Euphorbiaceæ*, *Urticaceæ*, *Apocynaceæ*, and *Asclepiadaceæ*. These latter do not exhibit the net-like anastomoses of the segmented forms, and usually have the branches terminating in blind extremities.

7. *Intercellular spaces* are the cavities between the elements of full-grown tissues, the cells in the meristem stage being in uninterrupted continuity. Some of the intercellular spaces are produced by the splitting of the cell-wall between three or more cells, others are formed by the destruction of the walls of a cell or group of cells during the formation, by desorganization, of some secretion. Lastly, large cavities appear in plants as the result of mechanical rupturing and tearing of the inner tissues during rapid growth of the part. De Bary distinguishes all these by separate names, viz., schizogenous when formed by splitting of the common wall between cells, lysigenous when formed by the destruction of certain cells and cell-groups, and rhexigenous when produced by mechanical disruption. From the nature of the contents, the intercellular spaces can be divided into two groups, the one containing substances or mixtures similar to those contained in gland-cells, the other containing air, or rarely water. Of the intercellular glands, spaces, or canals the following varieties may be distinguished:—(*a.*) mucilage or gum canals, of which examples may be seen in *Marattiaceæ*, *Lycopodiaceæ*, *Cycadaceæ*, *Canna*, *Opuntia*, and some *Araliaceæ*; (*b.*) resin, ethereal oil, or gum-resin canals, either in long canals, as in *Coniferæ*, *Alismaceæ*, aroids, *Compositæ* (*Tubulifloræ*), *Umbelliferæ*, *Araliaceæ*, &c., or short spaces as in *Rutaceæ*, *Hypericum*, *Oxalis*, *Myrtaceæ*, *Lysimachia*, &c. Of the intercellular air or water spaces there are several modifications. First there are the minute spaces between the walls of parenchymatous cells, the interstitial air spaces; and when the spaces are larger and accompanied with irregular growth of the wall, lacunæ are produced, as in the root of *Sagittaria sagittifolia*, or in the pith of *Juncus* or petioles of *Musa*, &c. Large schizogenous air-spaces with smooth walls are met with in *Isoetes*, *Potamogeton*, *Hippuris*, *Trapa*, *Nymphæaceæ*, and many others. Lysigenous spaces having the remains of the destroyed cells more or less marked on the walls are seen in *Equisetum*, *Cyperaceæ*, *Gramineæ*, *Typha*, *Iris*; while the large hollow stems of *Umbelliferæ*, *Compositæ*, grasses, and the leaves of *Allium*, &c., are rhexigenous. Occasionally flat cell-surfaces or diaphragms interrupt the continuity of long air-spaces, and not unfrequently internal hairs or peculiar hair-like idioblasts are formed, projecting into the intercellular spaces as in *Nuphar* and *Monstera*. It is only in the neighbourhood of water stomata that the spaces contain water for a short time. Cavities in tissues.

Systems of Tissues.—Sachs describes three systems of tissues, complex aggregations consisting of different kinds of tissue, but all so combined as to form readily recognizable parts of the root, stem, or leaf of a plant. Externally there is the epidermal or limitary system equivalent to De Bary's first division, excluding his parenchyma. This system is taken to include the epidermis of plants, with its cuticle, stomata, and hairs, and also to include the secondary modifications produced by the development of cork and bark. In the interior of most parts of the higher plants, and following in the direction of the long axis of growth, separate or united strings or bundles are seen running and usually branching or anastomosing. Generally these bundles are harder than the surrounding tissues and readily separable from them. Consisting as they do of many kinds of tissue of vessels, cells, and sclerenchyma, these structures are known as fibro-vascular bundles. Lastly, there exists a quantity of parenchyma or a mixture of parenchyma with other forms, packing up all the space between the fibro-vascular bundles on the one hand and the epidermal system on the other. This forms the ground tissue, and includes the parenchyma proper of De Bary.

1. *The Epidermal or Limitary System.*

The epidermal system takes its name from the chief member of the group, namely, the epidermis or outer skin of the plant. It is the superficial layer, and is variously developed in the higher and lower plants. In the lower forms, algæ, fungi, lichens, the external cells are usually smaller than those below, or the walls are thicker and coloured; while in many mosses and liverworts a true separable epidermis is only slightly indicated. In others, as in *Marchantia*, capsules of most mosses, and in *Sphagnum*, a specially differentiated epidermis appears, resembling that in the higher plants. The nature of the epidermis varies in accordance with the conditions to which it is exposed, as to air and light, or in water, or in the soil, and in darkness. The nature of the limitary tissue also varies with the stage of growth in such parts as are of perennial duration. Epidermal tissues.

Usually the epidermis is a single layer of cells producing stomata and hairs. In many plants the epidermis is strengthened by the formation of a corky outer layer, the cuticle, which develops wax; or in other cases a new formation takes place below the epidermis, usually in the ground tissue, and by the formation of layers of cork a secondary epidermal or limitary tissue is produced. Other parts of the ground tissue assist in forming the outer covering of plants, and may be considered physiologically to belong to the epidermal system. These will be described as hypoderma and collenchyma under the ground tissue.

Epidermis. *Epidermis.*—The cells of the single layer forming the epidermis vary in shape, but usually the form is determined by the shape of the part on which they are developed, being elongated on long leaves, broad with straight or wavy margins on broad leaves. Usually the cells of the epidermis, although parenchymatous, have no intercellular spaces, except in *Osmunda* and *Todea*, and a few other rare instances. The only openings are those in the stomata, schizogenous intercellular spaces, between the special cells (guard cells) of the stoma. In many plants, as monocotyledons and needle-leaved conifers, the epidermal cells contain no chlorophyll; but in ferns and in many dicotyledons, as has been shown by Stoehr (*Bot. Zeit.*, 1879, p. 581), chlorophyll is present. Not unfrequently anthocyan fills the epidermal cells, and completely obscures the green colour of the chlorophyll-bearing cells below. The outer wall of the epidermal cell is usually greatly thickened and corky, forming the cuticle, which generally forms a continuous sheet separable by the action of caustic potash from the rest of the wall below. In applying Schultz's solution to a thin section of an epidermal cell, the outer layers become brown, while the inner give the reaction of cellulose. The outer layers are soluble in boiling caustic potash and in nitric acid and chlorate of potash, but insoluble in sulphuric acid and in ammoniacal solution of cupric oxide. Many of the cells have a marked deposit of mineral matter, more particularly silica (*Equisetum*), in their walls. See Nageli and Schwendener, *Das Mikroskop* (2d ed.), p. 489.

Wax. Wax is frequently produced: either it is on the surface of the cuticle forming a variously constructed coating, or minute particles are embedded in its texture. The chief modifications are described by De Bary (*Vergleichende Anatomie*, p. 86):—(1) a layer or crust, either thin, homogeneous, and transparent, or thick and striated, the former seen in *Sempervivum*, the latter in the waxpalm (*Klopstockia*); (2) a coating of rod-like particles placed perpendicularly to the surface, either closely placed or somewhat loose and irregular (*Saccharum*, *Musa*, and *Scitamineæ*); (3) a layer of granular particles, close or widely separated, and not placed one over the other (*Allium*, *Acer*, *Vitis*), &c.; and (4) irregular granules piled up one over the other in several layers, as in *Eucalyptus*, *Ricinus*, *Abies pectinata*, &c.

Stomata. Stomata (De Bary, *Vergleich. Anat.*, p. 36 *sq.*) are the openings in the epidermis which permit the entrance and escape of gases. They are formed by two semilunar cells, the guard cells, with the pore or intercellular space between them, the pore opening into a large air-space in the tissue below, and in communication, by means of the small intercellular spaces of the parenchyma, with most of the tissues of the plant. The stomata are found on those parts above ground exposed to air and light, hence chiefly on the leaves and tender green stems of plants. On leaves they are most abundant on the under side, and are generally absent from the upper surface. In many leaves, however, especially of monocotyledons, they are equally distributed on both sides, and in water-plants with floating leaves they are abundant on the upper side but absent from the lower. They rarely occur on submerged water-plants and never on roots. As a rule the stomata are irregularly scattered, but in some plants, as in *Equisetum*, they occur in tolerably regular longitudinal rows on the stem. Usually the stomata consist of only two cells, the guard cells, or of two pairs of guard cells (*Equisetum*) one over the other, or there are many, as in the peculiar stomata of *Marchantia*. In some plants two or more additional cells, the accessory cells, are formed. These accessory cells differ from those of the epidermis on the one hand, and from the guard cells on the other. The position of the stoma varies. It is sometimes at the end of the long epidermal cells, as in the hyacinth, or at the side, in a few cases free in the centre of the epidermal cells (*Anemia*, &c.). The guard cells may be on a level with the epidermis; rarely they project slightly; but frequently they are depressed below the surface. The guard cells often contain chlorophyll and starch, the outer wall is often thickened, and occasionally even wax forms on their surface; but as a general rule no wax forms, and thus, when a thick coat of wax is developed, narrow canals through it indicate the position of the stomata.

Development of Stomata.—In long epidermal cells (hyacinth) a portion is cut off at one end by cell-division, and forms the mother-cell of the stoma. It then divides into two daughter-cells, each forming one of the guard cells. The lamella between the two splits, either from without inwards or within outwards, and forms a schizogenous intercellular space. When the epidermal cells are not elongated (*Œnothera*, *Silene*, &c.), a portion of the epidermal cell is cut off at one part by a bent wall. This is the mother-cell of the stoma, and either forms the daughter-cells immediately, or may divide by segments cut off at one side and then at the other side, either one, two, or more times before the central cell divides to form the daughter-cells which form the guard-cells of the stoma. The other cells cut off on each side are the accessory cells. In other cases the accessory cells have a different origin, being cut off from the neighbouring epidermal cells after the guard-cells are formed. Instances of the former may be seen in *Crassulaceæ*, *Cruciferæ*, and *Papilionaceæ*; of the latter in *Juncaceæ*, *Cyperaceæ*, and *Gramineæ*. In *Anemia* and some other ferns a cell is formed inside the epidermal cell, cutting a cylindrical piece out of it. This divides and forms the guard-cells of the stoma.

Water stomata. Two kinds of stomata exist in many plants. The one kind, already fully described, are the air-stomata, to distinguish them from the second kind, the water-stomata. The latter occur in many plants on the leaves, immediately over the ends of the fibro-vascular bundles, near the margin on the upper surface, and often on the serrations of the margin itself. They give off water, during a portion of the life of the leaf, which appears on the surface in the form of drops, under the action of root-pressure. They are at once distinguished by their large size, and by their not opening and closing like air-stomata.

Hairs. Hairs (De Bary, *Vergleich. Anat.*, p. 58) are usually out-growths of single epidermal cells; but occasionally some of the cells below the epidermis assist in the construction of large massive hairs or emergences, as they are called by Sachs. Hairs vary very much in construction, size, and appearance, and not unfrequently different kinds of hairs occur mixed together on the same part of the plant, although in many instances only a single characteristic variety of hair may be developed on the epidermis. De Bary distinguishes several typical varieties of hairs:—(1) hairs proper; (2) papulæ, short rounded sac-like structures; (3) scales; (4) villi; and (5) warts or prickles. The simplest hairs are outgrowths of single epidermal cells, having the cavity either continuous with that of the epidermal cell, or cut off by a wall. Long cylindrical unicellular hairs occur in cotton; and on most roots root-hairs, with thin or sometimes with peculiarly and irregularly thickened walls (*Viola tricolor*). The cells may divide and form a moniliform hair, as in *Tradescantia*, or much more complex branched (*Verbascum thapsus*) or club-shaped and glandular hairs may be produced. Flat, dry scales, either unicellular or multicellular, are seen in *Deutzia*, *Elæagnus*, and in many ferns. Papulæ are mentioned by De Bary as occurring on *Rochea*, *Begonia*, *Piper*, *Ampelopsis*, and others. The villi or colleteres occur on bud-scales and buds, while spiny hairs or warts occur frequently as the prickles of the rose and bramble, and in *Dipsacus*, *Smilax*, &c. The walls of hairs are often thin, and composed of nearly pure cellulose, or thickened and stratified in various ways, with an outer cuticular layer. The thickening is either general or local, and may assume the form of pores or spiral striation (hairs on stamen of *Bulbine aloides*), or may form peculiar warts or nodules. Silicious hairs (*Deutzia*), or hairs containing lime, sometimes occur. In some cases the hairs (nettle) are supported on cellular elevations of the epidermis. These may be distinguished as the accessory cells of the hair. Glandular hairs are of frequent occurrence, the end cell or cells secreting some ethereal oil or resin; the secretion collects below the cuticle, and either it remains there, causing the absorption of the secreting cells, or the cuticle ruptures. The villi or colleteres are peculiar many-celled glandular hairs on young leaves, stipules, or bud-scales (*Ribes*, *Viola*, *Polygonum*, *Æsculus*), and secreting a gum or resin. Frequently the secretion of these colleteres is supplemented by the formation of a resin from below the cuticle of the epidermis, forming the gelatinous secretion covering buds, termed blastocolla (horse-chestnut). In some plants, as *Populus*, the blastocolla is formed by the epidermal cells alone, in others both by the colleteres and epidermis.

Secondary epidermal tissue. Beneath the epidermis the cells are often peculiarly modified to form the hypoderma and collenchyma; but as these belong to the ground system of tissues they are described below. The secondary epidermal tissues, or the covering that replaces the epidermis on the perennial parts, consists largely of cork, either in the form of a thin layer or in repeated layers developing deeper and deeper in the tissues of the stem or root and forming the massive bark or rhytidome. Cork cells arise usually from the cortical cells, *i.e.*, those of the ground tissue placed a short distance below the epidermis (*Populus*, *Sambucus*). In other cases the cork forms still deeper, among the green chlorophyll-bearing cells of the cortex, as in *Rubus Idæus*, *Ribes*, &c. Rarely the cork-cells arise from the epidermis itself (*Salix*). In all cases cork is formed by the division of the cells of the cortex or epidermis by a tangential wall, separating the mother-cell into two daughter-cells. The outer cell becomes corky, rapidly losing its contents and becoming filled with air; while the inner one retains its protoplasm and forms new cork-cells by division. The formation of cork does not necessarily begin at all parts of the circumference simultaneously, but sooner or later a complete layer of cork is formed. When the layer has become a few cells thick, it is known as the periderm; while the active cells from which it arises are distinguished as the cork cambium or phellogen. Inside the cork cambium new cells are often formed, which contain chlorophyll, and are known as the phelloderma (*Fagus*, *Salix*), such cells being also formed by division of the cork cambium. After the formation of the periderm, as is easily seen in the stem of the black currant, the whole of the epidermis and of the ground tissue immediately below becomes withered, and is thrown off. In the formation of bark, the layers of cork form repeatedly in the cortical tissue of the stem, and even in the bast portion of the fibro-vascular bundles. The layers of cells between the plates of cork, being cut off from a supply of nourishment, soon wither; and thus occasionally the dead parts scale off, as in the *Platanus*, cherry, &c. The bark or rhytidome is thus a very complex structure, consisting of the secondary epidermal tissues either formed in the primary cortex alone or deep in the other tissues, and popularly it includes all the tissues outside the cambium layer, that is, the bast part of the fibro-vascular bundles and secondary epidermal tissues. Lenticels are special structures connected with the epidermal tissues, and are common on dicotyledons (*Sambucus*, *Populus*, *Juglans*, &c.), and on some monocotyledons, being formed on stems, branches, petioles, and roots. Below a stoma or group of stomata a few cells enlarge and divide, and form numerous colourless thin walled cells, which arise from the bent layer of lenticel cambium below. The epidermis becomes ruptured and the cells appear on the surface, forming a brownish wart-like marking. These lenticels are probably to be considered functionally as secondary stomata, as the cells have large intercellular spaces and readily permit the passage of air into the interior. Lenticels have the marked peculiarity of being sometimes closed in autumn by the formation of cork cells, but open again in spring.

enticels.

2. *The Fibro-vascular System.*

ibro-
ascular
undles.

String-like bundles, the fibro-vascular bundles, are common in vascular cryptogams, gymnosperms, and angiosperms, and are familiar in the leaves of plants as the veins. They run in the ground tissue either separately or united, as in many dicotyledons, and in most roots, &c., to form a central or hollow cylindrical vascular mass. When the bundles are separate they often branch and anastomose as in leaves, or they may only anastomose at the nodes of stems. The bundles are easily separable by maceration, except in water plants, and a few others, in which the bundles are very soft; or they may be examined in transverse and longitudinal sections of the part, more particularly in the latter case when the tissues have been rendered transparent by boiling in dilute caustic potash, or by being previously boiled in strong nitric acid. (See Nägeli and Schwendener, *Das Mikroskop*, p. 632.)

Vood
ylem)
id bast
hloem).

Each bundle in its perfect state consists of two groups of cells, the wood or xylem portion, and the bast or phloem. Bundles are either closed or open. In the former the procambium cells, the meristem, from which the permanent tissue of the bundle originates, entirely passes over into permanent tissue; while in the latter the cambium remains between the xylem and phloem, and is capable of forming new cells for an indefinite period. Closed bundles thus rapidly assume a permanent form, while open bundles go on growing. Fibro-vascular bundles are divided by De Bary into four groups by the mode of arrangement of the xylem and phloem. The first and commonest form is the "collateral" bundle, where the xylem and phloem are placed side by side with or without cambium between them, the xylem being always towards the pith or the central part of the stem, the phloem external. In *Cucurbita*, *Solanum*, and others the bundles are "bicollateral," there being an additional phloem portion inside the xylem. "Concentric" bundles occur in many vascular cryptogams, the central xylem being completely surrounded by the phloem. The last form is the "radial," where the bundles of phloem and xylem are arranged alternately in the central fibro-vascular axis, as in most roots. Irregular bundles also occur, and numerous intermediate forms connect the different types.

tructure
f xylem.

In each of the portions of the bundle different kinds of tissue occur; but there is a marked similarity in the construction of the phloem and xylem, at least in separate bundles and before circumferential growth takes place. In the wood, distinguished by the lignified hard brittle walls of the cells, there are four elements usually present:—(1) the wood vessels or cell fusions filled with air, having the transverse walls more or less completely absorbed, and having thickened walls marked with rings, spirals, reticulations, or pits of different kinds; the ends of the cells sometimes are more or less pointed and overlapping, with pitted markings, having, however, a free communication from cell to cell through the absorbed thin part of the pits; (2) tracheides, or vessel-like wood prosenchymatous cells, having walls marked like the vessels, and with the cavity containing air, but never showing any absorption of the end walls and fusion into vessels; (3) wood prosenchyma or libriform fibres, elongated, pointed, and overlapping cells, exactly resembling bast fibres, often with greatly thickened walls, these walls never having spiral or annular markings, but only small simple or occasionally exceedingly minute bordered pits; they are very common in the wood of dicotyledons, and may either be simple or have fine transverse partitions forming chambers in the long cell; (4) wood parenchyma, wood cells with thin walls, and simple pits; these in winter contain starch, and other reserve materials, along with the cells of the medullary rays, and at other times may contain tannin, chlorophyll, or crystals of calcium oxalate. In the bast or phloem portion of the bundle there are three elements only, as there are no cells equivalent to the tracheides. These are—(1) the sieve tubes or bast-vessels, cell-fusions like the wood vessels, but having the transverse portion forming the remarkable sieve plate perforated by the sieve pores, while occasionally such plates or similar markings occur on the side walls: the walls are soft and delicate, giving a cellulose reaction, and the cavity contains abundant protoplasmic contents with excessively minute starch granules; (2) bast prosenchyma or bast vessels, elongated prosenchymatous cells, with pointed and overlapping ends, the walls so thick as almost to obliterate the cavity; the walls are soft and flexible, often marked with fine pits; like the libriform fibres of the wood, they have occasionally the cavity chambered with thin transverse walls, and not unfrequently they branch; (3) bast parenchyma, repeating the wood parenchyma; but occasionally the cells are long and narrow, exactly like those of only slightly modified procambium, which they really are; in this state they are often called cambiform cells. The sieve-tubes and bast parenchyma or cambiform cells form the soft bast. These different elements of the wood and bast are not always present, and the secondary wood and bast developed from cambium are often very different from the primary portions developed from procambium. Thus in *Cucurbita* there are no bast fibres, while in most coniferous woods the tracheides alone are present in the xylem. At the ends of the fibro-vascular bundles in the leaves the different elements gradually disappear until one or two spiral vessels and a few cambiform cells alone remain. In most roots the fibro-vascular bundles form a central mass with the phloem and xylem in separate groups and arranged alternately; the xylem masses generally project into the centre, and the oldest vessels are nearest the centre. The whole mass, which is either a single bundle or a group of bundles, is usually surrounded externally by a peculiar layer, the pericambium, in contact with the endodermis or sheath, the inner layer of the ground tissue, which in roots forms the massive cortical portion.

Structure
of
phloem.

3. *Ground System of Tissues.*

The ground tissue comprises all that remains after the formation of the epidermal and fibro-vascular systems, and is usually composed of parenchymatous cells, not in any way distinguishable except by their position from parenchymatous cells in the other systems. In other cases the ground tissue contains prosenchyma, or the cells in certain regions are more or less thickened. When the part contains closed fibro-vascular bundles, as in monocotyledonous stems and in leaves, the ground tissue forms the chief bulk of the part; but in other cases, as, for instance, in the stems of conifers and dicotyledons, with circumferential growth, the ground tissue is very feebly developed. In such stems the ground tissue forms the pith and cortex, with the primary medullary rays joining the two. In roots with a central fibro-vascular mass, the cortex is the only part of the ground tissue represented. The ground tissue immediately below the epidermis may be simply parenchymatous, or it may exhibit certain modifications. Either the cells form collenchyma, as in many stems and petioles, a tissue consisting of mere elongated cells without intercellular spaces, and having special masses of thickening matter developed on the walls where neighbouring cells meet. These masses readily swell up in water, and probably act as a sort of erectile tissue. In other cases a greater or less development of hypoderma is observed in leaves and stems, the cells being elongated and greatly thickened and sclerenchymatous, resembling in most points the bast-fibres of the fibro-vascular bundles. In some plants, as in ferns, separate, often dark-coloured, bundles of sclerenchyma occur in the ground tissue. These different elements form part of what has been distinguished as the "mechanical" system of tissues, hardened cells giving rigidity to the different parts of the plant, and although such cells occur in very different parts of plants, as in fibro-vascular bundles and in the ground tissue, still they have a marked external resemblance, and are closely related physiologically. Thick, short, sclerenchymatous cells occur in the ground tissue, as in the pulp of the pear; in other cases the parenchyma is unthickened, and contains either colourless contents or develops chlorophyll. The part of the ground tissue next the fibro-vascular bundles forms the sheath or endodermis, a layer of cells often thickened or cuticularized, and surrounding either single bundles or the whole vascular mass or series of fibro-vascular bundles. In some cryptogams the endodermis is strengthened by numerous sclerenchymatous cells surrounding it either partially or completely. The ground tissue of tree *Liliaceæ*, and even in some abnormal dicotyledons, forms a layer of secondary meristem cells capable of developing both new ground tissue and new fibro-vascular bundles; and it is in this way that the secondary circumferential growth in the stems and roots of *Dracæna*, and probably of the fossil vascular cryptogams, took place. The secondary circumferential growth of gymnosperms and dicotyledons is the result of the activity of the cambium ring formed by the fascicular cambium and the interfascicular cambium in the ground tissue, as already described. The changes produced by secondary circumferential growth are very numerous, and are fully described by De Bary (*Vergleichende Anatomie*, chaps. xiv. and xv.).

Bibliography.—The chief works to be consulted on the subject of vegetable histology are—Beale, *On the Microscope*; Carpenter, *On the Microscope*; De Bary, *Vergleichende Anatomie* (Hofmeister's *Handbuch der Physiologischen Botanik*, vol. iii.); Dippel, *Das Mikroskop*; Lürssen, *Grundzüge der Botanik* (2d ed.); Nägeli und Schwendener, *Das Mikroskop*; Pelletan, *Le Microscope*; Sachs, *Text-Book of Botany*, or *Lehrbuch der Botanik* (4th ed.); Sachs, *Geschichte der Botanik*; Strasburger, *Ueber Zellbildung und Zelltheilung*; Strasburger, *Die Angiospermen und die Gymnospermen*; Van Heurck, *Le Microscope*. (W. R. M'N.)

HISTORY, in the most correct use of the word, means the prose narrative of past events, as probably true as the fallibility of human testimony will allow. This definition takes no account of chronicles in verse which were not uncommon in the Middle Ages. With this exception the definition is fairly exact, both in what it comprehends and what it excludes. Obviously prose narrative is not history when it deals with fictitious events, as in the case of the novel; and verse narrative, even when it deals with true events (as in the account of the battle of Salamis in the *Persæ* of Æschylus, or Guillaume le Breton's metrical chronicle of the reign of Philip Augustus), is either more or less than history, and in any case a sub-species by itself.

In practice, the line between history and mythus is often not easy to draw; but the theoretical distinction is plain. History reposes, however remotely, on contemporary witness to the fact related. Written records are not absolutely indispensable, as tradition *may* supply their place and represent authentic contemporary testimony. But tradition is very insecure and apt to be equally inventive and oblivious. It is in the half light of tradition that mythus is born of the creative fancy of man, and the difficulty of separating fact from fiction in this border-land of mingled fable and reality very often amounts to impossibility.

But even authentic facts alone are not sufficient to constitute history. Many facts and dates are recorded with reference to China, Egypt, and Assyria in olden times, which in all probability are true; but these facts and dates are not enough to give those countries a history. The bare fact that a certain king reigned in a certain year, and conquered or was defeated in battle with a neighbour, is perhaps chronologically valuable, but it is not history. History only attains its full stature when it not only records but describes in considerable fulness social events and evolution, when it marks change and growth, the movement of society from one phase to another.

The field of history is in consequence very limited, both in time and space, in proportion to the length of human existence and the area of the earth's surface occupied by man. Primitive and savage man has no history, because the struggle for existence consumes all his energies, and he has neither time nor faculty to think of himself as a social being, much less to make record of social events. But even when partially civilized, mankind is often incapable, not only of writing history, but of furnishing the materials of it. Under a system of caste, or conservative theocracy, or oppressive tradition, as in India, Egypt, and China respectively, the social evolution is so slow that it hardly seems to move at all. The grandson lives among conditions hardly differing from those of the grandfather. In such a state of things the very subject-matter of history is wanting. Nothing attracts less notice than immobility, and large populations have often lived under conditions which for whole generations did not seem to vary. The vast and vacant annals of the East show that the arts of peace and war may attain considerable development without history or its materials being produced in consequence.

If these views be correct we can only allow a period of about 4000 years as the limit of genuine history in point of time. The beginning would be with the historical books of the Old Testament. Before the Jewish records fail us the Greek have begun. The Romans follow in immediate succession, and the historical thread has never been broken since, though thicker and stronger in some epochs than in others. As regards area, history long dwelt exclusively on the shores of that inland sea which, if not the birthplace of the human race, have at least been the chief training-ground of its early youth and vigorous manhood. Civilization subsequently spread from the Mediterranean to remote islands and continents unknown to the ancients, and history has followed it. No doubt in time both will be coextensive with the globe; but that time has not yet come. It is still useful to remember that the materials of history now rapidly accumulating in the far West, the far South, and even the far East, owe their origin to that antiquity of which we are the heirs, to the civilization which took its rise in those ever memorable centres named Rome, Athens, and Jerusalem.

Early history is never critical and painstaking in the investigation of facts. Neither the historian nor his readers or hearers have reached a stage of culture in which accuracy is highly valued. Early history is essentially artistic, its object is much more to charm the fancy and warm the emotions than to instruct the understanding. A good story, pathetic or humorous, is appreciated for its own sake independently of its truth. Striking pictures, dramatic situations, often told in dialogue, scenes in which virtue and vice are depicted on a colossal scale—these are the chief objects of the early historical writer, who mingles fact and fiction with the same naiveté as his brethren, the writers of the early epos and drama. Indeed, their subjects are often the same,—the heroes whose prowess saved or achieved the national existence, the odious foreign foe who was beaten back; in either case characters appealing strongly to the imagination and the feelings, which would resent cold criticism, but gladly welcome eloquence and passion. History written under these circumstances has much of the character of the prose poem,—*carmen solutum*, as Quintilian called it. The artistic or imaginative element predominates in it rather to excess. Such is history as written by Herodotus and Froissart. The growth of accurate knowledge in other departments, the increased practice of affairs, the substitution of the political for the heroic and chivalrous sentiment, lead to a more sober and scrutinizing style of history without sacrifice of artistic form. Such is history as written by Thucydides and Tacitus.

Even a most hasty survey of so vast a subject as the historical literature of the world will be helped by its division.

History is of two kinds,—the old or artistic type of history, and the new or sociological type. The artistic type, invented by the Greeks, remained the ideal of history till comparatively recent times. Its aim was perfection of literary form, weight and dignity of language, depth of moral and sagacity of political reflexion. It was habitually careless and indifferent as regards research. But its chief distinction from the new history was a negative one; it had no conception of society as an organism, no suspicion of the depth and variety of the social forces which underlie and originate the visible events which it describes, often with admirable power. The new history is to a great extent characterized by opposite qualities. Its preoccupation about literary form is secondary, moral reflexion it rather avoids, but it is laborious beyond precedent in research, and above all it is pregnant with the notion that society is a great aggregate of forces moving according to laws special to it, and similar to those producing evolution and growth analogous to what we see in other forms of life. The remainder of this article could not perhaps be better employed than by a short examination of these two types of history, including some reference to the causes which brought about a transition from one to the other.

The Greeks were the inventors, and remain the unsurpassed masters, of the artistic form of history. That extraordinary insight into the true conditions of harmony, proportion, and grace which guided them in other departments of literature and art did not forsake them in this. As in the drama a few tentative and experimental essays soon led to the master works of Æschylus, Sophocles, and Aristophanes, so a few precursors were sufficient to direct Herodotus to the main outlines of historical composition. By one of those mysterious accidents, not to be accounted for, which produce genius, Herodotus was closely followed by the greatest mind that ever applied itself to history. Thucydides remains the unsurpassed ideal of artistic history. As the famous statue of Polycletus, called the Doryphorus, represented the proportions of the human body in such complete beauty "that it was regarded by the ancient artists as a canon of the rules on this point," so the history of the Peloponnesian War may serve, as its author seemed to know it would, as a model which all may copy but none may equal. Art, differing from science, allows of something like final perfection. Scientific work, however admirable, is always speedily superseded. Great artistic works remain perfect in their kind, and such was the work of Thucydides. History never deviated from the lines laid down by the Greeks till the advent of the modern school towards the end of the last and the beginning of this century. Between Thucydides and Gibbon there is no change of the ideal plan on which history should be written, though of course there is every degree of success and failure in striving after its realization.

A history of history is a desideratum in literature. The merit of such a work, if properly done, would consist, not only in the criticism of particular authors, but in a comparison of their epochs and social surroundings, and a pointing out how these influenced the character and quality of their historical writing. It is, for instance, worthy of notice that history is far more sensitive and dependent on public freedom than either poetry, science, philosophy, or jurisprudence. All these have flourished under governments more or less despotic, but history never. Tacitus seems to have felt this in the depth of his heart when he said that he was able to write as he did because of the "rara temporum felicitas ubi sentire quæ velis et quæ sentias dicere licet." Again, certain epochs are favourable to great historians, as periods of war are favourable to great soldiers. Rating the genius of the Greek historians as high as we please, and it is difficult to rate it too high, it is still manifest that they enjoyed exceptional advantages. The political condition of the Greek world in the 4th and 5th centuries B.C. was beyond measure stimulating to men of genuine historical power. That extraordinary collection of small states, full of the most active political life, full of wars, alliances, and brusque revolutions, was a scene of interest, of which no subsequent historian has ever seen the like. In this respect the Greek historians had a privilege similar to that enjoyed by the Greek sculptors. As the gymnasia displayed the finest type of manly beauty and strength ever seen, so the fervent energy and activity of the Greek states presented in unparalleled variety and fulness the features of political life most capable of interesting an historical mind. And it is perhaps hardly too much to say that what the palæstra was to Phidias, that the Peloponnesian War was to Thucydides.

Continuing this vein of reflexion, we might remark that it is a noteworthy fact that in history alone the Romans came nearest to their Greek models. Copyists in everything else, and inferior copyists, in history they equalled if they did not excel their masters. It is a moot point with many whether Tacitus should not be placed above Thucydides. In any case that steep inferiority which marked Roman imitation of Greek models in every other department was excepted in the case of history. Why was this so? Obviously because the Romans possessed a robust national life in many respects more lofty and inspiring even than that of the Greeks. The genius of individual men was kindled by the propitious *milieu*. And a disastrous *milieu*, injurious to all productions of the mind, is peculiarly fatal to history. The decay of historical writing in the later period of the declining Roman empire is a sufficient proof. Nothing so debased as the Augustan History can be found in any other province of Latin literature, and when a man of real power like Ammianus Marcellinus appears, if we compare him with Claudian in another department, we perceive that the muse of history is more austere than her sisters. The Middle Ages would offer the historian of history ample scope for connecting the quality of historical writing with the social surroundings of the authors. The great monastic houses, such as Malmesbury, St Albans, Eu, and many more, would be shown to have been such schools of history as they were, for very efficient reasons. The appearance of the modern Herodotus, Froissart, would seem meant expressly to show the union of opportunity and genius needed to produce great historical work. It was no accident which gave us the immortal chronicles. The first instalment of the Hundred Years' War between France and England, the grand but abortive outburst of Parisian democracy under Étienne Marcel, the energetic action of the first serious States-General of France—these were subjects to arrest a real historical eye, such as Froissart had, in spite of his many shortcomings. The dramatic struggle between feudalism and monarchy in the 15th century found a competent if somewhat rustic Tacitus in Comines, more friendly but on the whole not less severe to his bourgeois Tiberius, Louis XI. In the stirring times of the 16th century historians abound—Italians, Frenchmen, Dutchmen—too numerous to mention and too distinguished to be passed over with perfunctory notice here. But how much would an historian of history have to say of Fra Paolo, Davila, De Thou, Grotius, to name only the chief? And then occurs a really surprising phenomenon. History disappears from the continent of Europe for a century and a half. Between the Thirty Years' War and the Seven Years' War the Continent produced no historians whom the world cares to remember, for Mézeray is remembered, though hardly read, on account of his quaint and occasionally graphic style. Yet this was the great age of Louis XIV., the classic age of French literature and philosophy, and the commencement of French science. But history withered under the blight of the Catholic and monarchical reaction. History was indeed being written in France, the most witty, profound, and graphic since the days of Tacitus; but it was history which the author kept for himself and a remote posterity; not for a hundred years was the world to be permitted to gaze with wonder and admiration on the incomparable memoirs of St Simon. But Rebellious and Revolutionary England gives us Clarendon and Burnett—cause and effect as usual. A review of the 18th century and its performances in history would conclude this interesting retrospect. But it is time to return from this digression to our more immediate subject.

The old type of history, one might say, was a species of portrait-painting which had often every merit except that of close likeness to the original. Whether it is quite just to say this will be presently considered. But it cannot be denied that the old writers generally thought more of the brilliancy of their colours and the effectiveness of their pictures than of their exact truth. "My siege is finished," said Vertot, when offered new documents which stultified his narrative. The old masters of history resembled, it is to be feared (if so honourable a comparison can be considered derogatory), the old masters of painting. Both thought little of what we call "local colour," of close conformity to the scene or object delineated, provided they produced striking compositions with grand outline and rich tints which were attractive and beautiful for their own sake. When to this conception of their art we add their general apathy in research, the measure of their sins appears to be filled up in the eyes of a generation like ours, which has brought historical evidence under conditions nearly as stringent as those which regulate the depositions of a court of justice. Still it may occur to some persons that there is another side to this matter, and that the great men of old are not wholly without defence. They were indolent in research no doubt, or rather they did not attach the value that we do to it (if they had, they were not men to have spared their pains), but they were large, sympathetic, and humane. They wrote for a public composed of men of the world and not of specialists. Their manner is somewhat off-hand, but they are neither prigs nor pedants. After all, the most important facts of history, as Auguste Comte has weightily remarked, are the best known and the least dependent on minute rectification for their true appreciation. History has an ethical and psychological side as well as a documentary side supported by elaborate citation of chapter and verse for every statement. Chapter and verse, important as they are, are sometimes a little oppressive and overbearing. The most exhaustive knowledge of authorities will not give a dull man insight into character, or enable him to realize and paint a great historic scene, or teach him to use with skill the mass of erudition under which he staggers. It may be said generally, exceptions of course excepted, that the old historians were strong where their successors are weak, and the converse. Aiming chiefly at portraiture, they succeeded in it, as was only natural. Amid a crowd of errors on smaller matters, they often catch the true expression of a physiognomy, and hit off the salient points of a character with an insight and success which subsequent inquiry is often unable to modify. Bacon's portrait of Henry VII. remains substantially correct, though he wrote his book in four months, remote from the means of knowledge accessible even in his day, which did not represent a tithe of the knowledge accessible now. Even down to the practice of introducing fictitious speeches into their histories, the old writers are not without defence. Nothing more than these speeches has moved the contempt and indignation of modern critics. Macaulay says the practice was absurd, and that if an English writer were to attempt it now he would be laughed to scorn. Yet men of the calibre of Macchiavelli, Grotius, and Bacon resorted to it. It is more a question of form and less of substance than at first glance appears. It amounts to this—How are we to render our impression of a past epoch? We may give it in broad statement, in carefully reasoned argument, supported by apt quotation and appropriate footnotes. This is the modern plan, and, to speak frankly, unquestionably the best. But it is well to listen without impatience to what can be said for the old plan by the other side. Mr Spedding, referring to the speeches which Bacon introduced into his history of Henry VII., says:—"My own opinion is that the reader is less liable to be deceived by history written on this principle than upon the modern plan, though the modern be apparently the more scrupulous. The records of the past are not complete enough to enable the most diligent historian to give a connected narrative in which there shall not be many parts resting on guesses or inferences or unauthenticated rumours. He may guess for himself, or he may report other people's guesses; but guesses there must be. The advantage of the old practice is that the invention appears in the undisguised form of invention; whereas the modern practice, by scrupulously eschewing everything like avowed and deliberate invention, leaves it to be supposed that what remains is all fact, whereas in most cases of the kind the writer is but reporting his own or another man's conjecture, just as much as if he had sat down deliberately to compose a soliloquy or a speech in the first person" (Spedding's *Bacon*, vol vi. p. 76). Every one must be glad to see even plausible reasons suggested for not regarding the funeral oration of Pericles or the speech of Galgacus as "absurdities." Perhaps the truest view of this introduction of speeches into their histories by the ancients and their modern imitators is that it was their mode of offering generalizations. They adopted the concrete and dramatic form when we should use the abstract and impersonal, and perhaps, as Mr Spedding remarks, this practice was not necessarily exposed to more error than ours.

We have now to advert to the causes which led to the transformation of history from the old to the new type.

The inferior quality of history in the 17th century and the first half of the 18th is the more remarkable from the contrast presented by the brilliancy of contemporary literature in other departments. The age of Louis XIV. in France, as already remarked, and the age of Anne in England produced no histories of superior merit. Bossuet's famous discourse on universal history is no exception, being much more an eloquent sermon than a history in the true sense of the word. Written by inferior men from a low point of view, or no point of view at all, history at last sank to such a degree in the public esteem as to be spoken of in a tone of contempt. Dr Johnson openly despised it, and D'Alembert did nearly the same. And yet the time produced great antiquaries—Madox and Rymer in England, D'Achery and Mabillon in France, Maratori in Italy, Leibnitz in Germany. But history had no stamina or muscle. It was also from our point of view blind and utterly stupid: it could not see the plainest facts, and it perverted the facts it did see. Not only the inferior men whose names are barely remembered and whose works are entirely forgotten, the Daniels, the Vellys, the Creviers, the Hooks, the Eckards, but men of such magnitude as Hume and Robertson, Gibbon and Voltaire, often show such an unintelligence as to the past that this unintelligence itself becomes an interesting historical phenomenon, casting no slur on the great writers who displayed it, but deserving consideration for its own sake.

When 18th century writers are arraigned for their defective appreciation of the Middle Ages (the great stumbling-block) and remote periods generally, their critics forget the historical positions of the men they criticize. To write history in the 18th century was something very different from what it had been before, and this in several ways. First of all, the mere lengthening of the historic retrospect had enormously increased the field of historical survey. A writer of the 18th century looked back on nearly as much as we do; he had behind him the recent modern period, the long Middle Age, the barbarian epoch, those of Greece and Rome. And it was honourable to the men of the 18th century that they did not shrink from the task of writing on this immense expanse of history, imperfectly as they were prepared for it. It seems to be sometimes forgotten that most of the historical writing of the ancients, and a good part of that of the moderns up to the 18th century, had been the writing of contemporary history, or history of a quite recent past. This is true of Herodotus (when he is not merely a traveller telling travellers' stories), of Thucydides, of Polybius, of Sallust, of Tacitus, of Guicciardini, of Fra Paolo, of Davila, of Grotius, of Clarendon. Contemporaneous history may bring out some of the highest qualities of an historian—perspicacity, weightiness of judgment and language, skill in narrative, and so forth. But one quality it does not need and cannot display, insight into a remote age differing in culture, politics, and religion from those amid which the historian lives. Yet it was precisely the history of remote ages which the writers of the 18th century boldly undertook to treat. That they often failed is not surprising. It would have been a miracle if they had succeeded.

We are now so imbued with the notions of growth and development in all forms that we find no difficulty in applying them to society as well as other phenomena. But these notions were all but entirely wanting in the 18th century; indeed, they did not fully emerge till the 19th had run a good portion of its course. It was difficult for all true sons of the 18th century to conceive of men or of societies different from the men and the societies they saw around them. Or if they were forced to admit that men could exist under conditions widely differing from those in which they themselves lived, they unhesitatingly pronounced them barbarians, unpolished, hardly worthy of attention. They consequently speak of past ages habitually in a tone of supercilious contempt which is to us highly amusing. Men who differed in every other opinion agreed in this. "The Athenians of the age of Demosthenes were a people of brutes, a barbarous people," said Dr Johnson; and Voltaire was quite of his way of thinking on this point (*Dict. Philosophique*, art. "Anciens et Modernes"). With such views or rather feelings it was impossible to understand the past; they did not even wish to do so. They mostly regarded their own age as the only one worthy of respect and admiration, the only one in which "polite manners" had existed. The past to them was mainly a record of crime, ignorance, folly, and fanaticism (notice the way in which the sober Robertson speaks of the crusades); and they did not even wish to see it as it really was. It is obvious that such men could not write history as we understand it. The moral prejudices of the age shut out a true view of past times. Indeed they preferred a distorted view, if it represented better their notions of the seemly and the noble. They had always a tendency to dress up the past in the garb of the present. The French writers surpassed the English in this foible. For them the only ideal of a king is Louis XIV., and all kings must be made to resemble him more or less, though of course they were not so great. This disposition reaches its acme of absurdity in Scipion Dupleix, historiographer of France, who died in 1661. Describing the baptism of Clovis, he represents the barbarian Frank as approaching St Remi, "with lofty port and grave demeanour, richly dressed, scented, and powdered, with long wig carefully curled and perfumed according to the custom of the ancient French kings." More serious is the profound misapprehension of every great character and great period which differed from the current pattern. The unworthy interpretation of all political and religious phenomena with which the writers were unfamiliar, by sagacious references to state and priestcraft, is also apt at times to appear to us wilfully perverse, and even disingenuous. We may be sure it was nothing of the kind, and only resulted from the inadequate degree of culture then attained.

But the historians in question were hindered not only by prejudice which they could not avoid from understanding the past; they were also hindered by a want of knowledge which it was impossible for them to have. To say nothing of the larger conceptions of society which we have only recently acquired, they were unfurnished with those preparatory means of accurately observing the past which were soon to be discovered. The science of economics, as we shall presently see, was about to throw a broad and vivid light on many hitherto obscure problems of history. But the writers in question did not yet enjoy the benefit of it, and surely the fault was none of theirs. When we see a man of the genius and erudition of Montesquieu (*Grandeur et Décadence des Romains*, c. 17) gravely ascribing the decline of old Rome to the fact that all the gold and silver after the division of the empire were carried to Constantinople, we realize the value of true conceptions relative to the wealth of nations. But in Montesquieu's time the precious metals were regarded as the sole or chief sources of wealth, and he applied without hesitation to history a principle which he saw statesmen apply without hesitation to politics. Again, Gibbon, writing on the same subject, the decline and fall of Rome, considers the real cause to have been the reluctance of the soldiers to wear defensive armour. It seems hardly credible, but here are his words:—"They (the soldiers) complained of the weight of their armour, which they seldom wore; and they successively obtained permission to lay aside both their cuirasses and their helmets. The heavy weapons of their ancestors dropped from their feeble hands, and their pusillanimous indolence may be considered the immediate cause of the downfall of the empire" (chap. 27). Montesquieu and Gibbon were men of an historical genius second to none. Yet they could descend to such trivialities, and the reason was that the true sources of national wealth and military strength had not been laid open in their day. It would be easy to multiply examples of a similar kind, taken from the ablest writers, in which the most superficial explanation of wide-reaching events is hastily caught at, as if one were to explain an earthquake by a scratching of the earth's surface. In fact the old writers might be likened to surveyors as contrasted with geologists. They have little or no conception of the forces at work under the surface they see.

But a change was near—a change in feeling and a change in knowledge. That singular modulation of key in the moral life of Europe, often called, for want of a better term, the Romantic movement, which arrested and surprised the attention of the latter half of the 18th century, was felt in relation to history as well as to philosophy, politics, and religion. Whether represented by the fierce rebellion of Rousseau in France, or a milder literary reform in England and Germany, it essentially consisted in a weariness of and disenchantment with the present and the recent past, in a vague feeling after ideas and emotions outside the conventional circle in which men had been contented to live for several generations. The tastes and the tempers of men changed with a strange rapidity. The 18th century philosophy, as it is called, lately so high and apparently secure, was cast out with contumely. The recent idols—Locke, Hume, Voltaire, Diderot—were smitten down, and others needless to name were put in their place. The whole movement is now seen to have been retrograde, and finally abortive, though temporarily successful. But it had its *raison d'être* and even its uses, as all social phenomena have. Among its uses was the service it rendered to history. As it was a first principle with the Romantics to burn what their predecessors had worshipped and the converse, the past which had been recently an object of contempt was put in the place of honour. Especially the Middle Age, so unjustly despised, seemed to rise out of its grave as a lovely vision full of knights and chivalry, troubadour song, and Gothic architecture, the latter just beginning to be appreciated. Where men had only recently seen barbarism, superstition, and ignorance, they and their sons saw an enchanted land of beauty, piety, and grace. Then came Sir Walter Scott, who turned a current already flowing fast into a headlong torrent. The Middle Age was studied eagerly, sympathetically, perhaps a little too much so; zeal never is according to knowledge. But the bringing of the Middle Age into the circle of serious historic study had an influence beyond its immediate object. When men had brought themselves to study and understand 11th century popes and emperors, monasticism, feudalism, scholasticism, they became bold and capable of further adventures in historical enterprise. After the heroic ages of Christendom, the heroic ages of Greece were opened to explorers. And soon all exclusiveness disappeared. The whole past history of man was felt to be worthy of man's study,—a wide field into which many labourers entered. So much for the change in feeling.

No less a change had taken place in the condition of knowledge. Speculation had for a long time been feeling its way to a closer contact with the problems suggested by the growing wealth and industry of the modern world. Adam Smith in his memorable work resumed, co-ordinated, and enlarged the labours of his numerous predecessors, and placed the study of economics on a new and positive basis. But the suggestive stimulus of his researches spread beyond the limits of the science with which he was immediately concerned. The indirect services rendered by political economy to history have not perhaps been adequately recognized. The elucidation of the sources of wealth in the present became a means of explaining the prosperity and decay of states in the past, which soon led to valuable results, the more striking as they were unexpected. Hitherto wealth had been thought a source rather of degeneracy than of improvement. The great danger was always understood to be "luxury." Poverty was the parent of virtue. Primitive times were virtuous because they were poor. Pagan philosophers and Christian saints had agreed in condemning riches as the source of all evil, and denying the rich man a high place in their ideal republic or the city of God. Political economy cleared up the confusion of thought here implied. The wealth of states has nothing to do with the excessive opulence of a small class. Never has the mass of the people in any country or in any age suffered from an overabundance of wealth. The excessive wealth of the few generally means the poverty of the many. In short, the evil lies in the great inequality of the distribution of wealth. These common-places of economics would have been paradoxes in the early part of the 18th century, and the historians of that age show a profound ignorance of their bearing, as was only natural. So, when they have to explain the decay of a state they seek to show that it had lost its gold and silver, or that luxury had made fearful inroads, or that martial valour had somehow strangely declined. The notion that poverty in the mass of the people was very often the chief and sometimes the only cause did not occur to them. When therefore Adam Smith devoted the third book of the *Wealth of Nations* to "the different Progress of Opulence in different Nations," it seemed as if a lamp had suddenly been lit in a dark place. That book was in truth a lofty historical review of the facts of the past, guided by the principles of economic science. The question which has already come before us, and which exercised so much, as well it might, the thinkers of that age, the decline of Rome, was approached in a much more promising manner when one element of it, the decay of agriculture in Italy, was spoken of thus:—"Tillage in that part of ancient Italy which lay in the neighbourhood of Rome must have been very much discouraged by the distributions of corn which were frequently made to the people, either gratuitously or at a very low price. This corn was brought from the conquered provinces, of which several, instead of taxes, were obliged to furnish a tenth part of their produce at a stated price. The low price at which this corn was distributed to the people must necessarily have sunk the price of what could be brought to the Roman market from Latium or the ancient territory of Rome, and must have discouraged its cultivation in that country." This was catching a glimpse of a *vera causa* of the effect to be explained, and the vein of thought thus opened proved to be richer the further it was explored.

Both the moral and the intellectual tendencies at work to produce a new temper with regard to history received an incalculable impetus from the French Revolution. That cataclysm revealed the deeper forces of society which had lain silent and unsuspected under the deceitful calm of the *ancien régime* in its latter days. It was very certainly a revelation, though light came from the flames of Tophet, in Mr Carlyle's phrase. Men saw the depth of the abyss over which they had lived in quiet ignorance, and their notions on man, society, and history underwent a great change. Passions undreamed of were let loose, and the passions of the present threw light on those of the past. History was read with new eyes. "Whenever," says a man who lived through the tempest and profited as much as any one by it,—"Whenever," says Niebuhr, "an historian is reviving past times, his interest in them and sympathy with them will be the deeper the greater the events he has witnessed with a bleeding or rejoicing heart" (Preface to *Hist. of Rome*). Few generations have seen events which alternately made men's hearts bleed and rejoice more passionately than Niebuhr's own, and none have ever stimulated history so much. With the peace of 1815 historical studies acquired an activity and scope they never had before. All history, it was perceived, needed rewriting from new points of view, with more knowledge, deeper insight, keener sympathy. The French led the van of the new movement with their usual brilliancy and mastery of literary form. But it was their position as the nearest witnesses and the greatest sufferers and gainers by the Revolution which did most to open their eyes. A truly illustrious band of scholars and writers under the Restoration, the Monarchy of July, raised history into a position of honour it had never enjoyed before. Michaud, the two Thierrys, Sismondi, Guizot, De Barante, Michelet, and many more rendered services to history which must not be forgotten because on many points their labours have been superseded. It is indeed a capital proof of the merit of their labours that they furnished the means and the incentive to their supersession, a proof that their studies were vital and progressive. The Germans, with their solid erudition, were not slow in following the French. Between the two, the Middle Ages, Greek and Roman antiquity, and the history of the Christian Church were studied with a minuteness and breadth never known before. History had entered on its modern phase.

This is not the place to dwell in detail on the achievements of the modern school of historians. The whole field of history has been explored afresh with such superior insight, knowledge, and just conception of the task in hand that all historical writings anterior in date to the end of the 18th century are entirely superseded, with the single exception perhaps of Gibbon, who alone, as Mr Freeman says, has not been set aside by subsequent research. Ancient history, chiefly in consequence of the extraordinary zeal and diligence of the Germans in what they call the science of antiquity (Alterthumswissenschaft), has become a reality, vivid in interest, and fruitful in knowledge, instead of the nebulous unreality it had been before. The rejection of the fabulous elements in the histories of Greece and Rome was the first step, but a long one, which it required many years and much effort to make. The next was to obtain a firm grasp of the idea that the Greeks and Romans were living men, and not statues like the Elgin Marbles, and to look at their politics, institutions, and religions with the discriminating eye of common sense, and a real wish to see them as they were. The true nature of Athenian democracy, of the Spartan oligarchy, of the commons and patricians of Rome, of the party struggles which caused and justified the transition from the republic to the empire, has been put in a clear light, which can hardly be appreciated by those who are not aware of the darkness which it replaced. Points of view and lines of inquiry concerning the religion, government, institutions, taxation, and law of the ancient states have been opened up, of which the possibility in the old days was not suspected. The sociological knowledge of the present has illumined the past, an interesting example of which is afforded by the *rapprochement* between the English dominion in India and the Roman provincial administration.

The history of the Middle Age shows even greater results, and greater innovation, to which allusion has been already made. The great difficulty was the papacy. Between the Catholics, who regarded it as of divine institution, and the Protestants, who regarded it as a manifestation of Antichrist, and the sceptics, who despised both and regarded it as mere superstition, this great centre around which the life of the Middle Ages revolved had been unknown or misknown to a degree of absurdity. Gradually, as the 19th century arose wiser and sadder out of the chaos of the French Revolution, the immense part played by the church was at first dimly suspected, and at last with increasing clearness perceived. This must on every account be regarded as the greatest achievement of the modern school; it implied the unlearning of so many old errors, the acquiring of so many new truths, above all, the repression of so many deeply-rooted prejudices. It restored the continuity of history, in which the Middle Ages had hitherto appeared as an unexplained gap,—an unwelcome wedge of barbarism thrust between the ancient and modern civilizations.

After the Middle Ages, the period which has been most illumined by the new lamp of history is that of the early church and the whole subject of religious dogma and institutions. In spite of the fierce controversies which have raged over this region, a large residuum of undisputed fact has been rescued from ignorance and prejudice, and church history is no longer a legend, but one of the most interesting chapters in the annals of the human mind.

As regards modern history, we are oppressed and nearly overwhelmed with the mass of new materials and new discoveries which have been launched upon us. The diligent publication of state papers and documents, which all civilized states have taken in hand, has exceeded in the last half century all that had been done before in that direction. The result is that there are few periods of modern history which are not far better known to us than they were to the contemporaries who lived in them. But history in this field cannot boast of such laurels as she has won in the field of antiquity and the Middle Ages. There has been no great reversal of old points of view, no great triumph of historical perspicacity piercing through traditional error down to latent truth. Modern history has won its victories more by weight of metal than by the skill of its commanders, not that the generals have lacked skill, but they have had less occasion to display it.

The history of institutions has received much attention in recent times, and promises to be one of the most fruitful veins of inquiry yet opened, and this in reference both to primitive institutions, which are rather prehistorical than historical, and the constitutions of states which have reached adult political life. The old Aryan tenure of land and village communities, and ancient law, whether in old Rome or modern Bengal, have been the subjects of elaborate investigation, embodied in works which mark a new departure in knowledge. The institutional history of political states is at the present moment perhaps the subject which attracts the most lively attention of scholars. It is not confined to the constitutional history of England, though England, as the mother of parliaments, has a fair claim to priority of interest. But the subject is narrowed and degraded by contemplating it from the point of view of modern politics, and chiefly in reference to the popular freedom or national wellbeing produced. The earnest historical inquirer is as impartial as the pathologist who studies disease equally with health. The institutions of despotism have their *raison d'être* and normal evolution as well as those of free governments, and the scientific historian will neglect the one as little as the other. In any case the history of the institutions of Europe from the times of the Frankish empire to the end of the French monarchy offers the widest field for courageous historical research. It has absorbed and transcended all those inquiries which used to be included under the somewhat jejune title of the history of civilization. Institutions in the secular order, and religions in the spiritual order, are now seen to be the most massive and permanent factors in human life, capable indeed of evolution and change, but little susceptible to the immediate action of man's intelligence and will, and yielding only to the new modifications brought about by time and the gradual transformation of ideas and moral conceptions, the result of increased knowledge.

It is hardly necessary to add that a broad distinction must be made between history and what has been called the philosophy of history, a term now replaced by the far better one "sociology," invented by A. Comte. Sociology has the purely scientific aim of investigating the nature and constitution of societies, to discover the laws which regulate their growth and decay, to do in short for them what biology has already done for the animal and vegetable kingdoms. History, while it can never again dispense with the assistance of sociology, remains occupied with the description of the social organism (at a given period) in its *ensemble*, and the term "descriptive sociology" has been suggested as an improvement on the old one, history. We may question whether the innovation will be accepted or is needed. The human interest attaching to the story of man's past fortunes will always provoke the means of its own satisfaction, and there is little doubt that history, the name and the thing, as the highest form of prose literature, will continue to instruct and console mankind to the remotest generations. (J. C. MO.)

HIT, the ancient *Is* (see EUPHRATES, vol. vii. p. 670), a town of Asiatic Turkey, vilayet of Baghdad, is situated on the west bank of the Euphrates, 70 miles W.N.W. of Baghdad. Its streets are narrow and frequently steep, rising one above another along the side of a hill, and the houses, which are flat-roofed, and one or two stories in height, are built chiefly of clay. It contains a graceful minaret and some richly decorated tomb-towers. The prosperity of the town depends upon its fountain of bitumen, which has flowed from time immemorial, and, according to Herodotus, supplied that material for the building of Babylon. The inhabitants make use of the bitumen for lime burning, and also for covering boats. From water which bubbles up in the centre of the spring salt is manufactured. The population is about 3000.

HITCHCOCK, EDWARD (1793-1864), an American geologist, was born of poor parents at Deerfield, Massachusetts, May 24, 1793. He owed his education chiefly to his own exertions, and was preparing himself to enter Harvard College when he was compelled to interrupt his studies from a weakness in his eyesight. In 1815 he became principal of the academy of his native town; but he resigned this office in 1818 in order to study for the ministry. Having been ordained in 1821 pastor of the Congregational church of Conway, Massachusetts, he employed his hours of leisure in making a scientific survey of the western counties of the State. In 1825 he resigned his charge in order to become professor of chemistry and natural history in the newly-founded Amherst College, an institution which owed its early success, if not its continued existence, to his energetic efforts, both in rescuing it from financial difficulties, and in increasing its literary and scientific efficiency. More especially did he render to it invaluable service during the period when he was president, from 1845 to 1854. In 1830 he was appointed State geologist of Massachusetts, and in 1836 to the same office in connexion with the first district of the State of New York. On resigning the presidentship of Amherst College, he was induced to retain his professorship. In 1836 he received the degree of LL.D. from Harvard, and in 1846 that of D.D. from Middlebury College. Besides his constant labours in geology, zoology, and botany, Hitchcock took an active interest in agriculture, and in 1850 he was sent by the Massachusetts legislature to examine into the methods of the agricultural schools of Europe. In geology his most important achievement was the examination and exposition of the fossil footprints of the Connecticut valley. The collection which he accumulated in connexion with his investigations is contained in the Hitchcock Ichnological Museum of Amherst College, and a description of it was published in 1858 in his report to the Massachusetts legislature on the ichnology of New England. As a writer on geological science, Hitchcock was mainly concerned in determining the connexion between it and religion, and employing its results to explain and support what he regarded as the truths of revelation. He died at Amherst, February 27, 1864.

The following are his principal works:—*Geology of the Connecticut Valley*, 1823; *Catalogue of Plants within twenty miles of Amherst*, 1829; *Dyspepsia Forestalled and Resisted*, 1830; *Reports on the Geology of Massachusetts*, 1832, 1835, 1838, and 1841; *A Wreath for the Tomb*, 1839; *Fossil Footsteps in the United States*, 1848; *Outlines of Geology*, 1855; *Illustrations of Surface Geology*, 1856; *Ichnology of New England*, 1858; *Religious Lectures on the Peculiar Phenomena of the Four Seasons*, 1850; *History of a Zoological Temperance Convention in Central Africa*, 1850; *The Religion of Geology and its Connected Sciences*, 1851; *Religious Truths illustrated from Science*, 1857: *Reminiscences of Amherst College*, 1863; and various papers in the *Biblical Repository*, the *Bibliotheca Sacra*, the *American Journal of Science*, and other periodicals.

HITCHIN, a market-town of Hertfordshire, England, is situated on the small river Hiz, 34 miles from London, on the Great Northern Railway. It is for the most part neatly built of brick, and the streets are generally spacious. The principal buildings are the parish church in the later style of English architecture, with a fine porch, an Adoration of the Magi by Rubens, a small crypt said to have been used by Cromwell as a prison for the Royalists, and many interesting monuments; Hitchin Priory, the residence of the Radcliffe family; various chapels, schools, and banks; the infirmary, the workhouse, the town-hall, and the corn exchange. Malting and straw-plaiting are extensively carried on. There are also breweries and manufactories of agricultural implements. The population of the local board district in 1871 was 7630, and of the parish 8850.

Hitchin occurs in Domesday Book under the name of Hiz, a modification of the Saxon Hiece or Hitche, which appears more prominently in the present form of the name. During the Saxon heptarchy it formed part of the royal demesne of the king of Mercia. It was bestowed by Edward the Confessor upon Harold, and after the battle of Hastings it was retained by William the Conqueror. By William Rufus it was granted to Bernard de Baliol, and on the accession of John Baliol to the throne of Scotland it reverted to the crown of England, after which it was bestowed by Edward III. on his fifth son, Edmund de Langley.

HITTITES, a warlike and powerful nation, whose centre lay in the far north of Syria, between the Orontes and the Euphrates, but whose outposts about 1200 B.C. extended as far to the west as the Ægean sea. In the Egyptian inscriptions they are called the Khita or Kheta; in the Assyrian, the Khatti; in the Hebrew Scriptures, the Khittim. Some confusion has been caused in the treatment of the history of the Hittites by the uncritical use of the Old Testament. It is true that the Khittim or Hittites are repeatedly mentioned among the tribes which inhabited Canaan before the Israelites (Gen. xv. 20; Ex. iii. 8, 17, xiii. 5, xxiii. 23, 28, xxxiii. 2, xxxiv. 11; Num. xiii. 29; Deut. vii. 1, xx. 17; Josh. iii. 10, ix. 1, xi. 3, xii. 8, xxiv. 11; Judg. iii. 5; 1 Kings ix. 20; 2 Chr. viii. 7; Ezra ix. 1; Neh. ix. 8), but the lists of these pre-Israelitish populations cannot be taken as strictly historical documents. Not to dwell on the cases of the Perizzites (properly speaking, an appellative and not an ethnic name), and the Kenites and other Arab races, sometimes included, but evidently by an anachronism (see vol. iv. p. 763), it is obvious that narratives written, or (as all will agree) edited, so long after the events referred to cannot be taken as of equal authority with Egyptian and Assyrian inscriptions. How meagre the tradition respecting the Hittites was in the time of the great Elohistic narrator is shown by the picture of Hittite life in Gen. xxiii. As Ewald remarks, "Abraham's allies in war are Amorites; but when he desires to obtain a possession peaceably he turns to the Hittites." Yet the undoubtedly authentic inscriptions of Egypt and Assyria reveal the Hittites in far different guise, as pre-eminently a warlike, conquering race. Not less unfavourable to the accuracy of the Old Testament references to the Hittites is the evidence deducible from proper names. As we shall see presently, the Hittite names preserved in Egyptian and Assyrian records are on the whole strikingly un-Semitic. The three Hittite names given in the Old Testament (Ephron, Gen. xxiii. 8, 10; Ahimelech, 1 Sam. xxvi. 6; Uriah, 2 Sam. xi. 3, xxiii. 39) are, however, of undeniably Semitic origin. Is it unnatural to infer that these three names are no less fictitious than the Semitic names ascribed in the Old Testament to the non-Semitic Philistines? It is not surprising that at least two eminent Egyptologists (Chabas, Ebers) should absolutely deny the identity of the Khita and the Khittim. This, however, seems to be going too far. The Old Testament writers clearly meant by the latter name the same people as the Egyptian inscriptions by the former, but in their time the memory of the Khita had grown so dim that they could include it among other shadowy names of conquered Canaanitish peoples. No impartial scholar, indeed, will deny that a branch of the Khita may once have existed in Palestine. Unfortunately there is no historical evidence that it did so. In fact, the most trustworthy notices in the Old Testament itself point to the Hittites as a nation beyond the borders of the land of Israel. In 2 Kings vii. 6 we find "the kings of the Hittites" mentioned side by side with "the kings of the Egyptians;" in 1 Kings x. 29 the same phrase occurs parallel with "the kings of Aram"; and in 2 Sam. xxiv. 6 we should probably read, "and they came to Gilead, and to the land of the Hittites unto Kadesh." The position of Heth in the table of nations (Gen. x. 15) may also be regarded as a vestige of an accurate geographical tradition.

If then we continue to employ the familiar name Hittites instead of the Egyptian Khita and the Assyrian Khatti, let it be understood that by this term we do not indicate one of the Canaanitish peoples conquered by the Israelites, but an extra-Palestinian race capable of holding its own even against Egypt and Assyria. Its centre lay, as we have seen already, and as is admitted on all hands, between the Euphrates and the Orontes. This was in fact the region which—one fears to say for how many centuries—was designated in the Assyrian inscriptions *mat Khatti* or Khatti-land. Under the name of Khatti we already meet with the Hittites in the astronomical work in seventy tablets drawn up by Sargina, king of Agane, in the 16th century B.C. It appears from this venerable document that hostilities were constantly arising between Babylonia on the one hand and the Hittite country on the other (Sayce's translation of the tablets, *Transactions of Soc. of*

Biblical Archæology, iii. 245). Among the Assyrian kings it is Tiglath Pileser I. who makes the first mention of the Khatti; in his time they are already the lords paramount of the region between the Euphrates and Lebanon. Sargon, the most enterprising of the Assyrian monarchs, was impatient of such an obstacle to his victorious arms. By the conquest of Carchemish and Kummuch, Khatti-land lost its two great bulwarks on the east, and was open henceforth to the Assyrian hosts. The last reference to the Khatti is in the time of Esar-haddon, who speaks of "twenty-two kings of the land of Khatti, which is by the sea and in the midst of the sea." But it has been shown by Schrader that from the time of Sennacherib onwards the name Khatti was transferred to the western maritime lands in general, viz., Canaan and Philistia, including Edom, Moab, and Ammon (*Keilinschriften und Geschichtsforschung*, pp. 234–5).

Turning now to the hieroglyphic monuments, we find the Khita playing a still more important part in the history of Egypt,—first of all, under Thothmes III. One of his generals has left us an account of his personal experiences in the campaign against the Khita (Brugsch, *History of Egypt*, i. 354), and in the Statistical Tablet of Karnak we have a record of the tribute brought from "the great land of the [Khita]" (*ibid.*, p. 334, comp. *Records of the Past*, ii. 25). At this period, however, the Khita were but one among a number of peoples; in the wars of Seti I. and (especially) Ramses II., they occupy the first rank among the adversaries of Egypt. The account of the battle of Kadesh (the island city on the Orontes), given by the Theban poet Pentaur, presents a vivid picture of the military prowess of this rising power (comp. Brugsch's translation with that of Lushington in *Records of the Past*, ii. 65–78). Ramses was indeed victorious, but he owed his life and consequently his victory to his personal bravery, and, as Pentaur represents it, to his childlike faith in his god. On an outer wall of the temple of Karnak the treaty of peace between Egypt and Khita-land may still be read (comp. Brugsch's translation with that of Goodwin in *Records of the Past*, iv. 25–32), and the same fruitful source of primitive history has furnished inscriptions of Ramses, with the names of conquered towns of the Khita, corresponding with those already recorded by Thothmes III. Thus the long feud between Egypt and Khita was closed, and the happy result was celebrated by the marriage of the Pharaoh to a daughter of the king of his chivalrous antagonists. The name of the Khita almost disappears henceforth from Egyptian history. M. Lenormant indeed (*Ancient History of the East*, i. 268) mentions them as assailing Ramses III., but Dr Birch (*Egypt*, p. 139) and Brugsch Bey more accurately describe the war referred to as one between Ramses and the conquerors of the Khita, viz., the confederated "Carian-Colchian nations" (see Brugsch Bey, *History of Egypt*, ii. 147).

We have spoken of the Hittites as we know them from the monuments, as a people of Syria. But the extra-monumental history of the Hittites, which is only beginning to be divined from scattered indications, shows that their power was not limited to the area between the Euphrates and the Orontes. Not only had they their confederates or vassals in their near or more distant neighbourhood, but they also (as it seems) despatched conquering hosts into the far-off regions of Asia Minor. Even the Egyptian records have been thought to indicate this fact. At that great battle of Kadesh on the Orontes to which we have already referred, there were present, besides the princes of Khita, the kings of Arathu, Khilibu, Naharain, Qazanadana, Malunna, Pidasa, Leka, the Dardani or Dandani, the Masu, Kerkesh or Keshkesh, Kairkamasha (so Lushington; Brugsch, somewhat arbitrarily perhaps, Quirqimosh), Aherith, Anangas, Mushanath,—a mighty host "gathered" (as the poet Pentaur tells us) "from the margin of the sea to the land of Khita." The late M. de Rougé, a coryphæus in Egyptology, actually supposed that this list included the Dardani of Asia Minor, the Mysians, Ilion, and perhaps the Lycians; Brugsch Bey, however, who is now a greater authority, is satisfied to identify the Dardani with those of Kurdistan (comp. Herod., i. 189), the Leka with the Ligyes (comp. Herod., vii. 72), and the Masu with the people of Mount Masius. But putting M. de Rougé's opinion aside, it seems to be evident from other sources that the influence of the Khita extended even into Asia Minor. Prof. E. Curtius has already pointed out "that one of the paths by which the art and civilization of Babylonia and Assyria made its way to Greece was along the great high road which runs across Asia Minor," and Professor Tiele has been struck by the presence in the religions of Asia Minor of an unexplained element which with all reserve he conjectures may be Hittite. Professor Sayce has added an important contribution to the question by showing that the Hittite capital Carchemish (rightly identified by Mr George Smith with the modern Jerablûs) was the source from which that modified type of Assyrian art was derived, which specially characterizes the early monuments of Asia Minor. "The sculpture accompanied by inscriptions in Hittite (or Hamathite) characters which Mr Davis discovered at Ibreez in Lycaonia (*Transactions of Soc. of Bibl. Archæology*, iv. 2) proves that the Hittites had penetrated through the eastern barrier of Asia Minor formed by the Taurus range; and the two or three characters that still remain in the rock-cut inscription engraved in his *Life in Asiatic Turkey* (p. 222), and found near Bulgar Maden, make it clear that Hittite power had once extended at least as far as the central plateau of Asia Minor." Evidence has now been supplied of the extension of Hittite power to the very shores of the Ægean in the occurrence of Hittite hieroglyphics (the same which occur at Jerablûs or Carchemish) on the pseudo-Sesostris (a fellow to which has, however, been pointed out) at Ninfi, the ancient Nymphæum, on the road from Smyrna to Sardes (Letter of Professor Sayce, in *Academy*, Aug. 16, 1879). In a subsequent letter, Professor Sayce remarks that there were two roads open to the Hittites, and both, to judge by the scattered monuments already found, appear to have been travelled by their armies. The one was that taken by Crœsus on his march against Cyrus; its course was through Pessinus, Ancyra, and Pterium. The other was that traversed by Xenophon and the Ten Thousand; this road passed through the Cilician Gates by Iconium. Both roads met in Sardes.

Was this enterprising race a member of the Semitic family? Let us consider—

(1.) *The evidence supplied by the pictorial representations on the ancient monuments.*—"If it is allowable to form a judgment on the origin of this cultivated and powerful people from its outward bearing and appearance, it seems to us, under the guidance of the monuments, to be at least very doubtful whether we should reckon this chivalrous race among the Canaanites" (who, see art. CANAANITES, were probably in the main Semitic). "Beardless, armed in a different manner, fighting three men on each chariot of war [the Egyptian chariots only carry two], arranged in their order of battle according to a well considered plan previously laid down, the Khita present a striking contrast to their Canaanite allies." Such is the verdict of Brugsch and of all who have seen the wonderful wall-sculptures in the great temple of Abusimbel. No modern artist is more careful to represent distinctive racial features than this primitive sculptor. Even at such a distance from this national centre as Ninfi (see above), Professor Sayce maintains that no one who has once seen a Hittite figure can mistake the resemblance. The peaked tiara and the turned-up shoes are the peculiar marks of the Hittite, and of the Hittite alone.

(2.) *The evidence from language.*—Our knowledge of the Hittite language is confined to the proper names mentioned in the Egyptian and Assyrian inscriptions—those which occur in the Hebrew Bible being, as we have seen, of insufficient authority. Opinions differ as to the character of the names derived from hieroglyphic sources. M. de Rougé was strongly convinced of their Semitic origin, but his explanations are for the most part adventurous, and Brugsch Bey's verdict seems philologically much more sound, "that these names do not bear a Semitic, or at any rate not a pure Semitic stamp." The names of persons are the following, as represented by M. de Rougé:—Khetasar, Maursar, Kanisar, Taurteribu, Aktasib, Net'era, Tot'as, Rabasunana, Tarakaunasa, Mait'arima, Kamaiut'a, Taatur, Sapalel, Samarisa, Painsa, Akama, Tuher, Kirabsar. To these may be added the following from the list of nations of Thothmes III.:—Pirkheta, Ai, Anau, Thuka, Thel-manna, Legaba, Tunipa, Ni, Ar, Zizal, Zakal, Arzakana (Brugsch, *History of Egypt*, ii. 5). No less un-Semitic for the most part are the names of Hittite persons and places which occur on the Assyrian monument. The following is a list of the kings of Khatti-land given by Shalmaneser II. on the monolith inscription: "Sangar of Carchemish, Kundaspi of Kummuch, Arami, son of Gusi, Lalli of Lallid, Chayan, son of Gabar, Girparud of Patin, Girparud of Gamgum" (lines 82, 83), to which should be added "Sapalulmi of Patin" (lines 42, 43), which so strongly reminds one of the name of the king of Khita, Sapalili, mentioned in the treaty between Ramses II. and the Khita. The un-Semitic character of this group of names is the more remarkable, because (as Professor Sayce remarks) Assyrian, being itself a Semitic language, could not help representing foreign Semitic names in a form recognizable as Semitic. How obviously Semitic, for instance, are the names of the kings of Hamath and Damascus, handed down to us in the Assyrian inscriptions! True, one of the above names of Hittite places, Carchemish ("fortress of Chemosh"), has a Semitic air, and the same may be said of Kadesh, the scene of the victory of Ramses II. But (1) it is not quite certain that Carchemish is Semitic (the Assyrians generally reproduce it under the form Gargamis, though sometimes Kargamis), and (2) even if it is Semitic, this may arise from the towns having been occupied by Semites prior to the Hittites. As for Kadesh (in the Egyptian inscriptions, Ketesh), though under the jurisdiction of the Khita, it was reckoned as a Canaanitish or more strictly an Amoritish town (Birch, *Egypt*, p. 116), while Orontes (in Egyptian, Arunata) has not even a Semitic appearance. It is true, again, that several of the Hittite proper names are compounded with *sar—e.g.*, Khita-sar (the king who warred against Ramses II.), and that *sar* is evidently the Assyrian for "king" (also Hebrew for "prince"). But *sar* is also found in Egyptian inscriptions; it is in fact of Accadian (non-Semitic) origin, and was therefore borrowed by the Assyrians, before the Hittites and the Egyptians adopted it from them. The form of names like Kheta-sar (see list above) favours the view that the Hittite language was agglutinative, and consequently non-Semitic.

But this and all other aspects of Hittite culture will appear in a new light when the explorations have made further progress. At present we can only say that the probability is that the Hittites are not Semitic; in fact, they display an originality of genius which is not strikingly characteristic of pure Semitic races. The hypothesis which regards them as the early civilizers of Asia Minor seems confirmed by the position of Carchemish, so favourable to the radiation of civilizing influences. The importance of the Hittite capital in a commercial respect is known to all. The *maneh* or mina of Carchemish is constantly mentioned on the cuneiform tablets; probably it was of lighter weight than the silver mina in use in Phœnicia (see Mr Barclay V. Head's letter in *Academy*, Nov. 22, 1879). Of the religious life of the Hittites we are hardly in a position to speak. We know indeed that, like the Hyksos, they worshipped Sutekh (who was localized, like Baal, as the patron of particular cities on the treaty of Ramses II.), and, like the Canaanites, Astarata or Ashtoreth. The worship of Astarata will account for the name Hierapolis given afterwards, as it seems, to Carchemish, as well as to other Syrian cities (Jerablûs being a corruption of Hierapolis). But beyond this all is dark. Did the Hittites borrow in religious matters from the Assyrians? Had they legends relative to the origin of the world, and in what relation do these stand to the Hebrew narratives? Passing to philology in the narrower sense of the word, we wait longingly for a confirmation of Professor Sayce's view that the Hittites were the authors of the Hamathite hieroglyphics. No Semitic nation ever invented a syllabic system of writing; the Hittites are in all probability non-Semitic, and from their enterprising character are precisely the people likely to have invented such characters. Professor Sayce has followed up this conjecture by another of no less importance, viz., that the enigmatical Cypriote syllabary is really derived from the hieroglyphics of Hamath. If this be proved (and the propounder of it claims to have the evidence ready), and if the Hittites be really the inventors of the Hamathite hieroglyphics, this wonderful nation steps into a position hardly surpassed by that of any of the nations of the distant East.

Authorities.—Documents in Brugsch's *History of Egypt*, compared with the parallel passages in *Records of the Past*, vols. ii., iv.; "Monolith Inscription of Shalmaneser," *Records of the Past*, iii. 25–36; Schrader, *Keilinschriften und Geschichtsforschung*, pp. 225–236; Brugsch, *History of Egypt*, ii. 2–8; Chabas, *Voyage d'un Egyptien*, pp. 318–332; Vicomte de Rougé, *Mélanges d'archéologie Assyrienne et Égyptienne*, 1875, p. 264, &c. (posthumous); letters of Professor Sayce in *Academy*, Aug. 16 and Nov. 1, 1879. On the site of Carchemish, see Schrader, *Keilinschriften*, &c., pp. 221–225; Maspero, *Journal des Savans*, Oct. 1873; and Pococke's *Account of the Ruins of Jerabus (Jerablûs)*; *A Description of the East*, &c., 1743–45, ii. 165. (T. K. C.)

HITTORFF, JACQUES IGNACE (1793–1867), French architect, was born at Cologne, August 20, 1793. After serving an apprenticeship to a mason in his native town, he went in 1810 to Paris, and studied for some years at the Academy of the Fine Arts, where he was a favourite pupil of the Government architect Bélanger, who in 1814 appointed him his principal inspector. Succeeding Bélanger as Government architect in 1818, he designed many important public and private buildings in Paris and also in the south of France. After making architectural tours in Germany, England, Italy, and Sicily, he published the result of his observations in the latter country in the work *Architecture antique de la Sicile* (3 vols. 1826–30; new edition, 1866–67), and also in *Architecture moderne de la Sicile* (1826–35). One of his important discoveries was that colour had been made use of in ancient Greek architecture, a subject which he especially discussed in *Architecture polychrome chez les Grecs* (1830), and in *Restitution du temple d'Empédocle à Sélinunte* (1851); and in accordance with the doctrines enunciated in these works he was in the habit of making colour an important feature in most of his architectural designs. His principal building is the church of St Vincent de Paul in the basilica style. He also designed many of the embellishments of the Place de la Concorde, the Champs-Élysées—where he constructed the Circus of the Empress, which has been the model of many similar buildings in various parts of Europe—the Bois de Boulogne, and other places. In 1833 he was elected a member of the Academy of Fine Arts. He died at Paris, March 25, 1867.

HITZIG, FERDINAND (1807–1875), exegete and Biblical critic, was born at Hauingen, Baden, where his father was an evangelical pastor, on June 23, 1807, received his early education at the pädagogium of Lörrach and at the lyceum of Carlsruhe, and entered the university of Heidelberg as a student of theology in the autumn of 1824. There he remained for a year, attending the lectures in exegesis and church history of Paulus the famous "rationalist"; but in 1825 he removed to Halle where Gesenius first decided him to devote himself to Old Testament subjects. His next step was to Göttingen in 1828, where he had Ewald for his master, and where in 1829 he graduated, the subject of his thesis being *De Cadyti Urbe Herodotea*. Returning to Heidelberg shortly afterwards, he "qualified" as "privatdocent" in theology the same year, and in 1831 published his *Begriff der Kritik am Alten Testamente praktisch erörtert*, a treatise in which the critical principles of the grammatico-historical school were stated with great fulness, clearness, and cogency; also *Des Propheten Jonas Orakel über Moab*, an exposition of the 15th and 16th chapters of the book of Isaiah attributed by him, as by many subsequent critics, to the prophet Jonah mentioned in 2 Kings xiv. 25. His next literary performance was a commentary on Isaiah (*Uebersetzung u. Auslegung des Propheten Jesajas*), the publication of which in 1833 was soon followed by a call to an ordinary professorship of theology in the university of Zurich. There he laboured for a period of twenty-eight years, during which, besides commentaries on *The Psalms* (1835–36; 2d ed., 1863–65), *The Minor Prophets* (1838; 3d ed., 1863), *Jeremiah* (1841; 2d ed., 1866), *Ezekiel* (1847), *Daniel* (1850), *Ecclesiastes* (1847), *Canticles* (1855), and *Proverbs* (1858), he published a monograph, *Ueber Johannes Markus u. seine Schriften* (1843), in which he maintained the chronological priority of the second gospel, and sought to prove that the Apocalypse was written by the same author, and various treatises of archæological interest, of which the most important are *Die Erfindung des Alphabets* (1840), *Urgeschichte u. Mythologie der Philistäer* (1845), and *Die Grabschrift des Eschmunezar* (1855). In 1861 he was called to succeed

Umbreit in the chair of theology at Heidelberg; there he wrote his *Geschichte des Volkes Israel* (1869–70), in two parts, extending respectively to the end of the Persian domination and to the fall of Masada, 72 A.D., as well as *Zur Kritik Paulinischer Briefe* (1870), *Die Inschrift des Mescha* (1870), *Sprache u. Sprachen Assyriens* (1871), besides revising Hirzel's commentary on Job (1874). He was also a frequent contributor to the *Monatsschrift des wissenschaftlichen Vereins in Zürich*, the *Zeitschrift der Deutschen Morgenländischen Gesellschaft*, the *Theologische Studien u. Kritiken*, Zeller's *Theologische Jahrbücher*, and Hilgenfeld's *Zeitschrift für wissenschaftliche Theologie*. Hitzig died at Heidelberg on January 22, 1875. As a Hebrew philologist he holds very high rank; and as a constructive critic he is remarkable for the acuteness and sagacity shown in his combinations. His theories, however, are often carried out with a vigour and rigour quite unwarranted by the amount of evidence upon which they rest; and his deficiency as a commentator in ideality and religious sympathy sometimes almost approaches the ludicrous. His lectures on Biblical theology (*Vorlesungen über biblische Theologie u. Messianische Weissagungen*) have been recently published (1880), along with a portrait and biographical sketch by Kneucker. See also Kamphausen's article in Herzog and Plitt's *Realencyklopädie*, vol. vi.

HOACTZIN, or HOATZIN, a bird of tropical South America, thought by Buffon to be that indicated by Hernandez or Fernandez under these names, the *Opisthocomus hoazin* or *O. cristatus* of modern ornithologists—a very curious and remarkable form, which has long exercised the ingenuity of classifiers. Placed by Buffon among his "*Hoccos*" (Curassows), and then by P. L. S. Müller and Gmelin in the Linnæan genus *Phasianus*, some of its many peculiarities were recognized by Illiger in 1811 as sufficient to establish it as a distinct genus, *Opisthocomus*; but various positions were assigned to it by subsequent syste-

Hoactzin.

matic authors, whose views, not being based on any information respecting its internal structure, do not here require particular attention. L'Herminier was the first to give any account of its anatomy (*Comptes Rendus*, 1837, v. p. 433), and from his time our knowledge of it has been successively increased by Johannes Müller (*Ber. Akad. Wissensch. Berlin*, 1841, p. 177), Deville (*Rev. et Mag. de Zoologie*, 1852, p. 217), Gervais (Castelnau, *Expéd. Amérique du Sud, Zoologie, Anatomie*, p. 66), Prof. Huxley (*Proc. Zool. Society*, 1868, p. 304), Mr Perrin (*Trans. Zool. Society*, ix. p. 353), and Garrod (*Proc. Zool. Society*, 1879, p. 109). After a minute description of the skeleton of *Opisthocomus*, with the especial object of determining its affinities, Prof. Huxley declared that it "resembles the ordinary Gallinaceous birds and Pigeons more than it does any others, and that when it diverges from them it is either *sui generis* or approaches the *Musophagidæ*." He accordingly regarded it as the type and sole member of a group, named by him *Heteromorphæ*, which sprang from the great Carinate stem later than the *Tinamomorphæ*, *Turnicomorphæ*, or *Charadriomorphæ*, but before the *Peristeromorphæ*, *Pteroclomorphæ*, or *Alectoromorphæ*. This conclusion is substantially the same as that at which Garrod subsequently arrived after closely examining and dissecting specimens preserved in spirit; but the latter has gone further and endeavoured to trace more particularly the descent of this peculiar form and some others, remarking that the ancestor of *Opisthocomus* must have left the parent stem very shortly before the true *Gallinæ* first appeared, and at about the same time as the independent pedigree of the *Cuculidæ* and *Musophagidæ* commenced—these two groups being, he believed, very closely related, and *Opisthocomus* serving to fill the gap between them.

It would be impossible here to state at length the facts on which these views are grounded, and equally impossible to give more than a very few details of the anatomy of this singular form. The first thing that strikes the spectator of its skeleton is the extraordinary structure of the sternal apparatus, which is wholly unlike that of any other bird known. The keel is only developed on the posterior part of the sternum—the fore part being, as it were, cut away, while the short furcula at its symphysis meets the manubrium, with which it is firmly consolidated by means of a prolonged and straight hypocleidium, and anteriorly ossifies with the coracoids. This unique arrangement seems to be correlated with the enormously capacious crop, which rests upon the furcula and fore part of the sternum, and is also received in a cavity formed on the surface of each of the great pectoral muscles. Furthermore this crop is extremely muscular, so as more to resemble a gizzard, and consists of two portions divided by a partial constriction, after a fashion of which no other example is known among birds.

The Hoactzin appears to be about the size of a small Pheasant, but is really a much smaller bird. The beak is strong, curiously denticulated along the margin of the maxilla near the base, and is beset by diverging bristles. The eyes, placed in the middle of a patch of bare skin, are furnished with bristly lashes, resembling those of Hornbills and some few other birds. The head bears a long pendent crest of loose yellowish feathers. The body is olive-coloured, varied with white above, and beneath is of a dull bay. The wings are short and rounded. The tail is long, and tipped with yellow. The legs are long, the feet stout, the tarsi reticulated, and the toes scutellated; the claws long and slightly curved. According to all who have observed the habits of this bird, it lives in bands on the lower trees and bushes bordering the streams and lagoons, feeding on leaves and various wild fruits, especially, says Mr Bates (*Naturalist on the River Amazons*, i. p. 120), on those of a species of *Psidium*, and it is also credited with eating those of an arum (*Caladium arborescens*), which grows plentifully in its haunts. "Its voice is a harsh, grating hiss," continues the same traveller, and "it makes the noise when alarmed, all the individuals sibilating as they fly heavily away from tree to tree, when disturbed by passing canoes." It exhales a very strong odour—wherefore it is known in British Guiana as the "Stink-bird"—compared by Mr Bates to "musk combined with wet hides," and by Deville to that of a cow-house. The species is said to be polygamous; the nest is built on trees, of sticks placed above one another, and softer materials atop. Therein the hen lays her eggs to the number of three or four, of a dull yellowish-white, somewhat profusely marked with reddish blotches and spots, so as to resemble those of some of the *Rallidæ* (*Proc. Zool. Society*, 1867, pl. xv. fig. 7. p. 164). In the valley of the Amazon it is called the "*Cigano*" or Gipsy, and in no part of the country where it occurs does it seem to be regarded with much favour. Only one species of the genus is known to have existed, for Mr Wallace's statement (*Geogr. Distrib. Animals*, i. p. 164) that remains of a second have been found in Brazilian caves seems to have originated in a mistake. (A. N.)

HOADLY, BENJAMIN (1676–1761), the originator of the Bangorian controversy, was the second son of the Rev. Samuel Hoadly, and was born at Westerham, Kent, November 14, 1676. After receiving his early education under the direction of his father, he entered Catherine Hall, Cambridge, where he graduated M.A. and was for two years tutor, after which he held for ten years the lectureship of St Mildred in the Poultry, and along with it for the last eight years the rectory of St Peter-le-Poer, London. His first appearance as a controversialist was against Mr Calamy in reference to conformity, and immediately after this he engaged in a more important dispute with Bishop Atterbury against the Anglican doctrine of nonresistance. His principal treatises on this subject were the *Measures of Submission to the Civil Magistrate* and *The Origin and Institution of Civil Government discussed*; and his part in the discussion was so much appreciated by the Commons that in 1709 they presented an address to the queen praying her to "bestow some dignity in the church on Mr Hoadly for his eminent services both to church and state." The queen returned a favourable answer, but the dignity was not conferred. In 1710 he was presented by a private patron to the rectory of Streatham in Surrey. In 1715 he was appointed chaplain to the king, and the same year he obtained the bishopric of Bangor. In 1716 he published a *Preservative against the Principles and Practices of Nonjurors in Church and State*, and in the following year preached before the king his famous sermon on the *Kingdom of Christ*, which was immediately published by royal command. These works were attacks on the divine authority of kings and of the clergy, but as the sermon dealt more specifically and distinctly with the power of the church, its publication caused an ecclesiastical ferment which in certain aspects has no parallel in religious history. It was at once resolved to proceed against him in convocation, but this was prevented by the king proroguing the assembly, a step which had consequences of vital bearing on the history of the church, since from that period the great Anglican council ceased to transact business of a more than formal nature. The restrained sentiments of the council in regard to Hoadly found expression in a war of pamphlets known as the Bangorian controversy, which, partly from a want of clearness in the statements of Hoadly, due perhaps both to his intellectual defects and to a cautious regard to ulterior consequences, partly from the disingenuousness of his opponents and the confusion resulting from exasperated feelings, developed into an intricate and bewildering maze of side discussions in which the main issues of the dispute were concealed almost beyond the possibility of discovery. But however vague and uncertain might be the meaning of Hoadly in regard to several of the important bearings of the questions around which he aroused discussion, he was explicit in denying the power of the church over the conscience, and its right to determine the condition of men in relation to the favour of God. To such an extent was the mind of the religious world exercised on the matters in dispute that in July 1717 as many as seventy-four pamphlets made their appearance; and at one period the crisis became so serious that the business of London was for some days virtually at a standstill. Hoadly was translated in 1721 to the see of Hereford, in 1723 to Salisbury, and in 1734 to Winchester. He died at his palace at Chelsea, April 17, 1761. Though his writings possess no charm of style, and are not only devoid of originality, but characterized by great prolixity and dulness, they in their own day did important service to the cause of civil and religious liberty, and accidentally he was the occasion of a change in the practical authority of the church which had an influence of prime importance on its after history. He was an intimate friend of Dr Samuel Clarke, of whom he wrote a life.

The works of Hoadly were collected and published by his son in 3 vols., 1773. To the first volume was prefixed the article "Hoadly," from the supplement to the *Biographia Britannica*.

HOARE, SIR RICHARD COBB (1758–1838), Bart., English antiquary, eldest son of Sir Richard Hoare, the first baronet, an eminent banker, was born 9th December 1758. Having been accustomed in his youth to apply himself to business, the diligent habits which he then acquired induced him afterwards to relieve the tedium of his life by the study of topography and antiquities. In 1783 he married the eldest daughter of Lord Lyttelton, and on her death in 1785 he made a tour on the Continent, visiting France, Italy, and Switzerland. He succeeded to the baronetcy on the death of his father in 1787, and in the following year he left England on a second Continental tour. The record of his travels was originally published by him in four volumes, and these were afterwards condensed into two, which appeared in 1810 under the title *A Classical Tour through Italy and Sicily.* Travelling on the Continent having been rendered insecure on account of the war with France, he next resolved to make a tour in Wales, taking Giraldus Cambrensis (de Barri) as his guide, and in 1808 he published a translation of Giraldus, with notes, illustrations, and a life of the author, in two splendid quarto volumes. In 1807 he visited Ireland; and he also published an account of this excursion. His most important contribution to antiquarian science was, however, his history of his native county, Wiltshire. In 1821 he completed in two volumes folio the *History of Ancient Wiltshire*, after which he commenced the *History of Modern Wiltshire*, and confining his attention to South Wiltshire was able with the help of several coadjutors almost to finish the work before his death. The first part—the history of the hundred of Mere—appeared in 1822, and the last part in 1843. Hoare died at Stourhead, May 19, 1838. For a notice of him and a list of his works, many of which were printed privately, see the *Gentleman's Magazine* for July 1838.

HOBART TOWN, sometimes wrongly HOBARTOWN or HOBARTON, the capital of Tasmania (named by its founder, Colonel Collins, on the 19th February 1804, in honour of Lord Hobart, then secretary of state for the colonies), is situated in the south of the island in 42° 53′ 22″ S. lat. and 147° 21′ 20″ E. long. It occupies a succession of hills along a sheltered bight on the western bank of the Derwent river, known as Sullivan's Cove, about 17 miles from the ocean, and not far from the base of Mount Wellington, an eminence whose summit, 4166 feet above the level of the sea, is covered with snow during many months of the year. The city proper, forming nearly a square, and laid out in wide streets intersecting at right angles, has an area of 1270 acres, and contains about 5000 houses, with a population estimated on the 1st of January 1879 at 23,000. Of the public squares the most extensive is the Queen's Domain, and the most central the Franklin Square, with the bronze statue of the eminent Arctic explorer, who governed Tasmania from 5th January 1837 to 21st August 1843. Most of the public buildings (the houses of parliament, the town-hall, the supreme court, and the museum) are conveniently adjacent to each other in Magdalen Street. The town-hall, erected about 1872 at a cost of £12,000, contains a large reading-room and a suite of rooms for the free public library, which has upwards of 8000 volumes. The museum comprises a scientific library and apartments for the Royal Society of Tasmania. Besides the Anglican cathedral of St David's, founded in 1873, and the Roman Catholic cathedral of St Mary's, the churches comprise a Congregational memorial church, a Wesleyan "Centenary" chapel, and others belonging to Baptists, Independents, and Quakers. There is also a synagogue, but the Jewish community consists of only a few families. The charitable institutions of the town are maintained at the expense of the state. Among the remaining buildings may be mentioned five banks, a theatre, the freemasons' hall and the oddfellows' hall. In the neighbourhood of the city is the official residence of the governor of Tasmania, an ornate castellated mansion; the grounds of this adjoin the botanic gardens, which occupy an area of 21 acres.

Hobart Town has been under municipal government since 1853, and was incorporated as a city in 1857. There are nine aldermen elected by the ratepayers, and one of them is appointed mayor. The annual value of rateable property exceeds £100,000. An abundant supply of pure water is brought from the springs of Mount Wellington, and stored in a reservoir about a mile from the city, capable of holding 50,000,000 gallons. Among the industrial establishments are six breweries, a candle factory, a foundry, ten hat and cap factories, seven steam flour-mills, a pottery, twelve saw-mills, and a tin-smelting work. The commerce of the town is steadily increasing. The securely sheltered harbour is capable of accommodating ships of the largest tonnage, and is provided with three patent slips of considerable size; not only is the port the headquarters of the Tasmanian Steam Navigation Company, which trades with Melbourne, Sydney, and New Zealand, but a line of colonial vessels communicates regularly with London. During the year 1877 the total burthen of shipping inwards was 79,480 tons, of the shipping outwards 82,827 tons. The declared value of the imports at the Custom House was £664,439 (£255,344 from the United Kingdom), and that of the exports £720,136 (£301,477 to the United Kingdom), £715,304 worth being produce of the colony. The customs collected during the year 1878 amounted to £118,306, being an increase of about £4000 on the previous year. According to the returns for 1877 the principal exports were tin ore (value £61,765), tin (£20,886), bark (2086 tons, £13,410), fruit (138,585 bushels, £44,001), jam (3,742,341 lb, £100,069), hops (696,048 lb, £36,457), sperm-oil (450 tons, £33,410), rabbit skins (58,781 dozen, £5072), timber, shingles, railings, &c. (£351,851), and wool (£299,514). The principal imports are sugar, tea, oil, tobacco, live stock, machinery, spirits and wine, boots and shoes, wearing apparel, ironmongery and cutlery, glass and china-ware, books and stationery, saddlery, manure, drugs, &c. The first newspaper was published in Hobart Town in 1810. There are now (1880) two dailies, one weekly, and four monthlies. During the summer season the city is a favourite resort of Australian tourists attracted by the comparative coolness of the climate. The mean temperature for 35 years was 55·41° Fahr.; and in the same period the barometer at a temperature of 32° has registered an average of 29·82 inches.

HOBBEMA, MEYNDERT (*c.* 1638–1709), the greatest landscape painter of the Dutch school after Ruysdael, lived at Amsterdam in the second half of the 17th century. His merit has been but recently recognized, whence the obscurity in which his life remains. Nothing is more disappointing than to find that in Hobbema's case chronology and signed pictures substantially contradict each other. According to the latter his practice lasted from 1650 to 1689; according to the former his birth occurred in 1638, his death as late as 1709. That no attempt has yet been made to reconcile these contradictions is strange. It is perfectly clear that if the masterpiece of the late Bredel collection, called A Wooded Stream, honestly bears the date of 1650, or The Cottages under Trees of the Ford collection the date of 1652, the painter of these canvases cannot be Hobbema, whose birth took place in 1638, unless indeed we admit that Hobbema painted some of his finest works at the age of twelve or fourteen. No doubt, as regards signatures, there is much in Hobbema's creations to excite suspicion. For a considerable period it was profitable to pass Hobbemas as Ruysdaels, and the name of the lesser master was probably erased from several of his productions. When Hobbema's talent was recognized, the contrary process was followed, and in this way the name, and perhaps fictitious dates, reappeared by fraud. It is difficult to account for the discrepancies of pictures and chronology by any other cause. Yet this leaves unexplained why dates as well as names should have been forged. An experienced eye will note the differences which occur in Hobbema's signatures in such well known examples as adorn the galleries of London and Rotterdam, or the Grosvenor and Van der Hoop collections. The dates can only be tested by chemical means. Meanwhile, we must be content to know that, if the question of dates could be brought into accordance with records and chronology, the facts of Hobbema's life would be as follows. Meyndert Hobbema was married at the age of thirty to Eeltije Vinck of Gorcum, in the Oudekerk or old church at Amsterdam, on the 2d of November 1668. Witnesses to the marriage were the bride's brother Cornelius Vinck and Jacob Ruysdael. We might suppose from this that Hobbema and Ruysdael, the two great masters of landscape, were united at this time by ties of friendship, and accept the belief that the former was the pupil of the latter. Yet even this is denied to us, since records tell us that there were two Jacob Ruysdaels, cousins and contemporaries, at Amsterdam in the middle of the 17th century—one a frame-maker, the son of Solomon, the other a painter, the son of Isaac Ruysdael. Of Hobbema's marriage there came between 1668 and 1673 four children. In 1704 Eeltije died, and was buried in the pauper section of the Leyden cemetery at Amsterdam. Hobbema himself survived till December 1709, receiving burial on the 14th of that month in the pauper section of the Westerkerk cemetery at Amsterdam. Husband and wife had lived during their lifetime in the Rozengracht, at no great distance from Rembrandt, who also dwelt there in his later and impoverished days. Rembrandt, Hals, Jacob Ruysdael, and Hobbema were in one respect alike. They all died in misery, insufficiently rewarded perhaps for their toil, imprudent perhaps in the use of the means derived from their labours. Posterity has recognized that Hobbema and Ruysdael together represent the final development of landscape art in Holland. Their style is so related that we cannot suppose the first to have been unconnected with the second. Still their works differ in certain ways, and their character is generally so marked that we shall find little difficulty in distinguishing them, nor indeed shall we hesitate in separating those of Hobbema from the feebler productions of his imitators and predecessors—Isaac Ruysdael, Rontbouts, De Vries, Dekker, Looten, Verboom, Du Bois, Van Kessel, Van der Hagen, even Philip de Koningk. In the exercise of his craft Hobbema was patient beyond all conception. It is doubtful whether any one ever so completely mastered as he did the still life of woods and hedges, or mills and pools. Nor can we believe that he obtained this mastery otherwise than by constantly dwelling in the same neighbourhood, say in Guelders or on the Dutch Westphalian border, where day after day he might study the branching and foliage of trees and underwood embowering cottages and mills, under every variety of light, in every shade of transparency, in all changes produced by the seasons. Though his landscapes are severely and moderately toned, generally in an olive key, and often attuned to a puritanical grey or russet, they surprise us, not only by the variety of their leafage, but by the finish of their detail as well as the boldness of their touch. With astonishing subtlety light is shown penetrating cloud, and illuminating, sometimes transiently, sometimes steadily, different portions of the ground, shining through leaves upon other leaves, and multiplying in an endless way the transparency of the picture. If the chance be given him he mirrors all these things in the still pool near a cottage, the reaches of a sluggish river, or the swirl of the stream that feeds a busy mill. The same spot will furnish him with several pictures. One mill gives him repeated opportunities of charming our eye; and this wonderful artist, who is only second to Ruysdael because he had not Ruysdael's versatility and did not extend his study equally to downs and rocky eminences, or torrents and estuaries—this is the man who lived penuriously, died poor, and left no trace in the artistic annals of his country! It has been said that Hobbema did not paint his own figures, but transferred that duty to Adrian van de Velde, Lingelbach, Barendt Gael, and Abraham Storck. As to this much is conjecture.

The best of Hobbema's dated pictures are those of the years 1663 to 1667. Of the former, several in the galleries of Brussels and St Petersburg, and one in the Holford collection, are celebrated. Another was shown as the property of Lord Hatherton at Manchester. Of 1665 fine specimens are in the Grosvenor gallery and the collection of Sir R. Wallace. Of seven pieces in the National Gallery, including the Avenue at Middelharnis, which some assign to 1689, two are dated 1667. A sample of the last of these years is also in the Fitzwilliam museum at Cambridge. The value of Hobbema's pictures may be gathered from this that the Watermill bought from the Schneider collection in 1876 for the Antwerp museum cost 100,000 francs (£4000), whilst a smaller landscape in the Hodshen sale at Amsterdam was knocked down to Sir R. Wallace for 49,500 florins, or £4300. The Brussels gallery also bought a Hobbema in 1874 for 60,000 francs. Amongst the masterpieces in private hands in England may be noticed two landscapes in Buckingham palace, one belonging to Lord Overstone, two to the Earl of Ellesmere, and one to Mr Walter of Bearwood. On the Continent we register a Wood in the Berlin gallery, a Forest belonging to the duchess of Sagan in Paris, and a Glade in the Louvre. There are other fine Hobbemas in the Arenberg gallery at Brussels and the Belvedere at Vienna. (J. A. C.)

HOBBES, Thomas (1588–1679), was born at Westport, adjoining (now forming part of) Malmesbury, in North Wilts, on Good Friday, the 5th of April 1588,—brought prematurely into the world through his mother's fright at the rumours of the coming Spanish Armada. His father was vicar of Charlton and Westport, an illiterate and choleric man, who is said to have got into trouble later on by quarrelling with a rival at the church door, and been forced to decamp, leaving his three children (of whom Thomas was second) to the charitable care of an elder brother, a flourishing glover in Malmesbury. Hobbes was put to school at Westport church at the age of four, passed to the Malmesbury school at eight, and was taught again in Westport later, at a private school kept by a young man named Robert Latimer, fresh from Oxford and "a good Grecian." He had begun Latin and Greek early, and under Latimer made such progress as to be able to translate the *Medea* of Euripides into Latin iambic verse before he was fourteen. About the age of fifteen he was sent to Oxford by his uncle and entered at Magdalen Hall, which had just been put on an independent footing, after being first a grammar school in connexion with the great foundation of Magdalen College and then governed as a hall by one of the college fellows. While Hobbes was there as a student the first principal of Magdalen Hall, Dr John Hussee, gave way to a second, Dr John Wilkinson, who is noted as having ruled strongly in the interest of the Calvinistic party in the university; and this fact, with other circumstances in the Oxford life of the time, makes it not improbable that the destined foe of the Puritan Revolution was thus early led to mark the aggressive Puritan spirit. For the rest, Oxford did no more to train Hobbes's mind for his future philosophical work than the decayed scholastic regimen of the universities in that age was able to do for any other of the active spirits that then began in different countries to open the modern era of thought and inquiry. We have from himself a lively record of his experience and pursuits as a student (*Vit. carm. exp.*, p. lxxxv.),[1] which, though penned in extreme old age, may be taken as sufficiently trustworthy. In this he tells how he was set to learn "Barbara, Celarent," but, when he had slowly taken in the doctrine of figures and moods, he put it aside and would prove things only in his own way; how he then heard about bodies as consisting of matter and form, as throwing off species of themselves for perception, and as moved by sympathies and antipathies, with much else of a like sort, all beyond his comprehension; and how he therefore turned to things more congenial, took up his old books again, fed his mind on maps and charts of earth and sky, traced the sun in his path, followed Drake and Cavendish girdling the main, and gazed with delight upon pictured haunts of men and wonders of unknown lands. Very characteristic in this account is the interest in men and things, and the disposition to cut through questions in the schools after a trenchant fashion of his own. We may also believe that he was little attracted by the scholastic learning, and only should err if we took his words as evidence of a precocious insight into its weakness. The truth probably is that, finding himself left at Oxford very much to his own devices, he took no particular interest in studies which there was no risk in neglecting, and thought as little of rejecting as of accepting the traditional doctrines. He adds that he took his degree at the proper time; but in fact, upon any computation and from whatever cause, he remained at Magdalen Hall five, instead of the required four, years, not being admitted as bachelor till February 5, 1608.

In the same year, shortly after leaving the university, Hobbes was recommended by Wilkinson as tutor to the son of William Cavendish, baron of Hardwick, and thus began a connexion with a great and powerful family that ended only with his life. Twice it was loosened—once, for a short time, after twenty years, and again, for a longer period, during the Civil War—but it never was broken, and during more than fifty years, to the credit alike of him and his patrons, it was of the closest character. William Cavendish, second son of the famous "Bess of Hardwick" by the second of her four marriages, had just by the favour of King James obtained his barony, before being advanced, a few years later, to the earldom of Devonshire. His son, the heir to a name thus rising as well as to a great fortune, was hardly younger than Hobbes, and was indeed already married, a few months before, at the instance of the king, who made up the match, to the only daughter of the Scottish Lord Bruce of Kinloss, though by reason of the bride's age, which was only twelve years, the pair had no establishment for some time to come. In the circumstances Hobbes was companion rather than tutor (before becoming secretary) to young Cavendish; and, growing soon greatly attached to each other, they were sent abroad together on the grand tour in 1610. How long they were gone upon this journey, which lay through France, Germany, and Italy, is not known: but it was long enough to give

[1] There are three accounts of Hobbes's life, first published together in 1681, two years after his death, by R. B. (Richard Blackburne, a friend of Hobbes's admirer, John Aubrey), and reprinted, with complimentary verses by Cowley and others, at the beginning of Sir W. Molesworth's collection of the *Latin Works*:—(1) *T. H. Malmesb. Vita* (pp. xiii.-xxi.), written by Hobbes himself, or (as also reported) by T. Rymer, at his dictation; (2) *Vitæ Hobbianæ Auctarium* (pp. xxii.-lxxx.), turned into Latin from Aubrey's English; (3) *T. H. Malmesb. Vita carmine expressa* (pp. lxxxi.-xcix.), written by Hobbes at the age of eighty-four (first published by itself in 1680). The *Life of Mr T. H. of Malmesburie*, printed among the *Lives of Eminent Men*, in 1813, from Aubrey's papers in the Bodleian, &c. (vol. ii. pt. ii. pp. 593-637), contains some interesting particulars not found in the *Auctarium*.

Hobbes the opportunity of acquiring a moderate knowledge of French and Italian; and he did not return without having received a distinct mental impulse that had a lasting effect on his life. The real intellectual activity of that time (still more than five and twenty years before the definite inauguration of modern philosophy by Descartes's *Discourse on Method* in 1637) was in the newly enlarged if not newly opened domain of physical science; and Hobbes was little prepared by his juvenile training to understand the achievements of Galileo and Kepler, if he heard anything of them. But he had had a little modicum of scholastic philosophy retailed to him at Oxford; and now, wherever he went, he could hear nothing but words of scorn poured upon all such learning. How it had come to pass that the scholastic way of thinking, once so dominant, was thus discredited at the hands alike of revolutionary thinkers such as Bruno, of scientific workers like Galileo, and of men of the world like Montaigne, he could not know. Accordingly, it seems that at first he was more dismayed to find that the only knowledge to which he could pretend was laughed at by people whom he did not understand, than pleased to be furnished with such an excuse for his own youthful indifference to its value. It was not long, however, before he yielded to the stream. He was not yet able to strike out a new line of thought, and so (like Descartes) rise above the misconceptions mingled with the general aversion from scholasticism, amounting to a neglect of all philosophy. He had but sufficient force of mind to wish to be seen, like others, at work upon something else. The line he should take could hardly be doubtful; he had nothing to fall back upon except his Latin and Greek. He was no longer so familiar with them, but it was still open to him to become a scholar; nor in the age of Scaliger and Casaubon was there any lack of ambition in making classical study the occupation of a life. The resolution was made when he returned home, if not earlier, and made in a determined spirit; but when after many years' labour he had made himself a scholar, his true work was still to lie all before him.

Hobbes's period of scholarly acquirement lasted till 1628, and had as its immediate outcome a translation of Thucydides. In Derbyshire or in London, with his young master, he had abundant leisure and easy access to books, and he went carefully through the classical poets and historians, reading critically with the help of commentators, and at the same time bent on acquiring (as if for future use) a good Latin style, clear and easy to read, because fitting words to thoughts. Among all the ancient writers Thucydides attracted him most, and he seems to have set himself early to the work of translation, wishing others to share in the pleasure and instruction he derived from his favourite's pages. But when he had finished his work he kept it lying by him for years, being no longer so sure of finding appreciative readers; and when he did send it forth at last, in 1628, he was fain to be content with "the few and better sort."[1] That he was finally determined to publication by the political troubles of the year 1628 may be regarded as certain, not only from his own express declaration at a later time (*Vit. carm. exp.*), but also from unmistakable hints in the account of the life and work of his author prefixed to the translation on its appearance. 1628 was the year of the Petition of Right, extorted by the popular leaders from a reluctant king in the third parliament he had tried within three years of his accession; and, in view of Hobbes's later activity, it is very significant that just then he should come forward, at the mature age of forty, with his version of the impressive story of the Athenian democracy as the first production of his pen. Nothing else is known of his doings before 1628, except that through his connexion with young Cavendish, who from about the year 1619 became an important social and political figure, he had relations with literary men of note like Ben Jonson, and also with the two philosophical thinkers who before himself rendered the English name illustrious in the 17th century—Bacon and Lord Herbert of Cherbury. If he never had any sympathy with Herbert's intuitionalist principles in philosophy, he was no less eager, as he afterwards showed, than Herbert to rationalize in matters of religious doctrine, so that he may with the same reason be called the second of the English deists as Herbert has been called the first. With Bacon there is evidence of his having been so intimate (Aubrey's *Lives*, pp. 222, 602) that it is not surprising that some writers have been betrayed into describing him as the disciple and follower of the great Instaurator. The facts as recorded, however,—that he used sometimes to walk with Bacon at Gorhambury, and would jot down with exceptional intelligence the eager thinker's sudden "notions," also that he was employed to make the Latin version of some of the *Essays*,—prove nothing of the sort, when weighed against his own disregard of all Bacon's most characteristic principles, and the other evidence that the impulse to independent philosophical thinking came to him not from Bacon, and not till some time after Bacon's death in 1626.[2]

So far as we have any positive evidence, it was not before the year 1629 that Hobbes first entered on the path of philosophical inquiry; and meanwhile a great change had been wrought in his outer life. His friend and master, after only about two years' tenure of the earldom, fell a sudden victim to the plague in June 1628; and the affairs of the Devonshire family having become greatly disordered by lavish expenditure, the widowed countess was left with the task of righting them in the boyhood of the third earl. Hobbes went on for a time living in the household; but his services were no longer in demand as before, and, remaining inconsolable under his personal bereavement, he sought distraction, in 1629, in another engagement which took him abroad as tutor to the son of Sir Gervase Clifton, of an old Notts family. This, his second, sojourn abroad appears to have been spent chiefly in Paris, and the one important fact recorded of it is that he then first began to look into Euclid. Sojourn and engagement came to an end together in 1631, when he was recalled to train the young earl of Devonshire, now thirteen years old, as he never had had an opportunity of training the boy's father. In the course of the next

[1] The translation, under the title *Eight Books of the Peloponnesian War, written by Thucydides the son of Olorus, interpreted with faith and diligence immediately out of the Greek by Thomas Hobbes, secretary to the late Earl of Devonshire*, appeared in 1628 (given also as 1629), after the death of the earl, to whom touching reference is made in the dedication. It reappeared in 1634, with the date of the dedication altered, as if then newly written. Though Hobbes claims to have performed his work "with much more diligence than elegance," his version is remarkable as a piece of English writing, but is by no means accurate. It fills vols. viii. and ix. in Molesworth's collection (11 vols., including index vol.) of Hobbes's *English Works* (London, Bohn, 1839–45). The volumes of this collection will here be cited as *E. W.* Molesworth's collection of the Latin *Opera Philosophica* (5 vols., 1839–45) will be cited as *L. W.* The five hundred and odd Latin hexameters under the title *De Mirabilibus Pecci* (*L. W.*, v. 323–40), giving an account of a short excursion from Chatsworth to view the seven wonders of the Derbyshire Peak, were written before 1628 (in 1626 or 1627), though not published till 1636. A later edition, in 1678, included an English version by another hand.

[2] Hobbes, in minor works dealing with physical questions (*L. W.*, iv. p. 316; *E. W.*, vii. p. 112), makes two incidental references to Bacon's writings, but never mentions Bacon as he mentions Galileo, Kepler, Harvey, and others (*De Corpore*, ep. ded.), among the lights of the century. The word "Induction," which occurs in only three or four passages throughout all his works (and these again minor ones), is never used by him with the faintest reminiscence of the import assigned to it by Bacon; and, as will be seen, he had nothing but scorn for *experimental* work in physics.

seven years Hobbes took his young pupil over rhetoric,[1] logic, astronomy, and the principles of law, with other subjects. Most probably their life for the first three years was in Derbyshire, till they went abroad in the middle of 1634. They remained away till the spring of 1637, and Hobbes went over much the same ground as in his first journey, but now in a very different frame of mind. His head was now full of the thought of motion in nature, and whenever he could meet with the philosophical speculators or scientific workers who were then with a new-born ardour seeking for a clue to the secret of the physical world, none so forward to consort with them as he. He was still in time to pay his respects to the aged Galileo, for whom he conceived and ever retained the warmest admiration; and on the way homewards he spent no less than eight months in daily converse with the members of a busy scientific circle in Paris, held together by the genial influence of the Père Mersenne. From that time (the winter of 1636–7) he too, as he tells us, was numbered among philosophers.

It is not impossible to trace a little more exactly the steps by which Hobbes reached this consummation when he was just touching his fiftieth year. There can be no doubt, it seems, that his introduction to Euclid took place in 1629, and according to Aubrey, who tells the story with a quaint dramatic vigour (*Lives*, p. 604), the introduction was quite accidental. Euclid's manner of proof was as a revelation to him, and it became the model for his own way of thinking upon all subjects ever after; nor was he content till he too could be seen at work solving questions of geometry with as much confidence as if he had been, like Descartes, an accomplished mathematician from his boyhood. It is less easy to determine when he awoke to an interest in the physical doctrine of motion. The story told by himself (*Vit.*, p. xx.) is that, being struck one day in a company of learned men by the question, What is sense? which some one asked and nobody could answer, he fell to thinking often on the subject, till it suddenly occurred to him that if bodies and their internal parts were at rest, or were always in the same state of motion, there could be no distinction of anything, and consequently no sense; the cause of all things must, therefore, he presumed, be sought in diversity of movements, and starting from this principle he was driven to geometry for insight into the ground and modes of motion. Unfortunately no date or place is given; but if it may be supposed that he must already have known something of geometry to understand its bearing on the study of motion, the scene or at least the conclusion to which it led should be referred to some time after his casual introduction to Euclid. It is even suggested in one or two of the biographical narratives that the new mental advance was not made till the time of the third journey. Nothing is said, however, which should exclude another account, that on the third journey he began to study the doctrine of motion more seriously, being interested in it before; and as he claims more than once (*L. W.*, v. p. 303; *E. W.*, vii. p. 468) to have explained light and sound by a mechanical hypothesis as far back as 1630, the company-scene (which is more likely to have occurred abroad than in England) and the sudden inspiration may perhaps more safely be assigned to the time of the second journey. But it was not till the third journey that the new interest became an overpowering passion, and the "philosopher" was on his way home before he had advanced so far as to conceive the scheme of a system of thought to the elaboration of which his life should henceforth be devoted.

Hobbes was able to carry out his plan in some twenty years or more from the time of its conception, but the execution was so broken in upon by the dire political events that happened from the year 1637, and became so complicated with other labours, that its stages can hardly be followed without some previous understanding of the relations of the parts of the scheme, as there is reason to believe they were sketched out from the beginning. And there is the more need for some preliminary statement because at least one of the parts—the doctrine of Man—is far more effectively wrought out in other works than in the treatise *De Homine*, which professes to contain the formal exposition of it. Hobbes's notion was that the whole body of philosophical truth should be disposed in three sections, dealing progressively with Body, Man, and State or Society. An anxious political observer before he became a philosopher, he was supremely interested in the problem of conduct; but the philosopher could not be satisfied till the foundations of settled social life were based deep in the constitution of human nature; and his new philosophical insight revealed to him the need and the possibility of interpreting the facts of human nature by what had begun to be known of physical nature generally. He would therefore first work out, in a separate treatise *De Corpore*, a systematic doctrine of Body, showing how physical phenomena were universally explicable in terms of motion, as motion or mechanical action was now (through Galileo and others) understood,—the theory of motion being applied in the light of mathematical science, after quantity, the subject-matter of mathematics, had been duly considered in its place among the fundamental conceptions of philosophy, and a clear indication had been given, at first starting, of the logical ground and method of all philosophical inquiry. He would then single out Man from the realm of nature, and, in a treatise *De Homine*, show what specific bodily motions were involved in the production of the peculiar phenomena of sensation and knowledge, as also of the affections and passions thence resulting, whereby man came into relation with man. Finally he would consider, in a crowning treatise *De Cive*, how men, being naturally rivals or foes, were moved to enter into the better relation of Society, and demonstrate how this grand and beneficent product of human wit must be regulated if men were not to fall back into brutishness and misery. Such, in briefest summary, was the scheme conceived, at a time of new intellectual expansion, with reference to a threatening movement of social upheaval. We are now to see how it fared in the execution.

Hobbes came home, in 1637, to a country seething with discontent. The reign of "Thorough" was collapsing, and the forces pent up since 1629 were soon to rend the fabric of the English state to pieces. In February Hampden's case began to be tried; in July broke out the Edinburgh riot over Laud's prayer-book; next year was formed the Solemn League and Covenant; the year after the rebel Scots had the king at their mercy in the open field; and finally, in the spring of 1640, with a new prospect of war, Charles had no resource left but once more, after eleven years of personal rule, to call a parliament. Such a rush of events was but too likely to overpower Hobbes's resolution to work up to social problems from abstract questions of body and space and motion, and there is clear evidence that he was soon distracted from the orderly execution of his philosophic plan. The Short Parliament, as he tells us himself at a later time (*E. W.*, iv. p. 414), was not dissolved, in three weeks from the time of its meeting, before he had ready "a little treatise in English," in which he sought to prove that the points of the royal prerogative which the members were determined to dispute before granting supplies, "were inseparably annexed to the sovereignty which they did not then deny to be in the king." Now it can be proved that at this time he had written not only his *Human Nature* but also his *De Corpore Politico*, the two treatises, though published separately ten years later, having been composed as parts of one work;[2] and there cannot be the least question that together they make "the little treatise" just mentioned. We are therefore to understand, first, that he wrote the earliest draft of his political theory some years before the outbreak of the Civil War, and, secondly, that this earliest draft was not written till, in accordance with his philosophical conception, he had established the grounds of polity in human nature. The first point is to be noted, because it has often been supposed that Hobbes's political doctrine took its peculiar complexion from his revulsion against the state of anarchy before his eyes, as he wrote during the progress of the Civil War. The second point must be maintained against his own implied, if not express, statement some years later, when publishing his *De Cive* (*L. W.*, ii. p. 151), that he wrote this third part of his system before he had

[1] The free English abstract of Aristotle's *Rhetoric*, published in 1681, after Hobbes's death, as *The Whole Art of Rhetoric* (*E. W.*, vi. pp. 423-510), corresponds with a Latin version dictated to his young pupil. Among Hobbes's papers preserved at Hardwick, where he died, there remains the boy's dictation-book, interspersed with headings, examples, &c., in Hobbes's hand.

[2] Among the Hardwick papers there is preserved a MS. copy of the work, under the title *Elementes of Law Naturall and Politique*, with the dedication to the earl of Newcastle, written in Hobbes's own hand, and dated May 9, 1640. This dedication was prefixed to the first thirteen chapters of the work when printed by themselves, under the title *Human Nature*, in 1650.

been able to set down any finished representation of the fundamental doctrines which it presupposed. If his philosophical plans were disordered and the doctrine of Body was still in the air, he had, in the beginning of 1640, written out his doctrine of Man at least, with almost as much elaboration as it ever received from him.

When, in six months more, the Long Parliament succeeded to the Short, and set to work at once by sending Laud and Strafford to the Tower, Hobbes, who had become, or thought he had become, a marked man by the circulation of his treatise (of which, "though not printed, many gentlemen had copies"), instantly took fright and hasted away to Paris. He was now for the fourth and last time abroad, and did not see England again for eleven years. Apparently he remained the greater part of the time in or about Paris, though he can be traced to Rouen in 1646. In Paris he was welcomed back into the old scientific coterie about Mersenne, and forthwith had the task assigned him of criticizing the *Meditations* of Descartes, which had been sent from Holland, before publication, to Mersenne with the author's request for criticism from the most different points of view. Hobbes was soon ready with the remarks that were printed as "Third" among the six (later seven) sets of "Objections" appended, with "Replies" from Descartes, to the *Meditations*, when published shortly afterwards in 1641 (reprinted in *L. W.*, v. pp. 249–74). About the same time also Mersenne sent to Descartes, as if they came from a friend in England, another set of objections which Hobbes had to offer on various points in the scientific treatises, especially the *Dioptrics*, appended by Descartes to his *Discourse on Method* in 1637; to which Descartes replied without suspecting the common authorship of the two sets. The result in both cases was to keep the two thinkers apart rather than bring them together. Hobbes was more eager to bring forward his own philosophical and physical ideas, over which he had now been brooding for ten years, than careful to enter into the full meaning of another's thought; and Descartes was by nature too jealous, and had become too confident in his hard-won conclusions, to be able to bear with this kind of criticism. He was very curt in his replies to Hobbes's philosophical objections, and after a little impatiently broke off all correspondence on the physical questions, writing privately to Mersenne (who had continued to act as intermediary) that he had grave doubts of the Englishman's good faith in drawing him into controversy (*L. W.*, v. pp. 277–307).

Meanwhile Hobbes, however eager he might be to keep himself abreast of the general philosophical movement of the time, had his thoughts too full of the political theory which the rush of events in the last years had ripened within him, to be able to settle, even in Paris, to the orderly composition of his systematic works. Though connected in his own mind with his view of human nature and of nature generally, the political theory, as he always declared, could stand by itself. Also, while he may have hoped at this time to be able to add much (though he never did add much) to the first popular sketch of his doctrine of Man contained in the unpublished "little treatise," he might extend, but could hardly otherwise modify, the sketch he had there given of his carefully articulated theory of Body Politic. Possibly, indeed, before that sketch was written early in 1640, he may, under pressure of the political excitement, have advanced no small way in the actual composition of the treatise *De Cive*, the third section of his projected system. In any case, it was upon this section, before the others, that he set to work as soon as he was fixed in Paris; and before the end of 1641 the book, as we know from the date of the dedication (November 1), was finished. He determined, however, though it was forthwith printed in the course of the year 1642, not to commit himself to formal publication, but was content to circulate a limited number of copies privately;[1] and when he found his work received with great applause by his friends (it was praised even by Descartes), he seems to have taken this recognition of his philosophical achievement as but a reason the more for deferring publication till the earlier works of the system were completed. Accordingly, for the next three or four years, he remained steadily at work, and nothing appeared from him in public except a short treatise on optics (*Tractatus Opticus, L. W.*, v. pp. 217–248) included in the collection of scientific tracts published by Mersenne under the title *Cogitata Physico-Mathematica* in 1644, and a highly compressed statement of his psychological application of the doctrine of motion (*L. W.*, v. pp. 309–318), incorporated with Mersenne's *Ballistica*, published in the same year. Thus or otherwise he had become sufficiently known by 1645 to be chosen, with Descartes, Roberval, and others, a referee in a once famous controversy between Pell, an English mathematician in Amsterdam, and the Dane Longomontanus, over that problem of the quadrature of the circle which was seen later on to have such a fatal charm for himself. But though about this time he had got ready all or most of the materials for his fundamental work on Body, not even now was he able to make way with its composition. New distractions came to tear him away from the orderly execution of the fundamental part of his scheme, and when he returned to it after a number of years, he returned a different man.

The Civil War had broken out in the middle of 1642, and, after a period of varying fortunes on either side, the royalist cause began to decline from the time of the defeat of the marquis of Newcastle at Marston Moor, in the middle of 1644. Then commenced an exodus of the king's friends. Newcastle himself, a cousin of Hobbes's dead master and the patron to whom he dedicated the "little treatise" of 1640, found his way to Paris, and was followed, especially after the decisive defeat at Naseby in June 1645, by an ever increasing stream of fugitives, many of whom were known to Hobbes from former days. The sight of these exiles, from whom he learned all the details of the fierce work that had been going on in England while he was quietly busy with his studies in Paris, made the political interest once more predominant in Hobbes, and before long the revived feeling issued in the formation of a new and important design. It first showed itself in the publication of the *De Cive*, of which the fame, but only the fame, had extended beyond the inner circle of friends and critics who had copies of the original impression. Hobbes now entrusted it, early in 1646, to his admirer, the Frenchman Sorbière, by whom it was seen through the Elzevir press at Amsterdam in 1647,—having previously inserted a number of notes in reply to objections, and also a striking preface, in the course of which he explained its relation to the other parts of the system not yet forthcoming, and the (political) occasion of its having been composed and being now published before them.[2] So hopeless, meanwhile, was he growing of being able to return home that, later on in the year, he was on the point of leaving Paris to take

[1] The book, of which the copies are rare (one in Dr Williams's library in London), was printed in quarto size (Paris, 1642), with a pictorial title-page (not afterwards reproduced) of scenes and figures illustrating its three divisions, "Libertas," "Imperium," "Religio." The title *Elementorum Philosophiæ Sectio Tertia, De Cive*, expresses its relation to the unwritten sections, which also comes out in one or two back-references in the text.

[2] *L. W.*, ii. pp. 133-134. In this first public edition (12mo), the title was changed to *Elementa Philosophica de Cive*, the references in the text to the previous sections being omitted. The date of the dedication to the young earl of Devonshire was altered from 1641 to 1646.

up his abode in the south with a French friend,[1] when he was induced to remain as mathematical instructor to the young prince of Wales, who had come over from Jersey about the month of July. Thus thrown more than ever into the company of the exiled royalists, it was then, if not earlier, that he conceived his new design of bringing all his powers of thought and expression to bear upon the production of an English book that should set forth his whole theory of civil government in relation to the stupendous political crisis resulting from the war. The *De Cive*, presently to be published, was written in Latin for the learned, and gave the political theory without its foundation in human nature. The unpublished treatise of 1640 contained all or nearly all that he had to tell concerning human nature, but was written before the terrible events of the last years had disclosed how men might still be urged by their anti-social passions back into the abyss of anarchy. There was need of an exposition at once comprehensive, incisive, and popular. The State, it now seemed to Hobbes, might be regarded as a great artificial man or monster (*Leviathan*), composed of men, with a life that might be traced from its generation through human reason under pressure of human needs to its dissolution through civil strife proceeding from human passions. This, we may suppose, was the presiding conception from the first, but the design may have been variously modified in the three or four years of its execution. Before the end, in 1650-1, it is plain that he wrote in direct reference to the greatly changed aspect of affairs in England. The king being no more, and the royalist cause appearing to be hopelessly lost, he did not scruple, in closing the work with a general "Review and Conclusion," to raise the question of the subject's right to change allegiance when a former sovereign's power to protect was irrecoverably gone. Also he took advantage of the lax rule of the Commonwealth to indulge much more freely than he might have otherwise dared in rationalistic criticism of religious doctrines; while, amid the turmoil of sects, he could the more forcibly urge that the preservation of social order, when again firmly restored, must depend on the assumption by the civil power of the right to wield all sanctions, supernatural as well as natural, against the pretensions of any clergy, Catholic, Anglican, or Presbyterian, to the exercise of an *imperium in imperio*. We know the *Leviathan* only as it finally emerged from Hobbes's pen. During the years of its composition he remained in or near Paris, at first in attendance on his royal pupil, with whom he became a great favourite. The engagement must in any case have come to an end in the year 1648, when the prince removed to Holland, but it was probably broken off earlier by an illness that overtook Hobbes in 1647 and disabled him for six months. On recovering from this illness, which nearly proved fatal, he resumed his literary task, and carried it steadily forward to completion by the year 1650, having also within the same time translated into English, with characteristic force of expression, his Latin treatise. Otherwise the only thing known (from one or two letters) of his life in those years is that from the year 1648 he had begun to think of returning home; he was then sixty, and might well be weary of exile. When 1650 came, as if to prepare the way for the reception of his *magnum opus*, he allowed the publication of his earliest treatise, divided into two separate small volumes (*Human Nature, or the Fundamental Elements of Policy*, *E. W.*, iv. pp. 1-76, and *De Corpore Politico, or the Elements of Law, Moral and Politic*, pp. 77-228).[2] In 1651[3] he published his translation of the *De Cive* under the title of *Philosophical Rudiments concerning Government and Society* (*E. W.*, ii.). Meanwhile the printing of the greater work was proceeding, and finally it appeared about the middle of the same year, 1651, under the title of *Leviathan, or the Matter, Form, and Power of a Commonwealth, Ecclesiastical and Civil* (*E. W.*, iii.), with a quaint frontispiece in which, from behind hills overlooking a fair landscape of town and country, there towered the body (above the waist) of a crowned giant, made up of tiny figures of human beings and bearing sword and crozier in the two hands. It appeared, and soon its author was more lauded and decried than any other thinker of his time; but the first effect of its publication was to sever his connexion with the exiled royalist party, and to throw him for protection on the revolutionary Government. No sooner did copies of the book reach Paris than he found himself shunned by his former associates, and though he was himself so little conscious of disloyalty that he was forward to present a manuscript copy "engrossed in vellum in a marvellous fair hand"[4] to the young king of the Scots (who, after the defeat at Worcester, escaped to Paris about the end of October), he was denied the royal presence when he sought it shortly afterwards. Straightway, then, he saw himself exposed to a double peril. The exiles had among them desperadoes who could slay; and, besides exciting the enmity of the Anglican clergy about the king, who bitterly resented the secularist spirit of his book, he had compromised himself with the French authorities by his elaborate attack on the papal system. In the circumstances, no resource was left him but secret flight. Travelling with what speed he could in the depths of a severe winter and under the effects of a recent (second) illness, he managed to reach London, where, sending in his submission to the council of state, he was allowed without trouble to subside into private life.

Though Hobbes came back, after his eleven years' absence, without having as yet publicly proved his title to rank with the natural philosophers of the age, he was sufficiently conscious of what he had been able to achieve in *Leviathan*; and it was in no humble mood that he now, at the age of sixty-four, turned to complete the fundamental treatise of his philosophical system. Neither were those whom his masterpiece soon roused to enthusiasm, or those whom it moved to indignation, likely to be indifferent to anything he should now write, whether it lay near to or far from the region of practice. Taking up his abode in London on his return, and continuing to reside there for the sake of intellectual society, even after renewing his old ties with the earl of Devonshire, who lived in the country till the Restoration,[5] he worked so steadily upon the

[1] Described as "nobilis Languedocianus" in *Vit.*; doubtless the same with the "Dominus Verdusius, nobilis Aquitanus," to whom was dedicated the *Exam. et Emend. Math. Hod.* (*L. W.*, iv.) in 1660. Du Verdus was one of Hobbes's profoundest admirers and most frequent correspondents in later years; there are many of his letters among Hobbes's papers at Hardwick.

[2] The *Human Nature* corresponds with cc. i-xiii of the first part of the original treatise. The remaining six chapters of the part stand now as Part I. of the *De Corpore Politico*. Part II. of the *D. C. P.* corresponds with the original second part of the whole work.

[3] At the beginning of this year he wrote and published in Paris a letter on the nature and conditions of poetry, chiefly epic, in answer to an appeal to his judgment made in the preface to Sir W. Davenant's heroic poem, *Gondibert* (*E. W.*, iv. pp. 441-58). The letter is dated Jan. 10, 1650 (165½).

[4] This presentation copy, so described by Clarendon (*Survey of the Leviathan*, 1676, p. 8), is doubtless the beautifully written and finely bound MS. now to be found in the British Museum (Egerton MSS. 1910).

[5] During all the time he was abroad he had continued to receive from his patron a yearly pension of £80, and they remained in steady correspondence. The earl, having sided with the king in 1642, was declared unfit to sit in the House of Peers, and though, by submission to Parliament, he recovered his estates when they were sequestered later on, he did not sit again till 1660. Among Hobbes's friends at this time are specially mentioned Selden and Harvey, who each left him a legacy of £10 on dying, Selden in 1654 and Harvey in 1657. Harvey (not Bacon) is the only Englishman he mentions in the dedicatory epistle prefixed to the *De Corpore*, among the founders, before himself, of the new natural philosophy.

materials he had long had by him as to be printing the *De Corpore* in the year 1654. Circumstances (of which more presently), however, kept the book back till the following year, and meanwhile the readers of *Leviathan* had a different excitement. In 1654 a small treatise, *Of Liberty and Necessity* (*E. W.*, iv. pp. 229–278), issued from the press, claiming to be an answer to a discourse on the same subject by Bishop Bramhall of Londonderry, addressed by Hobbes to the marquis of Newcastle.[1] It was really such, and had grown out of an oral discussion between Hobbes and Bramhall in the marquis's presence at Paris in 1646,—Bramhall, a strong Arminian, having afterwards written down his views and sent them to Newcastle to be answered in this form by Hobbes, and Hobbes having duly replied, but not for publication, because he thought the subject a delicate one. Unpublished, accordingly, the piece remained; but it happened that Hobbes, in the interval between writing his own reply and receiving from the bishop in 1647 a rejoinder which he left unanswered, allowed a French acquaintance to have a private translation of his reply made by a young Englishman, who secretly took also a copy of the original for himself; and now it was this unnamed purloiner who, in 1654, when Hobbes had become famous and feared, gave it to the world of his own motion, with an extravagantly laudatory epistle to the reader in its front. Upon Hobbes himself the publication came as a surprise, but, after his plain speaking in *Leviathan*, there was nothing in the piece that he need scruple to have made known, and he seems to have readily enough condoned the offender's act. On the other hand, Bramhall, supposing Hobbes privy to the publication, might well resent the manner of it, especially as no mention was made of his rejoinder. Accordingly, in 1655, he printed everything that had passed between them (under the title of *A Defence of the True Liberty of Human Actions from Antecedent or Extrinsic Necessity*), with loud complaint against the treatment he had received, and the promise added that, in default of others, he himself would stand forward to expose the deadly principles of *Leviathan*. About this time Hobbes had begun to be hard pressed by other foes, and, being never more sure of himself than upon the question of the will, he appears to have welcomed the opportunity thus given him of showing his strength. By 1656 he was ready with his *Questions concerning Liberty, Necessity, and Chance* (*E. W.*, v.), in which he replied with astonishing force to the bishop's rejoinder point by point, besides explaining the occasion and circumstances of the whole debate, and reproducing (as Bramhall had done) all the pieces from the beginning. As perhaps the first clear exposition and defence of the *psychological* doctrine of determinism, Hobbes's own two pieces must ever retain a classical importance in the history of the free-will controversy; while Bramhall's are still worth study as specimens of scholastic fence. The bishop, it should be added, returned to the charge in 1658 with ponderous *Castigations of Hobbes's Animadversions*, and also made good his previous threat in a bulky appendix entitled *The Catching of Leviathan the Great Whale*. Hobbes never took any notice of the *Castigations*, but ten years later replied to the charges of atheism, &c., made in the non-political part of the appendix, of which he says he then heard for the first time (*E. W.*, iv. pp. 279–384. This *Answer* was first published after Hobbes's death. Bramhall had died, as archbishop of Armagh, in 1663).[2]

We may now follow out the more troublesome conflict, or rather series of conflicts, in which Hobbes became entangled from the time of publishing his *De Corpore* in 1655, and which checkered all his remaining years. In *Leviathan* he had vehemently assailed the system of the universities, as originally founded for the support of the papal against the civil authority, and as still working social mischief by adherence to the old learning. The attack was duly noted at Oxford, where under the Commonwealth a new spirit of scientific activity had begun to stir; and in 1654 Seth Ward, the Savilian professor of astronomy, replying in his *Vindiciæ Academiarum* to some other assaults (then very common) on the academic system, retorted upon Hobbes that, so far from the universities being now what he had known them in his youth, he would find his geometrical pieces, when they appeared, better understood there than he should like. This was said in reference to the boasts in which Hobbes seems to have been freely indulging of having squared the circle and accomplished other such feats; and, when a year later the *De Corpore* (*L. W.*, i.) finally appeared, it was seen how the thrust had gone home. In the chapter (xx.) of that work where Hobbes dealt with the famous problem whose solution he fondly thought he had found, there were left some self-complacent expressions vented against Vindex (Ward) at a time when the solutions still seemed to him good; but the solutions themselves, as printed, were allowed to be all in different ways halting, as he naively confessed he had discovered only when he had been driven by the insults of malevolent men to examine them more closely with the help of his friends. A strange conclusion this, and reached by a path not less strange, as was now to be disclosed by a relentless hand. Ward's colleague, the more famous John Wallis, Savilian professor of geometry, had been privy to the challenge thrown out in 1654, and it was arranged that they should critically dispose of the *De Corpore* between them. Ward was to occupy himself with the philosophical and physical sections, which he did in leisurely fashion, bringing out his criticism in the course of next year (*In Th. Hobbii Philosophiam Exercitatio Epistolica*). Wallis was to confine himself to the mathematical chapters, and set to work at once with characteristic energy. Obtaining an unbound copy of the *De Corpore*, he saw by the mutilated appearance of the sheets that Hobbes had repeatedly altered his demonstrations before he issued them at last in their actual form, grotesque as it was, rather than delay the book longer. Obtaining also a copy of the work as it had been printed before Hobbes had any doubt of the validity of his solutions, Wallis was able to track his whole course from the time of Ward's provocation—his passage from exultation to doubt, from doubt to confessed impotence, yet still without abandoning the old assumption of confident strength; and all his turnings and windings were now laid bare in one of the most trenchant pieces of controversial writing ever penned. Wallis's *Elenchus Geometriæ Hobbianæ*, published in 1655 about three months after the *De Corpore*, contained also an elaborate criticism of Hobbes's whole attempt to relay the foundations of mathematical science in its place within the general body of reasoned knowledge—a criticism which, if it failed to allow for the merit of the conception, exposed only too effectually the utter inadequacy of the result. Taking up mathematics when not only his mind was already formed but his thoughts were crystallizing into a philosophical system, Hobbes had, in fact, never put himself to school and sought to work up gradually to the best knowledge of the time, but had been more anxious from the first to become himself an innovator with whatever insufficient means. The consequence was that, when not spending himself in vain attempts to solve the impossible problems that have always waylaid the fancy of self-sufficient beginners, he took an interest only in the elements of geometry, and never had any notion of the full scope of mathematical science, undergoing as it then was (and not least at the hands of Wallis) the extraordinary development which made it before the end of the century the potent instrument of physical discovery which it became in the hands of Newton. He was even unable, in dealing with the elementary conceptions of geometry, to work out with any consistency the few original thoughts he had, and thus became the easy sport of Wallis. At his advanced age, however, and with the sense he had of his powers, he was not likely to be brought to a better mind by so insulting an opponent. He did indeed, before allowing an English translation of the *De Corpore* (*E. W.*, i.) to appear in 1656, take care to remove some of the worst mistakes exposed by Wallis, and, while leaving out all the references to Vindex, now profess to make, in altered form, a series of mere "attempts" at quadrature; but he was far from yielding the ground to the enemy. With the translation,[3] in the spring of 1656, he had ready *Six Lessons to the*

[1] The treatise bore the date, "Rouen, Aug. 20, 1652," but it should have been 1646, as afterwards explained by Hobbes himself (*E. W.*, v. p. 25).

[2] A little tract by Bishop Laney of Ely, directed against the concluding summary in Hobbes's original statement to Newcastle, was published in 1676, and called forth a printed reply from Hobbes, again addressed to Newcastle (who had meanwhile become duke). This letter is not reprinted by Molesworth.

[3] This translation, *Concerning Body*, though not made by Hobbes, was revised by him; but it is far from accurate, and not seldom, at critical places (*e.g.*, c. vi. § 2), quite misleading. Philosophical citations from the *De Corpore* should always be made in the original Latin. Molesworth reprints the Latin, not from the first edition of 1655, but from the modified edition of 1668—modified, in the mathe-

Professors of Mathematics, one of Geometry, the other of Astronomy, in the University of Oxford (*E. W.*, vii. pp. 181–356), in which, after reasserting his view of the principles of geometry in opposition to Euclid's, he proceeded to repel Wallis's objections with no lack of dialectical skill, and with an unreserve equal to Wallis's own. He did not scruple, in the ardour of conflict, even to maintain positions that he had resigned in the translation, and he was not afraid to assume the offensive by a counter criticism of three of Wallis's works then published. When he had thus disposed of the "Paralogisms" of his more formidable antagonist in the first five lessons, he ended with a lesson on "Manners" to the two professors together, and set himself gravely at the close to show that he too could be abusive. In this particular part of his task, it must be allowed, he succeeded very well; his criticism of Wallis's works, especially the great treatise *Arithmetica Infinitorum* (1655), only showed how little able he was to enter into the meaning of the modern analysis. Wallis, on his side, was not less ready to keep up the game in English than he had been to begin it in Latin. Swift as before to strike, in three months' time he had deftly turned his own word against the would-be master by administering *Due Correction for Mr Hobbes, or School Discipline for not saying his Lessons right*, in a piece that differed from the *Elenchus* only in being more biting and unrestrained. Having an easy task in defending himself against Hobbes's trivial criticism, he seized the opportunity given him by the English translation of the *De Corpore* to track Hobbes again step by step over the whole course, and now to confront him with his incredible inconsistencies multiplied by every new utterance. But it was no longer a fight over mathematical questions only. Wallis having been betrayed originally by his fatal cleverness into the pettiest carping at words, Hobbes had retorted in kind, and then it became a high duty in the other to defend his Latin with great parade of learning and give fresh provocation. One of Wallis's rough sallies in this kind suggested to Hobbes the title of the next rejoinder with which, in 1657, he sought to close the unseemly wrangle. Arguing in the *Lessons* that a mathematical point must have quantity, though this were not reckoned, he had explained the Greek word στίγμη, used for a point, to mean a visible mark made with a hot iron; whereupon he was charged by Wallis with gross ignorance for confounding στιγμή and στίγμα. Hence the title of his new piece:—Στιγμαί Ἀγεωμετρίας, Ἀγροικίας, Ἀντιπολιτείας, Ἀμαθείας, *or Marks of the Absurd Geometry, Rural Language, Scottish Church Politics, and Barbarisms of John Wallis, Professor of Geometry and Doctor of Divinity* (*E. W.*, vii. pp. 357–400). He now attacked more in detail but not more happily than before Wallis's great work, while hardly attempting any further defence of his own positions; also he repelled with some force and dignity the insults that had been heaped upon him, and fought the verbal points, but could not leave the field without making political insinuations against his adversary, quite irrelevant in themselves and only noteworthy as evidence of his own resignation to Cromwell's rule. The thrusts were easily and nimbly parried by Wallis in a reply (*Hobbiani Puncti Dispunctio*, 1657) occupied mainly with the verbal questions. Irritating as it was, it did not avail to shake Hobbes's determination to remain silent; and thus at last there was peace for a time.

Before the strife flamed up again, Hobbes had published, in 1658, the outstanding section of his philosophical system, and thus completed, after a fashion, the scheme he had planned more than twenty years before. So far as the treatise *De Homine* (*L. W.*, ii. pp. 1–132) was concerned, the completion was more in name than in fact. It consisted for the most part of an elaborate theory of vision which, though very creditable to Hobbes's scientific insight, was out of place, or at least out of proportion, in a philosophical consideration of human nature generally. The remainder of the treatise, dealing cursorily with some of the topics more fully treated in the *Human Nature* and the *Leviathan*, has all the appearance of having been tagged in haste to the optical chapters (composed years before)[1] as a makeshift for the proper transition required in the system from questions of Body Natural to questions of Body Politic. Hobbes had in fact spent himself in his earlier constructive efforts, and at the age of seventy, having nothing to add to his doctrine of Man as it was already in one form or another before the world, was content with anything that might stand for the fulfilment of his philosophical purpose. But he had still in him more than twenty years of vigorous vitality, and, not conscious to himself of any shortcoming, looked forward, now his hands were free, to doing battle for his doctrines. Rather than remain quiet, on finding no notice taken of his latest production, he would himself force on a new conflict with the enemy. Wallis having meanwhile published other works and especially a comprehensive treatise on the general principles of calculus (*Mathesis Universalis*, 1657), he might take this occasion of exposing afresh the new-fangled methods of mathematical analysis and reasserting his own earlier positions. Accordingly, by the spring of 1660, he had managed to put his criticism and assertions into five dialogues under the title *Examinatio et Emendatio Mathematicæ Hodiernæ qualis explicatur in Libris Johannis Wallisii*, with a sixth dialogue so called, consisting almost entirely of seventy or more propositions on the circle and cycloid.[2] Wallis, however, would not take the bait. Hobbes then tried another tack. Next year, having solved, as he thought, another ancient *crux*, the duplication of the cube, he had his solution brought out anonymously at Paris in French, so as to put Wallis and other critics off the scent and extort a judgment that might be withheld from a work of his. The artifice was successful, and no sooner had Wallis publicly refuted the solution than Hobbes claimed the credit of it, and went more wonderfully than ever astray in its defence. He presently republished it (in modified form), with his remarks, at the end of a new Latin dialogue which he had meanwhile written in defence of another part of his philosophical doctrine. This was the *Dialogus Physicus, sive De Natura Aeris* (*L. W.*, iv. pp. 233–296), fulminated in 1661 against Boyle and other friends of Wallis who, as he fancied, under the influence of that malevolent spirit, were now in London, after the Restoration, forming themselves into a society (incorporated as the Royal Society in 1662) for experimental research, to the exclusion of himself personally, and in direct contravention of the method of physical inquiry enjoined in the *De Corpore*.[3] All the laborious manipulation recorded in Boyle's *New Experiments touching the Spring of the Air* (1660), which Hobbes chose, without the least warrant, to take as the manifesto of the new "academicians," seemed to him only to confirm the conclusions he had reasoned out years before from speculative principles, and he warned them that if they were not content to begin where he had left off their work would come to nought. To as much of this diatribe as concerned himself Boyle quickly replied with force and dignity, but it was from Hobbes's old enemy that retribution came, in the scathing satire *Hobbius Heauton-timorumenos* (1662). Wallis, who had deftly steered his course amid all the political changes of the previous years, managing ever to be on the side of the ruling power, was now apparently stung to fury by a wanton allusion in Hobbes's latest dialogue to a passage of his former life (his deciphering for the Parliament the king's papers taken at Naseby), whereof he had once boasted but after the Restoration could not speak or hear too little. The revenge he took was crushing. Professing to be roused by the attack on his friend Boyle, when he had scorned to lift a finger in defence of himself against the earlier dialogues, he tore them all to shreds with an art of which no general description can give an idea. He got, however, upon more dangerous ground when, passing wholly by the political insinuation against himself, he roundly charged Hobbes with having written *Leviathan* in support of Oliver's title, and deserted his royal master in distress. Hobbes seems to have been fairly bewildered by the rush and whirl of sarcasm with which Wallis drove him anew from every mathematical position he had ever taken up, and did not venture forth into the field of scientific controversy again for some years, when he had once followed up the physical dialogue of 1661 by seven shorter ones, with the inevitable appendix, entitled *Problemata Physica, una cum Magnitudine Circuli* (*L. W.*, iv. pp. 297–384), in 1662.[4] But all the more eagerly did he take advantage of Wallis's loose calumny to strike where he felt himself safe. His answer to the personal charges took the form of a letter about him-

matical chapters, in general (not exact) keeping with the English edition of 1656. The Vindex episode, referred to in the *Six Lessons*, becomes intelligible only by going beyond Molesworth to the original Latin edition of 1655.

[1] They were composed originally, in a somewhat different and rather more extended form, as the second part of an English treatise on Optics, completed by the year 1646. Of this treatise, preserved in Harleian MSS. 3360, Molesworth otherwise prints the dedication to the marquis of Newcastle, and the concluding paragraphs (*E. W.*, vii. pp. 467–471).

[2] *L. W.*, iv. pp. 1–232. The propositions on the circle, forty-six in number (shattered by Wallis in 1662), were omitted by Hobbes when he republished the *Dialogues* in 1668, in the collected edition of his Latin works from which Molesworth reprints. In the part omitted, at p. 154 of the original edition, Hobbes refers to his first introduction to Euclid, in a way that confirms the story in Aubrey quoted in an earlier paragraph.

[3] Remaining at Oxford, Wallis, in fact, took no active part in the constitution of the new society, but he had been, from 1645, one of the originators of an earlier association in London, thus continued or revived. This earlier society had been continued also at Oxford after the year 1649, when Wallis and others of its members received appointments there.

[4] The *Problemata Physica* was at the same time put into English (with some changes and omission of part of the mathematical appendix), and presented to the king, to whom the work was dedicated in a remarkable letter apologizing for *Leviathan*. In its English form, as *Seven Philosophical Problems and Two Propositions of Geometry* (*E. W.*, vii. pp. 1–68), the work was first published in 1682, after Hobbes's death.

self in the third person addressed to Wallis in 1662, under the title of *Considerations upon the Reputation, Loyalty, Manners, and Religion of Thomas Hobbes* (*E. W.*, iv. pp. 409–440). In this piece, which is of great biographical value, he told his own and Wallis's "little stories during the time of the late rebellion" with such effect that Wallis, like a wise man, attempted no further reply. Thus ended the second bout.

After a time Hobbes took heart again and began a third period of controversial activity, which did not end, on his side, till his ninetieth year. Little need be added to the simple catalogue of the untiring old man's labours in this last stage of his life. The first piece, published in 1666, *De Principiis et Ratiocinatione Geometrarum* (*L. W.*, iv. pp. 385–484), was designed, as the sub-title declared, to lower the pride of geometrical professors by showing that there was no less uncertainty and error in their works than in those of physical or ethical writers. Wallis replied shortly in the *Philosophical Transactions* (August, 1666). Three years later he brought his three great achievements together in compendious form, *Quadratura Circuli, Cubatio Sphæræ, Duplicatio Cubi*, and as soon as they were once more refuted by Wallis, reprinted them with an answer to the objections, in compliment to the grand-duke of Tuscany, who paid him attentions on a visit to England in 1669 (*L. W.*, iv. pp. 485–522). Wallis, who had promised to leave him alone henceforward, refuted him again before the year was out. In 1671 he worked up his propositions over again in *Rosetum Geometricum* (*L. W.*, v. pp. 1–50), as a fragrant offering to the geometrical reader, appending a criticism (*Censura brevis*, pp. 50–88) on the first part of Wallis's treatise *De Motu*, published in 1669; also he sent *Three Papers* to the Royal Society on selected points treated very briefly, and when Wallis, still not weary of confuting, shortly replied, published them separately with triumphant *Considerations on Dr Wallis's Answer to them* (*E. W.*, vii. pp. 429–448). Next year, 1672, having now, as he believed, established himself with the Royal Society, he proceeded to complete the discomfiture of Wallis by a public address to the Society on all the points at issue between them from the beginning, *Lux Mathematica excussa collisionibus Johannis Wallisii et Thomæ Hobbesii* (*L. W.*, v. pp. 89–150), the light, as the author R. R. (Roseti Repertor) added, being here "increased by many very brilliant rays." Wallis replied in the *Transactions*, and then finally held his hand. Hobbes's energy was not yet exhausted. In 1674, at the age of eighty-six, he published his *Principia et Problemata aliquot Geometrica, ante desperata nunc breviter explicata et demonstrata* (*L. W.*, v. pp. 150–214), containing in the chapters dealing with questions of principle not a few striking observations, which ought not to be overlooked in the study of his philosophy. His last piece of all, *Decameron Physiologicum* (*E. W.*, vii. pp. 69–180), in 1678, was a new set of dialogues on physical questions, most of which he had treated in a similar fashion before; but now, in dealing with gravitation, he was able to fire a parting shot at Wallis; and one more demonstration of the equality of a straight line to the arc of a circle, thrown in at the end, appropriately closed the strangest warfare in which perverse thinker ever engaged.[1]

We must now turn back to trace the fortunes of Hobbes and his other doings in the last twenty years of his life. All these controversial writings on mathematics and physics represent but one half of his activity after the age of seventy; though, as regards the other half, it is not possible, for a reason that will be seen, to say as definitely in what order the works belonging to the period were produced. From the time of the Restoration he acquired a new prominence in the public eye. No year had passed since the appearance of *Leviathan* without some indignant protest against the influence which its trenchant doctrine was calculated to produce upon minds longing above everything for civil repose; but it was not until the old political order was set up again that "Hobbism" became a fashionable creed, which it was the duty of every lover of true morality and religion to denounce. Friends and foes alike were impressed by the king's behaviour to the aged philosopher. Two or three days after Charles's arrival in London, Hobbes, who had come up to town from spending the previous winter in Derbyshire, drew in the street the notice of his former pupil, and was at once received into favour. The young king, if he had ever himself resented the apparent disloyalty of the "Conclusion" of *Leviathan*, had not retained the feeling long, and could well enough appreciate the principles of the great book when the application of them happened, as now, to be turned in his own favour. He had, besides, from of old a relish for Hobbes's lively wit, and did not like the old man the less because his presence at court scandalized the bishops or the prim virtue of Chancellor Hyde. He even went the length of bestowing on Hobbes (but not always paying) a yearly pension of £100, and had his portrait hung up in the royal closet. These marks of favour, naturally, did not lessen Hobbes's self-esteem, and perhaps they explain, in his later writings, a certain slavishness of feeling toward the regal authority, which is wholly absent from his rational demonstration of absolutism in the earlier works. At all events Hobbes remained very well satisfied with the rule of a king who had the sense to appreciate the author of *Leviathan*, and to protect him, when after a time protection in a very real sense became necessary. His eagerness to defend himself against Wallis's imputation of disloyalty, and his apologetic dedication of the *Problemata Physica* to the king, are evidence of the hostility with which he was being pressed as early as 1662; but it was not till 1666 that he felt himself seriously in danger. In that year the Great Fire of London, following in ominous succession on the Great Plague of the year before, roused the superstitious fears and intolerant passions of the people, and the House of Commons embodied the general feeling in a bill against atheism and profaneness. On the 17th October it was ordered that the committee to which the bill was referred "should be empowered to receive information touching such books as tend to atheism, blasphemy, and profaneness, or against the essence and attributes of God, and in particular the book published in the name of one White,[2] and the book of Mr Hobbes called the *Leviathan*, and to report the matter with their opinion to the House." What steps were taken before the 31st of January following, when the bill was read a third time and passed, does not appear; but Hobbes, then verging upon eighty, was greatly terrified at the prospect of being treated as a heretic, and proceeded to burn such of his papers as he thought might compromise him. At the same time he set himself, with a very characteristic determination, to inquire into the actual state of the law of heresy. The results of his investigation were first announced in three short Dialogues added (in place of the old "Review and Conclusion," for which the day had passed) as an Appendix to his Latin translation of *Leviathan* (*L. W.*, iii.), included with the general collection of his works published at Amsterdam in 1668. In this appendix, as also in the posthumous tract, published in 1680, *An Historical Narration concerning Heresy and the Punishment thereof* (*E. W.*, iv. pp. 385–408), he aimed at showing that, since the High Court of Commission had been put down, there remained in England no court of heresy at all to which he was amenable, and that even when it stood nothing was to be declared heresy but what was at variance with the Nicene Creed, as he maintained the doctrine of *Leviathan* was not.

The only consequence that came of the parliamentary scare was that Hobbes could never afterwards get permission to print anything on subjects relating to human conduct. The collected edition of his Latin works (in two quarto volumes) appeared at Amsterdam in 1668, because he could not obtain the censor's licence for its publication at London, Oxford, or Cambridge. Other writings which he had finished, or on which he must have been engaged about this time, were not made public till after his death —the king apparently having made it the price of his protection that no fresh provocation should be offered to the

[1] Wallis's pieces were excluded from the collected edition of his works (1693–97), and have become extremely rare.

[2] The *De Medio Animarum Statu* of Thomas White, a heterodox Catholic priest, who contested the natural immortality of the soul. White (who died 1676) and Hobbes were friends.

popular sentiment. The most important of the works composed towards 1670, and thus kept back, is the extremely spirited dialogue to which he gave the title *Behemoth: the History of the Causes of the Civil Wars of England and of the Counsels and Artifices by which they were carried on from the year* 1640 *to the year* 1660.[1] To the same period probably belongs the unfinished *Dialogue between a Philosopher and a Student of the Common Laws of England* (*E. W.*, vi. pp. 1–160), a trenchant criticism of the constitutional theory of English government as upheld by Coke. Aubrey takes credit for having tried to induce Hobbes to write upon the subject in 1664 by presenting him with a copy of Bacon's *Elements of the Laws of England*, and though the attempt was then unsuccessful, Hobbes later on took to studying the statute-book, with *Coke upon Littleton*. One other posthumous production (besides the tract on Heresy before mentioned) may also be referred to this, if not, as Aubrey suggests, an earlier time—the two thousand and odd elegiac verses into which he amused himself by throwing his view of ecclesiastical encroachment on the civil power; the quaint verses, disposed in his now favourite dialogue-form, were first published, nine years after his death, under the title *Historia Ecclesiastica* (*L. W.*, v. pp. 341–408), with a preface by Thomas Rymer.

For some time Hobbes was not even allowed to utter a word of protest, whatever might be the occasion that his enemies took to triumph over him. In 1669 he had silently to bear the spectacle of an unworthy follower—Daniel Scargil by name, a fellow of Corpus Christi at Cambridge—made to act an edifying part in a public recantation of his principles, after having brought them into discredit by offensively supporting them in the public schools. A few years later, in 1674, he had another experience of academic disfavour when Dr John Fell, the dean of Christ Church, who bore the charges of the Latin translation of Anthony Wood's *History and Antiquities of the University of Oxford* (1670), struck out all the complimentary epithets in the account of his life, and substituted very different ones; but this time the king did suffer him to defend himself by publishing a dignified letter (*Vit. Auct.*, pp. xlviii.-l.), to which Fell replied by adding to the translation when it appeared a note full of the grossest insults. And, amid all his troubles, Hobbes was not without his consolations. No Englishman of that day stood in the same repute abroad, and foreigners, noble or learned, who came to England, never forgot to pay their respects to the old man, whose vigour and freshness of intellect no progress of the years seemed able to quench.

His pastimes in the latest years were as singular as his labours. The autobiography in Latin verse, with its playful humour, occasional pathos, and sublime self-complacency, was thrown off at the age of eighty-four. At eighty-five, in the year 1673, he sent forth a translation of four books of the *Odyssey* (ix.–xii.) in rugged but not seldom happily turned English rhymes; and, when he found this *Voyage of Ulysses* eagerly received, he had ready by 1675 a complete translation of both *Iliad* and *Odyssey* (*E. W.*, x.), prefaced by a lively dissertation "Concerning the virtues of an heroic poem," showing his unabated interest in questions of literary style. In that year (1675) he ceased coming to London, and thenceforth passed his time at his patron's seats in Derbyshire, always occupied to the last with some intellectual work in the early morning and in the afternoon hours, which it had long been his habit to devote to thinking and to writing. With such tenacity did he cling to his pursuits (always systematically keeping up exercise for the sake of health) that even as late as August 1679 he was promising his publisher "somewhat to print in English." The end came very soon afterwards. A suppression of urine in October, in spite of which he insisted upon being conveyed with the family from Chatsworth to Hardwick Hall towards the end of November, was followed by a paralytic stroke, under which he sank on the 4th of December, in his ninety-second year. He lies buried in the neighbouring parish church of Hault Hucknall.

In the foregoing sketch the aim has been to give a definite idea of the circumstances in which Hobbes, after slowly developing in the first forty years of his life, displayed a mental activity of such extraordinary variety in his last fifty years. The task of expounding and criticizing either his better-known or his less-known doctrines will not be attempted in this place; but a few remarks may be added as to his position in the general movement of English philosophy. As already suggested, it cannot be allowed that he falls into any regular succession from Bacon; neither can it be said that he handed on the torch to Locke. He was the one English thinker of the first rank in the long period of two generations separating Locke from Bacon, but, save in the chronological sense, there is no true relation of succession among the three. It would be difficult even to prove any ground of affinity among them beyond a disposition to take sense as a prime factor in the account of subjective experience: their common interest in physical science was shared equally by rationalist thinkers of the Cartesian school, and was indeed begotten of the time. Backwards, Hobbes's relations are rather with Galileo and the other inquirers who, from the beginning of the 17th century, occupied themselves with the physical world in the manner that has come later to be distinguished by the name of science in opposition to philosophy. But it happened that, even more than in external nature, Hobbes was interested in the phenomena of social life, presenting themselves so impressively in an age of political revolution. So it came to pass that, while he was unable, by reason of imperfect training and too tardy development, with all his pains, to make any contribution to physical science or to mathematics as instrumental in physical research, he attempted a task which no other adherent of the new "mechanical philosophy" conceived—nothing less than such a universal construction of human knowledge as would bring Society and Man (at once the matter and maker of Society) within the same principles of scientific explanation as were found applicable to the world of Nature. The construction was, of course, utterly premature, even supposing it were inherently possible; but it is Hobbes's distinction, in his century, to have conceived it, and he is thereby lifted from among the scientific workers with whom he associated to the rank of those philosophical thinkers who have sought to order the whole domain of human knowledge. Such as it was, the effects of his philosophical endeavour may be traced on a variety of lines. Upon every subject that came within the sweep of his system, except mathematics and physics, his thoughts have been productive of thought. When the first storm of opposition from smaller men, roused as much by his paradoxical expressions as by his doctrines, had begun to die down, thinkers of real weight, beginning with Cumberland and Cudworth, were moved by his analysis of the moral nature of man to probe anew the question of the natural springs and the rational grounds of human action; and thus it may be said that Hobbes gave the first impulse to the whole of that movement of ethical speculation that, in modern times, has been carried on with such remarkable continuity in England. In politics, the revulsion from his particular conclusions did not prevent the more clear-sighted of his opponents from recognizing the force of his supreme demonstration of the practical irresponsibility of

[1] *E. W.*, vi. pp. 161–418. Though *Behemoth* was kept back at the king's express desire it saw the light, without Hobbes's leave, in 1679, before his death.

the sovereign power, wherever seated, in the state; and, when in a later age the foundations of a positive theory of legislation were laid in England, it was extreme liberals of the school of Bentham—James Mill, Grote, Molesworth—that brought again into general notice the writings of the great publicist of the 17th century, who, however he might, by the force of temperament, himself prefer the rule of one, based his whole political system upon a rational regard to the common weal. Finally, the psychology of Hobbes, though too undeveloped to guide the thoughts or even perhaps arrest the attention of Locke, when essaying the scientific analysis of knowledge, came in course of time (chiefly through James Mill) to be connected with the theory of associationism developed from within the school of Locke, in different ways, by Hartley and Hume; nor is it surprising that the later associationists, finding their principle more distinctly formulated in the earlier thinker, should sometimes have been betrayed into affiliating themselves to Hobbes rather than to Locke.

Sufficient information is given in the *Vitæ Hobbianæ Auctarium* (*L. W.*, i. pp. lxv. *ff.*) concerning the frequent early editions of Hobbes's separate works, and also concerning the works of those who wrote against him, to the end of the 17th century. In the 18th century, after Clarke's *Boyle Lectures* of 1704-5, the opposition was less express. In 1750 *The Moral and Political Works* were collected, with life, &c., by Dr Campbell, in a folio edition, including in order, *Human Nature, De Corpore Politico, Leviathan, Answer to Bramhall's Catching of the Leviathan, Narration concerning Heresy, Of Liberty and Necessity, Behemoth, Dialogue of the Common Laws*, the Introduction to the *Thucydides, Letter to Davenant and two others*, the Preface to the *Homer, De Mirabilibus Pecci* (with English translation), *Considerations on the Reputation, &c., of T. H.* In 1812 the *Human Nature* and the *Liberty and Necessity* (with supplementary extracts from the *Questions* of 1656) were reprinted in a small edition of 250 copies, with a meritorious memoir (based on Campbell) and dedication to Horne Tooke, by Philip Mallet. Molesworth's edition (1839-45), dedicated to Grote, has been referred to in a former note. Of translations may be mentioned *Les Élémens philosophiques du Citoyen* (1649) and *Le Corps politique* (1652), both by Sorbière, conjoined with *Le Traité de la Nature humaine*, by D'Holbach, in 1787, under the general title *Les Œuvres philosophiques et politiques de Thomas Hobbes*; a translation of the first section, "Computatio sive Logica," of the *De Corpore*, included by Destutt de Tracy with his *Élémens d'Idéologie* (1804); a translation of *Leviathan* into Dutch in 1678, and another (anonymous) into German—*Des Engländers Thomas Hobbes Leviathan oder der kirchliche und bürgerliche Staat* (Halle, 1794, 2 vols.); a translation of the *De Cive* by J. H. v. Kirchmann—*T. Hobbes: Abhandlung über den Bürger, &c.* (Leipsic, 1873). No comprehensive monograph on Hobbes's whole philosophical performance has yet been produced. Molesworth had begun to make preparations for writing one when his energies were diverted into practical politics. (G. C. R.)

HOBOKEN, a city and port of entry of the United States, in Hudson county, New Jersey, is situated on the Hudson river, contiguous to Jersey city, which stretches immediately to the south. It lies opposite New York city, ¾ of a mile distant, and occupies a picturesque site at the foot of a steep hill, with a considerable river frontage. The principal public buildings are the Stevens institute of technology, the bequest of the late Commodore Stevens, whose mansion in the Gothic style of architecture is a noteworthy feature of the place; St Mary's Catholic hospital; and the Franklin lyceum association library. The manufactories include iron-foundries and a lead pencil work; and the trade in coal is important. Castle Point and the adjoining "Elysian Fields" afford delightful views of the river, and, before the recent building operations, used to be a favourite resort of the New-Yorkers. The city, which was originally settled by the Dutch, who named it after a village on the Scheldt, was incorporated in 1855. Population in 1870, 20,000; in 1880, 30,999.

HOCHE, Lazare (1768-1797), a French general of the time of the Revolution, was born of poor parents at Montreuil near Versailles, June 25, 1768. At the age of sixteen he enlisted as a private soldier with the intention of proceeding to the East Indies, but was sent instead to a depôt of the Gardes Françaises. Having risen to the rank of sergeant, he, at the outbreak of the Revolution, made an important stand with a mere handful of troops against a large body of insurgents; and it was he also who, at a later period, defended the entrance to the chamber of the queen when her apartments were invaded by a revolutionary mob. He distinguished himself at the siege of Thionville in 1792, and at the battle of Neerwinden, 18th March 1793. Shortly afterwards he received the brevet of general of brigade, and was appointed to the command of Dunkirk, for his brilliant defence of which against the duke of York he received the chief command of the army of the Moselle. The purpose which he originally proposed to himself in this campaign was to cut the communication between the Austrians and Prussians, and, though foiled in this attempt by the superior forces of the duke of Brunswick, he succeeded by a masterly manœuvre in effecting a junction of a portion of his troops with the army of the Rhine, and thus causing the Austrians to evacuate Alsace. Shortly afterwards he was assigned the chief command by the representatives of the people with the two armies, but, this promotion awakening the morbid suspicion of Robespierre, he was recalled and thrown into prison, and it was only the timely fall of Robespierre that saved him from the guillotine. On being released by the convention, he was so successful in pacifying La Vendée and Brittany that he was appointed to the command of the three united armies, numbering in all 100,000 men, in order to apply similar measures for the disarmament of the other departments. After accomplishing this task with an admirable combination of firmness and moderation, he was appointed to the command of an army organized for the conquest of Ireland. The expedition set sail from Brest, 16th December 1796, but was dispersed by a storm, scarcely one half of the vessels escaping shipwreck or capture. In the following year Hoche was sent to the eastern frontier to act against Austria, and by a series of masterly manœuvres he succeeded in surrounding the army of General Kray, and but for a declaration of peace would have taken him and all his troops prisoners of war. Not long after his return he was appointed to the command of the united army in Germany, but eight days afterwards he died suddenly at Wetzlar, 18th September 1797. The belief was widely spread that he had been poisoned, but the suspicion seems to have been without foundation. Though Hoche at his death had not attained the age of thirty, he had already displayed powers, both as politician and as strategist, which, had he lived, would have rendered him a formidable rival of Napoleon, and might have effectually frustrated the latter's unscrupulous ambition.

See *Notes historiques sur la vie morale politique et militaire du général Hoche*, Strasburg, 1798; Rousselin, *Vie de Lazare Hoche, général des armées de la république Française*, Paris, 1798; Dubroca, *Éloge funèbre du général Hoche*, Paris, 1800; *Vie et pensées du général Hoche*, Bern; Champrobert, *Notice historique sur Lazare Hoche, le pacificateur de la Vendée*, Paris, 1840; Dourille, *Histoire de Lazare Hoche*, Paris, 1844; Desprez, *Lazare Hoche d'après sa correspondance*, Paris, 1858.

HODGE, Charles (1797-1878), theologian, was born in Philadelphia, December 28, 1797. He was educated at the college of New Jersey in Princeton, where he graduated in 1815, and afterwards at the theological seminary of the Presbyterian Church in the same place, where he continued a student until 1819; in 1820 he became assistant teacher; and in 1822 he was chosen by the general assembly to be professor of Oriental and Biblical literature there. He spent two years on the Continent, from 1826 to 1828, studying under De Sacy in Paris, under Gesenius and Tholuck in Halle, and under Hengstenberg, Neander, and Humboldt in Berlin. In 1840 he was transferred to the chair of didactic and exegetical theology, to which subjects that of polemic theology was added in 1852, and this office he held to the day of his death. In 1825 he established a quarterly publication entitled the *Biblical Repertory*, designed to furnish translations and reprints of the best contemporaneous foreign essays on theological and religious subjects. On his return from Europe in 1828 he changed it into a vehicle for publishing original theological essays and reviews, and added the words *Princeton Review* to its title. He secured for it the position of theological organ of the old school division of the Presbyterian Church, and continued its principal editor and contributor until 1868. He contributed over 130 articles on subjects ranging through every department of theology and ecclesiology, and all the great practical, ecclesiastical, moral, and national questions of the day. From 1835 to 1868 he wrote yearly an article reviewing the action of each general assembly, which series has exerted a powerful influence over the current opinion and history of the church to which he belonged. The most important of these have been republished in Great Britain and in America, in volumes, under the titles of *Hodge's Essays*, *Princeton Theological Essays*, and *Hodge's Church Polity*. He was made doctor of divinity by Rutgers College, N.J., in 1834, moderator of the general assembly (O.S.) in 1846, member of the committee to revise the *Book of Discipline* of the Presbyterian Church in 1858, and LL.D. by Washington College, Pa., in 1864. April 24, 1872, the fiftieth anniversary of his election to his professorship, was observed in Princeton as his jubilee by between 400 and 500 representatives of his 3000 pupils, when he received congratulatory addresses and letters from all the Presbyterian theological faculties of Scotland and Ireland, and from a majority of those belonging to the various Evangelical churches of America. He continued to instruct his classes uninterruptedly up to the time of his death in Princeton, June 19, 1878. The main characteristics of Hodge were strength and persistence of conviction and of purpose, logical clearness and symmetry of thought and style, energy and effective vigour in the defence of his convictions and in assaults upon what he considered error, sunny cheerfulness of disposition, and humility, tenderness, and gentleness of heart and manner.

Besides his articles in the *Princeton Review*, he published a *Commentary on the Epistle to the Romans*, Phila., 1835, abridged 1836, rewritten and enlarged 1866; *Constitutional History of the Presbyterian Church in the United States*, 2 vols., 1840-41; *The Way of Life*, 1842; Commentaries on *Ephesians*, 1856, 1 *Corinthians*, 1857, 2 *Corinthians*, 1860; *Systematic Theology*, probably the best of all modern expositions of Calvinistic dogmatic, 3 vols., 2200 pp., 1871–73; *What is Darwinism?* 1874; and there have been published since his death *Hodge's Church Polity*, 1878, and *Conference Papers*, 1879.

HODGKINSON, EATON (1789–1861), a distinguished engineer, was the son of a farmer, and was born at Anderton near Northwich, Cheshire, 26th February 1789. He received his first stimulus to the study of mathematics at the grammar school of Northwich, and this interest was further quickened by the instructions of Dr Dalton at Manchester, whither he had removed in 1811, and where, instead of following his original purpose to study for the church, he was assisting his widowed mother to establish a business. For several years he carried on mechanical researches and experiments, but his first discovery of importance was that of a new form of iron girder, by which a gain of two-fifths in strength was obtained over that formerly in use. After this he carried on investigations of a similar character in conjunction with Sir William Fairbairn, who greatly profited by his suggestions and assistance in some of his more important inventions. In 1840 Hodgkinson communicated a paper to the Royal Society on *Experimental Researches on the Strength of Pillars of Cast-iron and other Materials* in recognition of which he in 1841 received the royal medal, and was also elected a fellow. His formulæ for solid and hollow pillars soon obtained general adoption in all engineering class-books. Subsequently he was employed by Stephenson to verify the experiments of Fairbairn on wrought-iron tubes, with a view to the construction of the Britannia Bridge; and for his co-operation in this work he received a silver medal at the Paris Exhibition of 1855. In 1847 he was appointed professor of the mechanical principles of engineering in University College, London. In 1848 he was chosen president of the Manchester Philosophical Society, of which he had been a member since 1826, and to which, both previously and subsequently, he contributed many of the more important results of his discoveries. For several years he took an active part in the discussions of the Institution of Civil Engineers, of which he was elected an honorary member in 1851. He died at Eaglesfield House, near Manchester, 18th June 1861. The name of Hodgkinson will always be associated with those of Fairbairn and Stephenson, and without his assistance it may safely be affirmed that the most brilliant achievements of both would have been impossible.

HÓDMEZÖ-VÁSÁRHELY, a corporate town in the county of Csongrád, Hungary, is situated on the lake Hód, and on the Alföld Railway, about 90 miles S.E. of Budapest, 46° 27′ N. lat., 20° 22′ E. long. The town is large and rapidly improving, and has many public buildings. Of these the most noteworthy are the town-hall, the Roman Catholic, Greek, and Protestant (one Lutheran and two Calvinist) churches, the Jews' synagogue, the Protestant gymnasium, and the royal law courts. Hódmezö-Vásárhely possesses also many elegant private residences, two hospitals, two banks, and several literary institutions, and has a flourishing trade. The soil of the surrounding country is exceedingly fertile, the chief products being wheat, mangcorn, barley, oats, millet, maize, and various descriptions of fruit, especially melons. Extensive vineyards, yielding large quantities of both white and red grapes, skirt the town, which has also a fine public garden. The horned cattle and horses of Hódmezö-Vásárhely are considered the best in the Alföld; sheep and pigs are also extensively reared. The commune is protected from inundations of the Theiss by an enormous dike, but the town, nevertheless, sometimes suffers considerable damage during the spring floods. In 1870 the population was 49,153, chiefly Magyars.

HODOGRAPH is the name given to a geometrical construction which greatly facilitates the study of kinematical questions. It was invented by Sir William Rowan Hamilton about 1845, and the first account of it, written by him, is to be found in the *Proc. R. I. A.* for 1846.

The hodograph may be thus defined:—If a point be in motion in any orbit and with any velocity, and if, at each instant, a line be drawn from a fixed point parallel and equal to the velocity of the moving point at that instant, the extremities of these lines will lie on a curve called the hodograph. Let PP_1P_2 be the path of the moving point, and let OT, OT_1, OT_2, be drawn from the fixed point O parallel and equal to the velocities at P, P_1, P_2 respectively, then the locus of T is the hodograph of the orbit described by P (fig. 1).

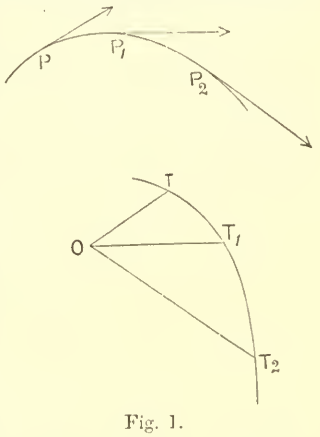

Fig. 1.

From this definition we have the following important fundamental property which belongs to all hodographs, viz., that at any point the tangent to the hodograph is parallel to the direction, and the velocity in the hodograph equal to the magnitude of the resultant acceleration at the corresponding point of the orbit. This will be evident if we consider that, since radii vectores of the hodograph represent velocities in the orbit, the elementary arc between two consecutive radii vectores of the hodograph represents the velocity which must be compounded with the velocity of the moving point at the beginning of any short interval of time to get the velocity at the end of that interval, that is to say, represents the change of velocity for that interval. Hence the elementary arc divided by the element of time is the rate of change of velocity of the moving-point, or in other words, the velocity in the hodograph is the acceleration in the orbit.

Analytically thus (Thomson and Tait, *Nat. Phil.*):—Let x, y, z be the coordinates of P in the orbit, ξ, η, ζ those of the corresponding point T in the hodograph, then

$$\xi=\frac{dx}{dt}\,,\quad \eta=\frac{dy}{dt}\,,\quad \zeta=\frac{dz}{dt}\,;$$

therefore

$$\frac{d\xi}{\frac{d^2x}{dt^2}}=\frac{d\eta}{\frac{d^2y}{dt^2}}=\frac{d\zeta}{\frac{d^2z}{dt^2}}\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Also, if s be the arc of the hodograph,

$$\frac{ds}{dt}=v=\sqrt{\left(\frac{d\xi}{dt}\right)^2+\left(\frac{d\eta}{dt}\right)^2+\left(\frac{d\zeta}{dt}\right)^2}\,,$$

$$=\sqrt{\left(\frac{d^2x}{dt^2}\right)^2+\left(\frac{d^2y}{dt^2}\right)^2+\left(\frac{d^2z}{dt^2}\right)^2}\quad . \quad . \quad (2).$$

Equation (1) shows that the tangent to the hodograph is parallel to the line of resultant acceleration, and (2) that the velocity in the hodograph is equal to the acceleration.

Every orbit must clearly have a hodograph, and, conversely, every hodograph a corresponding orbit; and, theoretically speaking, it is possible to deduce the one from the other, having given the other circumstances of the motion. We give a few examples:—

1. For uniform motion in a straight line the hodograph is easily seen to be a point.

2. For uniform or variable acceleration in a straight line the hodograph is the line described by a point moving with uniform or variable velocity.

3. For uniform circular motion the hodograph is also a circle. In this case it may be useful to show how the conception of the hodograph leads easily to the ordinary expression for the so-called centrifugal force.

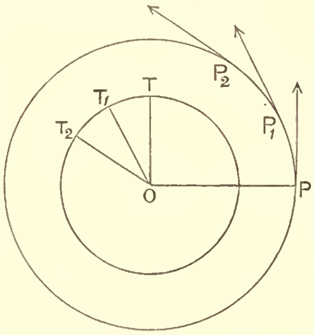

Fig. 2.

Let P (fig. 2) describe the circumference PP_1P_2 with uniform velocity v, and from the centre O draw OT, OT_1, OT_2, &c., equal to each other and parallel to the tangents at P, P_1, P_2 respectively, then TT_1T_2 is the hodograph circle. Also let a equal the acceleration of P, which also equals the velocity of T; then, since T describes the hodograph uniformly in the same time that P describes the orbit, we have

$$\frac{v}{a}=\frac{OP}{OT}=\frac{r}{v}\quad \therefore\ a=\frac{v^2}{r}\,.$$

It is evident that the tangent at T is parallel to PO the direction of acceleration at P.

4. For simple harmonic motion the hodograph is also simple harmonic motion, and similarly for elliptic harmonic motion. For the former we have

$$s=a\cos(nt+\epsilon)\,;$$

$$\therefore\ v=\dot{s}=-na\sin(nt+\epsilon)=na\cos(nt+\epsilon+\tfrac{1}{2}\pi)\,;$$

which indicates simple harmonic motion with changed amplitude and phase.

5. For parabolic motion the hodograph is a straight line.

Let OF (fig. 3) be the velocity of projection. Resolve it vertically and horizontally; the horizontal component OH is constant, so that the hodograph must be the vertical line FHT. The velocity at any point P of the parabola is evidently represented by the line OT drawn parallel to the tangent at P.

Analytically thus:—If x, y be the coordinates of the moving point and ξ and η those of the hodograph, we have

$$\ddot{x}=0\,,\ \ddot{y}=-f\ (f \text{ being the vertical acceleration})\,;$$

$$\therefore\ \dot{\xi}=0\,,\ \dot{\eta}=-f\,;$$

$$\therefore\ \xi=c\,,\quad \eta=c'-ft,$$

which indicates a vertical straight line described with uniform velocity f.

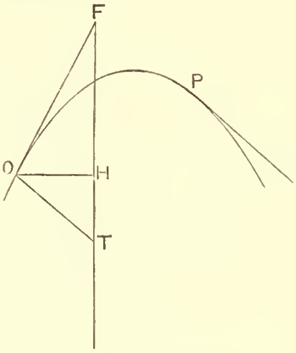

Fig. 3.

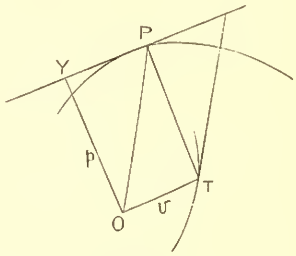

Fig. 4.

6. For central forces the hodograph will vary with the law of acceleration towards the centre. Hamilton showed that, for the Newtonian law of the inverse square of the distance, the hodograph is always a circle, and for that reason he designated that law the *law of the circular hodograph.*

Assuming the centre of force as origin for the hodograph, we see that, from definition, the tangent and radius vector at any point P of the orbit are respectively parallel to the radius vector and tangent at the corresponding point T of the hodograph (fig. 4). These four lines thus enclose a parallelogram PT, whose shape is constantly changing, although its area is constant, being equal to the constant rectangle YT contained by the velocity and the perpendicular on the tangent. As usual, let $TY=vp=h$. Also the angle between two consecutive tangents to the hodograph is equal to the angle between the corresponding radii vectores of the orbit, and hence, if θ be the angle between OP and some initial line, and s the arc of the hodograph, the ordinary formula for curvature gives

$$\frac{1}{\rho}=\frac{d\theta}{ds}=\frac{\dot{\theta}}{\dot{s}}\,;$$

but

$$h=r^2\dot{\theta}\,,$$

and $\dot{s}$ = velocity in hodograph = acceleration in orbit = P (say);

$$\therefore\ \frac{1}{\rho}=\frac{hr^{-2}}{P}\,;$$

$$\therefore\ \rho=\frac{Pr^2}{h}\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)\,;$$

a most useful expression for the radius of curvature of the hodograph to any central orbit.

If the acceleration vary inversely as the square of the distance, $P=\frac{M}{r^2}$, where M is the mass at the centre acting upon unit mass in the orbit. Substituting in (3), we get

$$\rho=\frac{M}{h}=\text{constant}.$$

Hence, for this law of force, and evidently for it only, the hodograph is a circle.

Assuming that the hodograph is a circle, we can show that the orbit for this law of force must be a conic section. Let CTB (fig. 5) be the hodograph circle, O the origin, and H the centre; and let the ratio $\frac{OH}{HT}=\epsilon$. Draw OP parallel to the tangent at T and, therefore, perpendicular to TG. Take OP such that the parallelogram contained by OP and OT = a constant = h. Draw OA perpendicular to CB; and let POA = θ; then,

$$OP\,.\,TG=h\,;$$

$$\therefore\ OP\,.\,(TH+HG)=h\,;\ \text{but}\ TH=\rho=\frac{M}{h},\ \text{and}$$

$$HG=HO\cos\theta=\epsilon\rho\cos\theta=\frac{\epsilon M}{h}\cos\theta\,;$$

$$\therefore\ OP\left(\frac{M}{h}+\epsilon\frac{M}{h}\cos\theta\right)=h\,;$$

$$\therefore\ OP=r=\frac{h^2}{M}\cdot\frac{1}{1+\epsilon\cos\theta}\,.$$

Hence the locus of P is a conic section whose semi-parameter is $\frac{h^2}{M}$. If $\epsilon < 1$, O is within the circle and the orbit is an ellipse; if $\epsilon = 1$, O is on the circumference and the orbit is a parabola; and if $\epsilon > 1$, O is without the circle and the orbit is an hyperbola.

Two values of the potential, V, can readily be found from the above:—

$$V = \frac{M}{r}\text{ ; but } r = \frac{h}{TG}\text{ ;}$$

$$\therefore\ V = \frac{M}{h}\ .\ TG = TH\ .\ TG\ .$$

Also, since OGH is a right angle, V = TH . TG = the square of the tangent from T to the circle described on HO as diameter.

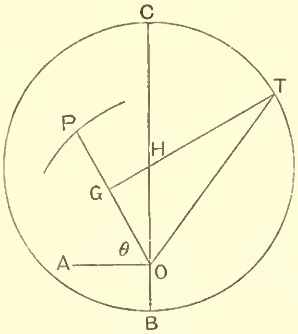

Fig. 5.

A beautiful result connected with the hodograph, and one which has attracted the attention of several of the ablest mathematicians, was communicated by Sir William Hamilton to the Royal Irish Academy in March 1847. It is called the theorem of hodographic isochronism, and is thus stated:—If two circular hodographs, having a common chord, which passes through, or tends towards, a common centre of force, be cut perpendicularly by a third circle, the times of hodographically describing the intercepted arcs will be equal. A purely quaternion proof is given of this theorem by Hamilton in his *Elements*, and, following the hints given by that method, he has also indicated the following geometrical proof.

Let TMT′M′, WMW′M′ (fig. 6), be the two hodographic circles with centres H and L and common chord MM′. Let P, P′, on the common chord produced, be the centres of two circles WTW′T′ and BAB′A′, near each other, which cut the hodographs orthogonally. Let O be the centre of force, OZ perpendicular to the tangent at T, and TR, T′R′ perpendicular to SX. Also let AT mean the arc AT, and similarly for the other small arcs. Draw PY perpendicular to PT.

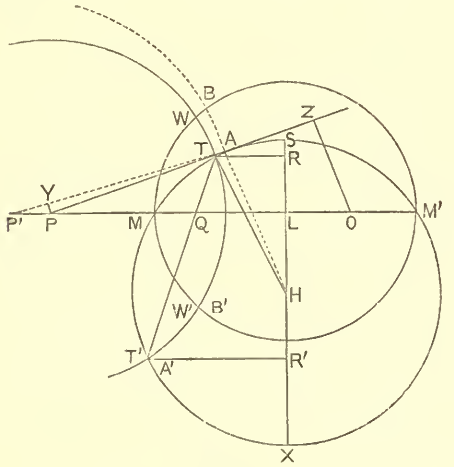

Fig. 6.

From similar triangles THA and TPY we have

$$\frac{AT}{TH} = \frac{PY}{PT}\ ;$$

also from similar triangles THR and PP′Y

$$\frac{TH}{TR} = \frac{PP'}{PY}\ \therefore\ \frac{AT}{TR} = \frac{PP'}{PT}\ ;$$

$$\therefore\ AT = \frac{PP'\ .\ TR}{PT}\ .$$

Similarly, $$A'T' = \frac{PP'\ .\ T'R'}{PT}\ .$$

If t and t' be the times of hodographically describing the arcs AT and A′T′ respectively,

$$t = \frac{AT}{Mr^{-2}} = \frac{M\ .\ AT}{M^2r^{-2}} = \frac{M\ .\ AT}{V^2}\ \text{(if V be the potential at T).}$$

But V = HT . OZ = OP . TR from similar triangles OPZ and THR;

$$\therefore\ t = \frac{M\ .\ AT}{OP^2\ .\ TR^2} = \frac{M\ .\ PP'\ .\ TR}{OP^2\ .\ TR^2\ .\ PT} = \frac{M\ .\ PP'}{OP^2\ .\ PT\ .\ TR}\ .$$

Similarly,

$$t' = \frac{M\ .\ PP'\ .\ T'R'}{OP^2\ .\ T'R'^2\ .\ PT} = \frac{M\ .\ PP'}{OP^2\ .\ PT\ .\ T'R'}\ .$$

$$\therefore\ t + t' = \frac{M\ .\ PP'}{OP^2\ .\ PT}\left\{\frac{1}{TR} + \frac{1}{T'R'}\right\} = \frac{2M\ .\ PP'}{OP^2\ .\ PT}\left\{\frac{TR + T'R'}{2TR\ .\ T'R'}\right\}.$$

Now $\frac{2TR\ .\ T'R'}{TR + T'R'}$ = the harmonic mean between TR and T′R′ = QL ;

$$\therefore\ t + t' = \frac{2M\ .\ PP'}{OP^2\ .\ PT\ .\ QL}\ .$$

From this expression we see that the time of describing the two small arcs TA and T′A′ is independent of the radius of the hodograph and the distance of its centre from L. Hence it is equal to the time of describing the two arcs BW and B′W′. By continuing the process of drawing orthogonals we arrive at the conclusion that the time of describing the whole arc ATT′A′ is equal to the time of describing the arc BWW′B′. A very simple analytical proof is given in Tait and Steele's *Dynamics of a Particle*. Others not so simple by Cayley and Droop are to be found in the *Quarterly Journal of Mathematics*. We can only mention that the theorem of Lambert can be deduced from the above theorem of hodographic isochronism without using any property of conic sections.

Sir William Hamilton has observed that we have a good instance of a hodograph in the curve of aberration of a star, which is merely the hodograph of the earth's annual motion. The fact that this curve is a circle in a plane parallel to the earth's orbit, abstracted, however, from the general idea of the hodograph, was known long before the date of the hodograph. It will be found clearly stated and proved in Woodhouse's *Astronomy*, of date 1821, and from allusions there it appears to have been known even earlier. As an application of the hodograph, Thomson and Tait point out that the heat and light received by a planet from the sun in any time are proportional to the corresponding arc of the hodograph.

HODY, Humphrey (1659-1706), an English divine, was born at Odcombe in Somersetshire in 1659. In 1676 he entered Wadham College, Oxford, of which, having proceeded M.A. in 1682, he became fellow in 1684. Previously he had published in 1680 *Dissertatio contra Historiam Aristeæ de LXX. Interpretibus*, in which he showed that the so-called letter of Aristeas, containing an account of the production of the Septuagint, was the late forgery of a Hellenist Jew originally circulated to lend authority to that version. The dissertation was generally regarded as conclusive, although Vossius published an angry and scurrilous reply to it in the appendix to his edition of Pomponius Mela. In 1689 Hody wrote the "Prolegomena" to the chronicle of John Malala, published at Oxford in 1691. The following year he became chaplain to Stillingfleet, bishop of Worcester, and, on account of his supporting the ruling party in a controversy with Dodwell regarding the nonconforming bishops, he was appointed chaplain to Archbishop Tillotson, an office which he continued to hold under Tenison. In 1698 he was appointed regius professor of Greek in the university of Oxford, and in 1704 he was promoted to the archdeaconry of Oxford. In 1701 he published *History of English Councils and Convocations*, and in 1704 in four volumes *De Bibliorum textis originalibus*, in which he included his original work on the Septuagint, and published a reply to the attack of Vossius. He died 20th January 1706. A work, *De Græcis Illustribus*, which he left in manuscript, was published in 1742 by Dr Jebb, who prefixed to it a Latin dissertation.

HOF, originally Regnitzhof, a town of Bavaria, circle of Upper Franconia, is beautifully situated on the Saale, on the north-eastern spurs of the Fichtelgebirge, and at the junction of several railways, 30 miles N.N.E. of Baireuth. It is the seat of district, town, country, and commercial courts, a chamber of commerce, and a head tax office. It is surrounded by walls, and has one Catholic and three Protestant churches, a town-house of 1563 in the Gothic style, a gymnasium with an extensive library, a trade and commercial school, a female school of the higher grade, a people's school, an orphanage, a richly endowed hospital founded in 1262, and an infirmary. Its industries are chiefly connected with wool and cotton, and include woollen, cotton, and jute spinning, jute weaving, and the manufacture of cotton and half-woollen fabrics. It has also dye-works, flour-mills, saw-mills, breweries, iron-works, and manufactures for machinery, iron and tin wares, chemicals, and sugar. In the neighbourhood there are large marble quarries and extensive iron mines. The population in 1875 was 18,122.

Hof was built about 1080, on the site of an old robber castle. Originally it belonged to the empire, but afterwards it was held by the dukes of Meran, and then by the counts of Orlamünde, until it was sold in 1373 to the counts of Nuremberg. The cloth manufacture introduced into it in the 15th century, and the manufacture of veils, begun in the 16th century, greatly promoted its prosperity, but it suffered severely in the Albertine and Hussite wars, as well as in the Thirty Years' War; and in 1823 the greater part of it was destroyed by fire. In 1792 it came into the possession of Prussia; in 1806 it fell to France; and in 1810 it was incorporated with Bavaria. See Widmann, *Chronik der Stadt Hof*, 1844; Ernst, *Geschichte und Beschreibung des Bezirks und der Stadt Hof*, 1866.

HOFER, Andreas (1767–1810), a Tyrolese patriot, was born October 2, 1767, at St Leonhard, in the Passeyr valley. There his father kept a tavern called the Sandhof, which Hofer inherited, and on that account he was popularly known as the "Sandwirth." In addition to this he carried on a trade in wine and horses with the north of Italy, acquiring a high reputation for intelligence and honesty. On the outbreak of the war in 1796, he commanded a company of riflemen against the French at Lake Garda, and after the peace of Lunéville he took an active part in organizing the Tyrolese militia. After the treaty of Presburg (1805), by which Tyrol was transferred from Austria to Bavaria, Hofer was chosen a member of the secret Tyrolese deputation which went to Vienna to confer with the emperor on the condition of their country; and when, on the advice of Austria, the whole of Tyrol in April 1809 rose in arms, Hofer was chosen to the command of a large division of the insurgents, and inflicted an overwhelming defeat on the Bavarians at Sterzing. Reinforcements sent by Napoleon defeated the Austrians at Woergl and the Tyrolese at Feuersinger, but Hofer coming to the rescue of his country repulsed the Bavarians with great loss at Innsbruck. Notwithstanding also that Austria after Napoleon's victory at Wagram agreed to evacuate Tyrol, Hofer resolved to maintain the struggle, and on the 13th August, at Berg Isel, routed with great slaughter a combined French and Bavarian force, and completely freed his country from foreign dominion. For some time the internal affairs of Tyrol were administered by an independent Government of which Hofer was the head, but after the peace of Vienna the Bavarians again endeavoured to assert their supremacy, and after a heroic resistance Hofer was compelled to flee for safety to the mountains. A price was set upon his head, and on account of the treachery of one of his most trusted followers, he was captured, January 27, 1810, in a châlet in the Passeyr valley. He was sent to Mantua for trial, and on the 20th February, by the orders of Napoleon, was executed twenty-four hours after his condemnation. In 1823 his remains were removed from the place of sepulture at Mantua to Innsbruck, where they were interred in the Franciscan church, and in 1834 a marble statue was erected over his tomb. In 1819 the patent of nobility decreed for him by Austria in 1809 was conferred upon his family by the title of Von Passeyr.

See *Leben und Thaten des ehemaligen Tyroler Insurgenten-Chefs Andr. Hofer*, Berlin, 1810; *Andr. Hofer und die Tyroler Insurrection im Jahre* 1809, Munich, 1811; Hormayr, *Geschichte Andr. Hofer's Sandwirths auf Passeyr*, Leipsic, 1845; B. Weber, *Das Thal Passeyr und seine Bewohner mit besonderer Rücksicht auf Andreas Hofer und das Jahr* 1809, Innsbruck, 1851; Rapp, *Tirol im Jahr* 1809, Innsbruck, 1852; Heigel, *Andreas Hofer*, Munich, 1874. His history has supplied the materials for tragedies to B. Auerbach and Immermann.

HOFFMANN, August Heinrich (1798–1874), known as Hoffmann von Fallersleben, German poet, philologist, and historian of literature, was born at Fallersleben, in Lüneburg, April 2, 1798. He was educated at Helmstädt and Brunswick, and afterwards at the universities of Göttingen and Bonn. His original intention was to study theology, but he soon devoted himself entirely to literature. In 1823 he was appointed librarian to the university of Breslau, a post which he held till 1838. He was made extraordinary professor of the German language and literature at the university in 1830, and full professor in 1835; but he was deprived of his chair in 1842 in consequence of his *Unpolitische Lieder*, which gave much offence to the ruling classes of Prussia. He then travelled for some time in Germany, Switzerland, and Italy, and lived for two or three years in Mecklenburg, of which he became a naturalized citizen. The revolution of 1848 brought him back to Prussia, where he was restored to his rights, and received as a pension the "Wartegeld," that is, the salary attached to a promised office which is not yet vacant. He married in 1849, and during the next ten years lived first in Bingerbrück, afterwards in Neuwied, and then in Weimar, where he was one of the editors of the *Weimarische Jahrbuch*. In 1860 he became librarian to the duke of Ratibor, and he retained this appointment till his death on the 20th of January 1874. Fallersleben was one of the best popular poets of modern Germany. In politics he ardently sympathized with the progressive tendencies of his time, and he was among the earliest and most effective of the political poets who prepared the way for the outbreak of 1848. As a poet, however, he acquired distinction chiefly by the ease, simplicity, and grace with which he gave expression to the passions and aspirations of ordinary life. Although he had not been scientifically trained in music, he composed melodies for many of his songs, and a considerable number of them are sung by all classes in every part of Germany.

The best known of his poetical writings is his *Gedichte* (8th edition, Berlin, 1874); but there is great merit also in his *Alemannische Lieder* (5th edition, Mannheim, 1843), *Soldatenlieder* (Mainz, 1851), *Soldatenleben* (Berlin, 1852), *Rheinleben* (Neuwied, 1865), and in his *Fünfzig Kinderlieder*, *Fünfzig Neue Kinderlieder*, and *Alte und Neue Kinderlieder*. His *Unpolitische Lieder*, *Deutsche Lieder aus der Schweiz*, and *Streiflichter* are not without poetical value, but they are mainly interesting in relation to the practical movements of the age in which they were written. As a student of ancient Teutonic literature Fallersleben ranks among the most persevering and cultivated of German scholars, some of the chief results of his labours being embodied in his *Horæ Belgicæ*, *Fundgruben für Geschichte deutscher Sprache und Literatur*, *Altdeutsche Blätter*, *Spenden zur deutschen Literaturgeschichte*, and *Findlinge*. Among his editions of particular works may be named *Reineke Vos*, *Monumenta Elnonensia*, and *Theophilus*. *Die Deutsche Philologie im Grundriss* (1836) was at the time of its publication a valuable contribution to philological research, and historians of German literature still attach importance to his *Geschichte des deutschen Kirchenliedes bis auf Luther* (1832; 3d ed., 1861), *Unsere volksthümlichen Lieder* (3d ed., 1869), and *Die deutschen Gesellschaftslieder des 16 und 17 Jahrh.* (2d ed., 1860). In 1868–70 Fallersleben published in 6 vols. an autobiography, *Mein Leben: Aufzeichnungen und Erinnerungen*. See also *Briefe von Hoffmann von Fallersleben und Moritz Haupt an Ferdinand Wolf* (Vienna, 1874); Wagner, *Hoffmann von Fallersleben*, 1818–68 (Vienna, 1869); and Gottschall, *Porträts und Studien* (vol. v., Leipsic, 1876).

HOFFMANN, Ernst Theodor Wilhelm (1776–1822), German romance writer (for whose name Wilhelm his own substitute, in homage to Mozart, was Amadeus), was born at Königsberg, January 24, 1776. His parents, who lived unhappily together, separating a year or two after his birth, he was brought up in his grandmother's house, under the care of a bachelor uncle. His relations seem to have been fairly puzzled at the waywardness, cunning, and precocity of the boy, who neglected his school lessons and hated routine, but applied himself with passionate zest to the study of music and painting, extemporized marvellously on the harpsichord, and with his pencil caricatured friend and foe alike with terrible facility. Incited by his friend Hippel, Hoffmann on leaving school turned to the hereditary profession of the law; but, as no immediate post offered itself, he gave lessons in music and painting, and wrote two novels, for which he could not find a publisher. A discreditable love episode with one of his pupils drove him at this time from Königsberg, and he went to act as assistant to another lawyer uncle at Gross-Glogau in Silesia. In 1798 he became referendary in the supreme court at Berlin, and in 1800 passed his final examination and was appointed assessor to the court of Posen. Here he seems to have led a dissipated life, and to have contracted the habit of excessive drinking which marred his whole career. He subsequently made enemies in Posen by sending a series of scandalous caricatures for distribution at a masquerade ball, and his appointment was on this account changed to a councillorship at Plozk, where, having married ere this time, he spent two years in retirement, studying in his leisure hours the theory of music, translating Italian poetry, and sketching plans for future literary work; but in 1804, again in favour at headquarters, he was transferred as councillor to Warsaw. There he found a true friend in Hitzig, his colleague, and made the acquaintance of Werner, at whose request he set music to some parts of the *Kreuz an der Ostsee*. He soon became the centre of musical society in Warsaw, helped to institute a concert-house or "Ressource," found leisure not only to paint its saloons but to compose music for its orchestra, and was actually conducting this orchestra before enthusiastic audiences when Warsaw was taken by the French in 1806. For some time he lingered in Warsaw; but in the spring of 1807, having recovered from a fever to find himself almost penniless, he returned to Berlin to seek some means of livelihood. His only child died in Posen while he was in Berlin; and, though he succeeded in obtaining the post of music-director to the Bamberg theatre, the theatre soon after became bankrupt, and Hoffmann was once more destitute. He now found occasional employment as a composer of operatic music, and, as a last resource, attempted authorship. The editor of the *Allgemeine Musikalische Zeitung* enlisted his services, and in that paper appeared a series, afterwards published, with a preface by Jean Paul Richter, as *Fantasiestücke in Callots Manier* (1814; 4th ed., 1864). He composed at this time, among other things, a *Miserere* by order of the grand-duke of Würzburg, and, for the proprietors of the Bamberg theatre, music to Kotzebue's opera *Das Gespenst*; and he also gave lessons in music and drawing, decorated saloons, and painted portraits to order. The misery of his condition was enhanced by his wife's illness and his own light-hearted recklessness. The money which he inherited at the death of his uncle did not suffice to pay his debts; and he had been reduced to selling his last coat for food when his friends obtained for him the post of music-director to another theatrical company, performing alternately at Dresden and Leipsic. Hoffmann was writing romances in a garret in Dresden, or, bedridden by gout, was drawing caricatures of the "verwünschte Franzosen" while Napoleon and the allied armies were struggling round its walls. In 1814 appeared his *Vision auf der Schlachtfelde von Dresden*; and in the same year, on the fall of Napoleon, he returned to Berlin, and was reinstated in the legal profession. Two years later he was appointed councillor in the supreme court, and from that time enjoyed a good income, a dignified position, and the society of his best friends. He was already, in virtue of his *Fantasiestücke*, regarded as one of the most notable romance writers of his day, but most of his works were yet to come. These followed each other in quick succession. *Die Elixire des Teufels* appeared in 1816; *Nachtstücke* in 1817; *Seltsame Leiden eines Theaterdirektors* in 1818; *Die Serapionsbrüder*, a collection of tales, in 1819–24; *Klein Zaches, genannt Zinnober*, in 1819; *Prinzessin Brambilla* in 1821; *Meister Floh* in 1822; and *Lebensansichten des Katers Murr* in 1821–22. He also composed the opera *Undine*, the libretto of which was prepared by Fouqué himself. It was performed with success in Berlin; but the music was lost in the subsequent destruction of the opera-house by fire. Hoffmann's prospects in Berlin were ruined by the old habit of intemperance, which had grown upon him during the years of his poverty. We are told that his legal duties were scrupulously performed, and that the remainder of his day was spent in literary work, but that, when this was over, he avoided refined society, and his nights became a series of wild pothouse revels. His health soon gave way; and, after intense suffering from spinal paralysis, he died at Berlin, July 24, 1822. *Der Feind*, his last work, remained unfinished.

Versatility is the chief characteristic of Hoffmann's genius, and it is also its greatest weakness. He is admitted to have been an excellent jurist. His paintings were clever, though fantastic. He was a popular composer and a brilliant romance-writer. But this very versatility prevented his rising to eminence in any one vocation; and, even as a romance-writer, in which capacity he will be longest remembered, he was deficient in some of the highest attributes. His imagination was unbounded, his wit light and acrid, his dialogue stirring. His descriptive passages, in their minute vividness, have been compared to those of Sir Walter Scott, and his romances abound in the superstitious and mythical, that dæmonic element which is so peculiarly German, and which in Hoffmann amounted almost to a frenzy. But, with all this, a perusal of his writings leaves a disagreeable impression on the mind, a feeling of dissatisfaction and unrest. They are the production of a misdeveloped nature, of a man full of feverish impulses, oddities, and weakness, not devoid of tenderness, but whose temper was unforgiving and malicious, whose prevailing mood was the sarcastic, and whose only religious creed was a blind, headlong fatalism. There is also a strong element in his writings which Carlyle in his biography of Hoffmann has called "playerlike," a glitter which is of tinsel, a something "false, brawling, and tawdry." His writings, like his character, are a curious mixture of what is really beautiful and rare with much that is petty and sordid. Their cleverness is irresistible; but the dignity of true greatness is not there.

Die Elixire der Teufels, his longest completed work, contains in a narrative form some of his own wildest and most revolting delusions; and the derisive *Kater Murr*, of which the third volume is wanting, is not less characteristic. Some of his smaller pieces have justly been thought the most pleasing and perfect of his works. Among these are *Der goldene Topf*, *Das Fräulein von Scudery*, *Doge und Dogaresse*, and *Meister Martin und seine Gesellen*. The delicacy and finish of the last, slight though it is, have stamped it as Hoffmann's masterpiece.

A life of Hoffmann has been written by Hitzig, his colleague first in Warsaw and afterwards in Berlin, under the title of *Hoffmann's Leben und Nachlass*. A selection of his writings was published in Berlin, 1827-28, and five more volumes (including Hitzig's life) were added by his widow in 1839. A selection of his writings by Kurz appeared in 1870, and an edition of his collected works, in 12 vols., in 1871-73. Most of his romances are to be obtained separately in the *Universal-Bibliothek*, a cheap edition of standard authors published at Leipsic. *Die Elixire des Teufels* has been translated into English (Edin., 1824), and Carlyle has given us a biography of Hoffmann, together with a translation of one of the *Fantasiestücke*, "Der Goldene Topf," in his *German Romance*. (F. M.)

HOFFMANN, Friedrich (1660-1742), the most famous physician in a family that had been connected with medicine for 200 years before him, was born at Halle, February 19, 1660. He received his school education at the gymnasium of his native town, where he acquired that taste for and skill in mathematics to which he attributed much of his after success. At the age of eighteen he went to study medicine at Jena, whence in 1680 he passed to Erfurt, in order to attend Kasper Cramer's lectures on chemistry. Next year, returning to Jena, he received his doctor's diploma, and, after publishing a thesis, was permitted to teach. Constant study then began to tell on his health, and in 1682, leaving his already numerous pupils, he proceeded to Minden in Westphalia to recruit himself, at the request of a relative who held a high position in that town. After practising his profession at Minden for two years, Hoffmann made a journey to Holland and England, where he formed the acquaintance of many illustrious chemists and physicians. Towards the end of 1684 he returned to Minden, and during the next three years he received many flattering appointments. In 1688 he removed to the more promising sphere of Halberstadt, with the title of physician to the principality of Halberstadt; and on the founding of Halle university in 1693, his reputation, which had been steadily increasing, procured for him the primarius chair of medicine, while at the same time he was charged with the responsible duty of framing the statutes for the new medical faculty. He filled also the chair of natural philosophy. With the exception of four years (1708-12), which he passed at Berlin in the capacity of royal physician, without however giving up his professorship, Hoffmann spent the rest of his life at Halle in instruction, practice, and study, interrupted now and again by visits to different courts of Germany, where his services procured him honours and rewards. His fame became European. He was enrolled a member of many learned societies in different foreign countries, while in his own he became privy councillor. He died at Halle, on November 12, 1742.

Hoffmann's writings, the result both of compilation and original research, have still a considerable suggestive value. His theories, though sometimes vague and even idle, contributed in some degree to introduce a revolution in medical science; while his doctrine of atony and spasm in the living solid as the sole cause of internal disorders turned the attention of physicians more directly to the primary moving powers of the system. He pursued with ardour the study of practical chemistry, and pharmacy owes to him several preparations which are still in general use. It was through Hoffmann also that many of the mineral springs of Germany first came into repute as health resorts.

Of his numerous writings a catalogue is to be found in Haller's *Bibliotheca Medicinæ Practicæ*. The chief is *Medicina Rationalis Systematica*, undertaken at the age of sixty, and published in 1730. It was translated into French in 1739, under the title of *Médecine Raisonnée d'Hoffmann*. A complete edition of Hoffmann's works, with a life of the author, was published at Geneva in 1740, to which supplements were added in 1753 and 1760. Editions appeared also at Venice in 1745, and at Naples in 1753 and 1793.

HOFFMANN, Johann Joseph (1805-1878), an eminent Chinese and Japanese scholar, was born at Würzburg on the 16th of February 1805. After studying in the philosophical department of the Würzburg university, the young man took to the stage in 1825; and it was only by an accidental meeting with the German traveller, Dr Siebold, in July 1830, that his interest was diverted to Oriental philology. From Siebold himself he acquired the rudiments of Japanese; and in order to take advantage of the instructions of Ko-ching-chang, a Chinese teacher whom Siebold had brought home with him, he made himself acquainted with Malay, the only language except Chinese which the Chinaman could understand. Such rapid advance did Hoffmann make that in a few years he was able to supply the translations for Siebold's *Nippon*; and the high character of his work soon attracted the attention of older scholars. Stanislas Julien invited him to Paris; and he would probably have accepted the invitation, as a disagreement had broken out between him and Siebold, had not M. Baud, the Dutch colonial minister, appointed him Japanese translator with a salary of 1800 florins or £150. The Dutch authorities were slow in giving him further recognition; and he was too modest a man successfully to urge his claims. It was not till after he had received the offer of the professorship of Chinese in King's College, London, that the authorities made him professor at Leyden, and the king allowed him a yearly pension. In 1875 he was decorated with the order of the Netherlands Lion, and in 1877 he was elected corresponding member of the Berlin Academy. But these honours came almost too late; for a disease of the lungs from which he had long suffered terminated fatally on the 19th of January 1878.

Hoffmann's chief work is his Japanese Dictionary. Though begun in 1839 it is still unfinished, for the difficulties against which he had to contend were immense. Unable at first to procure the necessary type, he set himself to the cutting of punches; and even when the proper founts were obtained he had to act as his own compositor as far as Chinese and Japanese were concerned. His Japanese grammar is a standard work; it was published in Dutch and English in 1867, and in English and German in 1876. Of his miscellaneous productions it is enough to mention "Japan's Bezüge mit der Koraischen Halbinsel und mit Schina" in *Nippon*, vii.; *Yo-San-fi-Rok, L'art d'élever les vers à soie au Japan, par Ouckaki Mourikouni*, Paris, 1848; "Die Heilkunde in Japan" in *Mittheil. d. deutsch. Gesellsch. für Natur- und Völkerk. Ost-Asiens*, 1873-1874; and *Japanische Studien*, 1877, dealing with Japanese poetry. The Dictionary is being continued by L. Serrurier.

For further details see Kern in *Koninklijke Akademie van Wetenschappen*; W. Vissering in *Het Vaderland*, 23d Jan. 1878; and *Leiden Studenten-almanak*, 1879.

HOFMANN, Johann Christian Konrad von (1810-1877), Lutheran theologian, was born December 21, 1810, at Nuremberg, whence, after passing through the usual gymnasium course, he in 1827 proceeded to the university of Erlangen as a student of theology and history. In 1829 he became the pupil of Schleiermacher, Hengstenberg, Neander, and Ranke, at Berlin; in 1832 he passed his examination as a candidate in theology at Erlangen; and in the following year he received an appointment to teach Hebrew and history in the gymnasium there. In 1835 and 1838 respectively he "habilitated" in the philosophical and in the theological faculty at Erlangen, where in 1841 he was appointed professor extraordinarius in theology. In 1842 he accepted a call to an ordinary theological chair at Rostock, but in 1845 he returned once more to Erlangen, where he had been nominated as successor of Harless. Apart from his professorial and literary activities, his life was a singularly uneventful one; he was, however, an enthusiastic adherent of the political party of progress, and as such sat as member for Erlangen and Fürth in the Bavarian second chamber from 1863 to 1868. His death occurred on December 20, 1877.

He wrote *Die siebzig Jahre des Jeremias u. die siebzig Jahrwochen des Daniel*, 1836; *Geschichte des Aufruhrs in den Cevennen*, 1837; *Lehrbuch der Weltgeschichte*, 1839, which became a text-book in the Protestant gymnasia of Bavaria; *Weissagung u. Erfüllung im alten u. neuen Testamente*, 1841–44, 2d ed., 1857–60; *Der Schriftbeweis*, 1852–56, 2d ed., 1857–60; *Die Heilige Schrift Neuen Testaments zusammenhängend untersucht*, 1862–75; and *Theologische Ethik*, 1878. He also edited, in conjunction with Höfling and Thomasius, the *Zeitschrift für Protestantismus u. Kirche* from 1846 onwards. His most important works are the four last named. In *Weissagung u. Erfüllung* he not only carries out the idea, originated by Herder, that the entire Old Testament as an organic whole is one great connected prophecy, pointing towards Christ, but elaborates the thought that the New Testament also is organically prophetic of the last things. In the *Schriftbeweis*, on the fundamental axiom that the history of redemption as recorded in Scripture is the history of a development he at great length sets forth the methods according to which dogmatic theology must seek for and use the Scripture proofs on which it is or ought to be based. His work upon the New Testament discusses the credibility of the several books, and seeks to ascertain the place occupied by each in the organic whole. The *Theologische Ethik* unfolds the scheme of Christian duty as arising out of the new relations of the believer to God through Christ. In theology as in ecclesiastical polity Hoffmann was a Lutheran of a very extreme type, although the strongly marked individuality of some of his opinions laid him open to repeated accusations of heterodoxy.

HOGARTH, WILLIAM (1697–1764). Apart from the story of his works, the life of the greatest English pictorial satirist, when divested of doubtful tradition, is singularly devoid of incident. It is mainly to be found in the autobiographical *Memoranda* published by John Ireland in 1798, and the successive *Anecdotes* of the antiquary, John Nichols. Hogarth was born in London on the 10th day of November 1697, and baptized on the 28th in the church of St Bartholomew the Great. His father was a schoolmaster and literary hack, who had come to the metropolis to seek that fortune which had been denied to him in his native Westmoreland. His son seems to have been early distinguished rather by a talent for drawing and an active perceptive faculty than by any close attention to the learning which he was soon shrewd enough to see had not made his parent prosper. "Shows of all sorts gave me uncommon pleasure when an infant," he says, "and mimicry, common to all children, was remarkable in me. . . . My exercises when at school were more remarkable for the ornaments which adorned them than for the exercise itself." This being the case, it is no wonder that, by his own desire, he was apprenticed to a silver-plate engraver, Mr Ellis Gamble, at the sign of the "Golden Angel" in Cranbourne Street or Alley, Leicester Fields. For this master he engraved a shop-card which is still extant. When his apprenticeship began is not recorded; but it must have been concluded before the beginning of 1720, for in April of that year he appears to have set up as engraver on his own account. His desires, however, were not limited to silver-plate engraving. "Engraving on copper was, at twenty years of age, my utmost ambition." For this he lacked the needful skill as a draughtsman; and his account of the means which he took to supply this want, without too much interfering with his pleasure, is thoroughly characteristic, though it can scarcely be recommended as an example. "Laying it down," he says, "first as an axiom, that he who could by any means acquire and retain in his memory perfect ideas of the subjects he meant to draw would have as clear a knowledge of the figure as a man who can write freely hath of the twenty-four letters of the alphabet and their infinite combinations (each of these being composed of lines), and would consequently be an accurate designer, . . . I therefore endeavoured to habituate myself to the exercise of a sort of technical memory, and by repeating in my own mind the parts of which objects were composed I could by degrees combine and put them down with my pencil." This account, it is possible, has something of the complacency of the old age in which it was written; but there is little doubt that his marvellous power of seizing expression owed less to patient academical study than to his unexampled eye-memory and tenacity of minor detail. But he was not entirely without technical training, as, by his own showing, he occasionally "took the life" to correct his memories, and is known to have studied at Sir James Thornhill's then recently opened art school.

"His first employment" (*i.e.*, after he set up for himself) "seems," says Nichols, "to have been the engraving of arms and shop bills." After this he was employed in designing "plates for booksellers." Of these early and mostly insignificant works we may pass over The Lottery, an Emblematic Print on the South Sea, and some book illustrations, to pause at Masquerades and Operas, 1724, the first plate he published on his own account. This is a clever little satire on contemporary follies, such as the masquerades of the Swiss adventurer Heidegger, the popular Italian opera singers, Rich's pantomimes at Lincoln's Inn Fields, and last, but by no means least, the exaggerated popularity of Lord Burlington's *protégé*, the architect painter William Kent, who is here represented on the summit of Burlington Gate, with Raphael and Michelangelo for supporters. This worthy Hogarth had doubtless not learned to despise less in the school of his rival Sir James Thornhill. Indeed almost the next of Hogarth's important prints was aimed at Kent alone, being that memorable burlesque of the unfortunate altarpiece designed by the latter for St Clement's Danes, and which, in deference to the ridicule of the parishioners, Bishop Gibson took down in 1725. Hogarth's squib, which appeared subsequently, exhibits it as a very masterpiece of confusion and bad drawing. In 1726 he prepared twelve large engravings for Butler's *Hudibras*. These he himself valued highly, and they are the best of his book illustrations. But he was far too individual to be the patient interpreter of other men's thoughts, and it is not in this direction that his successes are to be sought.

To 1727–28 belongs one of those rare occurrences which have survived as contributions to his biography. He was engaged by a certain Morris, a tapestry worker, to prepare a design for the Element of Earth. Morris, however, having heard that he was "an engraver and no painter," declined the work when completed, and Hogarth accordingly sued him for the money in the Westminster Court, where, on the 28th of May 1728, the case was decided in his (Hogarth's) favour. It may have been the aspersion thus early cast on his skill as a painter (coupled perhaps with the unsatisfactory state of print-selling, owing to the uncontrolled circulation of piratical copies) that induced him about this time to turn his attention to the production of "small conversation pieces" (*i.e.*, groups in oil of full-length portraits from 12 to 15 inches high), many of which are still preserved in different collections. "This," he says, "having novelty, succeeded for a few years." Among his other efforts in oil between 1728 and 1732 were The Wanstead Assembly, The House of Commons examining Bambridge, an infamous warden of the Fleet, and numerous pictures of the chief actors in Gay's popular *Beggar's Opera*.

On the 23d of March 1729 he was married at old Paddington church to Jane Thornhill, the only daughter of Kent's rival above-mentioned. The match was a clandestine one, although Lady Thornhill appears to have favoured it. We next hear of him in "lodgings at South Lambeth," where he rendered some assistance to the then well-known Jonathan Tyers, who opened Vauxhall in 1732 with an entertainment styled a *ridotto al fresco*. For these gardens Hogarth painted a poor picture of Henry VIII. and Anna Bullen, and for them he also made some designs of the Four Times of the Day, which he afterwards elaborated into a finished series. The only engravings between 1726 and 1732 which need be referred to are the Large Masquerade Ticket (1727), another satire on masquerades, and the print of Burlington Gate, 1731, evoked by Pope's *Epistle to Lord Burlington*, and defending Lord Chandos, who is therein satirized. This print gave great offence, and was, it is said, suppressed. To 1732 belongs that genial journey from London to Sheerness, of which the original record still survives at the British Museum in an oblong MS. volume, entitled *An Account of what seem'd most Remarkable in the Five Days' Peregrination of the Five Following Persons, Vizt., Messieurs Tothall. Scott, Hogarth, Thornhill and Forrest. Begun on Saturday May 27th* 1732 *and Finish'd On the 31st of the Same Month. Abi tu et fac similiter.—Inscription on Dulwich Colledge Porch.* The journal, which is written by Forrest, the father of Garrick's friend Theodosius Forrest, gives a good idea of what a "frisk"—as Johnson called it—was in those days, while the illustrations were by Hogarth and Samuel Scott the landscape painter. John Thornhill, Sir James's son, made the map. This version (in prose) was subsequently run into rhyme by one of Hogarth's friends, the Rev. Mr Gostling of Canterbury, and after the artist's death both versions were published. In the absence of other biographical detail, they are of considerable interest to the student of Hogarth.

In 1733 Hogarth moved into the "Golden Head" in Leicester Fields, which, with occasional absences at Chiswick, he continued to occupy until his death. By this date he must have completed the earliest of those great series of moral paintings which first gave him his position as a great and original genius. This was A Harlot's Progress, the paintings for which, if we may trust the date in the last of the pictures, were finished in 1731. The engravings, by the artist himself, were published in 1734. We have no record of the particular train of thought which prompted these story-pictures; but it may perhaps be fairly assumed that the necessity for creating some link of interest between the personages of the little "conversation pieces" above referred to led to the further idea of connecting several groups or scenes so as to form a sequent narrative. "I wished," says Hogarth, "to compose pictures on canvas, similar to representations on the stage." "I have endeavoured," he says again, "to treat my subject as a dramatic writer; my picture is my stage, and men and women my players, who by means of certain actions and gestures are to exhibit *a dumb show.*" There was never a more eloquent dumb show than this of the Harlot's Progress. In six scenes the miserable career of a woman of the town is traced out remorselessly from its first facile beginning to its shameful and degraded end. Nothing of the detail is softened or abated; the whole is acted out *coram populo*, with the hard, uncompassionate morality of the age the painter lived in, while the introduction here and there of one or two well-known characters like Colonel Charteris and Justice Gonson give a vivid reality to the satire. It had an immediate success. To say nothing of the fact that the talent of the paintings completely reconciled Sir James Thornhill to the son-in-law he had hitherto refused to acknowledge, more than twelve hundred names of subscribers to the engravings were entered in the artist's book. On the appearance of plate iii. the lords of the treasury trooped to Leicester Fields for Sir John Gonson's portrait which it contained. Theophilus Cibber made the story into a pantomime, and some one else into a ballad opera; and it gave rise to numerous pamphlets and poems. It was painted on fan-mounts and transferred to cups and saucers. Lastly, it was freely pirated. There could be no surer testimony to its popularity.

The favourable reception given to A Harlot's Progress prompted A Rake's Progress, which speedily followed, although it had not a like success. It was in eight plates in lieu of six. The story is unequal; but there is nothing finer than the figure of the desperate rake in the Covent Garden gaming-house, or the admirable scenes in the Fleet prison and Bedlam, where at last his headlong career comes to its tragic termination. The plates abound with allusive suggestion and covert humour; but it is impossible to attempt any detailed description of them here.

A Rake's Progress was dated June 25, 1735, and the engravings bear the words "according to Act of Parliament." This was an Act (8 Geo. II. cap. 13) which Hogarth had been instrumental in obtaining from the legislature, being stirred thereto by the shameless piracies of rival printsellers. Although loosely drawn, it served its purpose; and the painter commemorated his success by a long inscription on the plate entitled Crowns, Mitres, &c., afterwards used as a subscription ticket to the Election series. These subscription tickets to his engravings, let us add, are among the brightest and most vivacious of the artist's productions. That to the Harlot's Progress was entitled Boys peeping at Nature, while the Rake's Progress was heralded by the delighful etching known as A Pleased Audience at a Play, or The Laughing Audience.

We must pass more briefly over the prints which followed the two Progresses, noting first A Midnight Modern Conversation, an admirable drinking scene which comes between them in 1734, and the bright little plate of Southwark Fair, which, though dated 1733, was published with A Rake's Progress in 1735. Between these and Marriage *à la Mode*, upon the pictures of which the painter must have been not long after at work, come the small prints of the Consultation of Physicians, Scholars at a Lecture, and Sleeping Congregation, 1736; the Four Times of the Day, 1738, a series of pictures of everyday 18th century life, the earlier designs for which have been already referred to; the Strolling Actresses dressing in a Barn, 1738, which Walpole held to be, "for wit and imagination, without any other end, the best of all the painter's works;" and finally the admirable plates of the Distrest Poet, painfully composing a poem on "Riches" in a garret, and the Enraged Musician fulminating from his parlour window upon a discordant orchestra of knife-grinders, milk-girls, ballad-singers, and the rest upon the pavement outside. These are dated respectively 1736 and 1741. To this period also (*i.e.*, the period preceding the production of the plates of Marriage *à la Mode*) belong two of those history pictures to which, in emulation of the Haymans and Thornhills, the artist was continually attracted. The Pool of Bethesda and the Good Samaritan, "with figures seven feet high," were painted *circa* 1736, and presented by the artist to St Bartholomew's Hospital, where they remain. They were not masterpieces; and it is pleasanter to think of his connexion with Captain Coram's recently established Foundling Hospital (1739), which he aided with his money, his graver, and his brush, and for which he painted that admirable portrait of the good old philanthropist which is still, and deservedly, one of its chief ornaments.

In A Harlot's Progress Hogarth had not strayed much beyond the lower walks of society, and although, in A Rake's Progress, his hero was taken from the middle classes, he can scarcely be said to have quitted those fields of observation which are common to every spectator. It is therefore more remarkable, looking to his education and antecedents, that his masterpiece, Marriage *à la Mode*, should successfully depict, as the advertisement has it, "a variety of modern occurrences in high life." Yet, as an accurate delineation of the surroundings of upper class 18th century society, his Marriage *à la Mode* has never, we believe, been seriously assailed. The countess's bedroom, the earl's apartment with its lavish coronets and old masters, the grand saloon with its marble pillars and grotesque ornaments, are fully as true to nature as the frowsy chamber in the "Turk's

Head Bagnio," the quack-doctor's museum in St Martin's Lane, or the mean opulence of the merchant's house in the city. And what story could be more vividly, more perspicuously, more powerfully told than this godless alliance of *sacs et parchemins*—this miserable tragedy of an ill-assorted marriage? There is no defect of invention, no superfluity of detail, no purposeless stroke. It has the merit of a work by a great master of fiction, with the additional advantages which result from the pictorial fashion of the narrative; and it is matter for congratulation that it is still to be seen by all the world in the National Gallery, where it can tell its own tale better than pages of commentary.

The engravings of Marriage *à la Mode* were dated April 1745. Although the painter by this time found a ready market for his engravings, he does not appear to have been equally successful in selling his pictures. The people bought his prints; but the more opulent and not numerous connoisseurs who purchased pictures were wholly in the hands of the importers and manufacturers of "old masters." In February 1745 the original oil paintings of the two Progresses, the Four Times of the Day, and the Strolling Actresses were still unsold. On the last day of that month Hogarth disposed of them by an ill-devised kind of auction, the details of which may be read in Nichols's *Anecdotes*, for the paltry sum of £427, 7s. No better fate attended Marriage *à la Mode*, which five years later became the property of Mr Lane of Hillingdon for 120 guineas, being then in Carlo Maratti frames which had cost the artist four guineas a piece. Something of this was no doubt due to Hogarth's impracticable arrangements, but the fact shows conclusively how completely blind his contemporaries were to his merits as a painter, and how hopelessly in bondage to the all-powerful picture-dealers. Of these latter the painter himself gave a graphic picture in a letter addressed by him under the pseudonym of "Britophil" to the *St James's Evening Post*, in 1737.

But, if Hogarth was not successful with his dramas on canvas, he occasionally shared with his contemporaries in the popularity of portrait painting. For a picture, executed in 1746, of Garrick as Richard III. he was paid £200, "which was more," says he, "than any English artist ever received for a single portrait." In the same year a sketch of Simon Fraser, Lord Lovat, afterwards beheaded on Tower Hill, had an exceptional success. Our limits do not, however, enable us to refer to his remaining works in detail, and we must content ourselves with a brief enumeration of the most important. These are The Stage Coach or Country Inn Yard, 1747; the series of twelve plates entitled Industry and Idleness, 1747, depicting the career of two London apprentices; the Gate of Calais, 1749, which had its origin in a rather unfortunate visit paid to France by the painter after the peace of Aix-la-Chapelle; the March to Finchley, 1750; Beer Street, Gin Lane, and the Four Stages of Cruelty, 1751; the admirable representations of election humours in the days of Sir Robert Walpole, entitled Four Prints of an Election, 1755–8; and the plate of Credulity, Superstition, and Fanaticism, a Medley, 1762, adapted from an earlier unpublished design called Enthusiasm Delineated. Besides these must be chronicled three more essays in the "great style of history painting," viz., Paul before Felix, Moses brought to Pharaoh's Daughter, and the Altarpiece for St Mary Redcliff at Bristol. The first two were engraved in 1751–2, the last in 1794. A subscription ticket to the earlier pictures, entitled Paul before Felix Burlesqued, had a popularity far greater than that of the prints themselves.

In 1745 Hogarth painted that admirable portrait of himself with his pug-dog Trump, which is now in the National Gallery. In a corner of this he had drawn on a palette a serpentine line with the words "The Line of Beauty and Grace." Much inquiry ensued as to "the meaning of this hieroglyphic;" and in an unpropitious hour the painter resolved to explain his meaning in writing. The result was the well-known *Analysis of Beauty*, 1753, a treatise "to fix the fluctuating ideas of Taste," otherwise a desultory essay having for pretext the precept attributed to Michelangelo that a figure should be always "Pyramidall, Serpent-like, and multiplied by one two and three." The fate of the book was what might have been expected. By the painter's adherents it was praised as a final deliverance upon æsthetics; by his enemies and professional rivals, its obscurities, and the minor errors which, notwithstanding the benevolent efforts of literary friends, the work had not escaped, were made the subject of endless ridicule and caricature. It added little to its author's fame, and it is perhaps to be regretted that he ever undertook it. Moreover, there were further humiliations in store for him. In 1759 the success of a little picture called The Lady's Last Stake, painted for Lord Charlemont, procured him a commission from Sir Richard Grosvenor to paint another picture "upon the same terms." Unhappily on this occasion he deserted his own field of *genre* and social satire, to select the story from Boccaccio (or rather Dryden) of Sigismonda weeping over the heart of her murdered lover Guiscardo, being the subject of a picture by Furini in Sir Luke Schaub's collection which had recently been sold for £400. The picture, over which he spent much time and patience, was not regarded as a success; and Sir Richard rather meanly shuffled out of his bargain upon the plea that "the constantly having it before one's eyes would be too often occasioning melancholy thoughts to arise in one's mind." Sigismonda, therefore, much to the artist's mortification, and the delight of the malicious, remained upon his hands. As, by her husband's desire, his widow valued it at £500, it found no purchaser until after her death, when the Boydells bought it for 56 guineas. It was exhibited, with others of Hogarth's pictures, at the Spring Gardens exhibition of 1761, for the catalogue of which Hogarth engraved a Head-piece and a Tail-piece which are still the delight of collectors; and finally, by the bequest of the late Mr J. H. Anderdon, it passed in 1879 to the National Gallery, where, in spite of theatrical treatment and a repulsive theme, it still commands admiration for its colour, drawing, and expression.

In 1761 he was sixty-five years of age, and he had but three years more to live. These three years were embittered by that unhappy quarrel with Wilkes and Churchill, over which most of his biographers are contented to pass rapidly, Having succeeded John Thornhill in 1757 as serjeant painter (to which post he was reappointed at the accession of George III.), an evil genius prompted him in 1762 to do some "timed" thing in the ministerial interest, and he accordingly published the indifferent satire of The Times, plate i. This at once brought him into collision with his quondam friends, John Wilkes and Churchill the poet; and the immediate result was a violent attack upon him, both as a man and an artist in the opposition *North Briton*, No. 17. The alleged decay of his powers, the miscarriage of Sigismonda, the cobbled composition of the *Analysis*, were all discussed with scurrilous malignity by those who had known his domestic life and learned his weaknesses. The old artist was deeply wounded, and his health was failing. Early in the next year, however, he replied by that squinting portrait of Wilkes which will for ever carry his features to posterity. Churchill retaliated in July by a savage *Epistle to William Hogarth*, to which the artist rejoined by a print of Churchill as a bear, in torn bands and ruffles, not the most successful of his works. "The pleasure, and pecuniary advantage," writes Hogarth, "which I derived from these two engravings" (of Wilkes and Churchill), "together with occasionally riding on horseback, restored me to as much health as can be expected at my time of life." He produced but one more print, that of Finis, or The Bathos, March 1764, a strange jumble of "fag ends," intended as a tail-piece to his collected prints; and on the 26th October of the same year he died of an aneurism at his house in Leicester Square. His wife, to whom he left his plates as a chief source of income, survived him until 1789. He was buried in Chiswick churchyard, where a tomb was erected to him by his friends in 1771, with a well-known epitaph by Garrick. Not far off, on the road to Chiswick Gardens, is the now tumble-down house in which, for many years of his life, he spent the summer seasons.

From such records of him as survive, Hogarth appears to have been much what from his portrait one might suppose him to have been—a blue-eyed, honest, combative, little man, thoroughly national in his prejudices and antipathies, fond of flattery, sensitive like most satirists, a good friend, an intractable enemy, ambitious, as he somewhere says, in all things to be singular, and not always accurately estimating the extent of his powers. With the art connoisseurship of his day he was wholly at war, because, as he believed, it favoured foreign mediocrity at the expense of native talent; and in the heat of argument he would probably, as he admits, often come "to utter blasphemous expressions against the divinity even of Raphael Urbino, Correggio, and Michelangelo." But it was rather against the third-rate copies of third-rate artists—the "ship-loads of manufactured Dead Christs, Holy Families, and Madonnas"—that his indignation was directed; and in speaking of his attitude with regard to the great masters of art, it is well to remember his words to Mrs Piozzi:—"The connoisseurs and I are at war you know; and because I hate *them*, they think I hate *Titian*—and let them!"

But no doubt it was in a measure owing to this hostile attitude of his towards the all-powerful picture-brokers that his contemporaries failed to adequately recognize his merits as a painter, and persisted in regarding him as an ingenious humorist alone. Time has reversed that unjust sentence. He is now held to have been an excellent painter, pure and harmonious in his colouring, wonderfully dexterous and direct in his handling, and in his composition leaving little or nothing to be desired. As an engraver his work is more conspicuous for its vigour, spirit, and intelligibility than for finish and beauty of line. He desired that it should tell its own tale plainly, and bear the distinct impress of his individuality, and in this he thoroughly succeeded. As a draughtsman his skill has sometimes been debated, and his work at times undoubtedly bears marks of haste, and even carelessness. If, however, he is judged by his best instead of his worst, his work will not be found to be wanting in this respect. But it is not after all as a draughtsman, an engraver, or a painter that he claims his pre-eminence among English artists—it is as a wit, a humorist, a satirist upon canvas. Regarded in this light he has never been equalled, whether for his vigour of realism and dramatic power, his fancy and invention in the decoration of his story, or his merciless anatomy and exposure of folly and wickedness. If we regard him—as he loved to regard himself—as "author" rather than "artist," his place is with the great masters of literature,—with the Thackerays and Fieldings, the Cervantes and Molières.

Additions to Hogarth literature have not been numerous of late years. In 1860 Mr G. A. Sala contributed some picturesque pages to the *Cornhill Magazine*, which were afterwards republished in book form. Much minute information has also been collected in Mr F. G. Stephens's *Catalogue of the Satirical Prints and Drawings in the British Museum*, now in course of issue. Pictures by Hogarth from private collections are constantly to be found at the annual exhibitions of the Old Masters in the Royal Academy; but most of the best known works have permanent homes in public galleries. Marriage *à la Mode*, Sigismonda, and his own portrait are in the National Gallery; the Rake's Progress and the Election Series in the Sloane Museum; and the March to Finchley and Captain Coram at the Foundling Hospital. There are also notable pictures in the Fitzwilliam Museum at Cambridge, and the National Portrait Gallery at South Kensington. The Lady's Last Stake, to which reference has been made, is at present (1880) in the possession of Mr Louis Huth. (A. D.)

HOGG, James (1770–1835), a Scottish poet, best known by his title of the "Ettrick Shepherd," was born on the banks of the Ettrick in Selkirkshire in 1770. His ancestors had been shepherds for centuries. He received hardly any school training, and seems to have had difficulty in getting books to read. After spending his early years under different masters, first as cow-herd and afterwards as shepherd, he was engaged in the latter capacity by Mr Laidlaw, tenant of Blackhouse, in the parish of Yarrow, from 1790 till 1799. He was treated with great kindness, and had access to a large collection of books, which he soon exhausted, and then subscribed to a circulating library in Peebles. While attending to his flock, he spent a great deal of time in reading. His first printed piece was "The Mistakes of a Night," which appeared in the *Scots Magazine* for October 1794, and was succeeded by *Scots Pastorals* in 1801. A year or two after this publication Hogg became acquainted with Sir Walter Scott—a connexion which had a powerful influence for good on the peasant poet. He again appeared before the public in 1807 as the author of the *Mountain Bard*, to which Scott wrote an introductory notice. By this work, and by a *Treatise on the Diseases of Sheep*, Hogg realized about £300. With this money he unfortunately embarked in farming in Dumfriesshire, and in three years was utterly ruined, and had to abandon all his effects to his creditors. He returned to Ettrick, and there found only cold and estranged looks. He could not even obtain employment as a shepherd; so he set off in February 1810 to push his fortune in Edinburgh as a literary adventurer. In the same year he published a collection of songs, which, being dedicated to the countess of Dalkeith, and recommended to her notice by Scott, was rewarded with a present of 100 guineas. He then commenced a weekly periodical, *The Spy*, which he continued from September 1810 till August 1811. The appearance of the *Queen's Wake* in 1813 established Hogg's reputation as a poet; it was followed by *Mador of the Moor*, *The Pilgrims of the Sun*, and *The Poetic Mirror*. The duchess of Buccleuch, on her death-bed in 1814, had asked the duke to do something for the Ettrick bard; and the duke gave him a lease for life of the farm of Altrive in Yarrow, consisting of about 70 acres of moorland, on which the poet built a house and spent the last years of his life. He took possession of it in 1817; but his literary exertions were never relaxed. Before 1820 he had written *The Brownie of Bodsbeck*, and two volumes of *Winter Evening Tales*, besides collecting, editing, and writing part of two volumes of *Jacobite Relics*, and contributing largely to *Blackwood's Magazine*. In 1820 he married Miss Margaret Phillips, a lady of a good Annandale family, and found himself possessed of about £1000, a good house, and a well-stocked farm. Hogg's connexion with *Blackwood's Magazine* kept him continually before the public. The wit and mischief of some of his literary friends made free with his name, and represented him in ludicrous and grotesque aspects; but the effect of the whole was favourable to his popularity. He visited London in 1831, and was feasted by the nobility, literati, and public men of the metropolis. On his return a public dinner was given to him in Peebles,—Professor Wilson in the chair,—and he acknowledged that he had at last "found fame." His health, however, was seriously impaired. With his pen in his hand to the last, Hogg in 1834 published a volume of *Lay Sermons*, and in 1835 two volumes of *Montrose Tales*. His illness ultimately assumed the form of dropsy, and after a short confinement he died November 21, 1835, having nearly completed his sixty-fifth year. He was buried in the churchyard of his native parish Ettrick. His fame had seemed to fill the whole district, and was brightest at its close; his presence was associated with all the Border sports and festivities; and as a man James Hogg was ever frank, joyous, and charitable.

His *Shepherd's Calendar* is the best of Hogg's prose works; but it is mainly as a great peasant poet that he lives in literature. Nothing can be more exquisite than some of his lyrics and minor poems—his "Skylark," "When the Kye comes Hame," his verses on the "Comet" and "Evening Star," and his "Address to Lady Ann Scott." The *Queen's Wake* unites his characteristic excellences—his command of the old romantic ballad style, his graceful fairy mythology, and his aerial flights of imagination. The story of Kilmeny stands at the head of all our fairy tales, and is inimitable for its scenes of visionary splendour, purity, and bliss, linked to the fairest objects of earthly interest and affection. In such compositions Hogg seems completely transformed; he is absorbed in the ideal and supernatural, and might have claimed over all his contemporaries the Delphic laurel for direct and immediate inspiration.

See a memoir by Professor Wilson, prefixed to an edition of Hogg's works published by Blackie & Co. in 1850; Wilson's *Noctes Ambrosianæ*; Gilfillan's *First Gallery of Literary Portraits*; Cunningham's *Biog. and Crit. Hist. of Lit.*; and the general index to *Blackwood's Magazine*. A collected edition of Hogg's *Tales* appeared in 1838 in 6 vols., and a second in 1851; his collected *Poems* were published in 1850 and in 1852. For an admirable account of the social entertainments Hogg used to give in Edinburgh, see *Memoir of Robert Chambers*, by Dr William Chambers, pp. 263-270.

HOHENELBE (Bohemian, *Vrchlabi*), the chief town of a government district in Bohemia, is beautifully situated on both banks of the Elbe, crossed there by five bridges, on the southern spurs of the Riesengebirge, and on the north-west Austrian railway, 16 miles north-east of Gitschin. The houses with lofty gables and arcades supported by wooden columns have a picturesque appearance; and among the principal buildings are the decanal church, the castle surrounded by a fine park, the Augustine monastery, the citizen school, and the trade school. Linen and cotton are the staple manufactures, and there are also bleach-works, dye-works, and a paper-mill. A splendid view is obtained from the Heidelberg, which rises to the height of 3120 feet immediately behind the town. The population in 1869 was 5316.

HOHENLOHE, a German princely family, who took their name from the territory of Hohenlohe in Franconia, which, originally a countship and afterwards a principality, lost its independence in 1806, and is now included partly in Würtemberg and partly in Bavaria. They are first mentioned as possessing in the 12th century the castle of Holloch near Uffenheim. At an early period they extended their influence into several of the Franconian valleys, including those of the Kocher, the Jagst, the Tauber, and the Gotlach. The first count of the name was Gottfried, who was on terms of intimacy with the emperor Henry VI., and whose sons founded the lines of Hohenlohe-Bruneck and Hohenlohe-Holloch. The former became extinct in the fourth generation, and the latter in 1340 divided into the lines of Hohenlohe-Hohenlohe and Hohenlohe-Speckfeld. Of these the former became extinct in 1412, after the most of the possessions had been alienated through the marriage of the female heir; and the latter in 1551 divided into the present lines of Hohenlohe-Neuenstein and Hohenlohe-Waldenburg, which were elevated, the former in 1764 and the latter in 1744, to principalities of the empire. Hohenlohe-Neuenstein, which adopted Protestantism, became divided into the lines Hohenlohe-Neuenstein-Oehringen and Hohenlohe-Neuenstein-Langenburg, the former of which separated into the branches of Hohenlohe-Weickersheim and Hohenlohe-Oehringen, the one becoming extinct in 1756 and the other in 1805, after which their possessions were inherited by the Hohenlohe-Neuenstein-Langenburg line, which latter became divided into three branches—the Hohenlohe-Langenburg, the Hohenlohe-Langenburg-Oehringen, and the Hohenlohe-Langenburg-Kirchberg, the last becoming extinct in 1861. The line of Hohenlohe-Waldenburg, which remained Catholic, and in which was established in 1754 the order of the Phœnix, divided itself into two branches, the Hohenlohe-Waldenburg-Bartenstein and the Hohenlohe-Waldenburg-Schillingsfürst, the former subdividing into the branches of Hohenlohe-Bartenstein and Hohenlohe-Jagstberg. Of the Hohenlohe family the following members are noted as having attained individual eminence.

I. FRIEDRICH LUDWIG (1746–1818), prince of Hohenlohe-Ingelfingen, a Prussian general, was born 31st January 1746. Entering the Prussian service at an early age he became colonel in 1788, and in the campaigns of 1792 and 1793, where he was commander of a division, he distinguished himself in several engagements. In 1794 he gained a brilliant victory at Kaiserslautern, and in 1796 he was promoted lieutenant-general and appointed to the command of the army of the Ems. In the same year he succeeded to the principality of his father. Having been appointed general of infantry in 1800, he in 1805 commanded a Prussian corps between the Saale and the Thuringian Forest. He was severely defeated at Jena in 1806, and after the duke of Brunswick was mortally wounded at Auerstädt, he succeeded to the chief command, and led to the Oder the fragments of the Prussian army which capitulated at Prenzlau on the 28th October. On account of the blame to which this disaster exposed him, he had to retire from the army. He died at Slawentzitz, Silesia, 15th February 1818.

II. LUDWIG ALOYSIUS (1765–1829), prince of Hohenlohe-Waldenburg-Bartenstein, marshal and peer of France, was born 18th August 1765. In 1784 he entered the service of the palatinate, which he quitted in 1792 in order to take the command of a regiment raised by his father for the service of the emigrant princes of France. He greatly distinguished himself under Prince Condé in the campaigns of 1792–1793, especially at the storming of the lines of Weissenburg. Subsequently he entered the service of Holland, and, when almost surrounded by the army of General Pichegru, conducted a masterly retreat from the island of Bommel. From 1794 to 1799 he served as colonel in the Austrian campaigns; in 1799 he was named major-general by the archduke Charles; and after obtaining the rank of lieutenant-general he was appointed by the emperor of Austria governor of the two Galicias. Napoleon offered to restore to him his principality on condition that he adhered to the confederation of the Rhine, but as he refused, it was united to Würtemberg. After Napoleon's fall in 1814 he entered the French service, and in 1815 he held the command of a regiment raised by himself, with which he took part in the Spanish campaign of 1823. In 1827 he was created marshal and peer of France. He died at Lunéville, May 30, 1829.

III. ALEXANDER LEOPOLD FRANZ EMMERICH (1794–1849), prince of Hohenlohe-Waldenburg-Schillingsfürst, priest and reputed miracle-worker, was born at Kupferzell near Waldenburg, 17th August 1794. By his mother, the daughter of an Hungarian nobleman, he was from infancy destined for the church; and she entrusted the care of his early education to the ex-Jesuit Riel. In 1804 he entered the "Theresianum" at Vienna, in 1808 the academy at Bern, in 1810 the archiepiscopal seminary at Vienna, and afterwards he studied at Tyrnau and Ellwangen. He was ordained priest in 1815, and in the following year he went to Rome, where he entered the society of the "Fathers of the Sacred Heart." Subsequently, at Munich and Bamberg, he was blamed for Jesuit and obscurantist tendencies, but obtained considerable reputation as a preacher. His first so-called miraculous cure was effected, in conjunction with a peasant Martin Michel, on a princess of Schwarzenberg who had been for some years paralytic. Immediately he acquired such fame as a performer of miraculous cures that multitudes from various countries flocked to partake of the beneficial influence of his supposed supernatural gifts. Ultimately, on account of the interference of the authorities with his operations, he went in 1821 to Vienna and then to Hungary, where he became canon at Grosswardein, and in 1844 titular bishop of Sardica. He died at Vöslau near Vienna, 17th November 1849. He was the author of a number of ascetic and controversial writings, which were collected and published in one edition by Brunner at Ratisbon in 1851.

HOHENMAUTH, the chief town of a government district in Bohemia, Austria, is situated on the Lautchna, and on the Austrian States Railway 16 miles E. of Chrudim. It possesses a beautiful old decanal church, and has cloth manufactures, a brewery, a tannery, a sugar work, and flour and sago mills. It depends for its prosperity largely on the agriculture of the neighbourhood. The population in 1869 was 6018.

HOHENSTEIN, a town of Saxony, circle of Zwickau, stands on the slopes of the Erzgebirge, and on the Saxon States Railway, 12 miles N.E. of Zwickau. Since 1875 Ernstthal has been included within its limits. Hohenstein proper possesses a beautiful parish church, a town-house restored in 1876, and a monument to those who fell in the Prussian war of 1870–71; and Ernstthal has also a fine parish church. The principal industry is the spinning and weaving of cotton, the manufacture of waxcloth, stockings, and woollen and silk fabrics, cotton printing, and dyeing. Many of the inhabitants are also employed in the neighbouring arsenic mines. Not far from Hohenstein there is a mineral spring, connected with which there are various kinds of baths. Hohenstein is the birthplace of the physicist G. H. von Schubert, and of Schröter, one of the inventors of the pianoforte. The building of Ernstthal was occasioned in 1680 by the presence of the plague at Hohenstein, and it received its name from Count Christian Ernst of Schönburg, who was the principal instigator of its erection. The population of Hohenstein in 1875, including Ernstthal with a population of 4118, was 9844.

HOHENZOLLERN, an old German princely house, from which the present dynasty of Prussia is descended, takes its name from the old castle of Zollern, or Hohenzollern, on the mountain of Zollern, about 1½ miles south from Hechingen. There is a vague tradition connecting the house with the Colonna family of Rome, or the Colalto family of Lombardy, and a more definite one which mentions a Swabian count, Thassilo of Burchardinger, as having built the castle of Zollern about the beginning of the 9th century. The first counts of Zollern of whom there is historical mention are Burchard and Wezel, apparently brothers, who in 1061 fell in one of the party feuds during the minority of the emperor Henry IV. Count Frederick III. of Zolre, who died in 1200, one of the trusted councillors of the emperors Frederick I. and Henry VI., became count of Nuremberg in 1191, through having married the heiress of Count Conrad II. of Nuremberg. His sons, Conrad III. and Frederick IV., succeeded to the joint possession of his titles and estates, and founded respectively the Frankish and the Swabian lines. The Frankish house steadily and uninterruptedly increased its possessions and its influence; in 1363 it was raised to princely rank in the person of Frederick V.; in 1415 it obtained through Frederick VI. the electorate of Brandenburg from the emperor Sigismund; and in 1701 its head, the elector Frederick III., became the first king of Prussia. The influence of the Swabian line was greatly weakened by partitions, but in the beginning of the 16th century it rose to some eminence through Count Eitel Frederick II., privy councillor of the emperor Maximilian I., who received from the emperor the district of Hargerloch in exchange for Rhäzüns, in the Grisons, which had come into his family by marriage. His grandson, Charles I., received in 1529 from the emperor Charles V. the countships of Sigmaringen and Vöhringen. Eitel Frederick III. and Charles II. divided their states, the former taking Hohenzollern with the title Hohenzollern-Hechingen, the latter Sigmaringen and Vöhringen with the title Hohenzollern-Sigmaringen. Count John George of Hohenzollern-Hechingen, son of Eitel Frederick III., was raised to princely rank by the emperor Ferdinand II. in 1623, and John of Hohenzollern-Sigmaringen received the same honour in 1638. In 1695 the two Swabian branches entered conjointly into an agreement with the Brandenburg line that, in case of the extinction of the male line of either of the Swabian branches, the states should be inherited by the other branch, and that if both branches became extinct the states should be inherited by the Brandenburg line. In consequence of the political troubles of 1848, Prince Frederick William of Hohenzollern-Hechingen, and Charles Anton of Hohenzollern-Sigmaringen resigned their principalities, which consequently fell to the crown of Prussia, by whom they were taken possession of, March 12, 1850. By royal decree of 20th May of the same year the title of highness was conferred on the two princes, with the prerogatives of younger sons of the royal house. The proposal to raise Prince Leopold of Hohenzollern-Sigmaringen to the throne of Spain in 1870 was the immediate occasion of the war between France and Germany. In 1852 the lands of Hohenzollern were formed into an administrative division of Prussia. It is composed of a long narrow strip of land bounded on the N.E. and W. by Würtemberg and on the W. and S. by Baden, with an area of 440 square miles, and a population in 1875 of 66,614.

HOLBACH, Paul Heinrich Dietrich, Baron d' (1723–1789), *philosophe* of the Parisian school of the 18th century, was born at Heidelsheim in the palatinate in 1723. Of his family little is known; according to J. J. Rousseau, his father was a rich parvenu, who brought his son at an early age to Paris, where the latter spent most of his life. Much of Holbach's fame is due to his intimate connexion with the brilliant coterie of bold thinkers and polished wits whose creed, the new philosophy, is concentrated in the famous *Encyclopédie.* Possessed of easy means and being of hospitable disposition, he kept open house for such men as Helvetius, D'Alembert, Diderot, Condillac, Turgot, Buffon, Grimm, Hume, Garrick, Wilkes, Sterne, and for a time Rousseau, who, while enjoying the intellectual pleasure of their host's conversation, were not insensible to the material charms of his excellent cuisine and costly wines.

Although an atheist, or at least a materialist of the most material school, Holbach seems to have been endowed with a more than average share of virtue, and, whether by his courtesy, gentleness, or benevolence, inspired a warm affection in all he met. Even his failings, of which his simple credulity was perhaps the most prominent, were amiable. He was one of the best informed men of his day, and his excellent memory placed at his immediate disposal all the learning he had amassed. He visited England on one occasion, but the solemn stiffness of the British, even while amusing themselves, and the peculiar relations of society, disgusted as much as they surprised him. For the *Encyclopédie* Holbach compiled and translated a large number of articles on chemistry and mineralogy, chiefly from German sources. He attracted more attention, however, in the department of philosophy. In 1767 *Christianisme Dévoilé* appeared, in which he attacked Christianity and religion as the source of all human evils. Regarding religion as a blind superstitious bondage, maintained on men's minds by the self-interest of the priests, he tried to prove it not only unnecessary but absolutely prejudicial to human morality. This was followed up in 1770 by a still more open attack in his most famous book, *Le Système de la Nature*, in which it is probable he was assisted by Diderot. Denying the existence of a deity, and refusing to admit as evidence all *a priori* arguments, Holbach saw in the universe nothing save matter in spontaneous movement. What men call their souls become extinct when the body dies. Happiness is the end of mankind. "It would be useless and almost unjust to insist upon a man's being virtuous if he cannot be so without being unhappy. So long as vice renders him happy, he should love vice." Not less direct and trenchant are his attacks on political government, which, interpreted by the light of after events, sound like the first distant mutterings of the tempest that shortly after his death broke over the capital of France. The *Système de la Nature* struck horror into the minds of even the most "enlightened" of the Parisian philosophers. Charmed by the novelty of their own opinions, and dazzled by the glittering wit and argument with which they had supported them, they had never realized into what extremities they had hurried till this lurid torch revealed the hideous abyss from which they were so little removed. Voltaire hastily seized his pen to refute the philosophy of the *Système*, in the article "Dieu" in his *Dictionnaire Philosophique*, while Frederick the Great also drew up an answer to it. Though vigorous in thought and in some passages clear and eloquent, the style of the book is diffuse and declamatory, and asserts rather than proves its statements. Its principles are summed up in a more popular form in *Bon Sens, ou Idées naturelles opposées aux idées surnaturelles*, published at Amsterdam in 1772. In the *Système Social* (1773), the *Politique Naturelle* (1773-74), and the *Morale Universelle* (1776), Holbach attempts to rear a system of morality in place of the one he had so fiercely attacked, but these later writings had not a tithe of the popularity and influence of his earlier and more pernicious work. He published his books either anonymously or under a borrowed name, and was forced to have them printed out of France. He died in 1789. On the death of his first wife he obtained a papal dispensation to marry her sister, who survived him till 1814.

Holbach is also the author of the following and other works:—*Esprit du Clergé*, 1767; *De l'Imposture sacerdotale*, 1767; *Prêtres Démasqués*, 1768; *Examen Critique de la vie et des ouvrages de St Paul*, 1770; *Histoire Critique de Jésus Christ*, 1770; and *Ethocratie*, 1776. For further particulars as to his life and doctrines see Grimm's *Correspondance Litteraire*, &c., 1813; Rousseau's *Confessions*; Morellet's *Mémoires*, 1821; Madame de Genlis, *Les Dîners du Baron Holbach*, Madame d'Épinay's *Mémoires*; Avezac-Lavigne, *Diderot et la Société du Baron d'Holbach*, 1875; and Morley's *Diderot*, 1878.

HOLBEIN, HANS, the elder, belonged to a celebrated family of painters in practice at Augsburg and Basel from the close of the 15th to the middle of the 16th century. Though closely connected with Venice by her commercial relations, and geographically nearer to Italy than to Flanders, Augsburg at the time of Maximilian cultivated art after the fashion of the Flemings, and felt the influence of the schools of Bruges and Brussels, which had branches at Cologne and in many cities about the headwaters of the Rhine. It was not till after the opening of the 16th century, and between that and the era of the Reformation, that Italian example mitigated to some extent the asperity of South German painting. But this is not the place to give even an outline of this development. It must be sufficient to note that Flemish and German art was first tempered with Italian elements at Augsburg by Hans Holbein the elder. Hans first appears at Augsburg as partner to his brother Sigmund, who survived him and died in 1540 at Berne. Sigmund is described as a painter, but his works have not come down to us. Hans had the lead of the partnership at Augsburg, and signed all the pictures which it produced. In common with Herlen, Schongauer, and other masters of South Germany, he first cultivated a style akin to that of Memling and other followers of the schools of Brussels and Bruges, but he probably modified the systems of those schools by studying the works of the masters of Cologne. As these early impressions waned, they were replaced by others less favourable to the expansion of the master's fame; and as his custom increased between 1499 and 1506, we find him relying less upon the teaching of the schools than upon a mere observation and reproduction of the quaintnesses of local passion plays. Most of his early works indeed are taken from the Passion, and in these he obviously marshalled his figures with the shallow stage effect of the plays, copying their artificial system of grouping, careless to some extent of proportion in the human shape, heedless of any but the coarser forms of expression, and technically satisfied with the simplest methods of execution. If in any branch of his art he can be said to have had a conscience at this period, we should say that he showed it in his portrait drawings. It is seldom that we find a painted likeness worthy of the name. The drawings of which numbers are still preserved in the galleries of Basel, Berlin, and Copenhagen show extraordinary quickness and delicacy of hand, and a wonderful facility for seizing character; and this happily is one of the features which Holbein bequeathed to his son. It is between 1512 and 1522 that Holbein tempered the German quality of his style with some North Italian elements. A purer taste and more pleasing realism mark his work, which in drapery, dress, and tone is as much more agreeable to the eye as in respect of modelling and finish it is smoother and more carefully rounded. Costume, architecture, ornament, and colour are applied with some knowledge of the higher canons of art. Here too advantage accrued to Hans the younger, whose independent career about this time began.

The date of the elder Holbein's birth is unknown. But his name appears in the books of the tax-gatherers of Augsburg in 1494, superseding that of Michael Holbein, who is supposed to have been his father. Previous to that date, and as early as 1493, he was a painter of name, and he executed in that year, it is said, for the abbey at Weingarten, the wings of an altarpiece representing Joachim's Offering, the Nativity of the Virgin, Mary's Presentation in the Temple, and the Presentation of Christ, which now hang in separate panels in the cathedral of Augsburg. In these pieces and others of the same period, for instance in two Madonnas in the Moritz chapel and castle of Nuremberg, we mark the clear impress of the schools of Van der Weyden and Memling; whilst in later works, such as the Basilica of St Paul (1504) in the gallery of Augsburg, the wane of Flemish influence is apparent. But this altarpiece, with its quaint illustrations of St Paul's life and martyrdom is not alone of interest because its execution is characteristic of old Holbein. It is equally so because it contains portraits of the master himself, accompanied by his two sons, the painters Ambrose and Hans Holbein. Later pictures, such as the Passion series in the Fürstenberg gallery at Donaueschingen, or the Martyrdom of St Sebastian in the Munich Pinakothek, contain similar portraits, the original drawings of which are found in old Holbein's sketch-book at Berlin, or in stray leaves like those possessed by the duke of Aumale in Paris. Not one of these fails to give us an insight into the character, or a reflex of the features, of the members of this celebrated family. Old Holbein seems to ape Leonardo, allowing his hair and beard wildly to grow, except on the upper lip. Hans the younger is a plain-looking boy. But his father points to him with his finger, and hints that though but a child he is clearly a prodigy.

After 1516 Hans Holbein the elder appears as a defaulter in the registers of the tax-gatherers at Augsburg; but he willingly accepts commissions abroad. At Issenheim in Alsace, where Grünewald was employed in 1516, old Holbein also finds patrons, and contracts to complete an altarpiece. But misfortune or a bailiff pursues him, and he leaves Issenheim, abandoning his work and tools. According to Sandrart, he wanders to Basel and takes the freedom of its guild. His brother Sigmund and others are found suing him for debt before the courts of Augsburg. Where he lived when he executed the altarpiece, of which two wings with the date of 1522 are in the gallery of Carlsruhe, is uncertain; where he died two years later is unknown. He slinks from ken at the close of a long life, and disappears at last heeded by none but his own son, who claims his brushes and paints from the monks of Issenheim without much chance of obtaining them. His name is struck off the books of the Augsburg guild in 1524.

The elder Holbein was a prolific artist, who left many pictures behind him. Earlier than the Basilica of St Paul, already mentioned, is the Basilica of St Mary Maggiore, and a Passion in eleven pieces, in the Augsburg gallery, both executed in 1499. Another Passion, with the root of Jesse and a tree of the Dominicans, is that preserved in the Staedel, Saalhof, and church of St Leonard at Frankfort. It was executed in 1501. The Passion of Donaueschingen was finished after 1502, in which year was completed the Passion of Kaisheim, a conglomerate of twenty-seven panels, now divided amongst the galleries of Munich, Nuremberg, Augsburg, and Schleissheim. An altarpiece of the same class, commissioned for the monastery of St Moritz at Augsburg in 1504–8, has been dispersed and lost. 1512 is the date of a Conception in the Augsburg gallery, long assigned, in consequence of a forged inscription, to Hans Holbein the younger. A diptych, with a Virgin and Child, and a portrait of an old man, dated 1513, is in separate parts in the collections of Mr Posonyi and Count Lanckoronski at Vienna. The sketch-books of Berlin, Copenhagen, and Augsburg give a lively picture of the forms and dress of Augsburg residents at the beginning of the 16th century. They comprise portraits of the emperor Maximilian, the future Charles V., Kunz von der Rosen the fool of Maximilian, the Fuggers, friars, merchants, and at rare intervals ladies.

HOLBEIN, Hans, the younger (1497–1543), favourite son of Hans Holbein the elder, was probably born at Augsburg about the year 1497. Though Sandrart and Van Mander declare that they do not know who gave him the first lessons, he doubtless received an artist's education from his father. About 1515 he left Augsburg with Ambrose his elder brother to seek employment as an illustrator of books at Basel. His first patron is said to have been Erasmus, for whom, shortly after his arrival, he illustrated with pen-and-ink sketches an edition of the *Encomium Moriæ*, now in the museum of Basel. But his chief occupation was that of drawing titlepage-blocks and initials for new editions of the Bible and classics issued from the presses of Froben and other publishers. His leisure hours, it is supposed, were devoted to the production of rough painter's work, a schoolmaster's sign in the Basel collection, a table with pictures of St Nobody in the library of the university at Zurich. In contrast with these coarse productions, the portraits of Jacob Meyer and his wife in the Basel museum, one of which purports to have been finished in 1516, are miracles of workmanship. It has always seemed difficult indeed to ascribe such excellent creations to Holbein's nineteenth year; and it is hardly credible that he should have been asked to do things of this kind so early, especially when it is remembered that neither he nor his brother Ambrose were then allowed to matriculate in the guild of Basel. Not till 1517 did Ambrose, whose life otherwise remains obscure, join that corporation; Hans, not overburdened with practice, wandered into Switzerland, where (1517) he was employed to paint in the house of Jacob Hertenstein at Lucerne. In 1519 Holbein reappeared at Basel, where he matriculated, and, there is every reason to think, married. Whether, previous to this time, he took advantage of his vicinity to the Italian border to cross the Alps is uncertain. Van Mander says that he never was in Italy; yet the large wall-paintings which he executed after 1519 at Basel, and the series of his sketches and pictures which is still extant, might lead to the belief that Van Mander was misinformed. The spirit of Holbein's compositions for the Basel town-hall, the scenery and architecture of his numerous drawings, and the cast of form in some of his imaginative portraits, make it more likely that he should have felt the direct influence of North Italian painting than that he should have taken Italian elements from imported works or prints. The Swiss at this period wandered in thousands to swell the ranks of the French or imperial armies fighting on Italian soil, and the road they took may have been followed by Hans on a more peaceful mission. He shows himself at all events familiar with Italian examples at various periods of his career; and if we accept as early works the Flagellation, and the Last Supper at Basel, coarse as they are, they show some acquaintance with Lombard methods of painting, whilst in other pieces, such as the series of the Passion in oil in the same collection, the modes of Hans Holbein the elder are agreeably commingled with a more modern, it may be said Italian, polish. Again, looking at the Virgin and Man of Sorrows in the Basel museum, we shall be struck by a searching metallic style akin to that of the Ferrarese; and the Lais or the Venus and Amor of the same collection reminds us of the Leonardesques of the school of Milan. When Holbein settled down to an extensive practice at Basel in 1519, he decorated the walls of the house "Zum Tanz" with simulated architectural features of a florid character after the fashion of the Veronese; and his wall paintings in the town-hall, if we can truly judge of them by copies, reveal an artist not unfamiliar with North Italian composition, distribution, action, gesture, and expression. In his drawings too, particularly in a set representing the Passion at Basel, the arrangement, and also the perspective, form, and decorative ornament, are in the spirit of the school of Mantegna. Contemporary with these, however, and almost inexplicably in contrast with them as regards handling, are portrait-drawings such as the likenesses of Jacob Meyer and his wife, which are finished with German delicacy, and with a power and subtlety of hand seldom rivalled in any school. Curiously enough, the same contrast may be observed between painted compositions and painted portraits. The Bonifacius Amerbach of 1519 at Basel is acknowledged to be one of the most complete examples of smooth and transparent handling that Holbein ever executed. His versatility at this period is shown by a dead Christ (1521), a corpse in profile on a dissecting table, and a set of figures in couples; the Madonna and St Pantalus, and Kaiser Henry with the empress Kunigunde (1522), originally composed for the organ loft of the Basel cathedral, now in the Basel museum. Equally remarkable, but more attractive, though injured, is the Virgin and Child between St Ursus and St Nicholas (not St Martin) giving alms to a beggar, in the gallery of Solothurn. This remarkable picture is dated 1522, and seems to have been ordered for an altar in the minster of St Ursus of Solothurn by Nicholas Conrad, a captain and statesman of the 16th century, whose family allowed the precious heirloom to fall into decay in a chapel of the neighbouring village of Grenchen. Numerous drawings in the spirit of this picture, and probably of the same period in his career, might have led Holbein's contemporaries to believe that he would make his mark in the annals of Basel as a model for painters of altarpieces as well as a model for pictorial composition and portrait. The promise which he gave at this time was immense. He was gaining a freedom in draughtsmanship that gave him facility to deal with any subject. Though a realist, he was sensible of the dignity and severity of religious painting. His colour had almost all the richness and sweetness of the Venetians. But he had fallen on evil times, as the next few years undoubtedly showed. Amongst the portraits which he executed in these years are those of Froben, the publisher, known only by copies at Basel and Hampton Court, and Erasmus, who sat in 1523, as he likewise did in 1530, in various positions, showing his face three-quarters as at Longford, Basel, Turin, Parma, the Hague, and Vienna, and in profile as in the Louvre or at Hampton Court. Besides these, Holbein made designs for glass windows and prints, including subjects of every sort, from the Virgin and Child with saints of the old time to the Dance of Death, from gospel incidents extracted from Luther's Bible to satirical pieces illustrating the sale of indulgences and other abuses denounced by Reformers. Holbein, in this way, was carried irresistibly with the stream of the Reformation, in which, it must now be admitted, the old traditions of religious painting were wrecked, leaving nothing behind but unpictorial elements which Cranach and his school vainly used for pictorial purposes.

Once only, after 1526, and after he had produced the Lais and Venus and Amor, did Holbein with impartial spirit give his services and pencil to the Roman Catholic cause. The burgomaster Meyer, whose patronage he had already enjoyed, now asked him to represent himself and his wives and children in prayer before the Virgin; and Holbein produced the celebrated altarpiece now in the palace of Prince William of Hesse at Darmstadt, the shape and composition of which are known to all the world by its copy in the Dresden museum. The drawings for this masterpiece are amongst the most precious relics in the museum of Basel. The time now came when art began to suffer from unavoidable depression in all countries north of the Alps. Holbein, at Basel, was reduced to accept the smallest commissions—even for scutcheons. Then he saw that his chances were dwindling to nothing, and taking a bold resolution, armed with letters of introduction from Erasmus to More, he crossed the Channel to England, where in the one-sided branch of portrait painting he found an endless circle of clients. Eighty-seven drawings by Holbein in Windsor Castle, containing an equal number of portraits, of persons chiefly of high quality, testify to his industry in the years which divide 1528 from 1543. They are all originals of pictures that are still extant, or sketches for pictures that were lost or never carried out. Sir Thomas More, with whom he seems to have had a very friendly connexion, sat to him for likenesses of various kinds. The drawing of his head is at Windsor. The picture from that drawing belonged, and perhaps still belongs, to Mr Huth in London. A pen-and-ink sketch, in which we see More surrounded by all the members of his family, is now in the gallery of Basel, and numerous copies of a picture from it prove how popular the lost original must once have been. At the same period were executed the portraits of Warham (Lambeth and Louvre), Wyatt (Louvre), Sir Henry Guildford and his wife (Windsor and Mr Frewen), all finished in 1527, the astronomer Kratzer (Louvre), Godsalve (Dresden), and Bryan Tuke (Munich) in 1528. In this year, 1528, Holbein returned to Basel, taking to Erasmus the sketch of More's family. With money which he brought from London he purchased a house at Basel wherein to lodge his wife and children, whose portraits he now painted with all the care of a husband and father (1528). He then witnessed the flight of Erasmus and the fury of the iconoclasts, who destroyed in one day almost all the religious pictures at Basel. The municipality, unwilling that he should suffer again from the depression caused by evil times, asked him to finish the frescos of the town-hall, and the sketches from these lost pictures are still before us to show that he had not lost the spirit of his earlier days, and was still capable as a composer. His Rehoboam receiving the Israelite Envoys, and Saul at the Head of his Array meeting Samuel, testify to Holbein's power and his will, also proved at a later period by the Triumphs of Riches and Poverty, executed for the Steelyard in London, to prefer the fame of a painter of history to that of a painter of portraits. But the reforming times still remained unfavourable to art. With the exception of a portrait of Melanchthon (Hanover) which he now completed, Holbein found little to do at Basel. The year 1530, therefore, saw him again on the move, and he landed in England for the second time with the prospect of bettering his fortunes. Here indeed political changes had robbed him of his earlier patrons. The circle of More and Warham was gone. But that of the merchants of the Steelyard took its place, for whom Holbein executed the long and important series of portraits that lie scattered throughout the galleries and collections of England and the Continent, and bear date after 1532. Then came again the chance of practice in more fashionable circles. In 1533 the Triumphs of Wealth and Poverty were executed, then the portraits of Leland and Wyatt (Longford), and (1534) the portrait of Thomas Cromwell. Through Cromwell Holbein probably became attached to the court, in the pay of which he appears permanently after 1537. From that time onwards he was connected with all that was highest in the society of London. Henry VIII. invited him to make a family picture of himself, his father, and family, which obtained a post of honour at Whitehall The beautiful cartoon of a part of this fine piece at Hardwicke Hall enables us to gauge its beauty before the fire which destroyed it in the 17th century. Then Holbein painted Jane Seymour in state (Vienna), employing some English hand perhaps to make the replicas at the Hague, Sion House, and Woburn; he finished the Southwell of the Uffizi (copy at the Louvre), the jeweller Morett at Dresden, and last, not least, Christine of Denmark (Arundel and Windsor castles), who gave sittings at Brussels in 1538. During the journey which this work involved Holbein took the opportunity of revisiting Basel, where he made his appearance in silk and satin, and *pro forma* only accepted the office of town painter. He had been living long and continuously away from home, not indeed observing due fidelity to his wife, who still resided at Basel, but fairly performing the duties of keeping her in comfort. His return to London in autumn enabled him to do homage to the king in the way familiar to artists. He presented to Henry at Christmas a portrait of Prince Edward. Again abroad in the summer of 1539, he painted with great fidelity the princess Anne of Cleves, at Düren near Cologne, whose form we still see depicted in the great picture of the Louvre. That he could render the features of his sitter without flattery is plain from this one example. Indeed, habitual flattery was contrary to his habits. His portraits up to this time all display that uncommon facility for seizing character which his father enjoyed before him, and which he had inherited in an expanded form. No amount of labour, no laboriousness of finish—and of both he was ever prodigal—betrayed him into loss of resemblance or expression. No painter was ever quicker at noting peculiarities of physiognomy, and it may be observed that in none of his faces, as indeed in none of the faces one sees in nature, are the two sides alike. Yet he was not a child of the 16th century, as the Venetians were, in substituting touch for line. We must not look in his works for modulations of surface or subtle contrasts of colour in juxtaposition. His method was to the very last delicate, finished, and smooth, as became a painter of the old school.

Amongst the more important creations of Holbein's later time we should note his Duke of Norfolk at Windsor, the hands of which are so perfectly preserved as to compensate for the shrivel that now disfigures the head. Two other portraits of 1541 (Berlin and Vienna), the Falconer at the Hague, and John Chambers at Vienna (1542), are noble specimens of portrait art; most interesting and of the same year are the likenesses of Holbein himself, of which several examples are extant—one particularly good at Fähna, the seat of the Stackelberg family near Riga, and another at the Uffizi in Florence. Here Holbein appears to us as a man of regular features, with hair just turning grey, but healthy in colour and shape, and evidently well to do in the world. Yet a few months only separated him then from his death-bed. He was busy painting a picture of Henry the VIII. confirming the Privileges of the Barber Surgeons (Lincoln's Inn Fields), when he sickened of the plague and died after making a will about November 1543. His loss must have been seriously felt in England. Had he lived his last years in Germany, he would not have changed the current which decided the fate of painting in that country; he would but have shared the fate of Dürer and others who merely prolonged the agony of art amidst the troubles of the Reformation. (J. A. C.)

HOLBERG, Ludvig Holberg, Baron (1684–1754), the greatest of Scandinavian writers, was born at Bergen, in Norway, on the 3d of December 1684. Both Holberg's parents died in his childhood, his father first, leaving a considerable property; and in his tenth year he lost his mother also. Before the latter event, however, the family had been seriously impoverished by a great fire, which destroyed several valuable buildings, but notwithstanding this, the mother left to each of her six children some little fortune. In 1694 the boy Holberg was taken into the house of his uncle, who sent him to the Latin school, and prepared him for the profession of a soldier; but soon after this he was adopted by his cousin Otto Munthe, and went to him up in the mountains. His great desire for instruction, however, at last induced his family to send him back to Bergen, to his uncle, and there he remained, eagerly studying, until the destruction of that city by fire in 1702, when he was sent to the university of Copenhagen. But he soon exhausted his resources, and, having nothing to live upon, was glad to hurry back to Norway, where he accepted the position of tutor in the house of a rural dean at Voss. He soon returned to Copenhagen, where in 1704 he took his degree, and worked hard at French, English, and Italian. But he had to gain his living, and accordingly he accepted the post of tutor once more, this time in the house of Dr Smidt, vice-bishop of Bergen. The good doctor had travelled much, and the reading of his itineraries and note-books awakened such a longing for travel in the young Holberg that at last, in 1706, having scraped together 60 dollars, he went on board a ship bound for Holland. He proceeded as far as Aix-la-Chapelle, where he fell sick of a fever, and suffered so much from weakness and poverty, that he made his way to Amsterdam, and came back to Norway. Ashamed to be seen so soon in Bergen, he stopped at Christianssand, where he lived through the winter, supporting himself by giving lessons in French. In the spring he travelled, in company with a student named Brix, through London to Oxford, where he studied for two years, gaining his livelihood by giving lessons on the violin and the flute. He mentions, with gratitude, the valuable libraries of Oxford, and it is pleasant to record that it was while he was there that it first occurred to him, as he says, "how splendid and glorious a thing it would be to take a place among the authors." Through London and Elsinore he reached Copenhagen a third time, and began to lecture at the university; his lectures were attended, but he got no money. He was asked in 1709 to conduct a rich young gentleman to Dresden, and on his return journey he lectured at Leipsic, Halle, and Hamburg. Once more in Copenhagen, he undertook to teach the children of Admiral Gedde. Weary with this work, he took a post at Borch College in 1710, where he wrote, but did not print, his first work, *A Universal History*, and was permitted to present to King Frederick IV. two manuscript essays on Christian IV. and Frederick III. The king soon after presented him with the Rosenkrantz grant of 100 dollars for four years, the holder of which was expected to travel. Holberg accordingly started in 1715, and visited, chiefly on foot, a great portion of Europe. From Amsterdam he walked through Rotterdam to Antwerp, took a boat to Brussels, and on foot again reached Paris. Walking and skating, he proceeded in the depth of winter to Marseilles, and on by sea to Genoa. On the last-mentioned voyage he caught a fever, and nearly died in that city. On his recovery he pushed on to Civita Vecchia and Rome. When the spring had come, being still very poor and in feeble health, he started homewards on foot by Florence, across the Apennines, through Bologna, Parma, Piacenza, Turin, over the Alps, through Savoy and Dauphiné to Lyons, and finally to Paris, where he arrived in excellent health. After spending a month in Paris, he walked on to Amsterdam, took sail to Hamburg, and so went back to Denmark in 1716. He spent the next two years in extreme poverty, and published his *Introduction to Natural and Popular Law*. But at last, in 1718, his talents were recognized by his appointment as professor of metaphysics at the university of Copenhagen; and in 1720 he was promoted to the lucrative chair of public eloquence, which gave him a seat in the consistory. His pecuniary troubles were now at an end. Hitherto he had written only on law, history, and philology, although in a Latin controversy with the jurist Andreas Hover of Flensborg his satirical genius had flashed out. But now, and until 1728, he created an entirely new class of humorous literature under the pseudonym of Hans Mikkelsen. The serio-comic epic of *Peder Paars*, one of the great classics of the Danish language, appeared in 1719. This poem was a brilliant satire on contemporary manners, and enjoyed an extraordinary success. But the author had offended in it several powerful persons who threatened his life, and if Count Danneskjold had not personally interested the king in him, Holberg's career might have had an untimely close. During the next two years he published five shorter satires, all of which were well received by the public. The great event of 1721 was the erection of the first Danish theatre in Grönnegade, Copenhagen; Holberg took the direction of this house, in which was played, in September 1722, a Danish translation of *L'Avare*. Until this time no plays had been acted in Denmark except in French and German, but Holberg now determined to use his talent in the construction of Danish comedy. The first of his original pieces performed was *Den politiske Kandstöber* (The Pewterer turned Politician); he wrote other comedies with miraculous rapidity, and before 1722 was closed, there had been performed in succession, and with immense success, *Den Vægelsindede* (The Waverer), *Jean de France*, *Jeppe paa Bjerget*, and *Gert the Westphalian*. Of these five plays, four at least are masterpieces; and they were almost immediately followed by others. Holberg took no rest, and before the end of 1723 the comedies of *Barselstuen* (The Lying-in Room), *The Eleventh of July*, *Jakob von Thyboe*, *Den Bundeslöse* (The Fidget), *Erasmus Montanus*, *Don Ranudo*, *Ulysses of Ithaca*, *Without Head or Tail*, *Witchcraft*, and *Melampe* had all been written, and some of them acted. In 1724 the most famous comedy that Holberg produced was *Henrik and Pernille*. But in spite of this unprecedented blaze of dramatic genius the theatre fell into pecuniary difficulties, and had to be closed, Holberg composing for the last night's performance a *Funeral of Danish Comedy*. All this excessive labour for the stage had undermined the great poet's health, and in 1725 he determined to take the baths at Aix-la-Chapelle; but instead of going thither he wandered through Belgium to Paris, and spent the winter there. In the spring he returned to Copenhagen with recovered health and spirits, and worked quietly at his protean literary labours until the great fire of 1728. In the period of national poverty and depression that followed this event, a puritanical spirit came into vogue which was little in sympathy with Holberg's dramatic or satiric genius. He therefore closed his career as a dramatic poet by publishing in 1731 his acted comedies, with the addition of five which he had no opportunity of putting on the stage. With characteristic versatility, he adopted the serious tone of the new age, and busied himself for the next twenty years with historical, philosophical, and statistical writings. During this period he published his *Description of Denmark and Norway* (1729), *History of Denmark*, *Universal Church History*, *Biographies of Famous Men*, *Moral Reflections*, *Description of Bergen* (1737), *A History of the Jews*, and other learned and laborious compilations. The only poem he published at this time was the famous *Nicolai Klimii Iter Subterraneum*, 1741, afterwards translated into Danish by Baggesen. When Christian VI. died in 1748, the theatre was reopened and Holberg was appointed director, but he soon resigned this arduous post. His last published work was his *Epistles*, in 5 vols. In 1747 he was made Baron af Holberg. In August 1753 he took to his bed, and he died at Copenhagen on the 28th of January 1754, in the seventieth year of his age. He was buried at Sorö, in Zealand. He had never married, and he bequeathed all his property, which was considerable, to Sorö College.

Holberg was not only the founder of Danish literature and the greatest of Danish authors, but he was, with the exception of Voltaire, the first writer in Europe during his own generation. Neither Pope nor Swift, who perhaps excelled him in particular branches of literary production, approached him in range of genius, or in encyclopædic versatility. Holberg found Denmark provided with no books, and he wrote a library for her. When he arrived in the country, the Danish language was never heard in a gentleman's house. Polite Danes were wont to say that a man wrote Latin to his friends, talked French to the ladies, called his dogs in German, and only used Danish to swear at his servants. The single genius of Holberg revolutionized this system. He wrote poems of all kinds in a language hitherto employed only for ballads and hymns; he instituted a theatre, and composed a rich collection of comedies for it; he filled the shelves of the citizens with works in their own tongue on history, law, politics, science, philology, and philosophy, all written in a true and manly style, and representing the extreme attainment of European culture at the moment. Perhaps no author who ever lived has had so vast an influence over his countrymen, an influence that is still at work after 200 years.

The editions of Holberg's works are legion. During the last twenty-five years five complete editions of the *Comedies* have appeared, of which the best is that brought out in 3 vols. by F. L. Lichtenberg, in 1870. Of *Peder Paars* there exist at least twenty-three editions, besides translations in Dutch, German, and Swedish. The *Iter Subterraneum* has been three several times translated into Danish, ten times into German, thrice into Swedish, thrice into Dutch, thrice into English, twice into French, twice into Russian, and once into Hungarian. The life of Holberg was written by Welhaven in 1858. Among works on his genius by foreigners may be mentioned an exhaustive study by Robert Prutz, 1857, and *Holberg considéré comme imitateur de Molière*, by A. Legrelle, Paris, 1864. (E. W. G.)

HOLCROFT, Thomas (1745-1809), dramatist and miscellaneous writer, was born 10th December 1745 (old style) in Orange Court, Leicester Fields, London. His father, besides having a shoemaker's shop, kept riding horses for hire; but he fell into difficulties some six years later, and was reduced ultimately to the necessity of hawking pedlery from village to village. The son accompanied his parents in their tramps, and besides the hardships incident to such a life had often to endure the consequences of his father's passionate outbreaks of temper, which were, however, succeeded by equally violent transports of affection. In such circumstances he was disposed to regard it as an extraordinary piece of good fortune when he succeeded in procuring the situation of stable boy at Newmarket, an employment in which he manifested great coolness and courage, and acquired high proficiency. Previous to this he had received a pretty good education, and at Newmarket he spent his evenings chiefly in miscellaneous reading and the study of music. Gradually he also succeeded in obtaining a competent knowledge of French, German, and Italian. On the expiry of his term of engagement as stable boy he returned to assist his father, who had again resumed his trade of shoemaker in London; but after marrying in 1765, he procured the office of teacher in a small school in Liverpool. His subsequent career, like his earlier life, was hard and chequered, but it must suffice to state that, after failing in an attempt to set up a private school, he followed for several years the profession of an actor, often at a very meagre salary, and that he was more successful as a dramatist and novelist, but suffered much and frequent anxiety from pecuniary embarrassments and repeated disappointments. He died 23d March 1809 from enlargement of the heart, brought on, it is supposed, by the failure of several of his dramatic pieces. He was a member of the Society for Constitutional Reform, and on that account was, in 1794, indicted of high treason, but acquitted. The best known dramas of Holcroft are *Duplicity*, *The School for Arrogance*, *The Road to Ruin*, and *The Deserted Daughter*. Among his novels may be mentioned *Alwyn* and *Hugh Trevor*. He was also the author of *Travels from Hamburg through Westphalia, Holland, and the Netherlands to Paris*, and of some volumes of verse, and translated several works from the French and German with considerable elegance. The interest which still attaches to his career is, however, less on account of the intrinsic merit of his literary performances than his peculiarly chequered life and his persevering struggle to elevate himself above the ignorant and sordid condition of his early years. His *Memoirs written by himself and continued down to the time of his Death, from his Diary, Notes, and other Papers*, by William Hazlitt, appeared in 1815, and has gone into several editions.

HÖLDERLIN, JOHANN CHRISTIAN FRIEDRICH (1770–1843), German poet, was born March 29, 1770, at Lauffen on the Neckar. His mother removing, after a second marriage, to Nürtingen, he began his education at the classical school there, where Schelling was his schoolfellow and playmate. He was destined by his relations for the church, and with this view was later admitted to the free schools of Denkendorf and Maulbronn. At the age of eighteen, already an excellent classical scholar, he was sent to the university of Tübingen, where, however, he showed no inclination to the study of theology. He was already the writer of occasional verses, and had begun to sketch his first version of *Hyperion*, when he was introduced in 1793 to Schiller, and obtained through him the post of tutor to the young son of Frau von Kalb. A year later he left this situation to attend Fichte's lectures, and to become a disciple of Schiller in Jena. Schiller recognized in the young poet something of his own style of genius, and encouraged his early literary attempts by sending some of them to Goethe, and by superintending the publication of others in the *Thalia* and *Horen*. In 1796 Hölderlin obtained the post of tutor to the three young children of a banker named Gontard in Frankfort. Gontard's beautiful and gifted wife is the Diotima of Hölderlin's *Hyperion*. For this lady he conceived a foolish and hopeless passion; and she became at once his inspiration and his ruin. At the end of two years, during which time the first volume of *Hyperion* was published (1797), some kind of crisis appears to have occurred in their friendship, for the unhappy young poet suddenly left Frankfort and the Gontard family; but whether he was dismissed by the indignant husband of Diotima, or was impelled by his own better resolutions, has not been explained. In spite of ill health, he now completed *Hyperion*, the second volume of which appeared in 1799, and he began a tragedy, *Der Tod des Empedokles*, which is published in an unfinished condition among his works. Some of his verses appeared in the *Taschenbuch für Frauenzimmer* in 1799 and 1800; and he contemplated starting a new literary journal, of which he was to be the editor, but the scheme was a failure. His friends now became alarmed at the alternate depression and nervous irritability from which he suffered, and he was induced to go to Switzerland, as tutor in a family at Hauptwill. There his health improved; and several of his poems, among which are "Der blinde Sänger," "An Die Hoffnung," and "Dichtermuth," were written at this time. In 1801 he returned home to arrange for the publication of a volume of his poems; but, on the failure of this enterprise, he was obliged to accept another tutorship in the family of the Hamburg consul in Bordeaux. Diotima died a year later, in June 1802, and the news is supposed to have reached Hölderlin shortly afterwards, for in the following month he suddenly left Bordeaux, and travelled homewards on foot through France, arriving at Nürtingen destitute and insane. Kind treatment gradually alleviated his condition, and in lucid intervals he occupied himself by writing verses and translating Greek plays. Two of these translations—the *Antigone* and *Œdipus Rex* of Sophocles—appeared in 1804, and several of his short poems were published by Seckendorf in his *Musenalmanach*, 1807 and 1808. In 1804 Hölderlin obtained the post of librarian to the landgrave of Homburg, and went to live in Homburg under the supervision of friends; but the post was abandoned two years later, and he was taken to Tübingen, where he remained, irremediably but harmlessly insane, till his death, June 7, 1843.

Hölderlin's writings are the production of a beautiful and sensitive mind, a mind of high ideals and noble impulses; but they are intensely, almost morbidly, subjective, and they lack real human strength. Perhaps his strongest characteristic was his passion for Greek subjects, and the natural result of this was that he almost entirely discarded rhyme in favour of the ancient verse measures. His poems are all short pieces; of his tragedy only a fragment was written. *Hyperion, oder der Eremit in Griechenland*, is thus his one important work; and even to this a sequel is wanting. It may be called a prose poem, and is written in the form of letters. Its exquisite language, the purity of its tone, the sad philosophical vein which permeates it, together with its autobiographic character, claim for it a unique position among German classics.

An edition of Hölderlin's complete works, with his letters and biography, appeared in 1846; and there is a cheap edition of his selected works, with a biography by Christoph Theodor Schwab, published in 1874.

HOLESCHAU, HOLLESCHAU, or HOLESOV, chief town of a government district in Moravia, Austria, circle of Hradisch, is situated on the Russawa, 20 miles N.N.E. of Hradisch. It has a large castle in the Italian style (with a fine garden), a beautiful decanal church, and a synagogue. Linen and cloth-weaving are carried on, and there is some trade in honey, wax, hides, and wool. The population in 1869 was 5282, more than a third being Jews.

HOLIBUT, or HALIBUT (*Hippoglossus vulgaris*), is the largest of all Flat-fishes, specimens of 5 feet in length and of 100 lb in weight being frequently exposed for sale in the markets. Indeed, specimens under 2 feet in length are very rarely caught, and singularly enough, no instance is known of a very young specimen having been obtained. The holibut is much more frequent in the higher latitudes of the temperate zone than in its southern portion; it is a circumpolar species, being found on the northern coasts of America, Europe, and Asia, extending in the Pacific southwards to California. On the British coasts it keeps at some distance from the shore, and is generally caught in from 50 to 150 fathoms. Its flesh is considered coarse, though white and firm.

HOLINSHED, or HOLLINSHED, RAPHAEL, author of *Chronicles of England, Scotland, and Ireland*, flourished in the 16th century. He belonged to a family settled at Bosley, in Cheshire, and according to Anthony Wood he was educated at one of the universities and took orders in the church. In the compilation of the *Chronicles* called by his name he bore a leading part, but he received extensive and important aid from Stow the antiquary, Harrison, chaplain to Lord Cobham, Hooker (*alias* Vowell), an uncle of the divine of that name, and Francis Boteville (*alias* Thin), a learned antiquary. Holinshed's share in the work comprised the history of England down to the year 1577, the date of the first edition. His will—printed in Hearne's preface to Camden's *Annales*—shows that in the latter part of his life he was in the service of Thomas Bendet of Bromcote, in Warwickshire. He died between 1580 and 1584. The notice of Elizabeth's reign contained matter so offensive to her and her court that in the second edition, which appeared in 1587, some of the sheets were cancelled altogether. The castrations were published separately by Dr Drake in 1728, and in subsequent reprints have been restored. The history of Scotland, incorporated by Holinshed in his *Chronicles*, is for the most part a translation from the Latin of Hector Boece, and is interesting as having furnished Shakespeare with the groundwork of his tragedy of *Macbeth*. The *Chronicles*, being the work of so many different hands, present great varieties of literary quality; but the learning and research they show have made them an invaluable aid in the illustration of the early annals of England. An edition in accordance with the original text was published in 1808, 6 vols.

HOLKAR, the title of the mahárájá of INDORE (*q.v.*), whose territories are often designated Holkar's Dominions.

HOLLAND

PART I.—GEOGRAPHY AND STATISTICS.

Plate I. HOLLAND is the most usual English name of the country which is nationally designated the Kingdom of the Netherlands (*Koningrijk der Nederlanden*). The word, which is popularly explained as if it were Hollow-land, and referred to the same physical fact which has given rise to the terms Netherlands and the Low Countries, appears in an older form as Holtland, and is thus evidently equivalent to Wood-land. In French the usual expression is Pays-Bas, and in German Niederlande.

There is no country in Europe in which the character of the territory has exercised so great an influence on the inhabitants as in the Netherlands; and, on the other hand, no people has so extensively modified the condition of its territory as the Dutch. In a description of Holland, consequently, the greatest importance must be attached to the physical conformation of the country as it was and is; and most of the peculiarities of the political and social condition of the people must be considered in connexion with this conformation.

Extent. The size of Holland, being subject to perpetual diminution and increase, cannot be indicated by a definite figure except as at some definite period; on the one hand, there is loss of area still going on in consequence of the erosion of the coasts, and, on the other hand, this is more than counterbalanced by a continual acquisition of new ground due more especially to "impoldering" and draining operations. In 1833 the surface of the Netherlands was only 2,270,959 hectares (5,611,860 acres, 8768 square miles); on the 20th Oct. 1877, at the time of the conclusion of the cadastral survey, it was 3,297,268 hectares (8,148,020 acres, 12,731 square miles).

The kingdom extends from 53° 32′ 21″ (Groningen Cape on Rottum Island) to 50° 45′ 49″ N. lat. (Mesch in the province of Limburg), and from 3° 23′ 27″ (Sluis in the province of Zealand) to 7° 12′ 20″ E. long. (Langakkerschans in the province of Groningen). The greatest length from north to south, viz., that from Rottum Island to Eysden near Maestricht is estimated at 164 miles, and the greatest breadth from south-west to north-east, or from Zwin near Sluis to Losser in Overyssel at 144 miles. If the Zuyder Zee, the parts of Prussia which encroach on the eastern side, and the projecting portions of Limburg and Zealand are disregarded, the general form is almost an oblong. With the exception of Greece and Great Britain, no country of Europe has so many inlets of the sea as Holland.

Boundaries. The Netherlands are bounded on the E. by the Prussian provinces of Hanover, Westphalia, and the province of the Rhine, and on the S. by the Belgian provinces of Liége, Limburg, Antwerp, and East and West Flanders. A purely geographical boundary is formed to the W. and the N. by the North Sea, at the N.E. corner by the Dollart, and from Stevensweert southward to the extreme corner of Limburg (near Eysden) by the Maas or Meuse.[1] Natural ethnographic frontiers, such as occur where two neighbouring peoples of different origin, race, character, customs, and language are sharply marked off from each other, do not exist in the case of the Netherlands. The Low German element, indeed, of which the Netherlands form as it were the kernel, spreads beyond Dutch limits both north-east along the coast of the German Ocean and south-west into Belgium.

[1] At Maestricht, however, a portion lies on the left bank of the river, measured, according to the treaty with Belgium, 19th April 1839, art. 4, by an average radius of 1200 Dutch fathoms (7874 feet) from the outer glacis of the fortress.

Coast-line. As regards the seaward boundary—the coasts, river-mouths, and islands—it is necessary, for a just comprehension of its character and of its influence on the formation of the soil, to bear in mind that the coasts of the Netherlands shared in the general vicissitudes of the southern shores of the German Ocean at the time when the English Channel was still closed. Three periods may be distinguished in the history of these changes. During the first a row of dunes was formed on the sandy tongue of land which, beginning at Ostend, cut off and formed into an inland lake a portion of the German Ocean, at that time washing the diluvial strata; these are still indicated along the Dutch and the German coasts by a series of dune-formations, sandbanks, and islands. In the second period the separation between ocean and lake was still maintained, the river-water gained the upper hand over the sea-water in the lake, the matter brought down by the river began to settle, and the morasses and beds of marsh-plants, reeds, and rushes (*derrie*) were formed which are now found above the old sand beds and below the present clay beds. When in the third period the coasts subsided, the dunes were here and there carried away by the rise of the waters, portions of the land were submerged, and, mud being extensively piled up by the sea, the fertile clay (*zeeklei*) of the maritime provinces was formed, and at the same time the mouths of the rivers were changed in position. And all this took place on a still greater scale when the limestone rocks which united Calais and Dover at last gave way and the great ocean with its heavier incidence of billows and tides drove into the smaller sea. According to Dr Hartogh Heys van Zouteveen,[2] 150,000 hectares (370,670 acres) of land were lost on the coast of the German Ocean, 385,000 hectares (951,390 acres) on the Zuyder Zee and the Wadden, 8432 hectares (20,836 acres) in the Dollart, 10,000 hectares (24,711 acres) in the Biesbosch, and about 27,000 hectares (66,720 acres) more in other parts. According to Dr Staring, the province of Groningen, even during the 18th and 19th centuries, has been harassed with inundations once in every 155 years, Utrecht and North Holland south of the Y once in 83 years, South Holland once in 55 years, Friesland, Overyssel, North Holland north of the Y, and the coast of North Brabant every 40 years; while the Netherlands in general have been visited by such disasters in 1702, 1715, 1717, 1741, 1755, 1756, 1791, 1808, 1809, and 1825, or on an average once in every eleven years. In this last period, however, of the history of the land the lordship of man ultimately began to make itself felt. The formation of the first dykes to prevent inundations was quickly followed by the construction of a connected system of earthen ramparts, behind which the country lies secure, while at the same time hundreds of thousands of acres of fertile land have been recovered from the sea. The area gained from 1833 to 1877 has been already stated. The following table shows the amount reclaimed by endyking down to the dates given:—

In North Holland,	to 1864	72,283 acres.
,, South Holland Islands,	to 1850	168,302 ,,
,, Friesland,	,,	36,368 ,,
,, Groningen,	,,	86,838 ,,
,, North Brabant,	to 1843	95,391 ,,
,, Zealand,	to 1859	220,411 ,,

To return to the present condition of the seaboard of the Netherlands,—it follows from what has been said

[2] *Algemeene Statistiek van Nederland*, p. 61.

that it consists (1) of coasts still protected by dunes or fringed with sandbanks and islands indicating the direction of ancient lines of dunes; (2) of low coasts of sea-clay provided with dykes which in more than one quarter have been repeatedly extended so as to enclose land conquered from the sea (the sea-polders); and finally (3) of some high diluvial strata which rise far enough above the level of the sea to make dykes unnecessary. The dunes follow the west and north-west coast almost without a break, except in a few quarters where they have been removed and their place supplied by dykes or rubble, as in North Holland between Huisduinen and Nieuwe Diep and between Kamp and Petten, in South Holland on Voorne, and in Zealand on Schouwen and Walcheren, where the famous Westkappel dyke unites the village of Westkappel with the watering-place of Domburg. The breadth of the line of dunes naturally varies greatly—from 600 to 7000 feet; and there is a similar variety in the height of the individual dunes proper, called dune-hills (*duinheuvels*) as compared with the dune-pans (*duinpannen*) or depressions. The elevation of the High Blinkert near Haarlem (196 feet) is an extreme exception, for the average is not more than 50 or 60 feet even in the case of the high dunes which lie nearest the shore and are known as "sea-runners" (*zeelooper*) or the "shore-ridge" (*strandreeks*). The dunes show a tendency, except where the Dutch prevent it by planting wood or sand-oats, to wear away on the side towards the sea, and to "overstuiven" or drift off on the landward side. There is, indeed, a general degradation of the coast, and a recession towards the east, corresponding to the subsidence which may be observed along the German seaboard, and probably traceable also, in part at least, to the Channel current, which at mean tide has a velocity of 14 or 15 inches per second, and especially during strong west or north-west winds carries off large quantities of material. This alteration of coast-line appears at Loosduinen, where the moor or fenland formerly developed behind the dunes now crops out on the shore amid the sand, being pressed to the compactness of lignite by the weight of the sand drifted over it. Again, the remains of the Roman camp at Brittenburg or Huis te Britten, which originally lay within the dunes and, after being covered by them, emerged again in 1520, were, in 1694, 1600 paces out to sea, opposite Katwijk; while, besides Katwijk itself, several other villages of the west coast, as Domburg, Scheveningen, Egmond, have continually to be removed further inland. Two things special to Holland are worthy of particular notice, the artificial formation of dunes, as at Koegras, Callantsoog, Petten, Katwijk, Scheveningen, and Zandvoort, and the carrying away of the sand (*afzanderij*, "offsanding") by ship or rail, as in the "Westland," for example, to the south of the Hague, to serve elsewhere for engineering operations and the improving of the soil. Mingled with marsh-earth the sand forms a soil suited to the culture of flower-bulbs; with clay it produces that excellent soil for vegetable gardens for which the Westland is so famous. It must be further remarked that both the "dune pans," which are naturally marshy through their defective drainage, and the "geest" grounds—that is, the grounds along the foot of the downs—have been in various places either planted with wood or turned into arable and pasture land; while the numerous springs at the base of the dunes rise at such a height above the ordinary level of the country that the water is conveyed by canals to the great cities, and an improvement is thus effected at once in the agricultural condition of the coast-land and in the sanitary condition of the cities.

Sea-dykes.

The sea-dykes are found along the northern coasts, the coasts of the provinces which border on the Zuyder Zee, and the coasts of the islands of Zealand and South Holland so far as they are not protected by dunes. Only in a few places, it will be seen, are the sea-dykes unnecessary; as for example, in Friesland between Stavoren and Olde Mirdum (the bold and steep Roode and Mirdum cliffs) and near Doornspijk, 3 miles south of Elburg, where there are high grounds which stretch 6 miles to the south-west of Harderwijk. The earthen dykes are protected by stone-slopes and by piles, and at the more dangerous points also by "zinkstukken" (sinking pieces), artificial structures of bulrushes, reeds, and branches, laden with stones, and measuring some 400 yards in circuit, by means of which the current is to some extent turned aside. The Westkappel dyke already mentioned is 12,468 ft. long and 23 high, has a seaward slope of 300 ft., and is protected by rows of piles and basalt blocks. On its ridge, 39 ft. broad, there is not only a roadway but a service railway. When it is remembered that the woodwork is infested by the pile worm (*Teredo navalis*), the ravages of which were discovered in 1731, the enormous expense incurred in the construction and maintenance of the 1550 miles of sea-dykes now existing may be imagined. The cost of construction is not overestimated at 150,000,000 guilders or £12,500,000.

Islands.

The Dutch islands may be divided into two main classes —(1) those surrounded on all sides by the German Ocean or its inlets, and (2) those surrounded entirely or in great part by river arms, and separated by these from the mainland or from each other. The first division again comprises two groups—(*a*) the islands Texel, Vlieland, Terschelling, Ameland, Schiermonnikoog, and Rottum, which stretch in a long arc from the north point of North Holland to the mouth of the Ems, and indicate the old coast-line, so that they belong to the same physico-geographical group with the islands along the German coast; and (*b*) the islands Wieringen, Marken, Urk, and Schokland, which are the relics of the stretch of country formerly comprising the present bed of the Zuyder Zee. In the second class are to be reckoned the delta of the river Yssel (Camper Island) and the islands belonging to the contiguous deltas of the Rhine, the Meuse, and the Scheldt, including the island of Betuwe between the Rhine and the Waal and the archipelago of South Holland and Zealand.

River mouths.

As the river mouths of Holland must also be regarded as gulfs or inlets of the sea, they may be noticed here. The average breadth of the Haringvliet at Helvoetsluys is 8860 ft. and at Goedereede 18,045; that of the West Scheldt at Ter Neuzen 15,420 ft., and at Flushing (Vlissingen) 13,780; that of the East Scheldt at the harbour of Goes 13,780, and at the harbour of Zierikzee 13,450; and that of the Roompot 21,650 to 29,530 ft.

Influence of the coasts on industry.

The varying characteristics of the coasts in different places give rise to correspondingly different industries. As regards trade and navigation, the west coasts with their shallows and sandbanks can be approached only by small vessels of light draught (visscherspinken) unless where access is afforded by the inlets of the sea, especially the mouth of the West Scheldt at Flushing, that of the East Scheldt at Zierikzee, the Brouwershaven inlet between the islands of Schouwen and Goeree, the Goeree inlet at Helvoetsluys, the Marsdiep at the Helder, and the mouth of the Ems at Delfzijl, or where a way has been opened up by engineering works as at Rotterdam and Amsterdam (by the new waterway to the sea and the canal to Ymuiden). As we proceed from south-west to north-east the places along the coast become less and less important; in the provinces of Groningen and Friesland the approach to the mainland is obstructed by the Wadden or Shallows; and on the coast of the Zuyder Zee are those harbours, for the most part rendered useless by alluvial accretions, which have been so well described by Havard in his *Villes Mortes du Zuyderzee.* Along the greater part of these coasts the population is engaged in the fisheries rather than in trade, especially when the neighbourhood of a great town (as Alkmaar for Egmond, Haarlem for Zandvoort, Leyden for Katwijk, the Hague for Scheveningen) secures a good market or a ready means of exportation. Many fishing villages on the west coast, *e.g.*, Scheveningen, Domburg, and Zandvoort, have in recent years acquired repute as watering-places with both natives and foreigners.

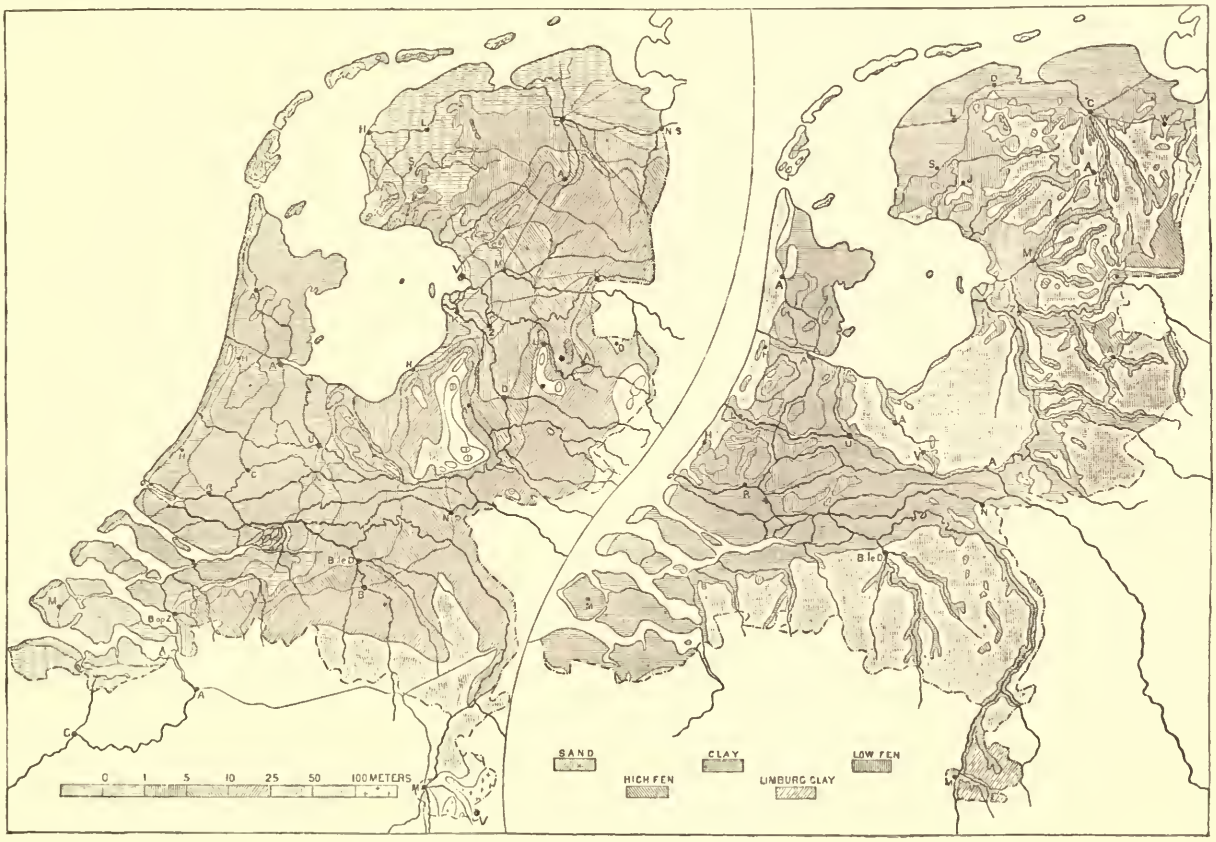
The availability of the flat coasts for trade and navigation is to a large extent dependent on the range of the rise and fall of the tides. As shown in the following table, this steadily decreases from south-west to north-east. In the Zuyder Zee it is naturally very small.

Places.	Range of Tides.	Places.	Range of Tides.
	Feet.		Feet.
Off Sluis	11·9	Petten	5·1
Flushing	12·1	Kijkduin	4·1
Westkapelle	11·2	Nieuwediep	3·7
Brouwershaven	9·8	Terschelling	5·2
Goedereede	5·9	Ameland	6·4
Helvoetsluys	5·7	Rottum	7·6
Briel	4·9	Amsterdam[1]	1·2
Coast of Delfland	5·7	Zwanenburg[1]	1·1
Katwijk	5·5	Spaarndam[1]	1·2

The Shallows (Wadden) of the German Ocean between Groningen and Friesland and the islands Rottum, Schiermonnikoog, and Ameland are usually left in great measure dry at ebb-tide.

The elevation of the surface of the country ranges from about 650 ft. above to 16 or 20 ft. below the Amsterdam zero, which marks the mean high-water level in the Y in front of the city. The circumstance that so much of it is below the sea-level necessarily exercises a very important influence on the drainage, the climate, and the sanitary condition of the country, as well as on its defence by means of inundation. From the history of the formation of the soil already given, and from the course of the rivers, it may be gathered that the low grounds are in the west, and the higher in the south and east. According to the relief map published by the minister of war (scale 1 : 600,000), the provinces of North and South Holland, the western portion of Utrecht as far as the Vaart Rhine, Zealand, except the southern part of Zealand-Flanders, and also the north-west corner of North Brabant, all lie, with the exception of the dunes, below the Amsterdam zero; while the eastern portion of the country, except a small strip along the Zuyder Zee in the provinces of Guelderland, Overyssel, and Friesland, as well as the lands in the neighbourhood of the Dollart, is situated above it. The regular slope of the ground from south-east to north-west, and the position of the highest and the lowest points, are indicated by the same authority. At Vaals, in the extreme south-east, the altitude is 656 ft., at Valkenberg 525, at St Pietersberg near Maestricht

Relief.



Relief and Geological Charts of Holland.
The positions of the chief towns are indicated by the initials of their names. In the left-hand chart the undivided horizontal lines show the tracts that lie below the Amsterdam zero, the broken horizontal lines those under 1 metre, &c.

403, at the Imbosch near Dieren and the Hettenheuvel near Heerenberg respectively 360 and 345, at Meerwijk near Nimeguen 318, at Apeldoorn 233, at Zeist 164, at Oldenzaal 154, at Wageningschenberg and Grebsohenberg respectively 151 and 131, at Hoenderloo and Kootwijk in the Veluwe 118 and 98, at Groenlo 78, in the "high fens" of Drenthe near Barge 85, at Lochen and Almelo 39, at Coevorden 31, at Steenwijk and Boertange 19, at Groningen 18, at Heerenveen 0·65. Below the Amsterdam zero lie naturally many impoldered districts, especially the marshes and meres which have been drained dry, as for example the Schermer and Purmer polders and the

[1] Before the construction of the canal to Ymuiden.

Haarlem lake, which are respectively – 10·66, – 12·46, – 13·61, the Schieveen polder near Schiedam – 16·27, the polders at Wo''brugge, the Bergschenhoek, and the Zuidplas – 16·86, – 17·58, and – 18·49.

Geology and soil. Of equal importance with the relief of the country is the geological composition of the soil. It is evident from the history of the origin of the land that Quaternary formations—alluvium and diluvium—must be well represented. In fact they constitute no less than 99·9 per cent. of the surface of the Netherlands, only ·1 per cent. thus remaining for all the older formations—the Tertiary and the Secondary, including the extremely limited Jurassic.

Fens. To the alluvial strata belong, in the first place, the fen (veen) strata, which are subdivided into low fens, high fens, marsh fens, and the "dalgronden" or "reclaimed high fens." The low fens, which are found in Groningen, Friesland, Overyssel, North and South Holland, and North Brabant (about the Langstraat), have been formed of aquatic plants, and, in the upper layers, of moss; their elevation is that of the mean sea-level; from them the "short turf," the best quality of peat, is obtained by dredging, and, when the standing water which collects after the peat has been dug out has been drained off, they may be turned into very productive arable land. The subsoil, on which the fertility then depends, consists usually of clays and alluvial sand or dune strata, rarely of diluvial sand strata. These low fens extend to no less than 904,597 acres, or about 11 per cent. of the surface. The high fens, of which the greater part have been "disfenned" or stripped of peat, are found in Groningen, Friesland, Drenthe, Overyssel, and the "Peel" or Marsh of North Brabant, in the more elevated plains or valleys. They have been formed of trees, heath-plants, and moss, and furnish the softer, inferior kind of peat, the "long turf." As the removal of the peat has been followed by the construction of canals to carry off the standing water, the high fens are of course free from marshes, but, resting as they do almost everywhere on diluvial gravel and sand, they do not furnish so fertile a soil as the low fens. They comprise 226,107 acres, or only about 2·8 per cent. of the surface of the country. The marsh fens are composed almost exclusively of a few species of sedge or carex, and constitute, not only in their method of formation, but also in their character and situation, the transition between the high and the low fens. They are widely scattered, especially along small streams which carry off water mingled with fenny materials, and are nowhere more numerously represented than in Drenthe, where all the drainage is of this character. The marsh fens occupy 168,551 acres, considerably less than the high fens. The "dalgronden" are formed where regular peat-fields are laid out along specially constructed canals, and the denuded surface is usually grubbed up for arable or pasture land, or on rare occasions planted with wood. They comprise about 207,576 acres, and naturally increase in proportion to the decrease of the high fens. We shall return to these "dalgronden" in connexion with the canals. Besides the fens, the clay lands and certain of the sand-strata belong to the alluvium. The clays—which

Clays furnish the richest arable soils, the most luxuriant meadowland, and in some places the material for bricks and earthenware—may be divided into the sea-clay, the river-clay, the stream-clay or green earth, and the old sea-clay of the districts recovered from the water. The exceptionally fertile sea-clay in the provinces of Groningen, Friesland, North and South Holland, and Zealand occupies no less than 1,676,860, or about 20 per cent. of the surface, while the river-clay, naturally situated along the banks of the larger rivers, takes up 854,284 acres, or about 10 per cent. The boundary between the sea-clay and the river-clay is formed in the case of these rivers by the maximum high-water line. The stream-clay or green earth, which is found, as the former name implies, on the banks of the smaller rivers or streams, is formed of course on a much smaller scale, and consists of a stratum on an average from 3 to 5 feet thick, resting almost exclusively on the sand diluvium, from which it is occasionally separated by a fenny stratum. It occurs in the east of Drenthe, Overyssel, and Guelderland, along the small tributaries of the Vecht, along the Vecht, Regge, and Schipbeek in Overyssel, and in like manner in North Brabant along the Dommel, Aa, Mark, and other unimportant streams. The green earth not unfrequently contains iron ore; from this the metal is extracted in Overyssel and Guelderland, and it is asserted that in thirty years the natural processes replace the excavated mineral. The stream deposits occupy about 2 per cent. of the surface—157,187 acres. Finally the old sea-clay of the reclaimed districts covers 127,518 acres, or 1½ per cent. of the surface. As already stated, the subsoil of the low fens is not everywhere clay. It is so in the main in the provinces of North and South Holland, where the drainage operations were consequently much more remunerative than in Friesland, and in the east of Utrecht, where the fens rested upon sand. Estimating the total area of the recovered districts at 197,690 acres, about five-eighths of this consists of old sea-clay; and these portions, such as the Haarlem lake grounds, the Beemster and Purmer polders in North Holland, and the Nieuwkoop and Zuidplas polders in South Holland, are reckoned among the richest and most fertile. How these low-lying areas have been endyked and drained, surrounded by canals and kept dry by gigantic steam-pumps, has been explained under the heading HAARLEM LAKE.

Alluvial sand. The alluvial sand-strata (to be distinguished from the diluvial sand) may be divided into (1) sand-drifts, (2) river-sand, river-downs, and "heibanen," and (3) old sea-sand and the sea-dunes with the geest-grounds. The last of these classes has already been considered in dealing with the sea-coast. The rivers bring down their sand as well as their gravel, not so much from the more elevated districts as from the diluvial valleys in which they have excavated their channels. The beds of the rivers themselves consist likewise of sand, mingled here and there with gravel or rolled and polished pebbles, and, where the current is not too strong, covered with a layer of clay. If sand has been accumulated on the shore, the wind soon transforms it after the retreat of the river into hillocks or river-dunes. When these contain a proportion of clay they are more fertile than the sea-dunes. They occur on both sides of the Guelderland Yssel (between Zalk and Oest), and on the Waal below Hulhuizen and opposite Rossum; and various eminences in other parts of the country, such as Agnietenberg near Zwolle, and the heights near Deventer, near Grafthorst opposite Kampen, and along the Meuse between Venlo and Mook, must be considered as of similar origin. "Heibanen," *i.e.*, heath-tracks, so called on account of their sterility, are beds of river gravel easily distinguished from the diluvial gravel by the smooth, worn, and uniform appearance produced ages ago by the action of the current. They are found, for example, in the Betuwe, about Avezaat, and between Lienden and Waddenoijen. Sand-drifts are dune formations originated by the action of the wind on the diluvial sand, where in one way or other it has been stripped of the heath-crust. They extend to 179,220 acres, or about 2¼ per cent. of the surface. The fen strata occupy in all 1,508,300 acres, or 18½ per cent.; the clay strata 2,815,850 acres, or about 35 per cent.; the alluvial sand strata 475,477 acres, or about 6 per cent.; and the whole alluvium 4,799,627 acres, or 59 per cent.

Diluvial strata. The diluvial or sand and gravel strata of the Netherlands are far from being of such economic importance as the alluvial strata. The agricultural products—mainly buckwheat and rye—are neither so abundant nor so valuable as the wheat and rape-seed of the clay soils; and neither stock-breeder nor dairy-farmer obtains so satisfactory results. The boundary of the diluvial strata may be roughly indicated by a line running through Winschoten, Groningen, Dokkum, Leeuwarden, Heerenveen, Steenwijk, Zwolle, Elburg, the coast of the Zuyder Zee, Naarden, Utrecht, Rhenen, Bois-le-Duc, Breda, Bergen-op-Zoom, and Antwerp. South and east of this line lies the diluvium, for the most part on the surface, except in the places already mentioned where the fens, the river-clay, the stream deposits, and the sand-drifts are situated, or in the extreme south and east where the older strata make their appearance. To the north and west of the line the only diluvial strata are those of the Zuyder Zee islands: in Texel, Wieringen, and Urk the soil is of diluvial origin; and this probably holds true also in whole or in part in Vlieland, Ameland, and Terschelling.

The diluvial formations are subdivided into gravel-strata and sand-strata. To the former belong (1) the Scandinavian diluvium, in which occur granites and chalk flints derived from Scandinavia, situated to the north of the Overyssel Vecht (that is, in Groningen, Drenthe, the south-west of Friesland, and the islands); (2) the mixed diluvium, which, besides the Scandinavian gravel contains stone-grit from Munster, the Teutoburger Wald, and the districts along the Rhine (it is situated between the Vecht and the Rhine, in Overyssel, Utrecht, the Gooiland,[1] and Guelderland); (3) the Rhine diluvium, destitute of granite, but with many fragments of white quartz, basalt, and other kinds of stone from the mountains along the river between Bonn and Coblentz (it lies between the Waal and the Meuse); (4) the Meuse diluvium, containing materials brought from the mountains higher up the stream; and finally (5) the Limburg flint diluvium, like the preceding variety destitute of any plutonic or volcanic rocks, but nevertheless consisting almost exclusively of flints occurring in the neighbouring chalk formation.

The sand-diluvium, which is of later date than the gravel, is found in great level stretches at the foot of the hills of diluvial gravel, and contains no pebbles or coarse gravel. It also occurs in the maritime provinces under all the marine and fluvial formations. According to some authorities it owes its origin to the influence of rain, or frost, or wind; according to others it has been formed by the sea like the Kempen sand and that of the dunes, and then transported by the south-westerly currents.

[1] A district formerly called Naardingerland, on the southern shores of the Zuyder Zee, including Naarden, Bussum, Huizen, Blaricum, Laren, Hilversum, and Muiderberg.

In the diluvium must also be included the loess, which occupies a large proportion of the province of Limburg. The whole diluvium comprises 3,308,330 acres, or about 40½ per cent. of the country, distributed thus:—Scandinavian 4½ per cent., mixed diluvium 4½, Rhine and Meuse diluvium and Limburg flint diluvium 1, loess 1½, and lastly the sand diluvium, which includes the diluvial river-banks, 2,376,770 acres, or about 29 per cent.

The older formations, which occupy a very limited area, occur in the east of Guelderland and Overyssel, in the south of Limburg, and in Zealand-Flanders. That they also form the substratum elsewhere, *e.g.*, in Zealand and Brabant, is not improbable. The area of the Tertiary strata is 3425, and of the Secondary 3746 acres.

As regards the capabilities of the soil, Holland does not hold an exceptionally favourable position,—34 per cent. of the country consisting of good and about 2 per cent. of inferior clay land, while more than 45 per cent. is poor and partially reclaimed sand, and fully 18·5 per cent. is covered with fens. The following figures show the account to which the soil is actually turned:—64·3 per cent. consists of arable and pasture land, gardens, hay-fields, and orchards; 6 per cent. is occupied by water and roads; 7 per cent. is woodland; 0·7 is covered with buildings; and the rest, or 22 per cent., must consequently be assigned to the waste lands, shores, and dunes, the reed-beds, heaths, and fens. The extent of this uncultivated area is of course being gradually diminished by the more general employment of improved methods of drainage, by prevention of the progress of the sand-drifts, by reclamation of the fens, by the extension of facilities for the carriage of manures, and by the parcelling out of the mark-lands or commons which are now used only as public pastures or for the digging of turf (*plaggen*). The distribution of the cultivated lands in the several provinces is considered below in connexion with the density of the population.

The Netherlands are watered by three main rivers—the Rhine, the Meuse or Maas, and the Scheldt or Schelde, besides a great number of smaller streams. How the Rhine breaks up into Rhine and Waal, Rhine and Yssel, Crooked Rhine and Lek, Old Rhine and Vecht, and finally reaches the sea at Katwijk, may be seen from the map; and also how the Meuse at Gorcum forms a junction with the Waal, flowing on to Dort under the name of the Merwede, and thence continuing to the sea between the South Holland Islands and South Holland, under the names of the North, the Old, and the New Meuse. There too may be traced the course of the Scheldt, with its broad mouths bounding the Zealand Islands and separating them from the mainland of Flanders, or that of the Yssel by Deventer, Zutphen, and Kampen to the Zuyder Zee. These great rivers render very important service as water-ways, as the following statistics may show:—

Name.	Breadth. Maximum.	Breadth. Minimum.	Discharge per Second at Mean Level.	Depth (Minimum). At Mean Level 1875.	Depth (Minimum). At lowest Level 1874.	Slope of the Surface per 1000 ft. At Mean Level.	Slope of the Surface per 1000 ft. At Flood.
	Ft.	Ft.	Cu. ft.	Ft.	Ft.		
Upper Rhine	2483	1260	88,250	5·08[1]	1·96[1]	0·10[1] to 0·13[1]	0·10[1] to 0·15[1]
Waal	2588	941	61.775	7·44	3·70	0·10 to 0·15	0·12 to 0·15
Lek	1240	410	17,650	6·36	2·23	...	...
Yssel	984	203	8,825	6·13	0·98	0·10 to 0·13	0·1 to 0·14
Meuse	656	541	4,412	4·62[2]	1·77[2]	Maestricht to Roermond...0·40	0·38
						Roermond to Venlo ......0·18	0·09
						Venlo to Grave 0·06	0·11
						Grave to Crèvecœur..........0·05	0·07

The depths are those of the fairway. The mean velocity seldom exceeds 4·9 feet, but rises to 6·4 feet when the river is high. In the lower reaches of the streams the velocity and slope are of course affected by the tides. In the Waal ordinary high water is perceptible as far up as Bommel; in the Lek the maximum limits of ordinary and spring tides are at Vianen and at Kuilenburg respectively, in the Yssel above the Katerveer and past Wijhe, and in the Meuse near Heusden and at Well. The following table shows the fall at ebb and flood tide respectively in the rivers named:—

	Ft.		Ft.
Lower Rhine and Lek, from Pannerden to Krimpen	38·827	and	32·638
Waal and Merwede, from Pannerden to Hardinxveld	33·479	,,	31·585
Guelderland Yssel, from Westervoort to Mond Ganzediep	31·06	,,	31·00
Meuse, from Grave to Woudrichem	13·97	,,	12·56

The fall in the Meuse from Maestricht to Venlo is 107·05 feet.

The total length of the navigable channels is 1135 miles, but in certain places sand-banks and shallows not unfrequently impede the shipping traffic at low water during the summer. As a drawback to the services rendered by the rivers must be mentioned the damage inflicted by their inundations and ice-drifts, for protection against which river-dykes were constructed as early as the days of the Romans, and, in the lower reaches, more especially in the course of the 11th, 12th, and 13th centuries. It is only in a few places—for example, on the right-hand side of the Rhine—that elevated banks are found. Elsewhere between the dykes and the stream lie "forelands" or "outwerders," which are usually submerged in winter. That the rivers cannot at all times, any more than the sea, be kept under control by the dykes is shown by the floods of 1775, 1776, 1784, 1799, 1809, 1820, 1861, &c.

The smaller streams are often of great importance. Except where they rise in the fens, they call into life a strip of fruitful verdure in the midst of the barren sand, and thus lead to the existence of many villages. The low-lying spaces at the confluences, being readily laid under water, have been not unfrequently chosen as sites for fortresses. As a matter of course, the streams are also turned to account in connexion with the canal system,—the Holland Yssel, the Gouwe, the Rotte, the Schie, the Spaarne, the Zaan, the Amstel, the Dieze, the Amer, the Mark, the Vecht, the Zwarte Water (Black-water), the Kuinder, and the numerous Aas in Drenthe and Groningen being the most important in this respect. Largely by means of these natural water-ways the Dutch have formed for themselves a network of canals, small and great, the united length of which amounts to 1522 miles. The canals differ greatly in character in the different provinces. In North Brabant and Limburg the Zuid Willemsvaart (South William's canal) unites Maestricht *via* Weert and Helmond with Bois le Duc ('s Hertogenbosch), communicates by a side branch with Eindhoven, and has a connexion with the canal from Maestricht to Liége. In Zealand the canals give the towns of the interior communication with the sea or the river mouths; for example, canals lead respectively from Terneuzen to Sas van Gent and to Ghent, from Middleburg to Veere and from Middleburg to Flushing, from Goes to the Eastern Scheldt, and from Zierikzee also to the Eastern Scheldt. The canal from Hansweert to Wemeldinge has been cut to allow ships to pass between the East and the West Scheldt. In South Holland many canals serve the like purpose; thus the Voorn canal unites the Haringvliet with the New Meuse, which does not allow the passage of large vessels above Briel; and similarly on account of the many banks and shallows in front of Helvoetsluys a new waterway has been opened up to Rotterdam by widening the channel of the Scheur north of Rozenburg, and cutting across the Hoek van Holland. The Goeree inlet unites that place with the Haringvliet. Of a different character is the Zederik canal, which unites the principal river of central Holland—the Lek—(at Vianen) by means of the Linge with the Merwede (at Gorcum). As Rotterdam has its new water-way, so in North Holland Amsterdam is connected with Nieuwe Diep by the canal *via* Purmerend and Alkmaar; and, this canal being too shallow for the largest class of vessels in cargo, the canal to Ymuiden has been constructed across Holland-op-zyn-smalst (*i.e.*, Holland at its narrowest). Amsterdam is further connected with the Vecht by the Keulsche Vaart, and with the Lek and the Zederik canal *via* Utrecht by the Vaart Rhine. In the province of Guelderland Nijkerk inlet unites that town with the sea, and Apeldoorn communicates with Hattem north-east through the Grift canal and south-east with the Yssel through the Dieren canal. A totally different character belongs to the canals in the east and north-east of the country, where, in the absence of great rivers, they form the only water-ways which render possible the drainage of the fens and the export of peat, and unite the lesser streams with each other. Thus in Overyssel the Willemsvaart connects Zwolle and the Zwarte Water with the Yssel, the Dedemsvaart connects the Vecht with the Zwarte Water near Hasselt, and a canal connects Almelo with Zwolle. In Drenthe the Smildervaart

[1] These figures have reference to the Lower not to the Upper Rhine.
[2] Below Grave.

or Drenther Hoofdvaart unites Assen with Meppel, and receives on the eastern side the drainage canals of the Drenthe fens (the Orange canal, the Beilerstroom, and the Hoogeveen Vaart), while the North Willemsvaart unites Assen with Groningen. In the province of Groningen the chief town communicates with Delfziji and the Dollart both by the Damsterdiep and by the new ship canal, while the canal to Winschoten brings it into connexion with the flourishing fen colonies, such as Wildervank and Veendam, which have sprung up in the east of the province and in Drenthe. In Friesland, finally, there are three ship canals :—that from Harlingen to the Lauwer Zee *via* Franeker, Leeuwarden, and Dokkum; that from Leeuwarden to the Lemmer, whence there is a busy traffic with Amsterdam; and that from Stroobos in the east of the province (in connexion with Groningen) to Stavoren in the south-west. It would be superfluous to enumerate the barge canals by which almost all the large towns communicate with each other; and it is equally unnecessary to mention all the lakes, which exist in great numbers, especially in Friesland and Groningen, and are connected with rivers or streamlets. Those of Friesland are of note for the abundance of their fish and their beauty of situation, on which last account the Uddelermeer in Guelderland is also celebrated. The Rockanje Lake near Briel is remarkable for the strong chalky solution which covers even the growing reeds with a hard crust. Many of the lakes are nothing more than deep pits or marshes from which the peat has been extracted.

Lakes.

Climate.

The climate of Holland[1] is such as might be conjectured from its geographical position and its generally low level. Situated in the temperate zone between 50° and 53° N. lat., it shows a difference in the lengths of day and night extending in the north to nine hours, and there is a correspondingly wide range of temperature; it also belongs to the region of variable winds. The following table, from the observations of Professor C. D. Buys Ballot, the well-known director of the Meteorological Institute at Utrecht, shows the average temperatures and the barometric heights re corded there during 1849–1878 :-

Month.	Thermometer.		Barometer.		Month.	Thermometer.		Barometer.	
	C.	Fahr.	Mill.	Inches.		C.	Fahr.	Mill.	Inches.
Jan.	1·94	35·49	759·88	29·916	July ...	18·52	65·33	760·53	29·943
Feb.	2·99	37·38	761·20	29·968	August	17·96	62·32	760·11	29·925
March ..	4·96	40·92	758 95	29·879	Sept. ...	14·99	58·98	760·70	29·948
April ...	9·39	48·90	759·71	29·909	Oct.	10·39	50·70	758 83	29 870
May.....	13·10	55·58	759·90	29 917	Nov.	4 98	40·96	758·97	29·880
June ...	16·99	62·58	760·90	29·956	Dec. ...	2·65	36·77	760·05	29·923

The mean annual temperature was 9·91° C., or 49·83° Fahr.

How largely the westerly winds predominate is shown by the following statistics. On an average of ten years 5 per cent. of the winds were N., 5 N.N.W., 7 N.W., 6 W.N.W., 7 W., 10 W.S.W., 12 S.W., 7 S.S.W. (total 59 per cent.), and 7 S., 5 S.S.E., 5 S.E., 2 E S.E., 3 E., 6 E.N.E., 8 N.E., 5 N.N.E. (total 41 per cent.). The west winds of course increase the moisture, and moderate both the winter cold and the summer heat, while the east winds blowing over the Continent have an opposite influence. The following table, derived from observations taken at Utrecht, shows that, as might be expected, the rainfall is large :—

Months.	Average Evaporation (1855–64).		Rainy Days (1848–78)	Average Rainfall (1848–78).	
	Millim.	Inches.		Millim.	Inches.
January	12·8	0·51	401	50·3	1·98

Yearly average...	810·2	31·88	148	695·4	27·37

It cannot be said that the climate is particularly good; indeed to strangers it is rather the reverse of pleasant. Fevers, colds, and, when proper precautions are not taken, chest disease and consumption, are results of the changeableness of the weather, which may alter completely within a single day. The heavy atmosphere likewise, and the necessity of living within doors or in confined localities, cannot but exercise an influence on the character and temperament of the inhabitants. Only of certain districts, however, can it be said that they are positively unhealthy; to this category belong some parts of Holland, Zealand, and Friesland, where the inhabitants are exposed to the exhalations from the marshy ground, and the atmosphere is burdened with the sea-fogs. To what extent the healthiness of the different provinces varies may be seen from the following table of the annual death-rate for the twenty-five years from 1840 to 1865 :—

Provinces.	Males.	Females.	Both Sexes.
Guelderland	1 in 42·10	1 in 44·00	1 in 42·95
North Brabant	,, 41·69	,, 43·03	,, 42·69
Limburg	,, 42 82	,, 42 61	,, 42·68
Drenthe	,, 41·98	,, 43 62	,, 42 54
Friesland	,, 40 84	,, 43·67	,, 42·07
Groningen	,, 40·00	,, 42·94	,, 41·24
Overyssel	,, 39·01	,, 40·54	,, 39·75
Utrecht	,, 33·68	,, 36·14	,, 34·90
North Holland	,, 30 33	,, 34·32	,, 32·35
Zealand	,, 29·51	,, 32·24	,, 30·84
South Holland	,, 29·04	,, 32·81	,, 30·60

For the whole kingdom the annual death-rate was 1 in 36·73—that for the males being 1 in 35·49, and for the females 1 in 38·14.

Density of population.

That the density of the population must, apart from other causes, increase through the acquisition and cultivation of new land, and that it visibly differs very greatly according to the difference of the soil in the different provinces, may be seen from the following table, wherein the increase of the percentage of cultivable land and of the population is indicated :—

Provinces	Waste Lands.		Buildings and Pleasure Grounds.		Arable Land.		Under Grass.		Orchards and Nurseries.		Population.		Mean Density per Sq. Mile.
	1833.	1876.	1833.	1876.	1833.	1876.	1833.	1876.	1833.	1876.	1829.	1878.	
Groningen	16	14·7	0·9	0·9	49·3	51·4	24·9	26·7	...	...	157,504	249,124	271

[1] See Dr F. W. C. Krecke, *Het Klimaat van Nederland*, Haarlem, 1863–64, and the *Jaarboek* of the Kon. Ned. Meteor. Inst.

The greater density of population in the Holland provinces as compared with Drenthe cannot be explained, however, merely by the character of the soil; the variety of industries and the great number of large towns contribute to the inequality. All the towns with 100,000 inhabitants and upwards (Amsterdam, Rotterdam, and the Hague) are situated in the provinces of Holland; of the 36 communes with more than 10,000, 9 are in Holland, none in Drenthe; of the 35 communes between 10,000 and 4000, 9 are in Holland and 2 in Drenthe. The reason why in the west, and especially in the district between Amsterdam and Rotterdam, there is such a clustering of large towns, only surpassed in a few parts of England and Belgium, is to be found in the facilities there afforded for earning a subsistence. Holland is emphatically a country of large towns. According to the census of 1869 there were forty-four which had a population of upwards of 5000. The greatest of all was Amsterdam, with 256,154 inhabitants; and next in order came Rotterdam, with 113,734. Two others had upwards of 50,000, the Hague and Utrecht, respectively 81,881 and 57,085. Arnheim, Leyden, Haarlem, Groningen, and Maestricht were all above 25,000; and Bois-le-duc, Delft, Dort, and Leeuwarden above 20,000. The five towns of Nimeguen, Gouda, Helder, Deventer, and Zwolle had each between 15,000 and 20,000; and Breda, Zutphen, Zaandam, Amersfoort, and Kempen were all above 10,000, though less than 15,000. Since that date many of these have considerably increased in size. In 1879 Amsterdam had about 300,000 inhabitants, Rotterdam 140,000, the Hague 100,000, and Utrecht 70,000.

ation- ties.

As the density of the population varies within the narrow limits of the Netherlands, so varies likewise the origin of the people. Although ethnographically the whole population belongs to the Indo-Germanic family, or more definitely to the Teutonic branch of it, the descendants of the Frisians may be clearly distinguished in the north-west. The mouths of the Meuse separate these from the descendants of the Franks, who pushed eastward across the Meuse but never settled beyond the Waal, while the territory of the Saxons, who came later from the east, extends no further than to the Utrecht Vecht. The descendants of the Saxons consequently lie between those of the two first-named peoples, although naturally much commingling has taken place between Frisians and Saxons, and Saxons and Franks, especially in the towns and on the newly-acquired lands. The representatives of the Semitic stock (Portuguese or German Jews), though their influence is not unimportant, number only 50,000 or 60,000, of whom about 40,000 reside at Amsterdam. The descendants of the three Teutonic peoples above named are very slightly distinguished from each other by their physical, intellectual, and moral characteristics, and all the less so because the Dutch type is not itself strongly marked and bears the traces of foreign commixture; for many Flemings and Brabanters settled in the country at the time of the revolt against Spain, many Germans, Englishmen, and Scandinavians during the prosperity of the republic, and many Frenchmen after the revocation of the edict of Nantes. The differences most clearly discernible are in the old local laws, in the peculiar customs, and above all in the dialects. Among these last must be distinguished the Holland dialect (Hollandsch) spoken in the provinces of Holland and part of Utrecht; the Zealand dialect (Zeeuwsch, in Staats Flanders inclining towards Flemish); the Brabantine (modified), also spoken in a part of Limburg and the south of Guelderland; the Lower Rhenish, which is again subdivided into the Guelderland, the Overyssel, and the Drenthe dialects; and, finally, the Groningen dialect. The peasant or country Frisian forms a completely separate language with a literature of its own. It has not been at all satisfactorily determined in what parts of the Netherlands the remains of a pre-German population are to be found, nor to what extent they are to be distinguished from the Germans by the form of the skull; but investigations are being carried on in this department of inquiry, and a map is being prepared to indicate the boundaries of the various dialects.

Government.

The government of the Netherlands is regulated by the constitution of 1815, revised in 1848, under which the king's person is inviolable and the ministers are responsible. The crown is hereditary in both the male and the female line according to primogeniture; but it is only on the complete extinction of the male line that females can come to the throne. The crown prince or heir apparent is the first subject of the king, and bears the title of the Prince of Orange. The king alone has executive authority. To him belong the ultimate direction of foreign affairs, the power to declare war and peace and to make treaties and alliances, the supreme command of the army and navy, the supreme administration of the finances and of the colonies and other possessions of the kingdom, and the prerogative of mercy. By the provisions of the same constitution he establishes the ministerial departments, and shares the legislative power with the first and second chambers. The heads of the departments to whom the especial executive functions are entrusted are eight in number,—ministers respectively of the interior, of public works (the "waterstaat," including trade and industry, railways, post-office, &c.), of justice, of finance, of war, of marine, of the colonies, and of foreign affairs. They are appointed and dismissed at the pleasure of the king, usually determined, however, as in all constitutional states, by the will of the nation as indicated by its representatives. The members of the first chamber are chosen by the provincial states from among those who bear the greatest burden of direct taxation in each province, the proportion of persons thus eligible being 1 to every 3000 of the population. North Brabant sends 5, Guelderland 5, South Holland 7, North Holland 6, Zealand 2, Utrecht 2, Friesland 3, Overyssel 3, Groningen 2, Drenthe 1, Limburg 3—or altogether 39. The duration of parliament is nine years, a third of the members retiring every three years. The retiring members are eligible for re-election. The members of the second chamber are chosen in the electoral districts by all citizens of full age who pay direct taxes varying according to local circumstances from 20 to 160 guilders. One member is elected for every 45,000 of the population. At present (1880) there are eighty-six; they must be at least thirty years old, and they cease to be members if they take a salaried Government appointment. They discuss all laws, and have the right of proposing amendments. Their term is four years, but they are re-eligible. All communications from the king to the states-general and from the states to the king, as well as all general measures relating to internal administration or to foreign possessions, are first submitted to the consideration of the council of state, which also has the right of making suggestions to the king in regard to subjects of legislation and administration. The king appoints the vice-president of the council, which consists of fourteen members; he is himself the president, and can name councillors, to the number of not more than fifteen, for special service.

Provincial administration.

The provincial administration is entrusted to the provincial states, which are returned by direct election by the same electors as vote for the second chamber. The term is for six years, but part of the members retire every three years. The president of the assembly is the royal commissioner for the province. As the provincial states only meet a few times in the year, they name a committee of deputy-states to which the management of current general business is entrusted, and which at the same time administers the affairs of the communes. At the head of every commune stands a communal council, whose members are chosen by the inhabitants for a definite number of years. The president of the communal council, the burgomaster, is named by the king in every instance for six years, and along with the magistrate to be chosen by and from the members of the council is charged with the ordinary administration. The provinces, as already stated, are eleven in number (the grand-duchy of Luxembourg, over which the king has control, is not incorporated with the kingdom); the number of communes at 31st December 1878 was 1128.

Justice.

The administration of justice is entrusted (1) to the high council, the supreme court of the whole kingdom, which holds its sessions at the Hague, and is the tribunal for all high Government officials and for the members of the states-general; (2) to the five courts of justice for criminal cases, and for appeal in more important police and civil cases; (3) to courts established in each arrondissement; (4) to cantonal judges appointed over a group of communes, whose jurisdiction is restricted to claims of small amount (under 200 guilders), and to breaches of police regulations, and who at the same time look after the interests of minors.

Finance. The following statement of the revenue for the year ending the middle of 1878, and of the expenditure for 1877, is taken from the *Staats Courant* for 1879, No. 6:—

Revenue.		*Expenditure.*	
Direct taxation	£2,000,748	Royal household	£72,916
Export and import duties	381,942	Superior authorities of the state	49,112

The following table shows the revenue and expenditure for the provinces and communes, and the contributions received from the Dutch Indies:—

Years.	Provincial.		Communal.		Contributions of Dutch Indies.
	Revenue.	Expenditure.	Revenue.	Expenditure.	
1867	£279,090	£261 646	...	...	...
1868	273,461	244,325	...	...	£897,613
1869	261,205	242,998	...	...	1,122,916
1870	322,909	315,477	...	...	1,083,973
1871	314,760	290,127	...	...	899,307
1872	278,983	261,537	£3,502,640	£3,169,554	1,832,100
1873	312,193	297,250	3,758,827	3,479,869	868 974
1874	322,256	322,256	3,547,573	3,277,634	878,714
1875	390,617	385,963	5,180,414	3,565,700	1,925,973

We append the total receipts of the ten years 1868–77, including the ordinary revenue, the Indian contributions, balances from previous budgets, proceeds of sale of domains, &c., and the total expenditure for the same years, including, besides the ordinary budget, the outlays in payment of annuities, in funding and discharging debt, in railway extension, &c.:—

	1868.	1869.	1870.	1871.	1872.	1873.	1874.	1875.	1876.	1877.

Army. The amount expended on the war and marine departments is given above. The standing army consists of infantry, cavalry, artillery, engineers, and gendarmerie, forming together a force of 60,000 men, with 3000 horses. Less than half, however, is kept in arms the whole year. The soldiers are raised partly by voluntary enlistment, and partly by conscription. In 1876, 1877, and 1878 the conscripts amounted to 10,808, 10,878, and 10,772 respectively. They are selected from the males who have entered their twentieth year and are not exempted for special reasons. The term of service in time of peace is five years, but may be extended in time of war; the conscript recruits, however, so far as the number of volunteers permits, are kept under arms for a few months only. A portion of the annual contingent is appropriated to the marine service. In the communes there are "schutterijen," militia "trainbands," which in time of war serve for the defence of the country, and at all times for the maintenance of order. Their actual term of service lasts only five years, but every male inhabitant from his twenty-fifth to his thirty-fourth year is liable to be called out. On the 1st of January 1879 there were of these on duty, in 88 communes, 212 companies, or 41,714 men, including 573 officers.

Navy. The strength of the navy in 1879 was—home service, 17 ships with 3162 men; Indian military marine, 23 ships with 1793 hands; auxiliary squadron, 4 ships with 900 hands; in the West Indies, 2 ships with 206 men. The fleet for the protection of the "seagates," or estuaries, coasts, roadsteads, and rivers on the 1st August 1878 amounted to 61 ships, of which 23 were armour-plated; 21 ships for general service, of which 2 were armour-plated; besides 7 guardships and tenders and 7 training vessels. The strength of the marine corps was in July 1878 returned at 2055, and the number of guns carried by the navy at about 500.

Fortifications. In accordance with the law of April 18, 1874, the military and naval defences are supported by a system of fortification which embraces the following lines:—the Nieuwe Hollandsche water-line from the Zuyder Zee by Utrecht, the Lek, and the Merwede, through the district of Altena to the New Merwede; the line of the Guelders valley and the Lower Betuwe; the lines of the Hollandsche Diep and the Volkerak, of the mouth of the Meuse and the Haringvliet, and of the Helder; the works for the protection of the river-crossings and the reception of troops on the Yssel, the Waal, and the Meuse; the Amsterdam line from the German Ocean, near Ymuiden, to the Zuyder Zee and the Nieuwe Hollandsche water-line; the southern water-line from the Meuse above St Andries to the Amer below Geertruidenberg; and the works on the Western Scheldt. As already mentioned, in many cases the fortifications can be supplemented by extensive inundations.

Relig[ion]. The inhabitants of Holland enjoy full religious as well as political liberty. Not only is the free profession of his religious opinions guaranteed to every one by the constitution; the same protection is accorded to all the various ecclesiastical bodies; all the adherents of the different creeds have equal civil and political rights, and equal claims to public offices, dignities, and appointments; and all denominations possess perfect freedom of administration in everything relating to their religion and its exercise.

At the census of 1869 the population was classified thus as regards religion:—

			Congregations.
Low-Dutch Reformed	1,956,852	with	1,343
Walloons	10,258	,,	17
Remonstrants	5,486	,,	20
Christian Reformed	107,123	,,	390
Baptists	44,227	,,	126
Evangelical Lutherans	57,545	,,	50
Old Lutherans	10,525	,,	8
Moravians	311	,,	2
English Episcopalians	456	,,	2
Scotch Church	84	,,	1
English Presbyterians	417	,,	4
Total Protestants	2,193,284	with	1963
Roman Catholics	1,307,765	,,	982
Old Catholics	5,287	,,	16
Greek Church	32	,,	2
Low-Dutch Jews	64,748	,,	167
Portuguese Jews	3,525	,,	2
Unknown	5,161	,,	...

Altogether there are about 2800 churches and chapels. The following table shows the percentage of Protestants, Catholics, and Jews in the several provinces:—

	Groningen.	Friesland.	Drenthe.	Overyssel.	Guelderland.	Utrecht.	North Holland.	South Holland.	Zealand.	North Brabant.	Limburg.	Holland.
Protestants	90·5	90	93·5	66·5	61	62	67·5	73·5	73·5	11·5	2·5	59
Roman Catholics	7·5	9	4·0	32·0	38	37	27·5	24·5	26·0	88·0	97·0	39
Jews	2·0	1	2·5	1·5	1	1	5·0	2·0	0·5	0·5	0·5	2

From this it appears that in the north-east the Protestant creed greatly preponderates, and that the majority of the Roman Catholics are found in the south, while both are fairly represented in the central provinces. That in the last fifty years there has been over the whole population a steady increase in the proportion of Protestants and Jews, and a corresponding decrease of Roman Catholics, is evident from the following table:—

Year of Census	Protestants.		Roman Catholics.		Jews.		Unknown.	
	Number	Per ct.	Number.	Per ct.	Number.	Per ct.	Numb.	Per ct.
1829	1,541,887	59·11	1,019,109	38·99	46,408	1·78	3,083	·012
1839	1,701,275	59 58	1,100,616	38·48	52,245	1·83	3,314	·011
1849	1,824,860	59·69	1,171,924	38 34	58,626	1·92	1,469	·005
1859	2,007,026	60·65	1,234,486	37 30	63,790	1·93	3,826	·012
1869	2,193,281	61·27	1,313,052	36·68	68,003	1·90	5,193	·015

The government of each of the Protestant bodies (with the exception of the Baptists, who have no central authority) is in the hands of an assembly or "synod" of deputies from the provincial judicatures. In the case of the Reformed Church the affairs of the community are entrusted to the provincial synods. The provinces are subdivided into "classes," and the classes again into "circles" (ringen), each circle comprising from 5 to 25 congregations, and each congregation being governed by a "church council" or session. The provincial synods are composed of ministers and elders deputed by the classes; and these are composed of the ministers belonging to the particular class and an equal number of elders appointed by the local sessions. The meetings of the circles have no administrative character, but are mere brotherly conferences. The financial management in each congregation is entrusted to a special court (kerk-voogdij) composed of "notables" and church wardens. In every province there is besides, in the case of the Reformed

Church, a provincial committee of supervision for the ecclesiastical administration. For the whole kingdom this supervision is entrusted to a common "collegium" or committee of supervision, which meets at the Hague, and consists of 11 members named by the provincial committee and 3 named by the synod. Some congregations have within recent years withdrawn from provincial supervision, and have thus free control of their own financial affairs. As a Roman Catholic province Holland is divided into 5 dioceses—the archbishopric of Utrecht, and the suffragan bishoprics of Haarlem, Bois le Duc, Breda, and Roermund, which are severally divided into deaneries (dekanaten).

The various denominations are subsidized by the state. The total thus expended in 1877 was £65,654.

ıca- ı. Primary education is being more widely diffused year after year, and at the same time receiving increased support from the state. While in 1868 there were 3675 schools, attended by 437,311 pupils, and conducted by 10,375 teachers, the corresponding figures for 1877 were respectively 3813, 522,861, and 12,292; and while in 1858 the state, the provinces, and the communes expended only 1,278,894 guilders (=1s. 8d. sterling) on the schools, the expenditure for education in 1877 was 7,271,484 guilders. In 1875, 1876, and 1877 there were 841, 848, and 847 in every thousand boys between six and eight years of age at school, and 786, 796, and 803 out of every thousand girls; and from nine to eleven years of age 881, 890, and 910 out of every thousand boys, and 812, 815, and 827 out of every thousand girls. There is thus a steady decrease of non-attendance. The improvement of primary education is shown by the growing decrease in the proportion of conscripts who could neither read nor write: from 1846 to 1858 this was 22·82 per cent.; 1859–62, 19·79; 1863–67, 17·74; 1868–71, 15·46; 1872–76, 13·13; and in 1876 only 11·99 per cent. There are no bilingual schools in Holland, and teachers discourage the use of the dialects.[1]

For secondary education there were in 1877 39 "burgher schools" (partly day schools, partly night schools), with 372 teachers and 4319 pupils; 43 industrial art and technical schools, with 203 teachers and 4145 pupils; 53 higher class "burgher schools," having courses of 5 or 6, of 4, and of 3 years, with 620 teachers and 4000 pupils; the polytechnic school, with 12 professors and 13 teachers, and attended by 319 pupils; and the national school of agriculture at Wageningen, with 100 pupils. Schools of navigation were maintained at Rotterdam, Amsterdam, Helder, Terschelling, Vlieland, Harlingen, Schiermonnikoog, Groningen, Delfzijl, and Veendam, with a total of 536 pupils and 26 instructors. The secondary school for girls (with courses of 5 and of 4 or 3 years) were 12 in number, and had about 900 pupils and a teaching staff of 140. For secondary education in 1876 the state expended 933,721 guilders, the provinces 24,329, and the communes 906,618, making a total of 1,864,668, or £155,389 sterling.

The higher education is provided for in the four universities of Leyden (founded in 1575), Utrecht (1636), Groningen (1614), and Amsterdam (1877), with 45, 34, 31, and 41 professors, and 627, 401, 189, and 389 students respectively. Instruction is also given by about 100 teachers to 1400 pupils in various seminaries and theological schools; the number of Latin or grammar schools and gymnasia in 1877–78 was 51, with 240 teachers and 1503 pupils. The total cost of the higher education amounted to 1,057,694 guilders.

A national institution at Leyden for the study of the languages, geography, and ethnology of the Dutch Indies has given place to communal institutions of the same nature at Delft and at Leyden, founded in 1864 and 1877. Military and naval instruction are provided for by corps schools, by a training battalion at Kampen, an artillery training company at Schoonhoven, and scientific courses for the several corps, by the royal military academy (founded 1828), the "school of war" for officers, the royal navy institute at Willemsoord (1856), and by training ships at Amsterdam, Rotterdam, and Helvoetsluys for apprentice boatswains, sailors, cabin-boys, pilots, and engineers. For the education of medical practitioners, civil and military, the more important institutions are the national obstetrical college at Amsterdam, the national veterinary school at Utrecht, the national college for military physicians at Amsterdam, and the establishment at Utrecht for the training of military apothecaries for the East and West Indies.

entific l art titu- ıs. Of the numerous institutions in Holland for the encouragement of the sciences and the fine arts, the following are strictly national—the royal academy of sciences (1855), the royal Netherlands meteorological institute (1854), the national academy of the plastic arts, the royal school of music, the national archives, the royal picture gallery at the Hague, and the national gallery of modern masters in the Pavilion at Haarlem, the national museum of antiquities, the national museum of ethnography at Leyden, the royal collection of curiosities at the Hague, &c. Provincial scientific societies exist at Middelburg, Utrecht, Bois le Duc, and Leeuwarden, and there are private and municipal associations, institutions, and collections in a large number of the smaller towns. Among others of general utility are the society for the service of the community (*Maatschappij tot nut van't algemeen*, 1784), and the geographical society at Amsterdam (1873), Teyler's Stichting or foundation, and the society of industry at Haarlem, the royal institute of languages, geography, and ethnology of the Dutch Indies (1851) and the Indian society at the Hague, the royal institute of engineers at Delft (1848), the association for the encouragement of music at Amsterdam, &c.

The agricultural methods vary according as the soils are sandy or clay. In the first the "three-crop" system (two crops of rye and one of buckwheat) differs widely from the careful Flemish method of cultivation, in which even the pastures are manured. On the clay there is still greater variety both in the modes of treatment and in the amount of care bestowed on weeding and draining. The produce of the land is thus very different in the various provinces for the same soil. The general value of the crops is gradually rising, as may be seen from the following statistics, in which the higher figures cannot be altogether ascribed to the greater extent of land brought under cultivation: improved education and the influence of local associations for the advancement of the interests of agriculture have contributed to the result. In 1851–60 there was under cultivation in grain and other marketable crops 1,637,512 acres, in 1861–70 1,770,890 acres, and in 1871–75 1,860,850 acres. The total value of the crops was £8,311,666 in 1851, £13,445,672 in 1862, £15,870,586 in 1871, and £19,001,598 in 1875. Of the total acreage just mentioned about 25·9 per cent. was devoted to rye, 17·3 to potatoes, 13·5 to oats, 8·6 to buckwheat, 7 to beans and pease, 7·1 to barley, 5 to rape seed, 3 to flax and hemp, 0·8 to madder, 0·6 to garden seeds, 0·2 to tobacco; while the rest is set apart for the special cultivation of chicory, hops, beetroot, mangold wurzel, market-garden produce, flowers, pharmaceutical plants, grapes, &c. The woods or rather the plantations, covering 6 per cent., consist—of (1) the so-called forest timber (opgaandhout; French, arbres de haute futaie),—including the beech, oak, elm, poplar, birch, ash, willow, and coniferous trees; and (2) the copse wood (akkermaal or hakhout),—embracing the alder, willow, beech, oak, &c. This forms no unimportant branch of the national wealth. Agriculture.

Stock-breeding varies in the different provinces. For cattle, Friesland and North and South Holland take the lead as regards both quality and numbers; sheep are best in Texel and North Holland, and most numerous in Drenthe, where their preponderance is due to the number of commons which still remain unbroken up. Pigs, for which the low lands are peculiarly favourable, are reared in all the provinces. Goats, mainly kept for their milk, are most numerous in Guelderland and North Brabant. Guelderland, Friesland, Zealand, and Groningen possess the greatest number of horses. Poultry, especially fowls, are generally kept. Bee culture is mainly carried on in buckwheat and heath districts (Guelderland, Overyssel, Drenthe, the Gooiland, and Utrecht). A bee market is held at Veenendaal in Utrecht. Stock breeding is mainly carried on along with dairy-farming and hay-making on the alluvial soils; and there the cereal crops give way to fodder plants. The permanent pasture in recent years extends to some 2½ millions of acres, and clover, artificial meadows, &c., occupy about 400,000. The production of milk, butter, and cheese amounts to the value of 90 millions of guilders (1s. 8d. each); butcher meat produces 35 millions, and wool, hides, fowls, and game 10 millions; while horse-breeding also yields a total of 10 millions. In 1870 the number of horses was 252,200; cattle, 1,410,800; sheep, 900,200; goats, 156,900; and pigs, 329,100; whereas in 1876 the horses numbered 268,000; cattle, 1,439,257; sheep, 891,090; goats, 150,000; and pigs, 352,000. The value of this live stock in 1870 was £22,087,375, and in 1876 £29,799,905. Live stock.

In the densely peopled Netherlands, with no extensive forests, hunting forms rather an amusement than a means of subsistence, the only exception being the pursuit of wild-fowl (ducks, geese, and snipes). Hares, partridges, wood-snipes, finches, and thrushes are the only form of game; a few roebucks and deer are found in Overyssel and Guelderland; rabbits are numerous in the dunes, and sea-gulls' eggs are gathered in the north of Texel, which consequently bears the name of Eijerland (*i.e.*, Eggland). Game.

Much more important as a means of subsistence are the fisheries, which, however, are not at present in a flourishing state. They are divided into the "deep-sea fishery" (buitengaatsch) in the German Ocean, and the "inner" fisheries (binnengaatsch) in the Zuyder Zee, the rivers of Zealand, and the inland waters. The deep-sea fishery may be further divided into the great (the so-called "salt-herring") fishery, mainly carried on from Vlaardingen and Maassluis, and the "fresh-herring" fishery, chiefly pursued at Scheveningen, Katwijk, and Noordwijk. The deep-sea fisheries also yield cod and flat fish. In the Zuyder Zee flat fish, herrings, anchovies, and shrimps are caught off the islands of Urk and Marken and the coast towns of Vollenhove, Kampen, Harderwijk, Huizen, and Vollendam; and there are oyster banks near Texel. In the Zealand rivers oysters Fisheries.

[1] See *Geschiedkundig overzigt van het lager onderwijs in Nederland*, Leyden, 1849; *De wet op het lager onderwys, met aanteekeningen door S. Blaupot ten Cate en A. Moens*, Gron., 1879; and Dr J. Stein Parvé, *Organisation de l'instruction primaire, secondaire, et supérieure dans le roy. des Pays-Bas*, Leyden, 1878.

and mussels are obtained at Bruinisse, Philippine, and Graauw, and anchovies at Bergen-op-Zoom; while salmon, perch, and pike are caught in the Meuse, the Lek, and the Merwede, and eels in the Frisian lakes. The fisheries not only supply the great local demand, but allow exports to the value of £250,000.

The numbers of men and vessels employed are as follows:—

	Vessels	Men.
Great "salt herring" fishery	114	1678
German Ocean fishery	410	2965
Zuyder Zee fishery	1282	3269
Groningen and Friesland fishery	183	524
Zealand fishery	472	1026
Total	2461	9462

In 1877 the produce (in cwts.) amounted to—

	Home Consumption.	Exported
Herrings, cured and salted	10,648	274,670
Red herrings	291	97,757
Various fresh sea-fish	72,941	83,546
Salt cod	2,020	19,957
Shrimps	...	15,174
Other smoked, salted, or dried fish	1,231	102,522
Oysters, lobsters, and crabs	405	13,694
Mussels	2,015	161,813
Stock-fish	56,160	31,790
River-fish	2,518	29,471
Anchovies	384	21,253
	148,613	851,557

Trade.

To obtain a correct idea of the trade of the Netherlands greater attention than would be requisite in the case of other countries must be paid to the inland traffic. It is impossible to state the value of this in definite figures, but an estimate may be formed of its extent from the number of ships which it employs in the rivers and canals, and from the quantity of produce brought to the public markets or daily transported by thousands of carts and delivered by the peasant direct to the salesman. Of the market traffic, even in places of secondary rank, the following facts may give some idea. There are yearly brought to market at Gorcum and Hoorn from 10,000 to 13,000 head of cattle; at Barneveld, more than 20,000 sheep; at Alkmaar about 10 million and at Hoorn 5½ million ℔ cheese; at Delft 1½ million ℔ butter and 2 million ℔ cheese; at Meppel 3 million ℔ butter; at Leeuwarden 9 to 11 million ℔ butter, 2 million ℔ cheese, and 7½ million ℔ of grain and seeds; at the Overyssel markets Zwolle, Deventer, and Kampen, and at Steenwijk and Almelo, 7½ million ℔ butter; at Utrecht 770,000 and at Groningen 330,000 bushels of grain and seeds. The turn-over at the cattle market at Leyden in 1877 was £639,278. In 1877 there were 700 steamboats afloat on the rivers and canals in the service of the inland traffic.

The foreign trade, although less than it was formerly, still continues to be considerable in proportion to the size of the country. In 1878 the merchant marine consisted of 1277 vessels of 958,652 cubic metres (the register ton is equal to 2·83 cubic metres); of which 79 were steamships of about 200,000 cubic metres. In 1877 there entered 8166 vessels with 3,000,000 tons, and cleared 4936 vessels with 1,800,000 tons; to which must be added 20,500 vessels with 2,400,000 tons, which came down the rivers in cargo from foreign countries, and 11,850 vessels, with 1,500,000 tons, which passed the frontier upward bound.

The extent of the trade and its increase or decrease from year to year is shown approximately in the following table:[1]—

Years.	Total Imports.	Imports for Home Use.	Total Exports.	Transit Trade.
	£	£	£	£
1846–1850	17,183,000	...	18,660,000	...
1851–1855	27,458,000	18,418,000	23,500,000	9,083,000
1856–1860	34,918,000	25,208,000	29,292,000	9,583,000
1861–1865	40,542,000	30,000,000	33,833,000	8,750,000
1866–1870	48,183,000	38,375,000	40,125,000	9,500,000
1871	65,418,000	48,918,000	54 083,000	15,750,000
	Tons.	£	Tons.	Tons.
1872	3,200,000	51,500,000	1,467,000	439,000
1873	3,450,000	56,813,000	1,742,000	592,000
1874	3,132,000	55,918,000	1,572,000	627,000
1875	3,290,000	59,918,000	1,614,000	569,000
1876	3,780,000	59,418,000	1,717,000	705,000
1877	3,949,000	62,583,000	1,712,000	594,000

The six ports which take the largest share in the foreign trade are Amsterdam, Rotterdam, Helder, Dort, Schiedam, and Harlingen; at a considerable distance follow Groningen, Middelburg, Vlaardingen, Purmerend, Zaandam, Edam, Zwolle, Kampen, and Delfzijl. The returns of recent years show best in the case of the South Holland towns; but it must be kept in view that the direct imports, the so-called "proper trade," are most important at Amsterdam, while a great part of the commercial business at Rotterdam belongs to the commission and transit trade. For exports Rotterdam is by far the most important, sending out nearly thrice as much as Amsterdam.

An examination of its lists of exports and imports will show that Holland receives from its colonies its spiceries, coffee, sugar, tobacco, indigo, cinnamon; from England, Prussia, and Belgium its manufactured goods and coals; grain from the Baltic provinces, Archangel, and the ports of the Black Sea; pease and beans from Prussia, timber from Norway and the basin of the Rhine, yarn from England, wine from France, hops from Bavaria and Alsace; while in its turn it sends its colonial wares to Germany, its agricultural produce to the London market, its fish to Belgium and Germany, and its cheese to France, Belgium, and Hamburg, as well as England. The briskest trade is carried on with Germany and England; then follow Java, France, Russia, the United States, &c.

The mineral resources of Holland give no encouragement to industrial activity, with the exception of the coal mining in Limburg, the smelting of iron ore in four furnaces in Overyssel and Guelderland, the use of stone and gravel in the making of dykes and roads and of clay in brick works and potteries, the quarrying of stone at St Pietersberg, &c. Still the industry of the country has developed itself in a remarkable manner since the separation of Belgium, and that in spite of the lack of iron and coal, and the rivalry of other productive forms of labour. The greatest activity is shown in the cotton industry, which especially flourishes in Twenthe (in Overyssel) and also at Haarlem and Veenendaal. In the manufacture of woollen goods Tilburg ranks first, followed by Leyden, Utrecht, and Eindhoven; that of half woollens is best developed at Roermond and Helmond. The cotton and woollen manufactures together furnish employment to 20,000 hands. The linen manufacture is carried on especially in Meierij van den Bosch, Helmond, Boxtel, Woensel, &c. Even iron works and machine factories have greatly increased since the free importation of the raw material was permitted—for example, at Amsterdam and at Fijenoord opposite Rotterdam; and in this department more than 6000 workers are employed throughout the country. It need hardly be said that shipbuilding is of no small importance in the Netherlands, not only in the greater but also in the smaller towns along the rivers and canals; and it is naturally associated with rope-spinning and other auxiliary crafts. Among the less noteworthy branches of industry are the making of cigars and snuff, especially at Eindhoven, Amsterdam, Utrecht, and Kampen; diamond-cutting at Amsterdam; beetroot-sugar refining at Amsterdam; paper-making in the Veluwe, on the Zaan, and in Limburg; shoemaking and leather-tanning in Brabant (Langstraat); mat-plaiting and broom-making at Genemuiden and Blokzijl; the manufacture of glass, crystal, and earthenware at Maestricht; carpet-weaving at Deventer; working in gold and silver in North and South Holland and on a smaller scale at Schoonhoven; and the distillation of brandy, gin, and liqueurs at Schiedam, Rotterdam, and Amsterdam. The number of hands occupied in the manufactories throughout the whole of the Netherlands is estimated at about 100,000, of whom three-fourths are settled in North and South Holland, North Brabant, and Overyssel. The following table shows how great has been the industrial development of the last thirty years:—

Years.	Steam Engines.	Horse-Power.	Workshops with Steam Engines.	Steam-boats.	Locomotives.	Boilers.
1852	364	6,537	...	...	...	..
1862	983	15,824	...	...	...	...
1872	1,815	20,918	...	...	...	...
1876	2.873	76,271	2,393	707	617	4,691
1878	5,140	87,338	2,612	622	822	5,396

As the development of trade and industry and agriculture was promoted by the improvement of education and the abolition of transit and export dues and the lessening of import dues, so also has it been advanced by the improvement of the means of communication, and of the postal and telegraph systems. The waterways of the country have been already considered. The roads are divided into national or royal roads, placed directly under the control of the "waterstaat" and supported by the state; provincial roads, under the direct control of the states of the provinces, and almost all supported by the provincial treasuries; communal and polder roads, maintained by the communal authorities and the polder boards; and finally, private roads. The system of national roads, mainly constructed between 1821 and 1827, but still in process of extension, brings into connexion nearly all the towns. The construction of railways was long deferred and slowly accomplished: the "Holland Railway" was laid down in 1839–47, the Rhine Railway in 1843–56, the Aix-Maestricht-Landen line in 1853–56, and the Dutch-Belgian in 1853–54. All the other lines, *e.g.*, that from Maestricht to Liége, the Central Railway, the Nimeguen line, the Almelo-Salzberg line, the State Railway system, &c., have been constructed since 1861, a large number of them having been opened about 1863 and 1864. A great improvement has in consequence been effected in the communication. The town of Utrecht, which

[1] The value of the total imports, exports, and transit trade cannot be given after 1871 in consequence of a royal decree of 1872, providing for the simplification of the formalities of fiscal registration, in virtue of which the quantities are in certain cases given only in bulk-weight.

is the centre both of the country and of the railway system, may be approached by six different lines. From Amersfoort, Zutphen, Zwolle, Hengelo, Boxtel, Rosendaal, Venlo, and Maestricht lines stretch out in four directions, while Groningen, Leeuwarden, Meppel, Enschede, Hilversum, Amsterdam, Haarlem, Uitgeest, the Hague, Rotterdam, Moerdijk, Breda, Tilburg, and Eindhoven are each the meeting place of three lines. With foreign countries the Netherlands communicate from Groningen by the Winschoten and Nieuwe Schans line; from Overyssel by the Almelo-Salzberg line; from Guelderland by the Arnhem-Emmerik and Nimeguen-Cleves lines, from Limburg by the Gennep-Goch, Venlo-Gladbach, and Maestricht-Aix-la-Chapelle lines; and in the south with Belgium by the Terneuzen-Ghent, Hulst-St-Nikolaas, Rosendaal-Antwerp, Tilburg-Turnhout, Eindhoven-Hasselt, Maestricht-Liége, &c. Among the lines at present projected or in construction may be mentioned the works at Amsterdam by which the Holland Railway along the Y is to be brought into connexion with the Eastern Railway and the Rhine Railway; the line between Zaandam and Enkhuizen *via* Purmerend and Hoorn; the Groningen-Delfzijl line; and those from Zwolle to Almelo, and from Rotterdam or Schiedam by Vlaardingen to Maassluis and the mouth of the New Waterway.

…t- …ce …n tele- …phs. The extent of the mail service routes was 26,898 miles in 1873, and 29,773 miles in 1877; and in the same years the post-office staff numbered 3026 and 3525 respectively. The number of letters (exclusive of newspapers, printed matter, and official letters), which in 1850 was only 7,000,000, had increased by 1877 to 50,000,000. The number of inland post-cards rose from 4,000,000 in 1871 to about 10,000,000 in 1877; the number of inland newspapers was in 1860 about 5,000,000, and in 1877 about 27,000,000. The following are the statistics for 1853 and 1877 of the national telegraph system, originated in 1852:—

	Miles Line.	Miles Wire.	Messages.	Receipts.	Expenditure.
1853	208	346	45,700	£4,325	£17,775
1877	2186	80,050	2,985,000	65,900	104,775

…onies. The Dutch colonies, originally mere trading communities, have so much increased in importance, through the cultivation of their various vegetable products, the reclaiming of their waste lands, and the working of their mines, that they cannot be left altogether out of view in considering the trade and finances of the mother country. The Dutch colonies in the East Indies, situated between 30° N. lat. and 6° S. lat., and between 95° and 141° E. long., comprise an area of 600,000 square miles, with a population of about 23,000,000, among which are 35,000 Europeans, 319,000 Chinese, 15,000 Arabs, and 10,000 other immigrant Asiatics. For convenience of supervision they are divided into the Great Sunda (Soenda) Islands, the Smaller Sunda Islands, and the Moluccas—a division which is based neither on political nor on ethnological considerations, nor on the phenomena of animal or vegetable distribution. The Great Sunda Islands are Java, Sumatra, Celebes, and Borneo, all with subsidiary islands; the Smaller Sunda Islands comprise Bali, Lombok, Soembawa, Flores, Sandalwood Island, and Timor; the Moluccas include Halmaheira, Ceram, Buru (Boeroe), Amboyna, Banda, and the south-eastern groups, besides Western New Guinea. The West Indian possessions of Holland include Dutch Guiana or the government of Surinam, and the Dutch Antilles or the government of Curaçoa and its dependencies (St Eustatius, Saba, the southern half of St Martin, Curaçoa, Bonaire, and Aruba), a total area of 60,000 square miles, with 90,000 inhabitants, of whom a small portion are Europeans, and the rest negroes and other people of colour, Chinese, and other emigrants. The East Indian possessions yield an annual average contribution, as already stated, of over £800,000; the West Indian, on the other hand, require aid to the amount of £500,000 or £600,000 yearly.

National character. The character of the Dutch people may be largely explained by their history, the conformation of the country, their means of subsistence, their strife with the sea, and their struggles to maintain their independence against Spain and against hostile neighbours. The love of freedom and independence is the leading element in their character; the peculiarity of their soil has constrained them to be industrious and economical; their contest against the sea, their wars, and their distant expeditions, have trained them to bravery and self-possession; and their liberality has been stimulated by the disasters which, falling upon one to-day, might be the lot of any other to-morrow. Of course the virtues of the Dutch are apt to be distorted to vices: their composure not seldom becomes indifference; their tendency to reflexion makes them laggard in action and deficient in enterprise; their love of liberty degenerates into an extravagant sense of independence that is more concerned about rights than about duties. Sociability is by no means a dominant characteristic of the Dutch; they speak little and laugh less. But their appearance and expression give a poor indication of their sterling qualities. Their general sincerity and uprightness are evident to every one whose own respectability gains him admission, on terms of familiar intercourse, to the respectable circles of Dutch society.

Bibliography.—The first place in a bibliography of Holland is due to the *Algemeene Statistiek van Nederland* (Leyden, 1st part, 1870, 2d part, 1873), a work of much vaster compass than is indicated by its title,—consisting, as it does, of separate articles on every scientific aspect of the country, contributed by specialists of high authority. The geodetic portion, for example is furnished by J. H. A. Kuijper; Dr H. Hartogh Heys van Zouteveen treats of the soil, rivers, islands, &c., the geology, and the fauna; the flora is described by Professor Hugo de Vries, Dr C. M. van der Sande Lacosta, and Professor W. F. R. Suringar; the meteorology is by Professor C. H. D. Buys Ballot, the account of the provinces and communes by Professor S. Vissering, and the vital statistics by M. von Baumhauer. As supplements to this, their greatest work, the Government Society for Statistics also publish *Bydragen en Mededeelingen voor die Stat. van het Kon. der Nederlanden*; *Staatkundig en Staathuishoudkundig Jaarboekje*; and *Stat. Jaarboek voor het Kon. der Nederlanden*. The following are convenient manuals:—Dr A. A. van Heusden, *Handboek der Aardrijkskunde, &c., van het Kon. der Nederlanden*, Haarlem, 1866, J. Kuijper, *Nederland, zijne Provincien en Kolonien*, Leeuwarden, 1878, Rijkens, *Aardrijkskunde van Nederland*, Groningen, 1879; M. H. J. Plantenga, *Militaire Aardrijkskunde van Nederland*, new ed., 1880; J. Craandijk and P. A. Schipperus, *Schetsen met pen en potlood*, Haarlem, 1874. The excellent works of W. C. A. Staring—*De Bodem van Nederland*, Haarlem, 1856-60, *Natuurkunde en Volksvlijt van Nederland*, Amsterdam, 1870; and *Voormaals en thans*, Haarlem, 1877—are of a more descriptive cast. For the fauna and flora of the country the reader may consult Professor Schlegel, *De dieren van Nederland*, Haarlem, 1862, C. A. J. A. Oudemans, *De Flora van Nederland*, Haarlem, 1871-74, Van Halls, *Neerlands Plantenschat*, Gron., 1855. Among the more recent of foreign publications in regard to Holland the following rank high:—Alph. Esquiros, *La Neerlande et la vie Hollandaise*, Paris, 1859 (English translation, *Dutch at Home*, London, 1863); J. G. Kohl, *Reisen in den Niederlanden*, Leipsic, 1850, Dr A. Wild, *Die Niederlande: ihre Vergangenheit und Gegenwart*, Leipsic, 1862; Henry Havard, *La Hollande Pittoresque: Voyage aux villes mortes du Zuiderzee*, Paris, 1874, *Les Frontières Menacées*, Paris, 1876; and *Au cœur du Pa s*, Paris 1878, and Edmondo de Amicis, *Olanda* (Dutch translation by D. Lodeesen, *Nederland en zijne bewoners*, Leyden, 1876). The most important maps and atlases are the topographic maps of the kingdom of the Netherlands, issued by the War Department, the Hague, 62 sheets, lithogr. scale 1:50,000; the *Waterstaats Kaart van Nederland* (1:50,000), issued by the Ministry of the Interior under the supervision of P. Caland and H. Rodi de Loo, W. C. H. Staring's *Geologische Kaart*, executed by the topographical office of the War Department (1:200,000), *Kaart voor de Natuurkunde en Volksvlijt*; and *Landbouwkaart van het Kon. der Nederlanden* (1:200,000); J. Kuijper, *Gemeente Atlas van Nederland, naar officieele bronnen ontworpen* (1205 commun al maps and one large general map); and *Natuur en Staathuishoudkundige Atlas van Nederland*. There are three good gazetteers:—A. J. van der Aa, *Aardrijksk Woordenboek*, Gouda, 1855; S. Gilie Heringa, *Handwoordenboek van Nederland*, 3d ed., Utrecht, 1874; and P. H. Witkamp *Aardrijksk. Woordenbock van Nederland*, Thiel, 1871-76. (C. M. K.)

PART II.—HISTORY.

…ly …abit-…s. The oldest inhabitants of Holland of whom anything is known were of Celtic origin; so much may be gathered from scanty remains found in cairns, from a few proper names, such as Nimeguen (Nimwegen) and Walcheren, and from the Druid altars found in that island. In Cæsar's day the whole district between the Rhine and the Scheldt was occupied by Belgæ, the bravest of Celts, while the Betaw, the "good meadow," the Insula Batavorum, was peopled by a portion of the Germanic tribe of the Chatti, and provided first the stoutest foes and then the most serviceable allies of the Roman empire. But if the Batavi were the most distinguished of the Germanic tribes in the country, the "free Frisians" (see FRISIANS), who filled the whole northern portion of it, were by far the most important; in addition to them, and mostly on the borderland, were others, Usipetes, Bructeri, Sicambri, Chamavi, Eburones, and the like, of whom we know little but the names.

Their struggles with Rome. From 28 to 47 A.D. a struggle went on between the Romans and the Frisians, which ended in the latter year in the complete reduction of the tribe by the vigour of Domitius Corbulo; the Batavi and Frisians were probably, in the earlier days of their connexion with Rome, admitted, if not to the more honourable position of "socii," at least to the lower grade of "auxilia," their relation to the empire doubtless varying from time to time. This friendly state of things did not last long; for in 70 A.D. Rome had dismissed her Batavian cohorts, and had turned Claudius Civilis, the "Mithridates of the West," into a bitter foe. This remarkable patriot had served for many years in the armies of Rome, and had learnt the secrets of the imperial strength and weakness. Taking advantage of the wrongs of Germans and Gauls, and skilfully using the divisions within the empire, he displayed high statesmanlike ability, while his energy and success in war placed him in the rank of great captains. He declared for Vespasian against Vitellius, and grouped together Celt and Teuton in an effort to sweep the tyrant Roman out of Gaul. At first all went well with them, and the Romans were driven out of all modern Holland, Belgium, and from the left bank of the Rhine as far as Alsace. Then the Roman power began to assert itself once more. An able general, Cerealis, was sent into the north-west, and after a chequered and exhausting struggle, in which both suffered greatly, the Batavian hero gave way. Peace was made on easy terms; Civilis laid down arms, and the Batavians submitted and resumed their old position towards Rome. The Batavian island was lined with forts, and became for the Romans the frontier between Gaul and German; much as in far later days the Spanish Netherlands were the barrier between the Dutch and the French.

The Franks.

For a time all was quiet on this north-western frontier, till late in the 3d century the Franks appeared (see FRANKS). In the course of the 5th century the Salian Franks had occupied a great part of the Netherlands, and when Hlodowig (Clovis) was lifted (481) on his warriors' shields, they were possessors of South Holland, the Veluwe, Utrecht, Brabant, Antwerp, Limburg, Liége, Hainault, Namur, and Luxembourg. After his death (511) these districts for the most part belonged to the Austrasian kingdom. Behind the Salians came the Saxons, who had made themselves felt in the Batavian island by the middle of the 4th century; in the course of the 5th and 6th centuries they had settled firmly in Overyssel and Drenthe, lying between the Frisians to the north and the Franks to the south. There they shared, in alliance with the Frisians, the varying fortunes of that struggle against the Frankish power which lasted 400 years, and was ended only by the genius and persistency of Charles the Great.

Spread of Christianity.

The first Christian church in the Netherlands was founded in the time of Dagobert I., who had reduced the Frisians and Saxons at the town of Wiltenberg, afterwards Utrecht, between 622 and 632. But the true apostle of the Netherlands was Willibrord the Northumbrian, first bishop of that see (695). He made Utrecht the centre from which Christian light spread across a wide circle of heathendom; and under the protection of Pippin of Heristal, the new faith was so firmly planted in those parts, that when Willibrord died Limburg, North Brabant, Utrecht, and other districts had accepted the faith of the Franks. After Willibrord, Christianity had in that part of Europe another stout champion, Wolfram of Sens, who had nearly persuaded the Frisian king, Radbod, to be a Christian; and lastly in 755, St Boniface, "the apostle of the Germans," was martyred at Dokkum in Friesland while preaching among the heathen. Towards the end of the century the stern methods of Charles the Great completed the conversion of the Netherlands.

Government and divisions of the country.

As an integral part of the Frankish empire, the land under Charles and his immediate successors was divided into "landschafts" and "gaus," ruled over by dukes and counts, by the side of whom the church also asserted her territorial rights. Hence sprang the dukedom of Brabant, the countships of Flanders, Holland, Guelderland, and the bishopric of Utrecht; and these, under the later Carolings, were independent in all but the name. Ecclesiastically the northern portion of the Netherlands, with South Holland and part of Zealand, was under the bishop of Utrecht; while the eastern districts were under the Saxon bishops of Münster and Osnabrück, and the southern parts under the Frankish bishops of Cologne, Liége, and Doornick. The original dukedoms were subdivided politically into countships, and geographically into gaus; each gau had a chief town, girt with a wall, wherein count and judges administered justice; such towns were also market-places. These districts were again subdivided into marks or villages, each with its headman, who acted as judge in lesser and local cases. These gaus were Frisian in the north, Saxon in the middle (about Drenthe, &c.), and Frankish in the south.

Char... of lo... ship 9th cent...

In the great partition of Verdun (843), Lothar, eldest son of Louis the Pious, became lord of North Brabant (as it is now called), Guelderland, Limburg, and all modern Belgium; Charles the Bald got Flanders and part of Zealand, while Louis the German had whatever lay on the right bank of the Rhine: this district (called Lotharingia in the days of his son Lothar II.) thus became a borderland between Gaul and Germany. When Lothar II. died without heirs in 869, his uncle Charles the Bald got all the northern Netherlands, with Friesland; but the Mersen agreement (870) redistributed these lands,—to Louis the German the districts south of the present Zuyder Zee, including Utrecht and the Veluwe; to Charles the Bald, Holland, Zealand, and modern Belgium. Eventually in 879 Louis, son of Louis the German, got these districts also. In 912 they accepted Charles the Simple of France as overlord; in 924 Henry I. brought them again under German lordship; afterwards Otto the Great granted them as a fief to his brother Bruno, archbishop of Cologne, who, dividing the land into Upper and Lower Lotharingia, set Gottfried, count of Verdun, over the latter as duke, and himself took the title of archduke. Thus, during this period, the Netherlands from 843 to 869 were a part of Lotharingia (as it came to be called); from 869 to 870 they were under French lordship, from 870 to 879 partly French partly German, from 879 to 912 altogether German, from 912 to 924 French again, and finally after 924 German.

The Nor... men

Throughout this time the country was swamp below and woodland above; and though much forest was cleared from time to time, it was still a difficult tangle, with little communication except down the rivers and by the old Roman roads. Yet, backward as they were, the Netherlands were rich enough to attract the Northmen, who ravaged the shores and river sides, and carried with them southward many a willing Saxon and Frisian warrior. Under Louis the Pious they got firm footing on the coast, and received the district from Walcheren up to the Weser as a group of fiefs under the emperors; they even took and sacked Utrecht. In 873 Rolf, founder of Normandy, seized Walcheren; in 880 the Northmen took Nimeguen, and spread up the left bank of the Rhine as far as Cologne; in the chapel of the Great Charles at Aix they stabled horses and held heathen revel, till bribed to withdraw by Charles the Fat. Their great leader Siegfried had the emperor's daughter to wife, with lands in Friesland; he was willing to become a Christian, though this put no stop to his demands; "as the lands granted him hitherto produced no wine," he demanded also Rhine towns and districts for the sake of their vintages. His father-in-law, however, sent instead men to murder him, and, this being done, the lord ship of the Northmen in the Netherlands came to an end.

The effect of these viking incursions on Frankish feudalism was great. "Eighty years of plunder and murder," says Gerlache (*Essai sur les grandes Epoques*, p. 94), "had turned the fields into a wilderness; the towns rose like oases in the desert; the wealth of the monasteries perished; the people were either slain with the sword or had taken to the sword as robbers; all the elements of political life, kingship, nobility, clergy, were confounded together, and every tie of civil society relaxed." The impoverished natives took refuge under the nobles, whose power made great advance. Now arose, too, a new title of nobility, that of margrave,—each margrave being bound to defend a piece of frontier, receiving in return an almost complete independence: such was the marquis of Antwerp, who guarded the mouth of the Scheldt. The towns also became as sanctuaries against the ravager; the serf who took refuge there presently became free; the burghers began to trade, and found encouragement in their traffic even from the Northmen themselves.

[…nts …lland.] Thus the whole district came to be covered with prosperous towns; it was also divided into independent lordships, among which the countship of Holland, as it soon afterwards was called, was the most prominent and important. The title "count of Holland" does not appear in history till the 11th century. In the latter part of the 9th century there was a certain Count Dirk, [...k I.] to whom, early in the 10th, Charles the Simple granted the abbey of Egmond near Alkmaar. Of his history almost nothing is known; he was dead before 942, as there exists still a document of that year signed by Dirk II. [...k II.] Dirk II. was a man of weight; he got for his younger son the archbishopric of Treves, and Arnulf his elder son married a kinswoman of the emperor Otto II. He himself received in 983 a broad district, that now covered by the Zuyder Zee, from Texel to the north, and the mainland southward down to Nimeguen. He died in 988; and Arnulf was count till 993. His son, Dirk III., [...k III.] a boy, on his accession found things in great confusion; the fiefs held under France were gone, and much besides. But the young count was full of vigour, and grew at last so strong that in 1018 the emperor ordered the duke of Nether Lotharingia to crush him. Dirk, however, completely defeated his assailant, and not only retained the disputed lands and powers, but added thereto Bodegrave, the Merwede, and Swammerdam, as fiefs of the church at Utrecht. It is here that the true history of Holland begins; for Dirk III. now firmly settled himself in this district, and became lord of the rich woodland ("Holt-land," *i.e.*, Holland) on the Rhine and Meuse. Having also subdued the Frisians and set his brother over them, he next went on pilgrimage to Jerusalem, and after his return in 1034 ruled in peace till his death in 1039. [...k IV.] His son, Dirk IV., was also a man of vigour; he began the long strife with the counts of Flanders as to the lordship over Walcheren and the other islands of Zealand, the quarrel was important, as dealing with the borderland between French and German overlordship. This strife, which lasted 400 years, did not at first break out into actual warfare, because both Dirk and Baldwin V. of Flanders had a common danger in the emperor Henry III., who in 1046 occupied the lands in dispute; but while other opponents gave in, Dirk, after the manner of his house, stood out, and in the winter of 1047 with his light boats took the imperial fleet, ruined the imperial army, and dictated his own terms. In 1049, in a fresh contest with the bishop of Utrecht and his allies, Dirk met with his death at Dort. [...ris I.] His brother, Floris I., succeeded, and carried on the quarrel; in 1061 he was slain on the battlefield, after having won a decisive victory over the bishop. [...k V.] His son, Dirk V., was a child, and the neighbouring princes thought the end of the house of Holland at hand; and though the boy had stout friends, especially Robert "the Frisian," who had married his widowed mother, his prospects were at first very gloomy. The battle of Cassel, however, in 1072, in which Robert the Frisian defeated Philip of France and Richilda of Flanders, secured his possessions for Dirk, who henceforth saw better days, and ruled in peace till his death in 1091. [...ris II.] His son, Floris II., the Fat, had also peace, and at his death in 1122 left Holland in great prosperity. His widow, [...k VI.] Petronilla of Saxony, governed for her young son Dirk VI., and continued the joint resistance of Holland and Saxony to the Franconian emperors. But when, on the death of Henry V., Lothair of Saxony became emperor, this quarrel came to an end, and the fortunes of the house of Holland rose greatly; the Frisian Ostergow and Westergow were transferred from the bishop of Utrecht to Count Dirk in 1125. The Hohenstaufen, on the contrary, favoured the bishop, and gave back the two "gows"; and thus, with gain and loss, Dirk VI. ruled till he died in 1157. It was in his time that Holland sent out her first colonists; invited by Adolf of Holstein and Albert the Bear of Brandenburg, Hollanders settled on the Elbe and the Havel, and by their skill in reclaiming marshlands, and their thrift and vigour, created a flourishing district out of a waste of wood and water.

[Floris III.] Floris III., the next count, allied himself with Frederick Barbarossa, thus reversing the traditional policy of his house. He was less fortunate than his fathers; the count of Flanders carried off a slice of his territory; he scarcely held his own against West Friesland and Groningen; his reign was marked by the great flood of 1170, which swept over Holland, Friesland, and Utrecht, and helped to form the Zuyder Zee. Later in life Floris followed the emperor on crusade, and soon after the death of the latter, perished in 1190 of pestilence at Antioch. [Dirk VII.] His son, Dirk VII., had a stormy time, losing rather than gaining in the long-run. He died in 1203, leaving an only daughter, Ada, with whom came up the question as to female succession to a male fief. Zealand mainly declared for William, the late count's brother, while Holland went with Ada; by 1206, however, William had beaten down all opposition, and was undisputed count. [William I.] He sided with the emperor Otto IV., and was present at Bouvines (1214), where Philip Augustus crushed the allied forces of Otto, John of England, Flanders, Holland, and Brabant. Soon after this William changed sides, and, attaching himself to Philip Augustus, accompanied Louis to England. After King John's death he joined the fourth crusade, in which his men distinguished themselves greatly at the siege of Damietta in 1219. Returning thence he reigned in peace till his death in 1224. His reign is notable by reason of the civic charters he granted,—one to Geertruidenberg in 1213, another celebrated one to Middelburg in Zealand in 1217. These charters were the models on which later ones were framed; they secured the existing liberties of towns, gave the burghers the right of being ruled by law, and established equal justice within the walls.

[Floris IV. William II.] William was succeeded by Floris IV., murdered at Corbie in 1235; his son, William II., was a man of mark. Pope Innocent IV. having deposed Frederick II., and wanting a prince to set up against the Hohenstaufen, thought that the young count of Holland might serve, and accordingly had him elected king of the Romans by an assembly composed chiefly of German ecclesiastics. He took Aix-la-Chapelle, and was there crowned king in 1248; and after Frederick's death in 1250 he had a considerable party in Germany. His foreign ambitions were, however, crossed by troubles at home, and before he received the imperial crown he perished in West Friesland, going down, horse and armour, through the ice. It was he who fixed the seat of government at the Hague. [Floris V.] His successor was Floris V., a babe. The father had been a young man of unusual promise, ruined by German politics; the son was destined to play a considerable part in Netherland history. Hitherto Holland had dealt only with smaller neighbours, Flanders, Friesland, Utrecht, or Guelderland; henceforward she takes part in European questions, interfering in the great strife between Edward I. of England and France. For when he came of age Floris allied himself closely with the English king, and secured great trading advantages for his people; the staple of wool was placed at Dort, and the Hollanders and Zealanders got fishing rights on the English coast. To balance the power of the nobles, which more and more took the form of oppression, he also granted charters to towns (notably to Amsterdam), and forwarded their growth. In 1296, finding that Edward of England was dealing with his rival of Flanders, Floris joined Philip the Fair of France; but this act and his severities towards the nobles led to a conspiracy, to which he fell a victim; the burghers and people, who knew him to be their best friend, took such vengeance on his slayers as permanently reduced the power of the nobles.

John I. John I., his son, was in England when his father was murdered; he was a feeble boy in body and mind, married to the daughter of Edward I. His reign was a struggle between Zealand, led by Wolfart van Borselen, and Holland, guided by John of Avennes, the young count's guardian and next heir. In 1299 Van Borselen was killed by the Hollanders, and soon after Count John died. John of Avennes was at once recognized as count by the Hollanders, and with John I. ended the first line of counts, after a rule of nearly 400 years. Europe has perhaps never seen an abler series of princes; excepting the last, there is not one weak man among them; they were ready fighters, brave crusaders, handsome well-built persons, with high chivalrous gifts tainted with corresponding chivalrous vices; they were all ready to advance the commerce of the country; they were the friends of the people, the supporters of the growing towns. They made their marsh lands fertile, and raised Holland to be a companion of kings.

The independence of Holland. During this time Holland became independent of the imperial authority. The fragments of Nether Lorraine, Holland, Guelderland, Utrecht, Brabant, and Flanders paid little heed to their nominal lord; Holland especially, so far from the centre of the empire, so nearly forgotten in the greater troubles of Italy or Switzerland, was left to herself. She made her own laws, imposed river-dues (a recognized imperial right), named her own officers, held high court of justice, coined money, made peace or war at will. Even the *de jure* authority of the empire over Holland is a matter of doubt, much debated by publicists and historians.

Constitution of her cities. The independent development of the country took, as we have said, a municipal form; and as the constitutions of her cities have throughout affected her history, they demand some consideration. Before the 14th century there were in Holland no estates, nor any general political life; the count was all powerful. Over the country districts he set his "baljews" or bailiffs, and in towns and villages his "schouts" or local judges. In the 13th century, when any greater matter had to be discussed in a city, all citizens were summoned by ring of the great bell to the public square, and there decided the question by democratic vote. Justice was administered "by a man's peers," according to the Saxon code in the east, the Frisian in the north, and the Frankish or Salian in the south,—each district having also its several uses or customs. Taxation for the count's benefit was styled his "beden" or prayer for supplies, and fell chiefly on the towns. And as the towns paid most, and were generally built on the count's lands, they claimed his protection, receiving charters and liberties from him in return for their dues and levies of men. In time the vague civic democracy gave place to an oligarchical government. While the Flemish towns were opposed to their feudal lord, in the north it was the other way; the counts of Holland were with the cities against the other classes of society. Consequently, though the Dutch towns began later, they in the end enjoyed far more steady prosperity than their southern neighbours. Thus under William II. and Floris V., Dort and Delft, Haarlem, Alkmaar, Middelburg, Leyden, Schiedam, and others began their prosperous career. Each of these cities was at first ruled by the count's "schepenen" or judges, supported by councillors, one from each quarter of the town, from whom sprang the title of burgomaster, by which they became known in later days. The "schepenen" administered justice, while the councillors or burgomasters attended to civil affairs, and by degrees threw the judges into the background. Peace and defence were entrusted to a local militia, armed with the cross-bow. Dort was the earliest of these prosperous towns; it enjoyed a very strict staple-right; the commerce of the northern districts was compelled to pass through its market. Two centuries later came the prosperity of Amsterdam, and with it the European fame of Dutch butter and cheese; then the wealth arising from the herring-fishery, of which the centre was Enkhuysen. In the 14th century the chief towns had joined the Hansa, and though that exclusive body in the 15th century ejected them, they far more than recovered the loss of their trade through the newly opened worlds of India and America.

John of Avennes. When John of Avennes succeeded in 1299 as first count of the house of Hainault, the Hollanders were willing to receive him, the Zealanders not; and a long struggle between the provinces ensued. In 1301 he coerced Utrecht into alliance, and got the bishopric for his brother Guy. In 1304 the Flemings were driven out of Holland, and John II. was for a few months real lord of the county. He died that year, and was succeeded by his son William

William III. III., "the Good" (1304-1337), who made peace with Flanders in 1323, settled the outstanding quarrel between Holland and Zealand, united the Amstelland and its city Amsterdam to his territories, encouraged civic life, and developed the resources of his country. He also entered into close relations with the states of Europe, having married Johanna of Valois, niece of the French king; in 1323 the emperor Louis the Bavarian wedded his daughter Margaret, and in 1328 his third daughter, Philippa of Hainault, was given to Edward III. of England. William III. was in all respects a great prince, and an acute statesman. In 1337 he died, and was succeeded by his son

William IV. William IV., who was killed fighting against the Frisians in 1345. He left no children, and the question as to the succession now brought on Holland a time of violent civil commotions. The county was claimed by Margaret, William's eldest sister, as well as by Philippa of Hainault, or, in other words, by Edward III. of England.

Margaret. Margaret eventually succeeded, siding with the older nobles, and being, therefore, not well received by the towns. These are the days in which came up the famous parties of "Kabbeljaus" and "Hooks," the "Cods" and the "Hooks," the fat burgher fish and the sharp steel-pointed nobles who wanted to catch and devour them. After much buffeting and many changes of fortune, Margaret resigned her lordship in 1349 in favour of her second son William,

William V. but again resumed it in 1350. Then the struggle between nobles and cities broke into open war. Edward III. came to Margaret's aid, winning a sea fight off Veere in 1351; a few weeks later the Hooks and the English were defeated by William and the Cods at Vlaardingen—an overthrow which ruined Margaret's cause. She made peace with her son in 1354, and died two years later. He, however, shortly after fell mad; so that in 1358 the Hooks had to

Albert of Bavaria. call in his younger brother, Albert of Bavaria, to be stadtholder or "ruwaard" in his stead; he ruled well, and restored some order to the land. In the latter part of his life he went over to the Cods, a step which led to another outbreak of civil war which lasted until 1395. In 1404

William VI. he died, and was succeeded by his son William VI. who upheld the Hooks with all his power, and secured their ascendency. He died in 1417, leaving only a daughter,

Jacoba. Jacoba (or Jacqueline), wife of John of France, who died that same year. Again was Holland rent with civil strife; the Hooks, as before, readily accepting a female sovereign, while the Cods declared for John of Liége. Jacoba was granddaughter of Philip of Burgundy, who behaved very ill towards her; her romantic and sad life has rendered her the most picturesque figure in all the history of Holland; she struggled long against her powerful kinsfolk, nor did she know happiness till near the end of her life, when she abandoned the unequal strife, and found repose with Francis of Borselen, ruwaard of Holland, her fourth husband. Him Philip the Good of Burgundy craftily seized, and thereby in 1433 Jacoba was compelled to cede her rights over the counties of Holland, Zealand, Friesland, and Hainault. Consequently, at her death in 1436, as she left no children, Philip seized on all her lands. He already held much of the Netherlands; he had inherited Flanders and Artois, had bought Namur, had seized Brabant, with Limburg, Antwerp, and Mechlin; he now got Holland, Zealand, and Hainault, with a titular lordship over Friesland; a few years later he became lord also of Luxembourg. By this incorporation with the possessions of the house of Burgundy, the commercial and artistic life of Holland was quickened, but political liberties suffered; for the rule of the "good duke" was far from being good. It was a time of luxury and show, of pageants and display, of the new and brilliant Order of the Golden Fleece (1430), and of the later days of feudalism, with all its brilliancy, corruption, and decline in the presence of the new monarchical spirit of Europe. Duke Philip on his accession declared that the privileges and constitutions of Holland, to which he had taken oath as ruwaard for Jacoba, should be null, unless he chose to confirm them as count. From that moment till the latter part of the next century the liberties of the Netherlands were treated with contempt. Holland, however, at first contented herself with growing material prosperity: her herring fishery, rendered more valuable than ever by the curing process discovered or introduced by Beukelzoon, brought her fresh wealth; and her fishermen were unconsciously laying the foundations of her maritime greatness. It was in the days of Duke Philip that Lorenz Koster of Haarlem contributed his share to the discovery of printing; the arts and learning of the Renaissance began to flourish greatly. The Burgundian dukes rivalled their contemporaries the Medici; under them grew up the Flemish school of painters, headed by the Van Eycks and Memling; architecture advanced as stately churches and town-houses were built; the dukes collected priceless manuscripts, founded libraries, and encouraged authors. But this speedy growth in art and letters belonged more to Flanders and Brabant than to Holland or Zealand.

In short, throughout the Burgundian time Holland plays but an insignificant part; and it may merely be remarked that the friendship of the dukes for the nobility did that class more harm than their hostility to civic liberties hurt the towns; for the lavish waste of Philip's court impoverished the nobles, and the wars of Charles destroyed them. After their days the Netherlands nobility were never again powerful. The church also suffered: it was enriched and corrupted by Philip, and was consequently very loyal to him; but his favour instead of strengthening it made the Reformation necessary. The cities, though oppressed and heavily taxed, grew stronger; and, when Duke Charles perished at Nancy, they at once stood out for their rights, and obliged his sole heir the duchess Mary, not unwillingly, to grant them the "Great Privilege" of March 1477, which affirmed the power of the cities and provinces to hold diets, and reserved to the estates a voice in the declaration of war, and authority to approve of the choice she might make of a husband. It was declared that natives alone might hold high office; no new taxes should be laid without the approval of the estates; one high court of justice was established for Holland, Zealand, and Friesland; the Dutch language was made official. Thus came to an end the centralizing despotism of the Burgundian dukes. This period is also remarkable for a reconstruction of the civic government, and for the appearance of the States General, first summoned by Philip the Good. In the states of Holland many nobles sat in person, though they had but one collective vote. At first all towns, larger and smaller, also sent representatives, but after a time the smaller ceased to appear, and only such larger cities as Dort, Haarlem, Leyden, Amsterdam, Gouda, were represented, each having one vote. The president was the "advocatus," or "vogt," of the country, afterwards styled "the pensionary," an officer regarded as the champion of the estates against the counts. In Zealand and elsewhere, clergy, nobles, and cities sat separately, each order having a single vote. The estates, under the Burgundians, had little power; they could not even control the taxation. Duke Philip in 1464 summoned them to meet him at Bruges, and, though some of the more distant held aloof, the majority obeyed. These States General, however, expressed no national feeling or union of the provinces: that was a far later state of things.

The States General.

After Mary of Burgundy had granted the Great Privilege, the provinces warmly supported her against Louis XI.; they approved her union with Maximilian of Austria in August 1477, though it brought them no rest; for the old parties still survived, and Hooks and Cods fought savagely in almost every town. Maximilian had allied himself with the Cods, and the Hooks were defeated at Leyden and Dort, and finally in their last stronghold, Utrecht, of which city the archduke was made temporal protector in 1483. Before that time (March 1482) Mary of Burgundy had died, and Maximilian, acting for his son Philip, became governor of the Netherlands. After fresh Hook and Cod troubles at Haarlem, he finally made peace with France in December 1482, and after the death of Louis XI. brought the Flemings to complete obedience by the peace of Frankfort in 1489. The provinces were still very uneasy, partly through the turbulence of the Hooks, partly because of the autocratic character of his rule, and partly through the so-called "Bread and Cheese" war, caused by famine in the northern provinces. War with France also complicated matters, and the government over the Netherlands was entrusted to Albert of Saxony. In 1494 Maximilian, having been elected emperor, laid down his office as guardian, and had Philip the Handsome declared of age. He was at once accepted by Brabant, and the estates of Holland even let him sweep away the Great Privilege. He ruled over them quietly, and got back their English trade. In 1496 he married Joanna of Aragon, daughter of Ferdinand and Isabella, and afterwards heiress to the new monarchy of Spain. On Philip's death in 1506, leaving two sons, Charles and Ferdinand, and four daughters, Maximilian again became guardian for his grandson Charles, then but six years old; he named Margaret of Savoy, his daughter, governess of the Netherlands in 1507.

Maximilian of Austria.

In 1515 Charles was declared of age, and received the homage of Holland and Zealand, Brabant and Flanders, as Count Charles II. In consequence of his friendly relations with Francis I. of France, Henry of Nassau, his comrade and trusted follower, was wedded to Claude, sister of Philibert, prince of Orange, and from this union springs the great house of Orange-Nassau. On his accession to the Spanish and imperial thrones successively, Charles continued his aunt Margaret of Savoy as governess of the Netherlands, with a privy council to assist her.

Count Charles II. (emperor Charles V.).

He brought all the provinces under one hand, having in 1524 become lord of Friesland by purchase, and in 1528 acquired the temporalities of Utrecht. He now ruled over seventeen provinces: that is, over four duchies—Brabant, Guelderland, Limburg, and Luxembourg; seven counties—Flanders, Artois, Hainault, Holland, Zealand, Namur, and Zutphen; the margraviate of Antwerp; and five lordships—Friesland, Mechlin, Utrecht, Overyssel, and Groningen with the Ommeland.

After the death in 1530 of Margaret, who had continued to act for him with her accustomed wisdom and prudence, Charles V. at first treated the provinces with studied moderation: he redressed some of their griefs, reformed the administration and the coinage, issued sumptuary edicts, regulated their commerce, while he also re-enacted the severe laws against heresy, and gave full powers to the supreme court of Holland—a body completely under his control. He then appointed his sister Mary, queen of Hungary, regent of the Netherlands. She had at first no easy task; for the provinces had on hand a war with Denmark, and Anabaptist troubles at home; before long also she had to ask for increased supplies; and while the Hollanders granted a large annual subsidy, they refused her a hearth tax which she demanded. Similar monetary questions in 1539 produced that famous struggle between the court and Ghent which was only ended by the personal intervention of the emperor; after punishing severely the rebellious burghers, he passed on into Holland, and in 1540, in defiance of the acknowledged rights of the provinces, established a foreigner, René of Chalons, prince of Orange, as stadtholder of Holland, Zealand, and Utrecht. He thus forced on them that great family which has both shed lustre on the history of Holland, and defended there and elsewhere the liberties of Europe. René himself ruled but a short time; he perished in France in 1544, leaving his territories to a little cousin, William of Nassau.

Mary of Hungary regent.

House of Orange-Nassau.

In 1545-46 the estates gave the emperor men and money for his war against the Protestant princes of Germany; after Mühlberg, the Netherlanders hoped that they might now be freed from the foreign troops Charles had quartered among them. He, however, had other plans on hand, and determined to place permanently in the provinces 4000 horse, entirely at his own orders; he also laid before the estates in 1548 a scheme of incorporation, which aimed at making the Netherlands an integral portion of the empire, under the name of the circle of Burgundy, and which he abandoned only after the refusal of the seven electors to make Philip king of the Romans. In 1549 he revisited the provinces and called Philip thither also, that they might see their future master; the young prince swore to maintain their rights and customs; and so began between the Netherlands and him the formal relation which under circumstances elsewhere related (vol. v. 416, 417) became so real on October 25, 1555.

Philip of Spain.

After appointing Margaret of Parma, a natural daughter of Charles V., to be regent in the Netherlands, in 1559 Philip set sail for Spain, leaving, in spite of the remonstrances of the estates, 4000 foreign troops, nominally to protect the frontiers, really to check the independence of the people, and to support the policy of religious persecution which had been resolved on. The real direction of all affairs was in the hands of the Burgundian churchman Antony Perrenot, bishop of Arras (afterwards so well known as Cardinal Granvella), who was chief of the "consulta" or secret council of three. A sharp attack on the Reformers now began. The first step, the proposal (which had originated with Charles) to reorganize the bishoprics of the Netherlands, was announced at once. Hitherto ecclesiastical affairs had been in the charge of four bishops,—Arras, Cambray, Tournay, Utrecht,—the last under the archbishop of Cologne, the others under Rheims. It was proposed now to establish a new and national hierarchy, independent of Germany and France, with three archbishops and fifteen bishops:—Mechlin, the chief archbishopric, having under it Antwerp, Herzogenbusch, Roermond, Ghent, Bruges, and Ypres; Cambray, with Tournay, Arras, St Omer, and Namur; Utrecht, with Haarlem, Middelburg, Leeuwarden, Groningen, and Deventer. Each bishop was to appoint nine new prebendaries to help him in his diocese; of the nine two should be inquisitors, specially told off to sniff out and hunt down heresy. Nor was this all; it was believed that not merely would these new bishoprics strengthen the old episcopal inquisition, but that a more stringent form of inquisition was to be introduced, organized after the Spanish system, which had been long known for its efficient severity. The Netherlanders regarded the change, in fact, as part of a general plan for the subjection of the provinces from abroad, by means of foreign troops and ecclesiastics, with contempt of their feelings, rights, and liberties. All classes—nobles, clergy, burghers, peasants—disliked the new ecclesiastical system, and regarded Granvella, who became first archbishop of Mechlin, with detestation. Though the Spanish troops were withdrawn in 1560, the ferment was not quieted; the nobles were uneasy, and, finding their position uncertain between the court and the populace, began to form confederacies and to head the resistance. Even such leading men as William of Orange, who tried to mediate between Government and the provinces, were driven into opposition; in 1561 Granvella's overbearing acts alienated them still more, and Orange and Horn withdrew from the council. Even Margaret felt she could no longer rule with Granvella at her side; and he at last, seeing that a crisis was coming on, withdrew into Burgundy in 1563. Now things were easier; party badges were dropped, and men felt cooler.

Granvella.

The new bishoprics.

But at this moment the long labours of the Council of Trent were ending; and, when in 1565 it finally promulgated its decrees, Philip determined to enforce their acceptance throughout his dominions. Accordingly, he now made a more vehement attack on the Reformers; and then it was that, in 1566, the Netherland nobles, led by Count Brederode, signed the famous "Compromise," with which the open rebellion of the provinces begins. Orange, Egmont, and Horn stood aloof. When, in their first interview with the regent, the nobles appeared on foot, in sedulously plain guise and without arms, Berlaymont standing by her side begged her not to be alarmed, "for they were but a pack of beggars;" and the phrase being overheard, at Brederode's banquet that night it was gaily adopted by the young nobles as a party name, "les gueux," and it became the fashion for patriots to wear beggar's garb, and a medal round the neck, bearing Philip's image on one side and a wallet on the other, with two hands crossed, and the legend "Fidèles au roy jusqu' à la besace." Orange, Egmont, and Horn, who dropped in on the revelry at Brederode's house, joined the merry scene and drank the beggars' health.

Tridentine decrees.

The "Compromise."

To deprecate Philip's anger at the "Compromise," the council of state sent the marquis of Bergen and Horn's brother, the lord of Montigny, Knights of the Golden Fleece and men of high repute, to Spain, where Philip received them kindly, but took good care that they should never again see their homes. Meanwhile he gathered forces with which to suppress the disturbances, which had become very serious. Open air preachings, guarded by armed men, were taking place throughout the provinces, and raised the excitement to such a height that it at last found vent in iconoclastic tumults, similar to those of France. This gave the court party only too good an excuse; it could now interpose with authority on behalf of public order. Matters threatened war. Margaret played with the discontented nobles, having orders from Spain to decoy

Deputation to Philip.

and capture the chief men, and so to break up the confederacy. Hereon Orange withdrew into Holland; Horn, in moody opposition, conscious of his integrity, retired to his country house; while Egmont still hovered, a bright flutterer, round the fatal taper of the court. The confederacy was in fact broken up; and Margaret saw with satisfaction a considerable body of German mercenaries enter the provinces to inflict punishment, in all its ghastliest and most brutal forms, on the iconoclasts. In 1567 it came to blows: the undisciplined rabble of Calvinists, who tried to raise the siege of Valenciennes, were cut to pieces by the troops of Egmont and other loyal nobles. William of Orange withdrew to Nassau, after vainly warning Egmont of the imminent peril which he ran.

...ir ...tgins.

...e duke ...Alva.

In spite of Margaret, who assured Philip that the heretics were completely put down, and their worship abolished, and that consequently there was no need of an army, and that on the contrary the time for mercy had come, the plan for the utter subjugation of the provinces was adhered to, and the duke of Alva, already famous for his harshness and bigotry, was named commander of the forces, with almost unlimited powers. He set forth in May 1567, and all hopes of peace or mercy fled before him. There was a great and desperate exodus of the inhabitants; thousands took refuge in England, Germany, and Denmark, carrying with them, it was thought, the last relics of their faith and party. The nobles' confederacy had already been broken up; now the popular movement was dispersed, despair and helplessness alone remained to greet the cold Spaniard and his train of orthodox executioners. He entered the Netherlands with about 20,000 men, all tried troops, ready for any cruelties. Their weakness lay in the fact that they were after all mere mercenaries,—Spaniards, Italians, Germans,—and as such ever ready for a mutiny, if pay fell short, or if there were none to plunder.

...rrest of ...gmont ...d ...orn.

Egmont and Horn were arrested at once; the Council of Troubles—the "Blood-tribunal"—was established; Margaret, thrust aside by the imperious general, resigned her weary office, and carried away with her the last hopes of the wretched people. Alva was now appointed governor-general, and the executions of his council filled the land with blood. Orange was outlawed on his non-appearance; it was about this time that he declared his conversion to Calvinism, and so fitted himself in every respect to lead the people when the time came. The hostilities of 1568 led to the execution of Egmont and Horn. Though the Gueux under Louis of Nassau won a considerable victory over the Spaniards at Heiligerlee, the arrival of Alva compelled him to raise the siege of Groningen, and to withdraw towards the Ems. At Jemmingen Louis was at last utterly defeated, and though the prince of Orange did his utmost to raise the country, and skilfully avoided a fatal battle, the campaign ended in his being obliged to withdraw out of the country. Alva was now at the highest point of his success; his statue, cast from cannon taken at Jemmingen, was set up at Antwerp; the exodus of the inhabitants continued incessantly, especially to England. The advice of Admiral Coligny, that the provinces should wage war from the sea, was hardly listened to at the first. In 1570, however, Orange turned his attention that way, and his little navy under William de la Marck annoyed Spanish commerce and took rich prizes. In 1572, being unable to find refuge in any ports,—for neither England, nor Denmark, nor Sweden, would allow them harbourage, and they were treated not merely as rebels but as pirates,—William de la Marck, with his "Water-Beggars," suddenly seized on Briel, at the mouth of the Meuse, and the face of the struggle began from that moment to change. Alva, partly from the general requirements of his position, partly from lack of funds and desire of his recently-imposed tenth penny, had at this moment driven the Netherlanders to desperation. He was engaged in a struggle with Brussels and Utrecht, in which city, to punish the inhabitants, he had collected his Spanish soldiery from all the neighbouring towns. The news of the capture of Briel woke him from his security. Flushing also fell into the hands of the "Water-Beggars," who surprised under its walls a rich convoy from Spain. About the same time, Louis of Nassau, who had been at La Rochelle with the Huguenots, and had received help and encouragement from Charles IX. of France, suddenly seized Mons in Hainault, thus giving the French sympathizers with the revolt the means of entering safely into the Walloon provinces. Alva, now seriously alarmed, withdrew from Zealand the whole of the forces with which he had intended to check the movement of the "Water-Beggars," in order that he might repair the great breach thus made in his southern system of defence, and so left the province free to develop its resistance. Holland followed quickly, Enkhuizen setting the example; so that, within three months of the capture of Briel, Amsterdam was the only town in Holland in the hands of the Spaniards. In Friesland also the revolt spread far and wide. The states of Holland met, and, acting under advice of Philip of Marnix, lord of St Aldegonde, the prince's deputy, declared that William of Orange was, by Philip's nomination, stadtholder of Holland, Zealand, and Friesland; they also declared their intention to raise money for the costs of war and the relief of Mons, and affirmed again the liberties of the provinces; finally they named the rough and ready William de la Marck captain-general—a man whose prompt and practical daring would supply the qualities which the caution and apparent irresolution and timidity of William of Orange seemed unlikely to provide for the emergency.

Alva's success...

Meanwhile Alva pressed the siege of Mons; French help failed utterly to relieve Louis of Nassau, nor could William of Orange either force his way through the Spanish lines or induce Alva to fight. At this moment came tidings of the massacre of St Bartholomew, and the prince, seeing that all hope of aid from France was utterly at an end, bade his brother make the best terms he could, and withdrew beyond the Rhine and thence into Holland. Mons at once capitulated, and Alva, passing on to Mechlin, pitilessly sacked that wealthy city. Thence he pressed forward to the north; Zutphen was taken, the towns of Guelderland and Friesland submitted, and for a while nothing seemed to stay his career of conquest and revenge. The prince of Orange was powerless; but the despair caused by the cruel destruction of Naarden roused a spirit which even Alva could not tame, and the famous siege of Haarlem, lasting through the winter of 1572 till July 1573, cost 12,000 Spanish troops, and gave the insurgent provinces time to breathe. A great mutiny among Alva's troops still more hindered the work of subjugation. The repulse of Don Frederick of Toledo, Alva's son, from Alkmaar, the capture of Geertruidenberg by the Dutch, and Admiral Dirkson's great victory over Alva's fleet, entirely changed the aspect of affairs, and saved the towns of North Holland. Alva, who had come as far as Amsterdam, returned to Brussels, and thence, obtaining his recall, bade farewell to his government. During the six years it had lasted, his executioners had put to death 18,000 persons, to say nothing of the victims in cities captured by his troops; the Spaniards plundered where they could, and considered the whole wealth of the Netherlands their lawful prey, forfeited by rebellion. But his pitiless severity only served to raise up a stubbornness of civic resistance, against which the tried discipline of the Spanish soldiery, and the consummate skill of their commander, reckoned to be the first general in Europe, were powerless.

Don Louis of Requesens, grand-commander of Castile, was appointed Alva's successor, and after a brief and deceptive lull the war went on. In January 1574, by the fall of Middelburg, the Spaniards lost their last hold on Walcheren and on Zealand, while by the splendid defence of Leyden, unparalleled in the history of heroic endurance, their efforts in another direction were effectually frustrated. After fruitless negotiations with Philip, the estates of Holland, in November 1574, formally offered to William "the Silent," prince of Orange, full authority by land and sea, with the title of governor or regent. Conferences were also held, with a view to peace, at Breda; and on their failure, in summer 1575, Holland and Zealand drew up articles of union, and an ordinance for their joint government under the prince of Orange. By it he received supreme command in war and absolute authority in all matters of defence, the control of all money voted by the estates, the maintenance of the laws as count, in the king's name, the ultimate appointment (after nomination by the estates) of all judicial officers. He undertook to protect Calvinism, and to suppress "all religion at variance with the gospel," while he forbade all inquisition into private opinions. These terms accepted, William became, in spite of their nominal recognition of Philip, the true prince of the two provinces. Still this union, brought about by the prince's personal character and ability, and by the popular faith in him, was distasteful to the larger cities. Already we may note the beginnings of that party division which was afterwards so prominent, and divided Holland between the land-party, popular, quasi-monarchical, Calvinistic, headed by the Orange-Nassau family, and the sea-party, the town-party, headed by the burghers of Amsterdam, Arminian, civic, and aristocratic.

[Margin: William proclaimed governor.]

Meanwhile the grand-commander made a successful attempt on the Zealand coast. His troops took Duiveland, and laid siege to Zierikzee, chief town of Schouwen, and key of the whole coast. The two provinces, unable to relieve the place, were driven to consider their position. So long as they paid any allegiance to Philip of Spain, against whom they were struggling for life, they could never get much help from any other prince, nor were they strong enough to assert their own sovereignty. Three powers lay near them:—the empire, already connected with them by old relations, and by the family connexion of the house of Orange; France, with her restless Valois dukes, ready for any venture, whether in Poland, England, or Holland; and, lastly, England, whose queen knew well that Philip was her foe, and that the Low Countries might effectually hinder his efforts against her. The provinces, though William had suggested it, refused to deal with the emperor, and turned to Elizabeth; she brought them little real help, and they seemed to be on the very brink of ruin when fever carried Requesens off in March 1576.

The breathing space thus gained enabled them to strengthen their union under William; but before the question respecting the position of the duke of Anjou could be settled, the siege of Zierikzee drew to an end. Boisot perished in a too gallant attempt to break the leaguer, and the town yielded. Things looked ill for the patriots, and Zealand would have been at the mercy of the conqueror, had not another great mutiny neutralized the success of the victors; the Spanish and Walloon troops left Zealand and, headed, as usual, by their "eletto," marched into the richer plains of Brabant, seizing Alost, whence they threatened both Brussels and Antwerp. One of the results of the panic they caused in Brabant was the capture of Ghent by William. Brussels was only saved from being pillaged by them by the vigour of the inhabitants, who armed in their own defence. Suffering under a powerless administrative, and smarting from the curse of the foreign soldiery, the southerners now began to wish for freedom and union with the other provinces. The broad liberality of Orange, moderating the Calvinism of the people, enabled the two groups to draw together. In October 1576 a congress of the States General of the provinces met at Ghent; the council of state at Brussels was forcibly dissolved; the frightful "Spanish Fury" at Antwerp struck such terror into all hearts that a treaty was concluded in November 1576 under the title of the "Pacification of Ghent." It was received with great enthusiasm; in it the provinces agreed first to eject the foreigner, then to meet in States General and regulate all matters of religion and defence; it was stipulated that nothing should be done against the Catholic religion; the Spanish king's name was still used; the prince of Orange was recognized only as stadtholder of Holland and Zealand. All the seventeen provinces accepted the Pacification; and for a brief space the "United Provinces" really did exist.

[Margin: Pacification of Ghent.]

Early in January 1577 the "Union of Brussels" was put forth. The document engaged all who joined to help in ejecting the foreign troops, in carrying out the Pacification, in maintaining the Catholic faith, in recognizing Philip's sovereignty, in defending the liberties and constitutions of the provinces. It was eagerly adopted; and even Holland and Zealand made no demur. When the paper, crowded with signatures, was laid before Don John of Austria, who meanwhile had arrived as regent, he also accepted it; and on the 17th February 1577 was signed the "Perpetual Edict," which ratified the Pacification of Ghent. Not till the troops were gone should Don John be received as governor-general. Philip II. ratified the Edict a few weeks later.

[Margin: Union of Brussels.]

[Margin: Perpetual Edict.]

Yet, after all, unity did not ensue from it. The natural divergency between north and south at once appeared; in character, in interests, above all, in religion, they had little in common; and when William of Orange refused to publish the edict in Holland and Zealand he was warmly supported by these provinces. This is perhaps the real point at which Dutch independence begins. Don John entered Brussels in triumph, and, by conciliation and winning manners, had already broken up the union; the whole of the southern provinces withdrew from it at once, and that well-marked difference in political life, which, after so many changes, still distinguishes Belgian from Dutchman, was from that moment made clear. Yet, though Don John had achieved so much, the result, after all, disappointed him; he was surrounded by difficulties, suspicions, and plots; he saw the failure of his larger schemes, and only the partial success of his effort to reduce the Netherlands; he recognized the dangers which the abilities and rivalry of William of Orange were preparing for him. This was soon shown in the seizure of Antwerp citadel by the patriots, and in the destruction of the hated fortifications, so long the sign and efficient cause of their subjection. Other castles, such as that of Ghent, were razed to the ground as soon as the fall of Antwerp citadel was known. Still less was Don John pleased by the election of his rival as ruwaard of Brabant, and by his enthusiastic reception at Brussels. The States General (7th December 1577) declared strongly against Don John's authority.

[Margin: Seizure of Antwerp.]

It was clear war must begin again; and the patriots raised an army nearly 20,000 strong, which was utterly defeated by Don John and Alexander Farnese, at Gembloux near Namur. But their campaign was wasted on isolated movements and town-taking, while William of Orange fell back unmolested to Antwerp. A sudden illness, so sudden as to arouse the common suspicion of poison, carried off the conqueror of Lepanto (1st October 1578), and Alexander of Parma succeeded him in the government.

The struggle had now entirely passed into the southern provinces; Holland and Zealand were left to gather strength; the recovery of Amsterdam (1578) removed the one hindrance to their prosperity. While the south trusted to foreign help, some John Casimir, or duke of Anjou, the north quietly consolidated itself. In January 1579 was proclaimed the famous "Union of Utrecht." The document professed to make no changes; it would but carry out the Pacification of Ghent by a closer junction of Holland and Zealand with Friesland, Guelderland with Zutphen, Utrecht, Overyssel, Groningen; united as one, these provinces should still retain their local uses and privileges. So long as the archduke Matthias, who had been appointed governor-general in 1577, remained, his authority would be respected; on his withdrawal in 1580 the States General named as stadtholder William of Orange, who had already exercised the real authority over the provinces. A considerable number of southern cities, Ghent, Antwerp, Bruges, and others, as well as some of the nobles, also joined this union. Thus did the United Provinces at last come definitely into being.

[U]nion of [U]trecht.

[T]he [U]nited [P]ro[v]inces.

During the next five years Spain devoted her efforts to the southern provinces alone; the union was unmolested. The Walloon provinces were reconciled to Spain; the others, with exception of Holland and Zealand, had accepted the duke of Anjou as their sovereign; Holland and Zealand had proclaimed William of Orange as their chief, though he did not finally accept sovereign power and the title of count till August 1582, by a sort of cross division, the seven northern provinces, meeting at the Hague, had (26th July 1581) made an "Act of Abjuration," and had issued their "Declaration of Independence," the five naming Anjou, the two William, as their sovereign in Philip's stead. Then Holland and Zealand framed an independent constitution, conservative of their ancient liberties, as expressed in the "Great Privilege of the Lady Mary;" they declared themselves a free country, severed alike from Spain and from the empire.

[D]eclaration of [I]ndependence.

But Spain was not yet ready to take up this challenge; and meanwhile she resorted to other weapons. A scandalous proclamation, offering rewards and honours to any ruffian who would serve church and king by murdering William of Orange, was now issued; and, roused by the double inducement, after many unsuccessful attempts, a paltry wretch (10th July 1584) succeeded in assassinating the greatest man of his age, the worthy "Father William" of the Dutch, and the only ruler in the world's history who may fairly be compared with Washington.

[M]urder [o]f William.

[M]aurice.

Fortunately for the Provinces, and for the world's liberties, the spirit of William of Orange survived in his second son Maurice, who now, though he was only seventeen and a student at Leyden, and though he had an older brother living in Spain, was at once, chiefly through the influence of that great statesman John Olden Barneveldt, named governor of the United Provinces, with a council of state, and with Count Hohenlohe, his brother-in-law, as lieutenant-general. He was also, soon after, made stadtholder of Holland and Zealand, while Utrecht was placed under the lord of Villars as stadtholder, Guelderland and Overyssel under the count of Meurs, and Friesland under William of Nassau. Never was any one better fitted for his life's task than was this boy, thus early called to rule in troubled times. For Maurice of Nassau had all the coldness and calculation of his family, all its ambition, all its firmness and tenacity of grasp, while he added thereto a quality wanting in the others, a genius for war, and those gifts which go to make what is commonly called a lucky commander—gifts which may be best described by saying that the lucky captain is he who in war leaves least to luck. For over forty years Maurice was the champion of the Provinces; and, if we except his treatment of Barneveldt, we may say that he comes next after his father as a founder of the Dutch republic.

At the outset his antagonist was that formidable captain, Alexander Farnese, who had by this time nearly subdued all the southern provinces, and whose arms proved successful at Ghent (1584) and at Antwerp (1585). The northern provinces, thinking it necessary to call in foreign aid, appealed to Henry III. of France, but the outburst of the "War of the three Henries," caused by the anxiety of the Guises lest Henry should draw too much towards the heretics, put a stop to all hope of help from that side. Olden Barneveldt, therefore, next crossed over to England with offers to Queen Elizabeth, who, though declining for herself the proffered sovereignty over the Provinces, undertook to appoint a governor-general, and to send over and pay 5000 foot and 1000 horse; in return for which she was to be put in possession of certain cautionary towns. Accordingly, Sir John Norris was at once sent over with the English forces; Sir Philip Sidney was appointed governor of Flushing, and the earl of Leicester was named governor-general by the queen. At first Leicester was welcomed with all the joy that his Calvinistic opinions, and his position as favourite and representative of Elizabeth, could elicit in the breasts of men who had now long been struggling for existence, and who, bereft of their great prince, were yearning for some strong hand to guide them. But it did not last: his high pretensions, and his mistress's haughty tone, joined with his foolish interference with Dutch commerce and with the religious difficulties now beginning to show themselves, soon offended the States General, and neutralized whatever good the active help of England might have promised them. In 1586 Sir Philip Sidney invaded Flanders, and the young stadtholder of Holland gladly served under him. In the same autumn Leicester himself took the field, and marched to meet Parma, who was threatening the provinces from the east. Under the walls of Zutphen Sir Philip Sidney fell; and Leicester, finding his efforts useless, soon raised the siege of that town, and withdrew to the Hague. The rest of his time was spent in bitter quarrels with the estates; Olden Barneveldt and Maurice were united for a time by his marked ill-will towards them both; and so strong did the feeling against him grow, that in 1587 Queen Elizabeth was fain to order his recall. For a while there was great soreness between the countries; the general interest, however, was far stronger than any partial pique, and in the crisis of the Spanish Armada in 1588 the Dutch did very great service to England by resolutely blockading in their ports the transports and army with which Parma had meant to invade the English shores. In the same year Maurice had the satisfaction of seeing the English and Dutch repulse the famous duke from the walls of Bergen-op-Zoom. In 1589, on the other hand, the English garrison of Geertruidenberg betrayed that important place, the doorway out of Brabant into Holland, into Parma's hands, and laid the United Provinces open to attack. In other places also the English forces, not yet withdrawn, were an anxiety and danger to the states. Still, from this moment the fortunes of the Dutch began to rise. No contrast could be more striking than that between the Spanish Netherlands and the United Provinces. In the fertile districts of Hainault and Brabant, where climate and soil are good and transit easy, utter ruin alone was seen: wolves and wild dogs swarmed; the land was overrun with weeds and briars; and even the wealthy cities of the past were almost deserted. In the United Provinces, on the contrary, the wellbeing of the country was steadily increasing: every year its hardy seamen brought back fresh wealth; and thousands of ingenious workers, turning in despair from the hopelessness of their condition in the

Earl of Leicester.

Spanish Netherlands and United Provinces contrasted.

Spanish Netherlands, brought their skill and industry into the north, which soon became as famous for its manufacturing excellence as for its energy in commerce. It was at this period that, just when the southern cities were languishing and losing ground, the northern burgher life made vigorous growth, and prepared the way for that supremacy of town aristocracy which characterized the history of Holland in the following century.

War against Spain.

The year 1590 opened well for the United Provinces: Utrecht joined its fortunes with those of Holland and Zealand; Guelderland and Overyssel made William Louis of Nassau their stadtholder, so strengthening the power of the family; and Breda was recovered by a daring stratagem. The duke of Parma also, with failing health, was called away to oppose the victorious progress of Henry IV. in northern France. In 1591 Prince Maurice still further strengthened himself by taking Zutphen, Deventer, Hulst, and eventually Nimeguen, which secured for him the complete submission of Guelderland. Parma was unable to oppose him effectually, for his troops were again mutinous; he was also once more called off into France. The reputation of Prince Maurice rose now to its highest point: the greatest captain in Europe seemed unable to cope with him, and the vigorous help of Barneveldt still secured him firm support at home. In 1593 he took Geertruidenberg; and in 1594 Groningen, the only stronghold left to the Spaniards in all the Seven Provinces, was reduced.

Archduke Albert.

The appointment of the cardinal archduke Albert as governor of the Spanish Netherlands did not much change the current of affairs; the Dutch now tried to open up a trade with the East Indies, and made some vigorous explorations in Arctic seas. In 1596 the archduke recovered Hulst, which commanded the northernmost parts of Flanders; the Dutch on the other hand, with the English, sacked Cadiz and destroyed the Spanish fleet; and in the next year Maurice inflicted a defeat on the Spaniards at Turnhout, transferred his sphere of action to the Rhine country, and took town after town, making the provinces secure on the side of Zutphen, Overyssel, and Friesland. The year 1598 gave a new aspect to affairs by the conclusion of the Franco-Spanish war in the treaty of Vervins, and by the death of Philip II. The Dutch, assisted only by the English, and that chiefly by volunteers, were now to bear the whole brunt of the efforts of Spain. In the autumn of 1599 Prince Maurice endeavoured to transfer the war into Germany; and after taking Emmerich in the Cleves country, delivered Bommel from the siege which Mendoza, the Spanish general, was laying to it. But dissatisfaction at home, and the unreadiness of his German allies, forced Maurice to turn his eyes towards Flanders, which he invaded in the summer of 1600. Surprised by the Spaniards in the neighbourhood of Nieuport, Maurice was attacked by the archduke Albert in a most critical position, but, after a long and well-balanced battle, inflicted on him (July 2) a disastrous defeat. Maurice could not, however, take the town, and winter put a stop to the campaign without any great change in the relative position of the belligerents. In 1601 the archduke began the famous siege of Ostend, which lasted three years and two months; the losses on both sides, more especially among the Spanish, were immense. While it continued, the coolness between the States General and Maurice steadily increased; for they thought his cold ambitious nature capable of anything, and saw with fear the paramount influence he had over the army. Their instincts led them to rest on the ships, to prefer peace to war, and commerce to glory. It was during the siege of Ostend that they established the Dutch East India Company in 1602, though its basis had been laid down by a group of Amsterdam traders in 1595.

Battle of Nieuport.

Siege of Ostend.

In 1604 Maurice took Sluis, and Ostend at last fell to Spinola. Thenceforward the main lines of the struggle by land were simple enough: the Spaniards tried to transfer the seat of war into the United Provinces, and were steadily foiled by Maurice. All the while the States General aimed at peace, though the naval war became vigorous as that on land languished. The sea fight off Gibraltar in 1607 utterly ruined the Spanish fleet, and left her commerce powerless. At last, after long negotiations, which served to emphasize the variance between the patriot party, headed by Barneveldt and Grotius, and the war party, which included the official classes, the army, navy, East India Company, the clergy, and the populace in the towns, a truce for twelve years was signed, on the *uti possidetis* ground, between Spain and Holland. In the war the Dutch had added Overyssel and Groningen to the union; they held Sluis, Hulst, and other ports on the Flemish side, in what is called "Dutch Flanders"; they had Bergen-op-Zoom, Breda, and Herzogenbusch on the Brabant frontier, and the forts which commanded the Scheldt and strangled Antwerp for the sake of Amsterdam; lastly, they were become lords of the sea, and the chief traders of the world.

Dutch gains i the wa

Theolo gical conflic

After a brief interference in the affairs of Germany, where the intricate question of the Cleves-Juliers succession was already preparing the way for the Thirty Years' War, Holland settled down into that hot and absorbing theological struggle, which was closely mixed up with political questions, and which stained with a deplorable triumph the last years of the career of Maurice of Nassau. In 1603 Jacob van Hermansen, or, in Latin form, Arminius (see Arminius), had been appointed one of the two professors of theology at Leyden, Francis Gomar being the other. The two men took opposite sides with zeal, Arminius assailing and Gomarus defending the current popular theology. The views of Arminius spread fast among the upper classes, especially in the larger towns, and became the theology of the civic aristocracy; the established opinions were tenaciously supported by the bulk of the clergy, the peasantry, the town populace, the army, and the navy. At their head stood Maurice, ready to use the strength of Calvinistic feeling to secure his own authority, however little he might care for the tenets of his side; at the head of the other party, more philosophical, less in earnest perhaps, was Barneveldt, with the town traders. King James of England as yet supported the Calvinists, and with Archbishop Abbot influenced greatly the proceedings of the famous synod of Dort (1618) in favour of Prince Maurice and the anti-Remonstrants. The results of the synod enabled the prince for his own political purposes to crush the aristocratic party. Barneveldt and Grotius (another leading Remonstrant) were seized, and in spite of all his great services to his country, his venerable age, and his past support of Maurice, the pensionary was brought to an infamous trial and executed at the Hague in 1619. Grotius afterwards escaped from prison and took refuge in France. The silenced Remonstrants, finding that there was no hope of toleration for them, left the country in great numbers, and formed a prosperous settlement in Holstein in 1621, where they founded the town of Frederickstadt on the Eider.

Thirty Years' War.

In 1621 the truce with Spain came to an end, and the Dutch were at once involved in the vortex of the Thirty Years' War, which had now been going on for a couple of years. Spinola, after taking Juliers, attempted Bergen-op-Zoom, hoping thereby to open a passage into Zealand; he was, however, foiled by Maurice. About this time a great coolness sprang up between Holland and England, the beginning of the deadly rivalry which lasted so long.

alry lland gland.

King James was eager to gain his objects without fighting, and to be on friendly terms with Spain; he and Laud were opposed to the Calvinism of the Dutch, and disliked their form of church government; and commercial jealousy was already beginning to arise. Successes and losses were evenly balanced in the war: the Dutch recaptured Juliers and took Cleves, while Spinola, after great losses caused by the gallant defence of the English, in 1625 took Breda. A few days before the town fell Maurice died, leaving the Spaniards in the heart of his territories, and the Dutch vexed with religious and domestic factions.

de- ; ary.

His brother, Frederick Henry of Orange-Nassau, succeeded him as stadtholder of Holland, Zealand, Guelderland, Utrecht, and Overyssel. The war by land became utterly spiritless, though by sea the Dutch still asserted their maritime supremacy. By land the chief operations were the siege and capture by Frederick Henry of Herzogenbusch, Maestricht, and Wesel in 1628; by sea the Dutch interfered, much against the popular feeling, to assist the French court against the Huguenots at La Rochelle. They blockaded Dunkirk, whence Spanish privateers had been wont to harass their commerce; under Piet Heyn of Delftshaven, boldest of their sea-captains, they vexed the Spanish coasts, captured Spanish war ships, carried off their "silver fleet," and finally in 1631 won near Tholen a brilliant victory over a great Spanish fleet commanded by Count John of Nassau, who was endeavouring to make a descent on the Zealand coast.

reli- y suc- sion in use of nge.

In this year the States, feeling that the moderation of the stadtholder was honest and salutary, that his influence alone seemed able to quiet the rage of religious faction, and that his military operations had secured the confidence of the provinces, took the important, and, as it turned out, the unwise step of securing to his infant son the reversion of all his great offices of stadtholder, captain, and admiral-general. The Calvinists were willing to grant so much to the head of their party, and made no objection to the introduction of the principle of hereditary succession; while the Remonstrants, discerning that Frederick Henry, like his brother before him, was personally more favourable to their tenets than to those of their adversaries, accepted the measure in the hope that when permanently established as their prince he would carry out those tolerant views which he was known to hold.

In 1632 he justified their confidence by his masterly siege and capture of Maestricht, in defiance of all the efforts of the Spanish and imperial generals; Namur, Luxembourg, and eastern Brabant were laid under contribution in consequence, and the States defended from danger of attack towards the east. As the war dragged on after the death of Gustavus Adolphus of Sweden, France and Holland drew more together, and in 1635 an alliance and partition treaty was made between them, in which it was proposed that the Spaniards should be driven out of the Netherlands, which should be made an independent state, guaranteed by the allies; that France should receive, as her share, the sea-coast up to Blankenberg, together with Thionville and Namur; and that a corresponding portion should be given to Holland; if this scheme of an independent state proved a failure, then France and Holland should divide the whole district between them. The joint operations consequent on this agreement proved a failure: Frederick Henry had always been opposed to the alliance, and probably did not wish its success; the divergence between him and the States General at this time gave Cardinal Richelieu the opportunity of restoring the Remonstrant party in Holland, and making it French in sympathy, in opposition to the House of Orange—a combination of which Louis XIV. afterwards made great use. In 1637 the stadtholder recovered Breda, though the gain was balanced by the loss of Roermond and other places; and in 1638 the war was favourable to the Spaniards. In 1639, however, a series of great naval triumphs under Tromp and De Witt turned the scale in favour of the Dutch.

iance h ance.

In 1640, on the death of Count Henry of Nassau, stadtholder of Friesland and Groningen, the latter province chose Frederick Henry as its stadtholder, and he thus became chief of six out of the seven United Provinces; in the next year he was able to arrange the marriage of his son William with Mary, eldest daughter of Charles I. of England, a match devised by the queen-mother of France, while a refugee in Holland, in order to increase the ill-will between Richelieu and the stadtholder. Thus began the dynastic relation between the Stewarts and the house of Orange, which led to such great results before the end of the century. The States General were not too well pleased with this alliance, and looked shyly at Henrietta Maria when she came over to Holland to get help for Charles I. in 1642. They were becoming alarmed at the great power and growing ambition of France under Richelieu, while they sympathized to a great extent with the English Puritans.

Connexion with England.

All parties, except the French, being now utterly weary of the war, negotiations for peace, long talked of, long prepared for, began in earnest at Münster and Osnabrück. Before their close Frederick Henry died in 1647, and was succeeded in his dignities and offices by his young son William II., and almost immediately afterwards (January 1648), in spite of the opposition of France and the young prince of Orange, the deputies of the Provinces (with exception of Zealand and Utrecht) signed a separate treaty of peace with Spain, which was confirmed and sworn to in May at Münster. It was a complete surrender of everything for which Spain so long had fought. The United Provinces were recognized as free and independent, and Spain dropped all her claims; the *uti possidetis* basis was adopted in the matter of all conquests; the two contracting parties agreed to respect and keep clear of each other's trading-grounds; each should pay, in the ports of the other, only such tolls as natives of the other paid; the Scheldt was entirely closed by the States, so that Amsterdam might strangle Antwerp—the chief harbour of the free Provinces thus ruining the chief harbour of those still subject to Spain. And so ended the so-called Eighty Years' War.

William II.

Peace with Spain.

No sooner was the peace concluded than bitter disputes arose between Holland, on the one hand, and the prince of Orange, supported by the army and navy and the smaller provinces, on the other. He was tempted into foolish acts: he arrested six of the deputies of Holland; he even tried to surprise and occupy Amsterdam; he favoured the English royalists, now plentiful in the Provinces, while Amsterdam and Holland inclined towards the Commonwealth. Things went so far that William II. had almost destroyed the liberties of the Provinces, and was intent on two schemes,—the resumption of war against Spain, with a partition with France of the Spanish Netherlands, and interference on behalf of Charles II. in England,—when his opportune death by small-pox occurred. A few days afterwards his widow, Mary of England, gave birth to a son, who was destined to be the most distinguished man of his race, William III. of Holland and England.

Holland and William II. at variance.

For a time the death of William II. restored the burgher-party to power, and made Amsterdam the head of the United Provinces. Holland triumphed over Zealand; the house of Orange, friend of the Stewarts, seemed to suffer eclipse with them; and though the royalist mob even at the Hague, set on by a princely rough of the palatine house, made it impossible for the envoys of the English Commonwealth to come to terms with the republic, still the popular monarchical party was in fact powerless in the Provinces for more

Amsterdam now rules.

than twenty years. It was with a view to the security of this aristocratic government that a great assembly of the Provinces was held in 1651, and established that form of rule which Sir William Temple has so well described in his *Observations upon the United Provinces of the Netherlands.*

Constitution of the United Provinces.

There were four chief elements in that federation:—the terms of the Union of Utrecht (1579); the claims and position of the house of Orange; the sovereignty, within its own borders, of each province; and lastly, the liberties and power of the cities. In the last two the lead was taken by Holland: Holland was the chief province, and Amsterdam, its capital, the chief city of the union. And these two parts of the federation were at one also in their resistance to the house of Orange, of which the chief strength lay in Zealand. The union was governed, in theory at least, by the States General of the provinces, which met at the Hague, and consisted of a fluctuating number of deputies (sometimes as many as 800), and was supplemented by a permanent council of state, a kind of cabinet composed of twelve deputies from the provinces, and a chamber of accounts. Besides this body each province had its own estates, and each great city its own senate. Thus Amsterdam was ruled by a senate of thirty-six burghers, who kept order, administered justice, raised local taxes. The office of senator was for life, originally by election of the whole body of freemen, but from the 16th century by cooptation, so that the government of the city became a close oligarchy. The chief towns followed Amsterdam in this direction. The senate elected the deputies of the city to the states of Holland.

The town-governments.

Commercial prosperity.

The commercial prosperity of the Provinces went on advancing throughout the 17th century; each town had its own work. Flushing received the West India trade; Middelburg was entrepôt for French wines; Terveer was the Scottish and Dort the English staple; Leyden manufactured; Haarlem made linen and mixed stuffs, and grew tulips for profit and pastime; Delft was known for beer and hardware; Zaandam built ships; Enkhuizen caught and cured herrings; Friesland had the Greenland trade; and lastly Amsterdam, recognized chief of Dutch cities, had the East India trade, with that of Spain and the Mediterranean: their whole carrying business reached from the Gulf of Bothnia to the farthest Indies. Their seafaring enterprise received an early scientific impulse from the labours of Coignet and G. Mercator. All questions as to the nature and development of wealth were still in their infancy: it was believed that all depended on balances of actual bullion; and the Spaniards were envied because their ships brought over masses of gold and silver. The "balance of trade," the establishment of banks at home and colonies abroad, especially mining colonies, a huge carrying trade, the making of goods to be sold for cash only, the discouragement of all imports, and the support of all monopolies—these things, chief elements of what is called the "isolation theory of trade," guided the politics of the 17th century, gave Holland vast temporary wealth, discouraged her power of production, and eventually have left her impotent among the nations.

The governor and States General.

At first William the Silent had been governor of the Provinces, nominally at least under the king of Spain; and in the reconstruction he secured his own rights, while the sovereign power was transferred to the States General. They took the right of making peace and war, of concluding alliances, of taxing and coining. The governor had all military commands, had power to pardon, and controlled the civil appointments; he represented the dignity of the state, with a court, and guards, and envoys from other lands. Each province had its own stadtholder, an office in name at least derived from the Spanish times; each town had its own pensionary or chief minister. But after the death of William II., the office of stadtholder of Holland was for a time suspended; there was no captain-general or admiral; and the grand pensionary of Holland, first minister of the state, became virtual president of the republic, as we see in the cases of John De Witt and Heinsius.

When the English envoys returned to tell their masters, the Commonwealth, of their failure at the Hague, parliament at once replied by passing the memorable Navigation Act of 1651, which aimed at destroying the carrying-trade of the Provinces. The struggle for the lordship of the seas which ensued, and with which the names of Tromp and Ruyter, Blake, and Monk are so splendidly associated, was waged with equal bravery and nearly equal success on both sides, until 1654, when peace was made by the Amsterdam burgher-party. By the terms of the treaty with Cromwell the Orange-Nassau family was altogether to be excluded from the stadtholderate of Holland, the other Provinces reserving their independence, and the Dutch populace also much disliking the peace. England preserved the honour of her flag, while Holland was seen to be a worthy and equal rival for the command of the sea.

War with Engla[nd].

War with Portu[gal].

Hostilities between the Dutch and Portuguese respecting their rights in Brazil followed, in which, after each side had done much damage to the other, peace was also made; and Holland in 1658 interfered to save the Danes from Charles Gustavus of Sweden. In 1659 a treaty of peace was made between France, England, and the United Provinces, with a view to the settlement of the Dano-Swedish question, which ended in securing a northern peace in 1660, and in keeping the Baltic waters open for Dutch trade. Since the abolition of the stadtholderate after William's death in 1650, the centre of authority had lain in the hands of John de Witt, the sagacious leader of the anti-Orange or Amsterdam burgher-party; and he guided the foreign affairs of the provinces in such a way as to secure the fair development of their commerce on every side.

John Witt.

War with Engla[nd].

The momentous year 1660 was almost as critical for Holland as for any state of Europe. Charles, in England, having re-enacted the Navigation Act, war again broke out in 1665, and the duke of York took the command of the English fleet. At the beginning of June he met the Dutch admiral Opdam, and, after a close-fought battle off Lowestoft, the English were completely victorious. But so bad was the condition of the home Government in England that in the following year the Dutch had by far the stronger fleet at sea, and for a time held their own in the Channel. The four-days' battle (June 1–4) between Prince Rupert and Monk on the one side and Ruyter on the other ended in an uncertain victory for the Dutch; but on July 25th they were decidedly defeated off the North Foreland, and driven back to their own shores with immense loss. The English were now masters of the sea; but both parties needed peace, and negotiations began at Breda. In the course of these Ruyter suddenly sailed up the Thames nearly to Gravesend, and struck terror into the very heart of London, which thus became all the more eager for a settlement. In July 1667 a treaty between England and Holland was signed at Breda; and in the following year Sir William Temple accomplished the triple alliance of England, Holland, and Sweden, against the aggressive views of Louis XIV., a hollow affair, and pernicious in its results to those who made it. It made Louis XIV. determine to take vengeance on the United Provinces and on the De Witts; it led at once to the humiliation of England by the treaty of Dover (1670), to the overthrow of the Amsterdam party, and to the miserable end of the De Witts; and it eventually raised the prince of Orange to supreme authority in the United Provinces.

Triple allianc[e].

ar ıewed th gland.

From 1668 to 1672 Louis XIV. made ready to destroy the Dutch; and so well had his diplomacy served him that they were left without a friend in Europe. In 1672 the storm broke: the English, without a declaration of war, tried unsuccessfully to intercept the Dutch Mediterranean fleet; and France at once set forth to conquer the hated tradesmen of the north. The States were ill-prepared on land, though their fleet was strong and ready; party spirit was exceedingly bitter, and the ruling party, well aware that the prince of Orange was very popular with the land forces, had utterly neglected their army. On May 28, 1672, Ruyter fought a great naval battle in Southwold Bay (Solebay) against the duke of York and Marshal D'Estrées: the French held aloof, pleased to see the Dutch and English destroy each other; the English suffered most, but, as the Dutch withdrew to their own ports, the others claimed the victory. Meanwhile Louis XIV. crossed the Rhine and threatened Amsterdam (see FRANCE). The young prince of Orange alone seemed to rise to the occasion; while others were panic-stricken, sending embassies of submission to the haughty monarch, making preparations for a great flight by sea, William with his miserable army did his best, and aroused so strongly the feelings of the people that Amsterdam, passing from dejection to despair and thence to reckless enthusiasm, rose against the De Witts and foully murdered both in the streets. They had just before proclaimed William stadtholder of Holland with powers unlimited. And thus Louis XIV. destroyed the proud republic, though in so doing he had raised up the most formidable enemy he was destined to encounter. His invasion did not prosper; other nations began to take up the Dutch cause; Germans and Spaniards threatened the embarrassed French army in the Provinces; so that in 1674 France was on the defensive on every side. William of Orange in that year was defeated at Senef, and had to abandon his plan of penetrating into France, and in 1675 the death of Marshal Turenne, and the retirement of the great Condé, turned the tide of war in favour of the Dutch, except on the sea, where the French fleet defeated and destroyed in the Mediterranean (in 1676) the united navies of Holland and Spain. In 1677 negotiations for peace went on, and were hastened by the marriage, at the close of the year, of William of Orange with the Princess Mary, daughter of the duke of York. At last, in 1678, came the great peace of Nimeguen, which secured the independence of the Dutch.

›e of illiam I.

The aggressive policy of Louis XIV., in the years which followed the peace of Nimeguen, enabled William to lay the basis of the famous confederacy which changed the whole front of European politics. Brandenburg, Denmark, and England sided with the French king; while the league of Augsburg (1686), following directly after the revocation of the edict of Nantes, placed William at the head of the resistance to French domination. The league was joined by the emperor, Spain, the United Provinces, Sweden, Bavaria, and other German princes. The accession of James II. to the throne of England made it easy for the stadtholder to keep up close relations with the malcontents in church and state, who regarded him and the Princess Mary as the natural successors to the English throne. On the birth of the prince of Wales the anti-Catholic feeling in England at last grew so strong that William was able to interfere with success; while the diversion of the attention of Louis XIV. from Holland to the Rhine relieved the timid rulers of Amsterdam from all anxiety. The Revolution of 1688 ensued, and England became, under William's strong rule, the chief member of the great coalition against France. In the grand alliance of 1689-90 he clearly sacrificed Dutch to English interests, and carried through his policy in spite of great irritation in Holland and Zealand. His power seemed almost autocratic, and the States impotent. Henceforward their part in history becomes quite secondary compared with that of England, and we may refer for details of the great wars to the articles ENGLAND and FRANCE.

Holland at war with France.

In 1690 Waldeck, commanding the Dutch, was defeated by Luxembourg at Fleurus; and the Anglo-Dutch fleet was also severely handled off Beachy Head by the French, who inflicted terrible losses on Dutch commerce. In 1691 the French took Mons; in 1692 the allied ships ruined Tourville's fleet off La Hogue, and recovered the command of the sea. On land the allies fared ill: Louis took Namur, and after a hard-fought battle William was defeated at Steenkirk; in 1693 the Dutch shared in the defeat of Neerwinden, and were not fortunate even on the sea. In 1695 the tide of affairs had turned, and William retook Namur, his greatest triumph after the battle of the Boyne. Negotiations for peace, first attempted in 1694, led to the peace of Ryswick in 1697, in which William was recognized by France as king of England, the Dutch obtaining a favourable commercial treaty, and the right to garrison the Netherland barrier-towns. Holland was still an important factor in the balancing system rendered necessary by the ambition of France. Louis XIV., however, held himself little bound by the peace. In 1701 he elbowed the Dutch troops out of the barrier-towns; he defied England by recognizing James III. on the death of his father; and it was clear to all that another war was imminent, when William III. died in 1702. He had been made hereditary stadtholder in five of the Provinces in 1672; but as he left no children as heirs, the old opposition of Holland to his house again sprang up, and, led by the grand pensionary Heinsius, Amsterdam successfully asserted her independence, and ruled throughout the coming struggle against France with energy and credit.

Peace of Ryswick

The triumvirat against France.

When war was declared in 1702, Marlborough was named commander-in-chief of English and Dutch troops, and thenceforward became the chief man in the famous "triumvirate" of Marlborough, Heinsius, and Prince Eugene. In 1703 the Dutch invaded Flanders, and fought the drawn battle of Eekeren; in 1704 they and the English took Gibraltar; in the same year they took part in the great battle of Blenheim. In 1705 Marlborough led them into the Netherlands; but, hampered by the deputies of the States, he achieved little. In 1706 he won the battle of Ramillies, and swept the French out of the Netherlands; in 1708 came Oudenarde, and after it an unsuccessful attempt of Louis XIV. to detach the Dutch from the alliance; in 1709 the terrible battle of Malplaquet and the capture of Mons. After this great changes followed in England, and Marlborough's power came to an end. Negotiations for peace, often tried before, drew towards success in 1712, and in 1713 the peace of Utrecht was signed. While France received Aire, St Venant, Bethune, and Douay, the Spanish Netherlands were formally handed over to the United Provinces, which in their turn passed them on, after conclusion of a barrier treaty, to Austria; henceforth they are known as the Austrian Netherlands. A favourable commercial treaty was also made between the Dutch and France. The peace of Utrecht made the republic almost as powerful on shore as she had been by sea; at the same time it taught her that the great powers around her would use her resources for war, and abandon her when they wanted peace: she therefore determined henceforth to stand clear of all foreign complications. With 1713 the importance of Holland in European politics comes almost to an end.

Peace of Utrecht.

The ruling party in the States took an active part in securing George I. on the throne of England; and on the death of Louis XIV. in 1715, the old ill-will between France and the provinces died entirely out, so that they were secure in a position of tranquillity; they also brought to a fair conclusion their difficulties with Austria on the subject of the Netherlands barrier. These, however, began again when in 1723 the emperor set on foot the Ostend East India Company, which was at once regarded as an offensive rival by the Amsterdam merchants. For the sake of crushing this competition the States in 1731 consented to guarantee the Pragmatic Sanction of Charles VI. In 1743 they joined England in supporting the claims of Maria Theresa, queen of Hungary, and fell consequently into complications with France, which invaded the barrier country. In 1744 they granted a subsidy in money and put 20,000 men in the field, and became a member of the Quadruple Alliance with Austria, England, and Saxony. In 1745 the Provinces took their part in the rout of Fontenoy, after which Marshal Saxe overran the Austrian Netherlands, while England and Holland were alike paralysed by the Jacobite rising in Scotland. The States lost every barrier-town, and lay defenceless before the French, who in 1747 entered Dutch Flanders, and made an easy conquest. And now the Orange party, supported by English aid, began to lift its head. The Provinces had fallen so low that all men began to wish for a dictator. Accordingly Prince William Charles Henry Friso was proclaimed stadtholder, captain, and admiral-general of Zealand at Terveer, under the title of William IV. The movement thus begun spread like wildfire; all Zealand accepted him with enthusiasm, and Holland was not far behind; even at Amsterdam and the Hague the popular feeling was too strong to be resisted, and the Government had to give way. William IV. became captain and admiral-general of the whole union, and stadtholder of the Seven Provinces; a little later these offices were declared hereditary in both male and female lines.

War with France.

William IV.

Peace of Aix-la-Chapelle.

The peace of Aix-la-Chapelle, in 1748, though it nominally restored things to their old estate, could not efface the mischief and humiliation which the war had caused to Holland. Nor were affairs mended by the death of the stadtholder William IV. in 1751, who, though dull and quiet, did his best to develop the commercial and manufacturing prosperity of the States. His widow, Anne of England, daughter of George II., carried on the government for her son William V. She showed but little aptitude for the post of regent, and the Provinces had great difficulty in standing clear of the European complications of the Seven Years' War. They did so, however, and after her death in 1759 were on better terms with England, which had urged them to take up the cause of Frederick the Great. In 1766 William V. was declared to be of age; irresolute and weak, he was entirely under the command of his old preceptor Louis of Brunswick, and his wife Frederica Wilhelmina, niece of Frederick the Great. His rule is only distinguished for the springing up of several learned societies, and for the stimulus, derived partly from England partly from France, given to scientific inquiries. In other respects the influences of England and France were not propitious to the Provinces. In the American War of Independence William sympathized with the English court against the French and the revolted colonies, while the Dutch people warmly embraced the other side. Hence arose again old maritime disputes. The Provinces quarrelled at home over the relative importance of army and navy, and strengthened neither. So things went on from 1776 to 1780, when the famous "Armed Neutrality," with which the Continental states replied to the demands of England on the seas, drew the Provinces once more into the arena of European politics. After a division of the States, in which four were on one side and three on the other, the United Provinces decided to adopt the Neutrality, and threw in their lot with France and Russia against England. But though war broke out at once, nothing could cure the violence of party spirit—the stadtholder and the court party going with the English, and neutralizing all the warlike efforts of the "patriot" party. In 1781 Dutch commerce was utterly paralysed; the other powers set on the Provinces, and took each its part. Their West India Islands were seized, and it seemed as if they could do nothing in their own defence. At last, however, an indecisive but not inglorious action with Admiral Parker at the Dogger Bank roused the national spirit, and the Orange party lost ground everywhere. In 1782 the Provinces recognized the independence of the United States of America; with generous sympathy the aged commonwealth saluted the rising republic of the West, which was destined to take its share also in the ruin of Dutch trade. In 1783 the States made an inglorious peace with England, in which the English got right of free traffic with the Dutch East India colonies.

William V.

War with England.

The patriot party was so much excited by this long series of blunders and humiliations that the fall of the house of Orange seemed imminent, and the king of Prussia had to interfere on behalf of his kinsfolk. In 1784 the States were in trouble with a new antagonist; the emperor Joseph II. sought to compel them to acquiesce in the reopening of the mouths of the Scheldt, so as to restore some of its ancient prosperity to Antwerp. But as neither party was able to fight, a peace was patched up in 1785, though its terms, as usual, were very humiliating to the States. The resistance against the princess of Orange continued to increase in violence, until in 1787 the Prussians again interfered, occupying Amsterdam, reinstating the stadtholder, who had been driven out, and compelling the states to ally themselves, much against their will, with England and Prussia.

Trouble with Prussia and Austria.

Under their sway the Dutch passively remained, and when the French Revolution came they stood neutral as long as they could between it and the kings; it was not till Dumouriez had overrun all the Austrian Netherlands in 1792, and had determined to secure justice to Antwerp by forcing open the passage of the Scheldt, that they were drawn into the strife. On the death of Louis XVI. in 1793 the national convention at once declared war against both England and the Provinces. Their first campaign against the Dutch under Dumouriez failed: the invaders were arrested before Willemstadt, and ultimately were compelled to retreat. But in the autumn of 1793 Jourdan restored the credit of the French arms in the Austrian Netherlands. In 1794 Pichegru brilliantly completed the conquest of Belgium, and before the end of the year invaded the Provinces. The very severe frost of that winter gave his army easy passage over all the rivers and low-lying lands, which still formed the chief defence of the states; he occupied Amsterdam, and with his hussars crossed the ice and took the Dutch fleet as it lay at the Texel; the stadtholder fled (1795) to England; and the shattered remains of the duke of York's army having reached Bremen returned home in disgrace. The republican party in the Provinces now reorganized the government so as to bring it into close harmony with that of Paris. A new constitution was framed; the ancient system of representative government, the stadtholderate, and the offices of captain and admiral-general were all swept away; a fair and open representation was established; and the Batavian republic came into being in close alliance with France. The French with one hand delivered the Provinces from a worn-out system of government, and with the other seized on a substantial return for their assistance. The new constitution, so excellent

War with France.

The Batavian Republic.

in appearance, soon proved a delusion. One change of government succeeded another: after the States General came a national convention; then in 1798 a constituent assembly with an executive directory; then chambers of representatives; then a return to the earlier system under the names of the eight provincial and one central commissions (1801).

The peace of Amiens gave the country a little rest, and the Dutch got back the Cape of Good Hope and their South American colonies: it was, however, but the brief and deceptive lull between two storms; when war began again England once more swept away all she had restored. In 1805 Bonaparte, with his usual high hand, imposed on them a new constitution, and set Schimmelpenninck over them with the ancient title of grand pensionary. In the next year Napoleon added Holland to the ring of great fiefs with which he surrounded his imperial system, and forced an unwilling brother, Louis, to be king of an unwilling people. Worthy of a better fate, the excellent king of Holland did all in his power to protect his new subjects from the crushing friendship of his brother; but his efforts were in vain, and he withdrew to Vienna. In 1810 Napoleon annexed all Holland to the empire, declaring that it was "in the nature of things nothing but a portion of France." In 1813 the change in the affairs of Europe encouraged the Dutch to join the general revolt, when they established a limited monarchy. The prince of Orange was recalled from England, and entered Amsterdam amidst the utmost enthusiasm. An assembly of notables met and declared him king with the title of William I., king of the Netherlands, in 1814. By the treaty of Paris Belgium was united to Holland, and the seventeen provinces were again forcibly joined together under one prince. It was settled that the house of Orange should have the hereditary sovereignty, with a fairly liberal constitution. To make up to the new king for the loss of his territories in Germany, the grand duchy of Luxembourg, with the exception of the town and fortress of Luxembourg, was handed over to him as his private possession, not as a part of the kingdom; the bishopric of Liége and the duchy of Bouillon also went with it. The episode of the "Hundred Days," though it delayed the conclusion of the very complicated arrangements involved in these transfers, gave the new kingdom an opportunity of distinguishing itself: it was the first point of attack, and met the crisis with vigour. The Dutch troops under William, eldest son of the new king, took considerable part in the short and striking campaign which was closed on June 18, 1815, by the final victory of Waterloo.

The allied powers now founded in Holland and Belgium what they hoped would be a solid and permanent kingdom as a barrier against France. It was felt that Napoleon had shown Europe the importance of this district in connexion with his scheme for European domination. The new kingdom under the house of Orange was therefore the subject of great and anxious consideration at Vienna. The king, an hereditary sovereign, received full executive powers, and the initiative in proposing laws. He had also the power of appointing his own council of state. As a legislative body there were the States-General, divided into two chambers; each province had also its own local states. Freedom of worship and political equality were secured for all.

A highly artificial arrangement like this, however, could not stand long, if Europe came to throw off the trammels of the monarchical reaction, and to give freer course to those liberal tendencies which had survived the drama of the French Revolution. In religious belief, in laws and usages, in language, in interests, the Belgic and Batavian provinces had little in common. Their inhabitants were different races, with instincts and feelings not merely diverse but opposed. The Belgic provinces spoke French or Walloon, the Batavians, Dutch. The Belgians were strict Catholics, while the Dutch were Protestants. The Dutch were chiefly a commercial and seafaring people, with interests in distant lands and colonial possessions; the Belgians were agriculturists, except where their abundance of minerals made them manufacturers. The Dutch connected themselves with Germany and (though often only by way of rivalry) with England; the Belgians drew their chief inspirations from France, and connected themselves with the French in traditions, religion, and commercial interests. Such a diversity could not possibly stand the brunt of any great political movement; especially as the Dutch were oppressive towards their Belgian partners in the kingdom. Accordingly we find that in 1830 the revolution at Paris at once aroused the strongest sympathy at Brussels. The dull obstinacy of William I. had emphasized the divergence, and his narrow and antiquated policy rendered an outburst inevitable.

The revolt at Brussels, which began on the 25th August 1830, spread instantly throughout the whole of Belgium. After a short struggle in November, a conference of France, England, Prussia, Austria, and Russia, sitting in London at the request of William I., proposed an armistice, to which both parties agreed. In the following January the conference attempted to settle the terms of a separation, and proposed that Holland should have Luxembourg and part of the left bank of the Scheldt; this the Dutch accepted, while the provisional Government at Brussels protested against it. The assembly at Brussels constructed a new and liberal constitution, with a broad representative government, liberty of teaching, of the press, of public meeting; and in April 1831 the crown was offered to Leopold of Saxe-Coburg, who, after ascertaining that he would be recognized by England and France, did not hesitate to accept it (see BELGIUM). This appointment caused the utmost irritation at the Hague, and the Dutch suddenly invaded Belgium; the opportune appearance of a French army checked the Dutch advance, and gave diplomacy time to interfere. The citadel of Antwerp, however, was still in Dutch hands, and the allied powers used in vain all their influence to persuade William I. to give it up to the Belgians. War was hereon declared, and France and England blockaded the Dutch ports, while a French army attacked the citadel, and, after a sharp struggle, compelled it to capitulate. The forts of Lillo and Liefkenshoek were left in the hands of the Dutch; on May 21, 1833, there was signed at London by the plenipotentiaries of Holland on one side, and those of England and France on the other, a convention in which William I. engaged not to recommence hostilities against Belgium, and to leave the Scheldt navigation open, till the relation between the two countries should be definitely settled by treaty. The final settlement of outstanding questions, however, was not reached till six years later, when Limburg and the eastern part of Luxembourg were secured to Holland, and heavy tolls were imposed on the navigation of the Scheldt; then the two kingdoms finally parted company on the 19th of April 1839.

In the following year William I. resigned his crown to his son William II., who reigned in peace till his death in 1849, when he was succeeded by his eldest son William III., who still reigns. The wave of revolution which passed over Europe in 1848 had in Holland comparatively little effect: the constitution of 1814 was revised, and the tranquillity of the country secured. In 1853, after the establishment by the papacy of Catholic bishoprics in England and Holland, a considerable excitement arose, which resulted in the accession to power of a moderate, liberal, and entirely Protestant cabinet, and in the main the Protestant-liberal party has guided the country for the last quarter of a century. The Dutch took but a secondary part in the disputes between France and Germany as to Dutch Luxembourg, which by the treaty of London (1867) was declared neutral, and guaranteed to Holland. Recently they have been engaged in a very vexatious and wasteful war with the sultan of Acheen, their neighbour on the island of Sumatra.

Fruin, *De Nederlandsche Wetboeken tot op 1 Jan.* 1876 (Utrecht, 1878); Nippold, *Die römisch-katholische Kirche im Königreich der Nederlande* (Leipsic, 1877); Wenzelberger, *Gesch. der Niederlande* (in Heeren and Uckert's series, Gotha, 1878–79); Kemper, *Gesch. van Niederland na* 1830 (Amsterd., 1873–76). For English readers the older works of Grattan, *History of the Netherlands* (Lardner's series), and Davies, *History of Holland* (3 vols., 1841), have been cast completely into the shade by Motley's *Rise of the Dutch Republic* (Lond., 1856), and *The United Netherlands* (Lond., 1861–68). A *Repertorium der verhandl. en bijdragen betr. de gesch. des vaderlands in tijdsch. verschenen* appeared at Leyden, 1863, and a *Register van acad. dissertatien*, having the same scope, in 1866. (G. W. K.)

PART III.—LANGUAGE.

Of the Low German tribes the Old Saxons, the Anglo-Saxons, the Franks, and the Frisians played a specially important part both in north-western Europe in general and in the Low Countries in particular; and accordingly it is with these tribes that we have in the first place to do when investigating the origin and development of the Dutch language. A great many dialects formerly existed side by side on Dutch ground, and many of them still live on the lips of the people; but they all belonged to one or other of three well-defined groups—Frisian, Saxon, and Frankish.

In the earliest times about which records have come down to us, the Frisian dialect, in various shades of difference indeed, occupied a very extensive area. It was the language universally spoken in the provinces of Groningen, Friesland, and North Holland. But in Groningen the Frisian has been superseded by the Saxon, and in North Holland by the Low Frankish dialect; and the three leading dialects of the Dutch are now distributed in Holland nearly as follows:—(1) Saxon in Groningen, Drenthe, Overyssel, and the county of Zutphen; (2) Frisian (more or less corrupt in the towns) in Friesland; and (3) Low Frankish in Guelderland (excepting the county of Zutphen), Utrecht, North and South Holland, Zealand, North Brabant, and Limburg.

In Groningen and North Holland the Frisian dialect has left more or less marked traces of its former predominance in the pronunciation, vocabulary, and phraseology of the present spoken language. During a considerable period laws, ordinances, contracts, and similar documents were drawn up in the various provinces in the peculiar dialect of each, and many of these documents, especially in Frisian, have come down to our time. The inhabitants of the northern provinces, however, had neither superiority of culture nor political preponderance enough to secure the assimilation of the adjoining populations. The occupants of the tract in which Low Frankish was spoken were much more favourably situated; and that dialect has in the end ousted the two others, and become the speech, both oral and written, of cultured Dutchmen.

From the documents collected by Müllenhoff and Scherer, and from many others, it is evident that between the 8th and the 12th century the different German dialects served as vehicles of literary composition, and this, it appears, must also have been the case in the Netherlands. It may therefore be safely taken for granted that, among the *libri Teuthonice scripti* referred to in the act given in the year 1202 by the papal legate Guido for the organization of the bishopric of Liége, there were some written in the vernacular, *i.e.*, in Low Frankish, which after the subjugation of the Frisians and Saxons by the Franks was the idiom of the victors. Whatever pains Charlemagne took to raise the dignity of the German language, the practice, prevailing at the time and long afterwards, of using Latin in official documents emanating from the authorities, prevented the predominant form of speech from encroaching to any considerable extent on the other dialects. Still it is in this period that we must seek the first indications of the future victory of the Frankish dialect over the two others. And in course of time the Franks strengthened their political pre-eminence by a superiority of a different character, which, added to the first, went far to secure to the Frankish dialect the prerogative of being the universal vehicle of cultured thought, written and spoken, throughout the Netherlands. The barbarous victors could not resist the humanizing influence of the higher culture resulting from a lengthened intercourse with the Romans. And when, after a considerable lapse of time, the new idiom, thus born from Latin, began to be employed in the composition of literary productions, the influence of these writings soon made itself sensibly felt in the southern Netherlands. The inhabitants of ancient Belgium had always continued in close intercourse with their brethren in France; and the literary productions put forth in France, especially after the crusades, soon began to engage the attention of the opulent citizens of the thriving towns of Flanders and other parts of the southern Netherlands, and were diligently translated by them into their own tongue. Holland, Zealand, and Utrecht in their turn were connected with the southern Netherlands by many close ties. The language spoken in the southern and in the northern Netherlands was the same for all practical purposes; and so it happened that the French literary works and their Flemish reproductions attracted no small share of attention also in the northern Netherlands. The "Dietsch" dialect, in which the oldest and most popular works, such as *Reynard the Fox* and the works of Jacob van Maerlant, dating from the close of the 13th century, were composed, became the model speech for every one who wanted to address a larger public than that of his immediate vicinity. It was in this Dietsch dialect that Melis Stoke, an inmate of the monastery of Egmond, composed his *Rhymed Chronicle* (*c.* 1305).

From Holland and Utrecht the Dietsch dialect readily found its way farther north. What the Franks had tried to achieve in times long past was now undertaken by the counts of Holland and the bishops of Utrecht, viz., the total subjection of the northern provinces to their rule. These efforts on the part of the princes just named again made Frankish the dialect of the dominant, Frisian and Saxon the idiom of the conquered race. In this way Dietsch, *i.e.*, Low Frankish, became the predominant dialect all over the Netherlands.

At a time when laws, mutual contracts, and other official documents issued in Friesland between the Vlie and the Lauwers are still drawn up in pure Old Frisian, the treaty by which the citizens of Stavoren recognize Count Floris for their sovereign lord in 1292 is written in Dutch. The contracts drawn up by Frisians on both sides are nearly always in Frisian, even down to the close of the 15th century, though occasionally Dutch was used. In deeds of sale, contracts, &c., drawn up between 1490 and 1500, we meet with all possible shades and varieties of the Dutch dialect, which is seen to be rapidly gaining ground. Still, this substitution of Dutch for Frisian in documents of this nature by no means proves that Frisian was falling into desuetude among the country population. A good deal of course depended on the persons who were employed to compose the documents above referred to. The historian of Friesland, Gabbema, writing about 1650, bitterly laments the decay of the Frisian tongue; and even foreign writers, such as Conrad Gesner, refer to the fact in a similar way. But in spite of his lamentations Gabbema submits to the pressure of the times and writes his history not in Frisian but in Dutch. Nay, his friend Gysbert Japix, the cultivator *par excellence* of Frisian, the national poet of Friesland, wrote the introduction to his *Friesche Rijmelerije* ("Frisian Rhymes"), and many a manly poem besides, in the same language. They were by no means averse to seeing cultured non-Frisians take cognizance of their literary labours; and to satisfy this ambition, there was no other course open than to employ the language which such eminent men as Marnix, Coornhert, Roemer, Visser, Spiegel, Hooft, Huygens, and Vondel had permanently made the approved vehicle of thought and poetical utterance throughout the Netherlands, more especially after the fall of Antwerp, in 1585, had induced the most highly cultured minds of the southern Netherlands to migrate to Holland. This had been achieved partly by direct endeavours tending to the improvement of the language and the excision of all "foreign dross," partly by the creation of beautiful works of literary art, and solid contributions to history and erudition. For the language and intellectual culture of Holland had now each attained a stage of advancement where neither imperiously demanded new capabilities in the other. What thus happened in Friesland also took place elsewhere, the same or nearly the same causes bringing about the same results throughout the country.

The language of the Dutch has travelled to their transmarine possessions, without engendering a new dialect either in the East or West Indies. But a very different result might be expected if at any time their East Indian possessions should enter upon an independent career. A kind of mongrel dialect would arise, which may be seen foreshadowed in official papers and letters composed by so-called *sinjos*, or "half-breeds," in the island of Java. We may even now point to one such dialect, the speech of the Dutch settlers in the Transvaal and the Orange Territory in South Africa, who have actually begun to raise their clipped Dutch to the dignity of a written language, in which they are now composing works of general literature, and even poems, diligently editing class-books and theological treatises, and printing such newspapers as *Den opregten Afrikaander*.

Flemish or South Dutch, *i.e.*, Belgian Dutch, though very nearly allied to North Dutch or the Dutch of Holland, essentially differs from the latter in many important points of detail. In its vocabulary, its phraseology, and the structure of its sentences, it clearly betrays the influence of the French-speaking part of the nation. In a novel by a very popular Flemish author, A. C. van der Cruyssen, printed in bold type in small octavo, and numbering less than 200 pages, the present writer noted far more than 200 cases in which a North-Dutchman would have chosen quite another turn of expression. The South Dutch dialect, which after the fall of Antwerp had remained almost stationary, but which in our days has become a cultured written language through the diligent efforts of various writers of great talent, bears the evident marks of this recent emergence from a state of utter neglect on the part of cultured men, and to a North-Dutchman has an air of simple-minded artlessness and innocent naiveté.

The complexity of origin of the Dutch language is most noticeable in the case of the vowels. In the consonants the Saxon and the Frankish did not differ greatly, and the Frisian has had a much smaller influence. To the Saxon must be ascribed the dropping of the nasal before *s*, *f*, *th*, as well as before *b* and *v*, in *vyf* (five), *sedert* (sinthe, since), *muiden* (mouth), in proper names, &c. At the same time there are several words in which the *n* is preserved,—most of these being borrowed from the Frankish, as *ander*, *kunde*, *Yselmonde* in Holland (alongside of *Yselmuiden* in Overyssel), and *gans* (for which we have *goeze* in the Overyssel dialect). The *s* in the nom. plur. of the vowel stems is only partially retained: side by side there exist in Middle Dutch plural forms like *honde*, *dorpers*, *kinder*, *kinde*, *kyne*, which have almost all in later Dutch assumed either *s* simply, *s* after the plural form *r*, or *en* (originally the plural form of *n* stems), the *s* and *n* being erroneously regarded as a sign of the plural (see *infra*). On the whole the Frankish influence has been the most potent,—that of the other two tongues being only observable here and there in the terminations, or in a comparatively limited number of words and expressions. The history of the development of the language may be divided into two great periods. In the first, the Middle Dutch, the fuller forms and long vowels of inflexional and derivational suffixes and the final elements of compound words, which are preserved in Gothic and High German, have already become short and unaccented, while at the same time, through the loss of the accent, the final elements have partly lost their significance, and occasionally a notable abbreviation has been effected both in their pronunciation and their orthography. From the Middle Dutch the modern language is distinguished by a greater neglect and confusion of inflexional forms, by the presence of a large number of foreign words introduced about the end of the 15th century, as well as of a multitude of dialect and modern terms, and by the disuse or modified significations of many of the older words.

Of the Middle Dutch we have no remains earlier than the beginning of the 13th century, though Saxon and Frankish linguistic monuments go back to the 8th or 9th. Middle Dutch extends from the 12th century to 1450; then follows a transition period, reaching to 1550, from which date Modern Dutch has prevailed to the present time. In the period last named a subdivision may be made at 1865, the date of the introduction of the new spelling.[1]

In Modern Dutch there is a considerable difference between the latest and the earliest forms. The older language still preserves many words that have now become obsolete, and the style is modelled more closely on that of the classical writers. Towards the end of the 18th century the influence of Van Effen, Stijl, Bilderdijk, and others effected great changes; and while the deflexion largely increased, the Hollandsch dialect began to make itself predominant, especially in regard to the vowels *u* and *y* or *ij* (*î*). Indeed the main difference between Middle and Modern Dutch is due to the fact that the former is under the influence of Dietsch (the Flemish-Zealand dialect), while in the latter Hollandsch has the supremacy.

In the transition period the language was adulterated by a great number of bastard words and bastard forms derived from French, which obtained currency throughout Holland, Zealand, Utrecht, and the southern provinces, from the influence of the court and government of the dukes of Burgundy.

The study of the dialects and grammar of Middle Dutch has not been prosecuted far enough to allow of very detailed statements regarding them. Our principal authorities for the interpretation of the literary remains are the works of De Vries, Verwijs, Verdam, Moltzer, and others. Most of these remains are in Dietsch, as the romances of chivalry, the works of Maerlant, the chronicles and songs; others, as the *St Servaas* of Van Veldeke, are in the language of the south-east (Limburgsch). Of the mediæval language, as it was spoken in Utrecht or in the Saxon provinces[2] (the countship of Zutphen, Overyssel, and Drenthe), the only remains are in charters and similar documents. Since the Saxon, as is indicated by the conjugation of the verb, has exercised no dominant influence, and the Hollandsch on the other hand is closely connected with the Dietsch, we will only quote as an example of the language a single strophe from Maerlant's *Wapene Martyn*, with a metrical translation (hitherto unpublished) from the pen of Nicolas Beets (1880).

God, diet al bi redene doet,	God, die het al met wijsheid doet,
Gaf dit wandel aertsce goet	Gaf dit vergauklijk aardsche goed
Der menscheit gemene,	Den menschen in't gemeen,
Dattere mede ware gevoet,	Op dat zij zouden zijn gevoed,
Ende gecleet, ende gescoet,	Het lijf gekleed, geschoeid de voet
Ende leven soude rene.	En leven rein van zeen.
Nu es gierieheit so verwoet,	Maar zie nu hoe de hebzucht woedt
Dat ele settet sinen moet	Dat iedereen in arren moed
Om al te hebbene allene.	't Al hebben wil alleen!
Hieromme stortmen menscenbloet,	Hierom vergiet men menschenbloed,
Hieromme stichtmen metter spoet	En bouwt met roekeloozen spoed
Borge ende hoge stene	Burchtsloten, zwaar van steen,
Menegen te wene.[3]	Tot smart van menigeen.

The Consonants.—As regards the consonants, Dutch in the main does not differ from the other Low German languages. The explosive *g* and the *th* are wanting. Instead of the former there is a *g* with "fricative" pronunciation, and as in High German the *th* has passed over into *d*.

Nearly all the final consonants in Middle Dutch are sharpened, and the sharp sounds are graphically represented; in Modern Dutch, on the other hand, the historical development of the language being more distinctly kept in view, and the agreement observed with the inflexional forms, the soft consonant is written more frequently than it is sounded; thus we have Middle Dutch *dach*, Modern Dutch *dag*, in analogy with the plural *dagen*.

The gutturals are *g*, *k*, *ch*, and *h*. The aspirate sound of the *g* is of very early date; even in the Old Dutch psalms *g* interchanges with *h* (*weh* side by side with *weg*, just as in Gothic *fakeds* and *faginon*, Anglo-Saxon *borh* and *borges*, Old Saxon *manah* and *manag*). The *gh*, which in Middle Dutch frequently appears before *e* and *i*, served to distinguish the fricative *g* from the French *g*; in later Middle Dutch we find this object lost sight of, and the *gh* also written before *a*, *o*, or *u*. In Maerlant *ghans* and *ghene* both occur. In the 15th century the *gh* was also employed instead of *ch*, when people began to observe the etymological agreement of *ik lach* and *si laghen*, and in this way arose the spelling *ik lagh*. This indicated no change in pronunciation. That in Middle Dutch, however, an explosive pronunciation existed (in some words, more especially after *n*), as well as the aspirated pronunciation, is evident from words like *dinc*, *ginc*; this sound did not hold its ground but passed into the nasalized guttural now written *ding*, *ging*. The explosive force, however, was preserved where the diminutive suffix *je* followed immediately after *ng*, as well as before *lijk* and some other affixes, and it is now expressed by *k* (*koninkje*, *jonkman*). In combination with *s*, *g* became *k* (*speeksel*, *fluks* from *vlug*). So also in intensive verbs like *bukken*, *knikken*, where the *k* arose from an explosive *g* before *j* of the suffix, and was doubled after the short vowels. In non-intensives, as *liggen*, *zeggen*, where the *g* was aspirated, that letter was doubled in the same way from *gj*. The Dutch *g* is besides sometimes derived from the common German *g* (*gans*, *dag*); sometimes it is the Old German *h* at the end of a word, between vowels, or after liquids (*hoog*, *zuig*). Sometimes it is a survival of the compound *gw*, and exists along with a form in *w*, as *spugen*, *spuwen*. *G* arose out of *j* in *kruisigen* and other verbs in *-igen*, just as in Anglo-Saxon. In the beginning of some words in Middle Dutch *g* passed into *j*, as *jonst* for *gonst*, while Modern Dutch again has *gunst*. The passage of *g* into *j*, and *i* after *a* or *e*, and before a vowel, is found both in Middle Dutch and Modern Dutch: *segel* becomes *zeil*, *gezegd gezeid*. In some words the explosive *g* has passed into *k*; in others, and indeed the majority, the *k*, both in the body of the word and as an initial and a final letter, is the common Low German *k*. After short vowels the *k* of the compound *kj* was doubled, and the *j* dropped off after producing "umlaut" (*dekken*, *wekken*). An original *k* remained as an initial letter before *n* or *r* in *kring*, *knijpen*, &c., alongside of which we have *ring*, *nijpen*, &c., in which the *k* passed into *h* and then disappeared. The *k* also remains undisplaced in the diminutive *ken* (*Taal- en Letterbode*, ii. 105). Before *t*, *k* became *ch* in *zucht* (*ziek*), *wacht* (*waken*).

In Middle Dutch *c* and *k* are interchanged without distinction of sound. *C* is used before vowels except *e* and *i*, and before *l*, *n*, and *r*, and at the end of a word (*cop*, *cleen*, *cranc*). After *n* sometimes *ck* is also employed (*ganc* and *ganck*). In later Middle Dutch the *ck* is more frequent; in other cases *k* is common (*kint*, *kerke*). Frequently we find *k* as well as *c*,—never, however, *c* before *e* or *i*, except in French words, where *c* had the sound of *s* (*citroen*). Sometimes *ch* (as in *cheins*, *chessen*) occurs as well as *c* (*ceins*, *cessen*), where *ch* represents the palatal sound of the *s*, which in the more modern language is rather represented by *sj* (*korsjet* and *corset*, *sjokken* and *sokken*, &c.). The doubling of the *k* was indicated by *ck* (*decken*), while *qu* was the ordinary for *kw* (*bequame*, *quedelen*, *quene*), in Modern Dutch *dekken*, *bekwaam*.

In the beginning of words *h* has lost its original aspirate sound and become a mere breathing, and consequently it has often dropped off both before other consonants and between vowels: thus *hring* becomes *ring* (as early as in the Old Frankish psalms), *slahan* becomes *slaan*, *vliehen* in Middle Dutch *vlien*. In some of these words a *d* has been afterwards inserted out of a supposed analogy with weak verbs, as *e.g.*, with *belien*, *belîde*; where Modern Dutch has *vlieden*, *geschieden*, Middle Dutch had *vlien*, *gescien*; even in Middle Dutch, indeed, *geschiede* (Modern Dutch *geschiedde*) was an alternative form with *geschach*. In the dialects *h* is frequently prefixed improperly (*harm* for *arm*, &c.). At the end of words the *h* occasionally kept its fricative sound (*hooch*, *geschach*, *tooch*), as the *ch* shows. In the verbs *tiegen* (*tiuhan*) and *tijgen* (*tîhan*), which sounded *tien* and *tijen* in Middle Dutch, the *g* has been afterwards introduced into the present stem, probably through the similarity of the sound of the *h* (*ch*) in *tooch* with the *ch* sound which *g* acquires as a final consonant, and through the *g* of the plural preterite *togen*. *Ch* did not remain in the preterite of all verbs in Middle Dutch: *vlien* has *vloe* as well as *vlooch*; alongside of this, however, there is an infinitive *vlieghen*, also with a preterite *vlooch*. From the compound *hw* the *h* soon dropped off in the Middle Dutch (*walrisch*, *wie*, *waar*), not, however, where the *w* was vocalized (compare *hui* with *wei*, *hoe* with *woe* in the Saxon; in this last case *woe* passes further into *boe*). Before *t*, *h* retains its aspirate sound, as in *vlucht* (*ch* pronounced as the German *ch* without *i*); and *g* also before *t* takes the sharp sound of *ch*, although this is not represented by the spelling in substantives in *-te*, as *gebergte*, adjectives in *-lijk*, as *genoeglijk*, and in the conjugation *hij ligt*. The *ch* in *sch* (pronounced as *s*: *vleesch*, pron. *vlees*), derived from the Middle Dutch *sc* (*sk*), is a mere orthographical convention; as an initial consonant *sch* is now pronounced *sg* (*schip*), but in the Saxon dialects and in Frisian the old sound is preserved: *skip*, *skool* (*schola*). *Sculan* has already in Middle Dutch changed the *sc* into *s*, and in Modern Dutch it appears as *z* (*zullen*). *Ch* before *t*, except where it stands for *g*, is derived from an *f* (compare *gehucht*, *kocht*, *sticht*, alongside of which we have words in which the *f* has been retained, as *stift* and *bruiloft*, Middle Dutch *brulochte*). Before *s* the guttural is assimilated or syncopated: examples are *bus* (High German *büchse*), *vos* (*fox*), *zes*, *deesem* (*deegsem*).

There is in Dutch a *d* which corresponds to the English *th* and

[1] For information regarding the results furnished by an investigation of the proper names, see Professor H. Kern in *Taal- en Letterbode*, part iii. p. 275.
[2] See Sloet, *Oorkondenboek van Gelre en Zutphen: Taalkundige Bijdragen*, i.
[3] *Van Jacob ende van Martine*, ed. E. Verwijs (Bibliotheek van Middelnederl. Letterkunde, 27).

the High German *d*; it is formed by the tongue and the upper row of teeth; the *d*, on the other hand, which is like the English *d* and the High German *t* is formed by the tongue and the roof of the mouth (or the gums above the teeth).[1] In the Old Frankish psalms *ðferde* and *ðferthi* still exist side by side, but even then the distinction was probably not a great one; in Middle Dutch *th* has become *d*, or the *th* is retained as a mere orthographical convention. While in the psalms a distinction is still preserved between *th* and *d* as a final letter, inasmuch as *d* passes into *t*, but *th*, or *d* derived from *th*, remains, *d* at the end of words always changes in Middle Dutch into *t* or into *dt*. Where, however, the *d* had remained before vowels in the conjugations of the verbs or the inflexions of the nouns, the *d* was in several words afterwards restored, although the sharp sound was preserved. In other instances the sharp sound of the nominative affected the oblique cases, and all forms acquired the sharp sound which then remained in Modern Dutch (*gezant*, *gezanten*; *rit*, *ritten*; *verwant*, *verwanten*); and the same change took place especially in indeclinable words, as *want*, *met*.

In Middle Dutch a *tenuis* or spirant before *d* changes it into *t*; but whether it be owing to difference of dialect or to inaccuracies of orthography, many instances may be pointed out where this does not occur; thus we find *nochtan*, *ontaen* (for *onttaen*), but along with these also *nochdanne*, *ontdaen*. In Modern Dutch this is not the case, but a number of forms are due to the same principle, especially in compounds of prepositions with the article (*metten*, *metter*), while in the conjugation of weak verbs also the suffix *de* turns into *te* after sharp consonants (*legde*, *lachte*, Middle Dutch *loech*). On account of the sharpening of the *d* as a final letter, no *d* is ever found before the suffix *-nis*, and *t* even occurs before an afterwards inserted *e*, as in *beeltenis* (the same is the case with *f*, *b*, *v*, as *vergiffenis* for *vergifnis*).

After *o*, *oe*, or *ui* the *d* passes into *j*, though in Middle Dutch instances seldom occur (Middle Dutch *ruden*, Modern Dutch *ruien*; Middle Dutch *roden*, Modern Dutch *uitroeien*); sometimes it drops out (*kwede*, *kwee*). The spoken language goes much farther than the written in this use of *j* for *d*; thus *dooje*, *goeje* are written *doode*, *goede*. In like manner the spoken language has changed *d* into *w* after *au* or *ou* derived from *al* or *ol*; thus we find the pronunciation *ouwe*, *gouwen*, *kouw*, with the spelling *oude*, *gouden*, *koude*. In the adjectives *ouwelijk* and *kouwelijk* the *w* has become established. Except after vowels in verbs where *h* has dropped out, whenever there is no preceding consonant, and an *r* follows either immediately or after an *e*, *d* is inserted after *l*, *n*, *r* (*kelder*, *zwaarder*, *helder*, *diender*, *donder*), an insertion which is less common in Middle Dutch (*helre*, *solre*, *donre*; also, however, *dondre*). At the end also of words we often have a paragogic *d* after *n* where the Middle Dutch kept the *n* as the final letter (thus *iemand*, *arend*; Middle Dutch *ieman*, *aren*); after sharp consonants *t* is added, as *gedrocht*, *burcht*, *borst* (High German *bursche*), and also in *mijnent*, &c.

D is frequently syncopated as a penultimate consonant before *s*: *thans* for *thands*, *volgens* for *volgends*. *Asem*, *wasem*, perhaps, have not dropped the *d* (*th*) before *s*, but have changed *th* into *s*. While the final *t* has partly grown out of *d*, it is partly also the common Low German and English *t* (*tal*, *laten*, *haat*). Between *s* and *r* in words derived from the Romance tongues a *t* is inserted owing to the common German dislike to *sr* (*stroop* from *sirop*); after *n*, and also before the suffix *-lijk*, the introduction of *t*, which was frequent in the 16th century, is less and less heard, and on this point the written speech is far before the spoken (*wezenlijk*, *eigenlijk* are frequently pronounced *wezentlijk*, *eigentlijk*; *ordentelijk* alongside of *ordelijk* at an early date has acquired the *t*, and afterwards an inserted *e*, at the same time modifying its signification). In the dialects (Limburg, Brabant, Utrecht) the final *t* after consonants and vowels is frequently dropped: *hij heef* (*heeft*), *nie* (*niet*). The compound *ts* serves in words borrowed from the French to represent the Dutch pronunciation of the French sound *ç* (*fatsoen*, Fr. *façon*). While the present language, both in orthography and pronunciation, makes a distinction between *s* (as in the English *sound*) and *z* (as in the English *hazel*), the Middle Dutch had only *s* (though in the later MSS. *z* begins to appear), and Frisian is still in the same position. Before a vowel or *w*, *s* has for the most part passed into *z*, except in those words in which it is followed either by a long or short vowel succeeded by *s*, or by a short vowel before *s* or *k*; or *z* was sharpened into *s* by a *t* from the preposition *te*: *zoel*, *zwak*, *zitten*; *sissen*, *suizen*, *sokken*, *samen* (from *tsamen* for *te zamen*). In foreign words the *s* usually remains (*saluut*, *soldij*). Contrary to the pronunciation, *z* is written in *zestig* and *zeventig* (pronounced *sestig*, *seventig*, and in dialects *tsestig*, *tseventig*).[2] The *z* in the middle of a word, after a syllable which originally had no accent, has passed into *r*: *generen*, *bevrooren*; at the same time we have the forms *genezen* (to heal), *bevrozen*, and in the Middle Dutch *vroos* along with *vroor*, and *kozen* with *koren*. In many cases the meaning has been modified.

Prothesis of *s* occurs in *smoel* for *moel*. Such forms as *slink* and *link*, *snebbe* and *nebbe*, *zwenken* and *wanken*, go back to older forms, and are thus probably doublets of much older date than the breaking off of the German languages from each other.

As in English so in Dutch *b* is the undisplaced German medial. At the beginning and in the body of a word it has the same sound; at the end it is pronounced as *p* (see p. 86). In Middle Dutch for the most part *b* was followed by a vowel (Middle Dutch *webbe*, Modern Dutch *web*); this vowel fell away in Modern Dutch, but the *b* remained in the written language. Wherever the *b* represents *bj* it is doubled, just as after a short vowel (*krab*, *krabben*). So, too, frequentatives have *bb* (*krabbelen*, *kibbelen*, with which compare Modern Dutch *kijven*, Middle Lower German *kibben*; *stribbelen* side by side with *streven*; compare also *hebben* and *heeft*, Old Frankish *libban*, Dutch *leven*). After *ă* or *ŏ* + *m*, *b* fell away both as a middle letter and as a final consonant; but this is not as yet general in Middle Dutch; alongside of *crom*, *omme*, we find *cromp*, *ombe*, while in Modern Dutch we always have *lam*, *krom*, *dom*, *om*. In substantives ending in *m* with a preceding long vowel, wherever the diminutive particle *je* is appended, a *p* is inserted (*kruim*, *kruimpje*; *bloem*, *bloempje*); but this does not take place after an imperfect vowel where an *e* is inserted (*kam*, *kammetje*). As in English the *p* has not been displaced, and it has the same sound (*paard*, *post*, *pink*, *lap*).

For the English *f* as an initial letter (*cf.* Sweet, *Hist. of English Sounds*, p. 78), Modern Dutch as well as Middle Dutch has *f* and *v*. In the body of a word the *f* passes into *v* (= *v* in English *lover*), or is doubled after short vowels (*leef*, *leven*; *plof*, *ploffen*). At the end and also before consonants after vowels, *v* becomes *f* (*hoofd*, Middle Dutch *hoved*; *af*, Middle Dutch *ave* and *af*). Verbs in *-elen* have *f* before *e* (*schuifelen* from *schuiven*).

F (*v*) is the common German *f*, and accordingly interchanges with *th*, as in *ofte* (Got. *aiththau*) = English *or*; but *of* (Got. *iba*) = English *if*; *veel* (*filu*). Before vowels and *l*, *f* is sometimes preserved in pure German words, while in others of the same sort *v* appears (*frisch*, *versch*; *flink*, *vlak*; *fel*, *vechten*); so also in the Old Dutch psalms we find *vater* along with *fader*, while in Middle Dutch likewise a similar variation prevails. Usually the precedence of a sharp consonant in Middle Dutch causes the *v* to become *f* (*mesfal*, *ontfaen*; *cf.* *val* and *vaen*; but also *mesval*, &c.).

The combination *ft* has in Dutch passed into *cht*, but it appears in the dialects, and was more frequent in Middle Dutch (*verkocht*, *hecht*, *sticht*, *achter*; *verkoft*, *heft*, *stift*, *after*). On the other hand in the psalms and the *Glossæ Lipsianæ*, and also in dialectic charters, we find occasionally *ft* for *ht*: *druften* (*druhtin*), *sufte* (stem *sûk*), *eendraftig* (for *eendrachtig*).

The liquids are unchanged, except *m* and *n* in inflexional terminations. In certain other cases *l* interchanges with *n*: for example, *slak*, High German *schnecke*; *Schevelingen* (17th century), *Scheveningen*, &c. By the *l* sound a preceding *a* or *e* is turned into *o*, as *overtollig* (*tal*); in some instances *ol* changes into *ou*, *e.g.*, *goud*, *oud*, *zout*; if the *o* before *e* passes into *u* (see under *o*), then the solution does not take place (*gulden*; Middle Dutch *hulten*, Modern Dutch *houten*; *menigvuldig*). In Middle Dutch we have *ul*, *ol*, and *ou* side by side. *M* remains with stem vowels, in the suffix *-ma* (even where it becomes *n* in High German), as *bloem*, *bezem* (High German *besen*), and in *hem*, dat. sing. 3d pers. pron. In other cases it passes into *n* in inflexional terminations; *den* (High German *dem*), *geven* (1st pers. plu. pres.); *mb* becomes *mm*, and consequently *m*. In *maar*, *m* represents *nw* (*nware* for *ne ware*). In *drempel*, *m* is inserted.

The *r* is of very various character. In the first place we have the dental *r*, agreeing with the Italian *r* in *ragazzo*—for example, *raad*, *rust*, *hart*; and secondly we have the guttural *r*, only heard in words which had *hr* in Old German (*ring*, *ros*, *reuzel*). As the former is a difficult sound for many Dutchmen, especially for those of the Saxon district, the guttural *r* is used instead of it. In the Saxon districts we find, besides, a very strong consonant called by Sievers the "cerebral" *r* (*e.g.*, *hard*, *worst*, *marsch*). Although it is not distinctly audible, a practised observer can hear it, just as in the English *letter*, *hard*.[3] The *r* derived from *z* belongs to the first class. Through the influence of the *r*, short vowels are lengthened in Middle Dutch (*aerch*, *aerbeid*, for *arg*, *arbeid*). Transposition of the *r*, both before and after the vowel, is frequent in Middle Dutch and in Modern Dutch: *godsvrucht*, *nooddruft*, *dertig*, *barnen*, *kersten* (*krist*). Before *r*, *n* was elided in Middle Dutch (*mire* for *minre*, &c.); before *m* it was assimilated (*onmate*, *ommate*), and before *b* it passed into *m* (*omberaden*); but in Modern Dutch this change does not take place.

In some words beginning with a vowel, *n* has been prefixed through the influence of the declined article, the possessive pronoun, or the preposition *in*: thus *naarstig*, Middle Dutch *naernst*, grew out of *in ernst*; *navonds* from *avond*; *noom* (17th century) out of *min oom* (Modern Dutch, however, has *oom*). As regards the preterites *dacht* and *bracht* along with *denken* and *brengen*, which appear in Middle Dutch, no certainty has been attained. The *n* in this case

[1] Compare on this point Kern in the *Taalkundige Bijdragen*, i. 175.

[2] This dialect *t* has probably come from the Old Saxon *ant-* (*hund*), which stood before *zeventig*, *tachtig*, *negentig* (dialect *tnegentig*). From these words the sharpening of the initial consonant has spread to the other numerals: *veertig* and *vijftig* are pronounced *feertig* and *fijftig*.

[3] Kern, *Taalk. Bijdr.*, i. 21

may have dropped out, as in the other German languages, while before *ch* the *â* was shortened to *a*, which like *a* in other cases before *ch* passed into *o* (hence, in the spoken language, *brocht*, *docht* exist side by side with *bracht*, *dacht*), or the suffix may be appended to the non-nasalized stem. That each Germanic language may in these cases have gone its own way is evident from the Anglo-Saxon, where such a form as *gipohta* indicates an older form *gipanhta*.

Vowels.—As early as the Middle Dutch period, the final vowels of the inflexions, *i* and *u* as well as *e*, had for the most part lost their sound. The *i* which gave rise to the umlaut was in great measure elided in some words before the umlaut period, in others later. The number of words in which no umlaut occurs is increased; in some words it is absent, even while *i* is retained or has passed into *e*; this depends on the greater or less sensitiveness of the dialect for the umlaut:—*laat*, comparat. *later*; *beter*; Middle Dutch *hoved*, Modern Dutch *hoofd*; *teugel*; Middle Dutch *hoge*, Modern Dutch *verheugd*, *heug*; *bleu[de]*, *bloode*; *edel*, *adel*. Analogy has also played a great part in the modification of formations (*vast*, *vaster*, along with *vesting*, *vesten*; *macht*, *machtig*, along with *amechtig*; *hand*, *handen*, *handig*, along with *behendig*).

A has in open syllables the sound of English *a* in *father*, in closed syllables that of the English *a* in *as*; when there is a perfect sound in closed syllables the spelling is *aa* (*jaar*), in open syllables *a* (*maken*); in *bad*, *nat*, *a*=*ă*. An original short *a* and a long *a* in open syllables are even in Middle Dutch pronounced alike, and may be rhymed with each other (*dagen*, *lagen*, a rhyme which was not permitted in Middle High German). In the Saxon dialects *â* was expressed by *ao* (some words came in this way into Dutch with *oo* for *ao*, as *moot*, a slice of fish), and *a* or *â* in the Frisio-Saxon districts passes into *è* before *r*, as *jèr* (*jaar*). Middle Dutch preserved *a* in several words where in Modern Dutch it passes into *e* before *r* (*arg*, *erg*; *sarc*, *zerk*; *warf*, *werf*); in others, as *aarde*, *staart*, *zwaard*, the Middle Dutch had *e* and *a* (*erde*, *stert*, *swert*, *swart*, *start*; Modern Dutch *zwaard*, *staart*). In foreign words, likewise, *e* before *r* has become *a*; *paars*, *perse*; *lantaarn*, *lanterne* (in the dialects *e* is still frequently retained). In Middle Dutch *a* before *l* sometimes, but not usually, becomes *o* (*overtallich* side by side with *drievoldich*); the passage of *a* into *o* before *ch* also occurs (*ambocht*, *brocht*, &c.).

In the preterite singular of the first conjugation of strong verbs the *a* is always retained in Middle Dutch, and has not passed, as in Modern Dutch, into *o* through the influence of the plural (Middle Dutch *ic vant*, *bant*, *wi vonden*, *bonden*, Modern Dutch *ik vond*, *bond*, &c.). It is also retained before *l* and *r*, *e.g.*, *barg*, *starf* (though side by side with these we have *berg*, *sterf*), where Modern Dutch has *borg*, *stierf*, *hielp*, &c. In *ic sel*, *hi sel*, the *e* came from the plural *wi selen*, whereas the present form is again *ik zal*. A similar influence of analogy is observable in the *o* for *a* in the verbs *scheren*, *zweren*, and *wegen*, which now have *schoor*, *schoren*, *zwoor*, and *woog*; Middle Dutch *scar*, *scâren*, *wach*, &c., in which the *a* has been displaced by the *o* of the preterite participle. In the conjugation of the verbs Middle Dutch has *e* where Modern Dutch has *a* (*geslegen*, *dregen*, Modern Dutch *dragen*). In *geheven* alone *e* has been kept. In the 3d pers. sing. forms like *ontfeet*, *geet*, *steet*, occur in Middle Dutch, along with *ontfaet*, *gaet*, *staet* (Modern Dutch *ontvangt*, *gaat*, *staat*). In participles of verbs in the Germanic *-jan*, Middle Dutch has in some cases the original form without the umlaut, where Modern Dutch, through the analogy with the present, has the umlaut: Middle Dutch *becant*, *genant*, *gesant*; Modern Dutch *bekend*, *gezonden*. This last arose through confusion with the participle of the verb *sinden*, which had become obsolete, *gezant* continuing to exist as a substantive.

In substantives and adjectives we find *e* (derived from *a* through *i*) along with the unchanged *a* (*gretig*, *graag*, from *gradig*; *hekel*, *akelig*; *edel*, *adel*).

The sound of the *e* derived from *a* does not differ from that of an original *e*, or of an *e* derived from *i*, as they appear in open syllables (*vele*, *steden*, pronounced as *a* in English *name*). If the *e* derived from *a* or *i* or the original *e* occurs in closed syllables, it has a short sound, as in English *men*, *end*, Modern Dutch *stem*; while before *r* it is pronounced almost as the *e* in the High German *Herr*. The *e* in closed syllables with a full sound (as English *a*; Sweet, *ei*) is spelled *ee*: *veel*, *week* (*e* from *i*), *beek*. The sharp, clear *ee* which comes from *ai* before *r* and *w*, followed or not by *i* or *j*, is indicated by the same letters in both open and closed syllables: *eer*, *sneeuw*, *zee*. Before other consonants followed by *i* or *j* we always find *ei*: *verbreiden*, *heil*, *leiden*, *-heid*, Middle Dutch *-hede*, (hence in Modern Dutch plural *-heden*). If no *i* or *j* followed, then *ai* became *ee* (*leed*, *breed*). While in the Saxon dialect of Guelderland and Overyssel *ai* is always *ee* except when *i* or *j* follows, an *ei* often occurs in the western dialects, which has not arisen through the umlaut; in some places it is even pronounced as *ai* where the written form has *ee*: *Yselstein* (proper name), *gemein*, &c.; Modern Dutch *steen*, *gemeen*.

Sometimes the *ei* has come from *ag* or *eg* through vocalization of the *g* to *j* (*meid*, *maged*; *zeil*, *segel*); sometimes it is from the French *ai*, *ei*, *é*, *ée* (*fontein*, *hakkenei*, *balein*, &c.). In individual cases *ei* stands where the Middle Dutch has *e* before *n*: *deinzen*, Middle Dutch *denzen*; *peinzen*, Middle Dutch *penzen* and *peizen*; sometimes it is the result of an *i* following: *heinde* (*hende*, *handi*).

Since the umlaut has not been equally effective in all dialects, being even wanting where *i* has passed into *e* or dropped out, we find words with *ee* side by side with words with *ei*. Thus, Middle Dutch has *reene*, *kleene*, where Modern Dutch, through the influence of another dialect, has *rein*, *klein*. In Modern Dutch *ee* frequently exists side by side with *ei* (*verbreeden*, *verbreiden*; *heelen*, *heil*); in this case there is usually a differentiation of meaning. The dialect of North Holland turns *ee* into *ie* (*biest*, *stien*, *bien*, for the Dutch *beest*, *steen*, *been*); and this explains some words with *ie* in the spoken language: for example, *tientje* (*twig*), *driegen* (*dreigen*)—17th century.

The letter *o* represents three sounds:—(1) the short sharp *o* and (2) the short soft *o*, the former like the *o* in English *not* and French *soldat* (Dutch *bod*, *belofte*, *tocht*, *kolf*), the latter like the French *o* in *ballon* (Dutch *vod*, *ploffen*, *ochtend*, *rol*; Middle Dutch has frequently *u*, as *uchtend*); and (3) the full *o* as in French *noter* (Dutch *kolen*, *sloten*, *verloren*). The sharp clear *oo* has almost the same sound as the full *o*; in some dialects (among others the Saxon) it is pronounced as double *oo*, in others (Flemish and Hollandsch) somewhat like *au*. In Middle Dutch, the lengthening of the vowels was frequently indicated by *e* (before *r* sometimes by *i*, as in *oir*); hence *ae* for *â*, *oe* for *ô*. Where *oe* occurs in the modern language, it has the sound of *u* (pronounced like the *u* in High German, and answering to the Gothic *ô*, Old High German *uo* from *ua*), which in Middle Dutch was frequently represented by *ou* (*au*; Sweet, p. 6), still so pronounced in West Flemish and the Groningen dialects,[1] though before labials and gutturals it was expressed by *ue* and *oe* (*boue*, *souken*, and also *guet*, *vuerin*, but usually *goet*, *socken*, *boec*). The Saxon dialects still preserve in these cases an *ô* sound which agrees with the Middle Dutch *oe* (*bôk*, *môder*); in two words—*romer* (*roemer*, however, is also used) and *spook*—*o* has passed from these dialects into Dutch. As the *u* (Old German *û*), which in the modern tongues has passed into *ui* except before *r* and *w*, retains the *u* sound in the Saxon districts, some words have come into Dutch from these dialects, being written with *oe* from the similar sound of *oe* (from *ô*) and *ua* (*snoet*, *boer*, *soezen*, alongside of which are Frankish words, *snuit*, *suizen*, &c.). Except in the Saxon dialects, which are more sensitive to the umlaut, the modification of *oe* by *i* seldom occurs (Modern Dutch *groen*, *zoet*, *zoeken*, but Saxon *gryn*, *zyt*, *zyken*,—*cf.* Sweet, *History of English Sounds*, p. 6). In the Groningen dialect, *öi* in *zöiken* is umlaut of *ou* (*oe*=*ou*; *mouder*, Modern Dutch, *moeder*). Forms in Modern Dutch as *reukeloos*, *beuk*, *geneugte* alongside of *roekeloos*, *boek*, *genoegen*, show the *oe* changed before *i* in *eu*, when *oe* was still pronounced *ô*; they have thus not umlaut of *oe* but of *ô*.

In French words which are completely naturalized long *o* becomes *oe* (*façon*=*fatsoen*).

In Middle Dutch, *o* in some cases occurs instead of *oe* (*u*) in open syllables (*gode*, *moder*). This *o* for *oe* rhymes with *o*; rhymes like *gode* (*goede*) and *gode* (Goth. *Gups*), *stoect* (*stookt*) and *soect* (*zoekt*), are repeatedly introduced. Thus, too, *oe*=*ô* from *au* and *oe*=Goth. *ô* and *û* rhyme with each other.

The Modern Dutch *oo* from *au* is represented by *oo* both in open and in closed syllables. The full clear *o* from the German *o* or *u* is expressed in closed syllables by *oo*, in open syllables by *o*: *kool*, *kolen* (English *coal*), *stroom*, *stroomen*. The umlaut of the soft and sharp *o* (*eu*=*ö* in High German *schön*) is rare in Middle Dutch: Modern Dutch *vleugel*, Middle Dutch *vlogel*; *keuken*, *kokene*; *verheugen*, *hogen*. Side by side with some cases where the umlaut occurs the form without the umlaut is also retained in Modern Dutch (*leugen*, *logen*), sometimes with a difference in the meaning (*spreuk*, *sprook*; *heusch*, *hoofsch*). In the dialects the area of the umlaut is wider.

Oe before *m* and *oe* and *oo* before *ch*, especially in monosyllables, have changed into *ŏ*: *bloem*, *blom*; *zoeken*, *zocht*; *roepen*, *rocht* (whence *berucht* and *gerucht*); *koopen*, *kocht*. As in *rocht*, *gerucht*, the short soft *o* from the Middle Dutch has in many words passed into *u* (Middle Dutch *connen*, *gonnen*, *joffer* (*jonevere*); Modern Dutch *kunnen*, *gunnen*, *juffer*); sometimes both forms have continued in use: *snorken*, *snurken*; *plonderen*, *plunderen*; *veelvoudig* (*veelvoldig*), *menigvuldig*. In like manner, the forms *u* and *o* from *ŭ* exist side by side (*droppel*, *druppel*; *gort*, *grut*), as also *u* from *e* before *l* (*spul*, *spel*).

The *û* had still the Old German pronunciation in the Old Frankish psalms, and this was probably the case also in the oldest Middle Dutch. In Maerlant's style, however, it had already acquired the sound of the French *u* in *nature*: thus, Maerlant rhymes *nature*, *cure*; *gure*, *pure*; *sure*, *creature*. In the dialects we still hear the old sound *û* and not *y* (Sweet, p. 6), *e.g.*, Guelders dialect *zur*, Dutch *zyr*. Under the influence of the Hollandsch in the 16th and 17th centuries, the *û* has passed over through *öi* into *ui*

[1] See De Bo, *Westvlaamsch Idioticon*, 1804.

(pronounced nearly as the High German *eu*, English *oy*), except before *r* and *w*, where the *û* keeps the sound *ü*. Middle Dutch *oi* also passed into *ui* (*sloier, sluier*), just as *wi* after consonants: *hui* (*hwei*), *duit* (*thweit*). From the common German *û* thus arose the Middle Dutch *u* in *duve, dusent, mues*, and in the verbs *sugen, supen, luken*, corresponding to the Modern Dutch *ui* in *duizend, duif, muis, zuigen, zuipen, luiken* (in which the High German has *au*, Old High German *û*). The words in which the Saxon has the umlaut have in Middle Dutch likewise *u*, but in Modern Dutch *ui*: Middle Dutch *budel, surer, lusteren*; Modern Dutch *buidel, zuiver, luisteren*; Saxon *büdel, zürer, lüsteren*, &c. In Modern Dutch *moel, snoet, knoest*, &c., have *oe* along with forms in *ui* (*muil, snuit, knuist*). In the Saxon dialect, *oe* (*u*) and *ü* occur in some cases in the oblique cases (*knoest*, pl. *knüste*). The same thing takes place in the strong verbs, which in Anglo-Saxon have *û*, in Old High German *io* (Modern Dutch *buigen*, Anglo-Saxon *bûgan*, Old High German *biogan*); the Saxon dialects have here sometimes *ü* (*bügen, slüten*), sometimes *oe* (*kroepen, schoeren*). Old German *iu* passes before the suffix *a* into *eo, io*, and finally in Middle Dutch and Modern Dutch into *ie* (*dier, bieden, kiezen*). Before *r* Middle Dutch has the *û* frequently along with *ie* (*onghiere, ongehure*); Modern Dutch *duur* along with *dierbaar* (Belgian *duurbaar*), *vuur* (from *viwar*) along with *vier*. Sometimes *ie* changes into *e*: *deemoedig*, (*diemoedig, dienen*), *dre* as well as *drie, heden* and Modern Dutch *huiden* (Cosijn, *Noord en Zuid*, i. 219). In some cases *ui* comes from the degradation of *ai* or *i*, especially in words borrowed from the French (*fruiten*, Fr. *frite*, Lat. *frictare*; *fornuis*, Fr. *fornaise*, Middle Dutch *fornays*).

If an original *eu* is followed by *j, i*, or *u*, then *eu* becomes *iu*, Middle Dutch *u*, Modern Dutch *ui*: *beduden, dutsch, luden*, Modern Dutch *beduiden, duitsch, luiden*, along with which, however, exist the forms *dietsch* (derived from *diet*), *lieden, bedieden*, which must be ascribed to the influence of the Flemish and Zealand dialects. To this influence must also be assigned the *ie* before *r* and *l* in strong verbs of the first class which originally had *a* (*stierf, hielp*, &c.), while the reduplicative verbs in the preterite have *ie*, just as in Middle German and Modern German it is produced through contraction, according to analogy, and passes before double consonants into *ī* (*sliep, ving*).

Ie further indicates a lengthened *i* and *ī* in syllables on which the chief accent falls (*fabriek, fabrieken*), while *i* is used for short *i* and in unaccented syllables, or, it may be, for short *i* in closed syllables (*fabrikant, sikkel, midden, binden*). The long *i* is indicated by *ie*, where *ij* (which was originally the sign of *ī*, and in Middle Dutch and the dialects is still so pronounced) passes over into *ai* and *ei* through dialect influence, but retains the written form *ij*: *sijsje* (Eng. *siskin*), *partij, pijn, ijs*, &c. In some words in which the original *i* sound has been preserved, *ī* is also expressed by *ie* (*gerief, wierook, kiem*, &c.).

The sounds in Dutch which are the most difficult for foreigners to pronounce are the aspirated *g*, the *ch* after vowels, the *sch* before vowels, and *r*. This last letter is pronounced by the Germans either as *w* or as *f*, and they also usually confound *b* and *p* as initial consonants. Of the vowels, the most difficult is the *ui*, which is almost never pronounced with perfect accuracy by a foreigner. The *ij* and *ei* are generally sounded too closely like *ai*.

Grammar.—In Middle Dutch the different noun-stems are divided into two principal classes:—(1) a combination of the various vowel stems, which have more or less lost their individual characters, though here and there, in particular expressions and dialects, the difference of the stems makes itself apparent; and (2) a consonantal declension, that of the *n* stems—the other consonantal stems having been assimilated partly to the *n* stems and partly to the vowel stems. Gradually, however, the two classes begin to be confused with each other; thus in the vowel stems *s* completely ousts the *e* as a sign of the nominative plural, and consequently acquires a plural significance as well as *en*, so that (with some exceptions, like *graaf, hertog*, &c., and adjectives employed as substantives) *s* and *en* are in Modern Dutch used indifferently as plural terminations, the selection mainly depending on the nature of the foregoing consonant. In the words already mentioned—*graaf, heer, vorst*, &c., and in compounds like *gravenkroon, hanenkam*, the genitive termination *en* is preserved. The *s* of the genitive is employed in feminines whenever the qualified word stands after it, as *moederskind*; with this exception, the *s*, especially in the spoken speech, is almost entirely superseded by the periphrasis *van den*; *des heeren* becomes *van den heer*, the two forms having the same meaning, which is not the case in High German.

Neuters have in the plural the same inflexion as masculines; but they more frequently than these have the plural termination *-er*,—corrupted, however, to *-ers* or *-eren* (*kind, kinders* or *kinderen*), no plural termination in *-er* alone being now recognized. Some words, which in the singular had a parallel form with another termination, have the plural according only to one form: *stad* and *stede*, for example, have the plural *steden*. In some cases (as *schip*, plur. *schepen*; *smid*, plur. *smeden*) the plural form has not yet been explained. In the dialects, especially in the Saxon, the older forms, more particularly of the plural, are still in force; and there is still a certain difference between the several stems: *boom*, pl. *beume* (*bōme*); *gast, geste*.

The old genitive and dative forms are only retained in individual expressions, as *den lande, des huizes*, &c.; in all other cases the genitive and dative are expressed by the prepositions *van* or *aan*. The accusative is like the nominative, while in the neuter the dative also without *aan* is like the accusative. From the similarity of the dative and accusative masculine and neuter of the article great similarity has arisen in the government of the prepositions; it is only in a few expressions (*metterdaad, van goeden huize*) that the original cases have been maintained; in all other instances *voor, van, door, met*, &c., govern the accusative. In Middle Dutch this confusion had not advanced so far. The dropping of the *n* at the end after vowels—a special peculiarity of Hollandsch—has given rise to great neglect of the genders in the spoken language; and this confusion has even made itself felt in the literary style, though it is kept in check by the Saxon dialects, which are strongly conservative in this respect.

The singular of the second personal pronoun *du* (still used in Middle Dutch) has been displaced by the plural *gij*, which was originally used out of politeness; and *U* derived from *Uwe Edelheid* is now employed as the honorific. As dative and accusative of *gij, jou* is familiar in the spoken language (Eng. *you*, Goth. *jus*). The third person has, as in English, for the masculine *hij* (*hī*), thus diverging from the High German; the neuter is *het*. The form in use for the neuter article also sounds *het*; this *het* is due to the fact that the abbreviation *'t* for the pronoun *het* and for the article *dat* was the same,—a coincidence which led to an erroneous identification. In Middle Dutch the reflexive pronoun was *hem*; Modern Dutch (agreeing in this with the Old Frankish psalms) has *zich*.

Though the strong verbs and the various classes of weak verbs are always kept separate, many verbs have become through association of ideas almost unrecognizable. Strong verbs have become wholly or partially weak: *bannen, bande, gebannen*; *spannen, spande, gespannen*; *helen, heelde, verholen* and *verheeld*, *beseffen, besefte, beseft* (Middle Dutch *besief, beseven*); weak verbs have become strong: *jagen* (Middle Dutch *jaagde*), *joeg* and *jaagde, gejaagd*; *schenden, schond, geschonden*; *zenden* (see above); *prijzen* and *wijzen* pass through the *ij* (the weak) into the strong *ī* class (Middle Dutch, *prisde, wīsde*; Modern Dutch, *prees, wees, geprezen, gewezen*. In *belijden, beluidde*, Middle Dutch *beliën, belide*, the *d* of the preterite found its way into the present also and into the infinitive; and the *beliden*, Modern Dutch *belijden*, thus formed passed into the *ī* class of strong verbs. The *a* of *ward*, the preterite of *werden*, has passed into *werd*, and the plural has through analogy become *werden*, the present being *ik word* and the infinitive *worden*. The first class of strong verbs has before *n* + a consonant *i* in the stem of the present (*binden*) or else *e* (*helpen*), this *e* remaining throughout the conjugation of the present (*hij helpt*, not, as in High German, *hilft*). In the preterite the *a* has changed into *o* through the influence of the plural, as has already been mentioned under *o*. The conjunctive or optative is frequently neglected even in Middle Dutch; in the living language it is sometimes used after certain verbs and conjunctions (*op dat* and *ten einde*), but in expressing a wish it is sometimes periphrased by *mogen* or *laten*, and it is very frequently displaced by the indicative. The High German construction of the verb with *zich* to express a passive idea is contrary to the genius of Dutch, which employs the periphrastic passive form *het wordt daar gevonden* instead of *es findet sich da* (Fr. *il se trouve là*). The formation of the future likewise differs from that of the High German, the auxiliary being not *werden* but *zullen* (Eng. *shall*): *ik zal het doen* = both *I shall do it* and *I will do it*.

Much of the vocabulary of Middle Dutch has now become obsolete. Some words have altogether disappeared:—*dorper, dorperlike* (Modern Dutch, *gemeen*), *graen* (*knevel*), *grein* (*kern*, excellent person), *ontstaen* (*afwachten*), *ors* (*paard*), *oorbaer* (*nut*). Others have changed their meaning:—*cousc*, "breeches," now "hose"; *clene*, "few," now "small"; *onnoozel*, "innocent," now "half-witted"; *slecht*, "simple," now "wicked"; *beproeven*, "to prove," now "to attempt"; *crane*, "weak," now "sick."

Many new native words have grown up in connexion with trade, industry, art, and science; many foreign words have also been introduced, such as those taken from the French with the suffixes *eeren, iek, ief*; and many words from the dialects have received rights of citizenship.

For a fuller survey of the history of Dutch, the reader is referred to W. Dwight Whitney's *Language and its Study*, and the excellent translation of it by J. B. Vinckers, *Taal en Taalstudie, volgens de 3de uitgave voor Nederlanders bewerkt*. The grammar of the current speech may be studied in the *Spraakkunsten* of Kern, P. J. Cosijn, Van Helten. For the explanation of Middle Dutch words and forms, see the papers of De Vries, Verwijs, and Verdam in the *Taalgids*, the *Taal- en Letterbode*, and the *Taalkundige Bijdragen*; De Vries, *Middelnederlandsche Taalzuivering*; the editions of the *Spieghel Historiael* by Maerlant, of De Rose, William van Hillegaerdsberg, Seghelyn; and the *Bibliotheek van Middelnederlandsche Letterkunde*, by H. E. Moltzer. For explanation and history of words of the current language see the *Woordenboek der Ned. Taal*, by De Vries, Te Winkel, &c. The old Saxon and Frankish forms are treated by Kern in *Taal- en Letterbode*, Cosijn in the *Oud Frank. Psalmen*, Gallée in *Altsächsische Laut- und Flexionslehre* (1st part). A good survey of the orthography is given in De Vries and Te Winkel's *Grondbeginselen der Nederlandsche Spelling* and *Woordenlijst voor de Spelling der Nederlandsche Taal*. (J. B. V.—J. H. G.)

PART IV.—LITERATURE

As has been shown above, the language now known as Dutch or Flemish did not begin to take distinct shape till about the end of the 11th century. From a few existing fragments—two incantations from the 8th century, a version of the Psalms from the 9th century, and several charters—a supposed Old Dutch language has been recognized; but Dutch literature actually commences in the 13th century, as Middle Dutch, the creation of the first national movement in Brabant, Flanders, Holland, and Zealand. From the wreck of Frankish anarchy no genuine folk-tales of Dutch antiquity have come down to us, and scarcely any echoes of German myth. On the other hand, the sagas of Charlemagne and Arthur appear immediately in Middle Dutch forms. These were evidently introduced by wandering minstrels and jongleurs, and translated to gratify the curiosity of the noble women. It is rarely that the name of such a translator has reached us, but we happen to know that the fragments we possess of the French romance of *William of Orange* were written in Dutch by a certain Klaas van Haarlem, between 1191 and 1217. The *Chanson de Roland* was translated about the same time, and considerably later *Parthenopeus de Blois.* The Flemish minstrel Diederic van Assenede completed his version of *Floris et Blanchefleur* about 1250. The Arthurian legends appear to have been brought to Flanders by some Flemish colonists in Wales, on their return to their mother-country. About 1250 a Brabantine minstrel translated Walter Map's *Lancelot du Lac* at the command of his liege, Lodewijk van Velthem. The *Gauvain* was translated by Penninc and Vostaert before 1260, while the first original Dutch writer, the famous Jakob van Maerlant, occupied himself about 1260 with several romances dealing with Merlin and the Holy Grail. The earliest existing fragments of the epic of *Reynard the Fox* were written in Latin by Flemish priests, and about 1250 a very important version in Dutch was made by Willem the Minstrel, of whom it is unfortunate that we know no more, save that he was the translator of a lost romance, *Madoc.* In his existing work the author follows Pierre de Saint-Cloud, but not slavishly; and he is the first really admirable writer that we meet with in Dutch literature. It is not necessary to dwell at any length on the monkish legends and the hymns to the Virgin Mary which were abundantly produced during the 13th century, and which, though destitute of all literary merit, were of use as exercises in the infancy of the language. The first lyrical writer of Holland was John I., duke of Brabant, who practised the *minnelied* with success, but whose songs are only known to us through a Swabian version of a few of them. In 1544 the earliest collection of Dutch folk-songs saw the light, and in this volume one or two romances of the 14th century are preserved, of which *Het Daghet in den Oosten* is the best known. Almost the earliest fragment of Dutch popular poetry, but of later time, is an historical ballad describing the murder of Count Floris V. in 1296. A very curious collection of mystical mediæval hymns by Sister Hadewych, a nun of Brabant, was first printed in 1877.

Willem the Minstrel.

John I., duke of Brabant.

Hitherto, as we have seen, the Middle Dutch language had placed itself at the service of the aristocratic and monastic orders, flattering the traditions of chivalry and of religion, but scarcely finding anything to say to the bulk of the population. With the close of the 13th century a change came over the face of Dutch literature. The Flemish towns began to prosper and to assert their commercial supremacy over the North Sea. Under such mild rulers as William II. and Floris V., Dort, Amsterdam, and other cities contrived to win such privileges as amounted almost to political independence, and with this liberty there arose a new sort of literary expression. The founder and creator of this original Dutch literature was Jakob van Maerlant, born near Bruges between 1225 and 1250. His youth was spent in Holland, and probably in connexion with the court, but in 1261 he returned to Flanders, where he died about thirty years later. Maerlant commenced, as his predecessors had done, by translating the courtly romances of the French, but when he returned to Flanders he began to take his true position as an original didactic poet. His *Flowers of Nature*, written about 1263, forms an epoch in Dutch literature; it is a collection of moral and satirical addresses to all classes of society. With his *Rijmbijbel* (Rhyming Bible) he nearly brought down on his too secular head, in 1270, the chastisement of the bishop of Utrecht, and thus early in Dutch history foreshadowed the courage and free-thought of the Reformation. It was not until 1284 that he commenced his masterpiece, *De Spieghel Historiael* (The Mirror of History), at the command of Count Floris V. After writing a great many important works, lyrical and didactic, Maerlant died at Damme, about 1291. Of his disciples, the most considerable in South Holland was Jan van Boendale (1280–1365). He was a politician of considerable influence, and his works are historical and moral in character. In him the last trace of the old chivalric and romantic element has disappeared. He completed his famous rhyme chronicle, the *Brabantsche Yeesten*, in 1315; it contains the history of Brabant down to the times of the author himself. For English readers it is disappointing that Boendale's other great historical work, an account of Edward III. and his expedition to Flanders in 1338, has survived only in some fragments. The remainder of Boendale's works are didactic poems, pursuing still further the moral thread first taken up by Maerlant, and founded on mediæval scholastic literature. In Ypres the school of Maerlant was represented by Jan de Weert, a surgeon, who died in 1362, and who was the author of two remarkable works of moral satire and exhortation. In North Holland a greater talent than that of Weert or of Boendale was exhibited by Melis Stoke, a monk of Egmond, who wrote the history of the state of Holland to the year 1305; this work, the *Rijmkronik*, was printed in 1591, and for its exactitude and minute detail has proved of inestimable service to later historians.

Maerlant. Boendale. Weert. Stoke.

With the middle of the 14th century the chivalric spirit came once more into fashion. A certain revival of the forms of feudal life made its appearance under William III. and his successors. Knightly romances came once more into vogue, but the new-born didactic poetry contended vigorously against the supremacy of what was lyrical and epical. It will be seen that from the very first the literary spirit in Holland began to assert itself in a homely and utilitarian spirit. Jan van Heelu, a Brabanter, was the author of an epic poem on the battle of Woeronc (1288), and to him has been attributed the still finer romance of the *War of Grimbergen.* Still more thoroughly aristocratic in feeling was Hein van Aken, a priest of Louvain, who lived about 1255–1330, and who combined to a very curious extent the romantic and didactic elements. As early as 1280 he had completed his translation of the *Roman de la Rose*, which he must have commenced in the lifetime of Jean de Meung. More remarkable than any of his translated works, however, is his original romance *Heinric en Margriete*, upon which he was at work for thirty-seven years. During the Bavarian period (1349–1433) very

Heelu. Aken.

little original writing of much value was produced in Holland. Buodewijn van der Loren wrote one excellent piece on the Maid of Ghent, in 1389. Augustijnken van Dordt was a peripatetic minstrel of North Holland, who composed for the sheriff Aelbrecht and for the count of Blois from 1350 to 1370. Such of his verses as have been handed down to us are allegorical and moral. Willem van Hildegaersberch (1350–1408) was another northern poet, of a more strictly political cast. Many of his writings exist still unpublished, and are very rough in style and wanting in form. Towards the end of the 15th century an erotic poet of considerable power arose in the person of the lord of Waddinxsveen and Hubrechtsambacht, Dirk Potter. During a stay of three years in Rome, from 1409 to 1412, this eminent diplomatist made himself acquainted with the writings of Boccaccio, and commenced a vast poem on the course of love, *Der Minnen Loep*, which is a wonderful mixture of classical and Biblical instances of amorous adventure, set in a framework of didactic philosophy. In Dirk Potter the last traces of the chivalric element died out of Dutch literature, and left poetry entirely in the hands of the school of Maerlant.

.: ter.

It is now time to consider the growth of prose literature in the Low Countries. The oldest pieces of Dutch prose now in existence are charters of the towns of Flanders and Zealand, dated 1249, 1251, and 1254. A prose translation of the Old Testament was made about 1300, and there exists a *Life of Jesus* of about the same date. Of the mystical preachers whose religious writings have reached us, the Brussels friar, Jan van Ruysbroec (1294–1381), is the most important. But the most interesting relics of mediæval Dutch prose, as far as the formation of the language is concerned, are the popular romances in which the romantic stories of the *trouvères* and minstrels were translated for the benefit of the unlettered public into simple language. As in most European nations, the religious drama takes a prominent place in every survey of mediæval literature in Holland. Unfortunately the text of all the earliest mysteries, the language of which would have an extraordinary interest for us, has been lost. We possess records of dramas having been played at various places—*Our Lord's Resurrection*, at the Hague, in 1400; *Our Lady the Virgin*, at Arnheim, in 1452; and *The Three Kings*, at Delft, in 1498. The earliest existing fragment, however, is part of a *Limburg-Maestricht Passover Play* of about 1360. The latest Dutch miracle play was the *Mystery of the Holy Sacrament*, composed by a certain Smeken, at Breda, and performed on St John's Day, 1500. This play was printed in 1867. With these purely theological dramas there were acted mundane farces, performed outside the churches, by semi-religious companies; these curious moralities were known as "Abelespelen" and "Sotternieën." In these pieces we discover the first traces of that genius for low comedy which was afterwards to take perfect form in the dramas of Brederôo and the paintings of Teniers.

The theatrical companies just alluded to, "Gesellen van den Spele," formed the germ out of which developed the famous "Chambers of Rhetoric" which united within themselves all the literary movements that occupied the Low Countries during the 15th and 16th centuries. The poets of Holland had already discovered in late mediæval times the value of guilds in promoting the arts and industrial handicrafts. The term "colléges de rhétorique" is supposed to have been introduced about 1440 by the courtiers of the Burgundian dynasty, but the institutions themselves existed at least from 1400. These literary guilds lasted for two centuries, and during the greater part of that time preserved a completely mediæval character, even when the influences of the Renaissance and the Reformation obliged them to modify in some degree their outward forms. They were in almost all cases absolutely middle class in tone, and opposed to aristocratic ideas and tendencies in thought. Of these remarkable bodies the earliest were almost entirely engaged in preparing mysteries and miracle-plays for the populace. Each chamber, and in process of time every town in the Low Countries, possessed one, and took as its title some fanciful or heraldic sign. The earliest of all, "The Alpha and Omega," at Ypres, was founded about 1398; that of the "Violet," at Antwerp, followed in 1400; the "Book," at Brussels, in 1401; the "Berberry," at Courtrai, in 1427; the "Holy Ghost," at Bruges, in 1428; the "Floweret Jesse," at Middelburg, in 1430; the "Oak Tree," at Vlaardingen, in 1433; and the "Marigold," at Gouda, in 1437. The most celebrated of all the chambers, that of the "Eglantine" at Amsterdam, with its motto *In Liefde Bloeyende* (Blossoming in Love), was not instituted until 1496. Among the most influential chambers not above mentioned should be included the "Fountain" at Dort, the "Corn Flower" at the Hague, the "White Columbine" at Leyden, the "Blue Columbine" at Rotterdam, the "Red Rose" at Schiedam, the "Thistle" at Zierikzee, "Jesus with the Balsam" at Ghent, and the "Garland of Mary" at Brussels. And not in these important places only, but in almost every little town, the rhetoricians exerted their influence, mainly in what we may call a social direction. Their wealth was in most cases considerable, and it very soon became evident that no festival or procession could take place in a town unless the "Kamer" patronized it. Towards the end of the 15th century the Ghent chamber of "Jesus with the Balsam" began to exercise a sovereign power over the other Flemish chambers, which was emulated later on in Holland by the "Eglantine" at Amsterdam. But this official recognition proved of no consequence in literature, and it was not in Ghent, but in Antwerp, that intellectual life first began to stir. In Holland the burghers only formed the chambers, while in Flanders the representatives of the noble families were honorary members, and assisted with their money at the arrangement of ecclesiastical or political pageants. Their pompous *landjuweelen*, or tournaments of rhetoric, at which rich prizes were contended for, were the great occasions upon which the members of the chambers distinguished themselves. Between 1426 and 1620 at least 66 of these festivals were held. There was a specially splendid *landjuweel* at Antwerp in 1496, in which 28 chambers took part, but the gayest of all was that celebrated at Antwerp on the 3d of August 1561. To this the "Book" at Brussels sent 340 members, all on horseback, and clad in crimson mantles. The town of Antwerp gave a ton of gold to be given in prizes, which were shared among 1893 rhetoricians. This was the zenith of the splendour of the "Kamers van Rhetorica," and after this time they soon fell into disfavour. We can trace the progress of literary composition under the chambers, although none of their official productions have descended to us. Their dramatic pieces were certainly of a didactic cast, with a strong farcical flavour, and continued the tradition of Maerlant and his school. They very rarely dealt with historical or even Biblical personages, but entirely with allegorical and moral abstractions, until the age of humanism introduced upon the stage the names without much of the spirit of mythology. Of the pure farces of the rhetorical chambers we can speak with still more confidence, for some of them have come down to us, and among the authors famed for their skill in this sort of writing are named Cornelis Everaert of Bruges and Laurens Janssen of Haarlem. The material of these farces is extremely raw, consisting of rough jests at the expense of priests and foolish husbands, silly old men and their light wives. Laurens Janssen is also deserving of remembrance for a satire against the clergy, written in 1583. The chambers also encouraged the composition of songs, but with very little success; they produced no lyrical genius more considerable than Matthijs de Casteleyn (1488–1550), the founder of the Flemish chamber of "Pax Vobiscum" at Oudenarde, a personage whose influence as a fashioner of language would have been more healthy if his astounding metrical feats and harlequin *tours-de-force* had not been performed in a dialect debased with all the worst bastard phrases of the Burgundian period.

In the middle of the 16th century a group of rhetoricians in Brabant and Flanders attempted to put a little new life into the stereotyped forms of the preceding age by introducing in original composition the new-found branches of Latin and Greek poetry. The leader of these men was Jean Baptista Houwaert (1533–1599), a personage of considerable political influence in his generation. He considered himself a devout disciple of Matthijs de Casteleyn, but his great characteristic was his unbounded love of classical and mythological fancy. His didactic poems are composed in a wonderfully rococo style, and swarm with misplaced Latinities. In his bastard Burgundian tongue he boasted of having "poëtelijck geïnventeert ende rhetorijckelijck ghecomponeert" for the Brussels chamber such dramas as *Æneas and Dido*, *Mars and Venus*, *Narcissus and Echo*, or *Leander and Hero*. But of all his writings *Pegasides Pleyn*, or the Palace of Maidens, is the most remarkable; this is a didactic poem in sixteen books, dedicated to a discussion of the variety of earthly love. Houwaert's contemporaries nicknamed him "the Homer of Brabant;" later criticism has preferred to see in him an important link in that chain of homely didactic Dutch which ends in Cats. His writings are composed in a Burgundian so base that they hardly belong to Flemish literature at all. Into the same miserable dialect Cornelis van Ghistele of Antwerp translated, between 1555 and 1583, parts of Terence, Virgil, Horace, and Ovid, while the painter Karel van Mander (1547–1609) put a French version of the *Iliad* and of the *Eclogues* of Virgil into an equally ill-fitting Flemish dress. In no country of Europe did the humanism of the 16th century at first affect the national literature so slightly or to so little purpose.

Houwaert.

Psalms and hymns.

The stir and revival of intellectual life that arrived with the Reformation found its first expression in the composition of Psalms. The earliest printed collection appeared at Antwerp in 1540, under the title of *Souter-Liedekens*, and was dedicated to a Dutch nobleman, Willem van Zuylen van Nieuvelt, by whose name it is usually known. This collection, however, was made before the Reformation in Holland really set in. For the Protestant congregations Jan Utenhove printed a volume of Psalms in London in 1566; Lucas de Heere, and immediately after him, with much greater success, Petrus Datheen (1531–1590), translated the hymns of Clément Marot. For printing this last volume, in 1567, Herman Schinkel of Delft was burned to death in 1568. Datheen was not a rhetorician, but a person of humble origin, who wrote in the vulgar tongue, and his hymns spread far and wide among the people. Until 1773 they were in constant use in the state church of Holland. But the great events of the period of reformation are not marked by psalms only in Dutch literature. Two collections of hymns and lyrical pieces, printed in 1562 and 1569, perpetuate the fervour and despair of the martyrs of the Mennonite Church. Similar utterances of the persecuted Protestants were published at Haarlem and Leeuwarden, at Ghent and at Bruges. Very different in tone were the battle-songs of liberty and triumph sung a generation later by the victorious Reformers or "Geuzen." The famous song-book of 1588, the *Geusen Lieden Boecxken*, was full of ardent and heroic sentiment, expressed often in marvellously brilliant phrases. In this collection appeared for the first time such classical snatches of Dutch song as the Ballad of Heiligerlee, the Ballad of Egmond and Horn, and the song of the Storm of Leyden. The political ballads, with their ridicule of the Spanish leaders, form a section of the *Boecxken* which has proved of inestimable value to historians. All these lyrics, however, whether of victory or of martyrdom, are still very rough in form and language.

Battle-songs.

Anna Bijns.

The first writer who used the Dutch tongue with grace and precision of style was a woman and a professed opponent of Lutheranism and reformed thought. Modern Dutch literature practically begins with Anna Bijns. Against the crowd of rhetoricians and psalm-makers of the early part of the 16th century she stands out in relief as the one poet of real genius. The language, oscillating before her time between French and German, formless, corrupt, and invertebrate, took shape and comeliness, which none of the male pedants could give it, from the impassioned hands of a woman. Anna Bijns, who is believed to have been born at Antwerp in 1494, was a schoolmistress at that city in her middle life, and in old age she still "instructed youth in the Catholic religion." Hendrik Peppinck, a Franciscan, who edited her third volume of poems when she was an old woman in 1567, speaks of her as "a maiden small of descent, but great of understanding, and godly of life." Her first known volume bears the date 1528, and displays her as already deeply versed in the mysteries of religion. We gather from all this that she was a lay nun, and she certainly occupied a position of great honour and influence at Antwerp. She was named "the Sappho of Brabant" and the "Princess of all Rhetoricians." She bent the powerful weapon of her verse against the faith and character of Luther. In her volume of 1528 the Lutherans are scarcely mentioned; in that of 1540 every page is occupied with invectives against them; while the third volume of 1567 is the voice of one from whom her age has passed. All the poems of Anna Bijns which we possess are called *refereinen* or refrains. Her mastery over verse-form was extremely remarkable, and these refrains are really modified chants-royal. The writings of Anna Bijns offer many points of interest to the philologist. In her the period of Middle Dutch closes, and the modern Dutch begins. In a few grammatical peculiarities—such as the formation of the genitive by some verbs which now govern the accusative, and the use of *ghe* before the infinitive—her language still belongs to Middle Dutch; but these exceptions are rare, and she really initiated that modern speech which Filips van Marnix adopted and made classical in the next generation.

Marnix.

In Filips van Marnix, lord of St Aldegonde (1538–1598), a much greater personage came forward in the ranks of liberty and reform. He began life as a disciple of Calvin and Beza in the schools of Geneva. It was as a defender of the Dutch iconoclasts that he first appeared in print, with his tract on *The Images thrown down in Holland in August* 1566. He soon became one of the leading spirits in the war of Dutch independence, the intimate friend of the prince of Orange, and the author of the glorious *Wilhelmuslied*. It was in the autumn of 1568 that Marnix composed this, the national hymn of Dutch liberty and Protestantism. In 1569 he completed a no less important and celebrated prose work, the *Biencorf* or Beehive of the Romish Church. In this satire he was inspired in a great measure by Rabelais, of whom he was an intelligent disciple. It is written in prose that may be said to mark an epoch in the language and literature of Holland. Overwhelmed with the press of public business, Marnix wrote little more until in 1580 he published his *Psalms of David newly translated out of the Hebrew Tongue*. He occupied the last years of his life in preparing a Dutch version of the Bible, translated direct from the original. At his death only Genesis was found completely revised; but in 1619 the synod of Dort placed the unfinished work in the hands of four divines, who completed it.

Coornhert. In Dirck Volckertsen Coornhert (1522–1590) Holland for the first time produced a writer at once eager to compose in his native tongue and to employ the weapons of humanism. Coornhert was a typical burgher of North Holland, equally interested in the progress of national emancipation and in the development of national literature. He was a native of Amsterdam, but he did not take part in the labours of the old chamber of the Eglantine, but quite early in life proceeded to Haarlem, of which place he remained a citizen until his death. He practised the art of etching, and spent all his spare time in the pursuit of classical learning. He was nearly forty years of age before he made any practical use of his attainments. In 1561 he printed his translation of the *De Officiis* of Cicero, and in 1562 of the *De Beneficiis* of Seneca. In these volumes he opposed with no less zeal than Marnix had done the bastard forms still employed in prose by the rhetoricians of Flanders and Brabant. During the next decade he occupied himself chiefly with plays and poems, conceived and expressed with far less freedom than his prose, and more in the approved conventional fashion of the rhetoricians; he collected his poems in 1575. The next ten years he occupied in polemical writing, from the evangelical point of view, against the Calvinists. In 1585 he translated Boetius, and then gave his full attention to his original masterpiece, the *Zedekunst*, or Art of Ethics, a philosophical treatise in prose, in which he studied to adapt the Dutch tongue to the grace and simplicity of Montaigne's French. His humanism unites the Bible, Plutarch, and Marcus Aurelius in one grand system of ethics, and is expressed in a style remarkable for brightness and purity. He died in 1590; his works, in three enormous folio volumes, were first collected in 1630.

Amsterdam the centre of letters. Towards the end of the period of transition, Amsterdam became the centre of all literary enterprise in Holland. In 1585 two of the most important chambers of rhetoric in Flanders, the "White Lavender" and the "Fig-Tree," took flight from the south, and settled themselves in Amsterdam by the side of the "Eglantine." The last-named institution had already observed the new tendency of the age, and was prepared to encourage intellectual reform of every kind, and its influence spread through Holland and Zealand. In Flanders, meanwhile, crushed under the yoke of Parma, literature and native thought absolutely expired. From this time forward, and until the emancipation of the southern provinces, the domain of our inquiry is confined to the district north of the Scheldt.

In the chamber of the Eglantine at Amsterdam two men took a very prominent place, more by their intelligence and modern spirit than by their original genius. Hendrick

Spieghel. Laurenssen Spieghel (1549-1612) was a humanist of a type more advanced and less polemical than Coornhert. He wrote a charming poem in praise of dancing; but his chief contributions to literature were his *Twespraeck van de Nederduytsche Letterkunst*, a philological exhortation. in the manner of Joachim du Bellay's famous tract, urging the Dutch nation to purify and enrich its tongue at the fountains of antiquity, and a didactic epic, entitled *Hertspieghel*, which has been greatly praised, but which is now much more antiquated in style and more difficult to enjoy than Coornhert's prose of a similar tendency. That Spieghel was a Catholic prevented him perhaps from exercising as much public influence as he exercised privately among his younger friends. The same may be said of the man who, in 1614, first collected Spieghel's writings, and

Roemer Visscher. published them in a volume with his own verses. Roemer Pieterssen Visscher (1545-1620) proceeded a step further than Spieghel in the cultivation of polite letters. He was deeply tinged with a spirit of classical learning that was much more genuine and nearer to the true antique than any that had previously been known in Holland. His own disciples called him the Dutch Martial, but he was at best little more than an amateur in poetry, although an amateur whose function it was to perceive and encourage the genius of professional writers. Roemer Visscher stands at the threshold of the new Renaissance literature, himself practising the faded arts of the rhetoricians, but pointing by his counsel and his conversation to the naturalism of the great period.

The Renaissance. It was in the salon at Amsterdam which the beautiful daughters of Roemer Visscher formed around their father and themselves that the new school began to take form. The republic of the United Provinces, with Amsterdam at its head, had suddenly risen to the first rank among the nations of Europe, and it was under the influence of so much new emotion and brilliant ambition that the country no less suddenly asserted itself in a great school of painting and poetry. The intellect of the whole Low Countries was concentrated in Holland and Zealand, while the six great universities, Leyden, Groningen, Utrecht, Amsterdam, Harderwijk, and Franeker, were enriched by a flock of learned exiles from Flanders and Brabant. It had occurred, however, to Roemer Visscher only that the path of literary honour lay, not along the utilitarian road cut out by Maerlant and Boendale, but in the study of beauty and antiquity. In this he was curiously aided by the school of ripe and enthusiastic scholars who began to flourish at Leyden, such as Drusius, Vossius, and Hugo Grotius, who themselves wrote little in Dutch, but who chastened the style of the rising generation by insisting on a pure and liberal Latinity. Out of that generation arose the greatest names in the literature of Holland,—Vondel, Hooft, Cats, Huygens,—in whose hands the language, so long left barbarous and neglected, took at once its highest finish and melody. By the side of this serious and æsthetic growth there is to be noticed a quickening of the broad and farcical humour which had been characteristic of the Dutch nation from its commencement. For fifty years, and these the most glorious in the annals of Holland, these two streams of influence, one towards beauty and melody, the other towards lively comedy, ran side by side, often in the same channel, and producing a rich harvest of great works. It was in the house of the daughters of Roemer Visscher that the tragedies of Vondel and the comedies of Brederôo, the farces of Coster and the odes of Huygens, alike found their first admirers and their best critics.

Roemer Visscher's daughters. Of the famous daughters of Roemer, two cultivated literature with marked success. Anna (1584–1651) was the author of a descriptive and didactic poem, *De Roemster van den Aemstel* (The Glory of the Aemstel), and of various miscellaneous writings; Tesselschade (1594–1649) wrote some lyrics which still place her at the head of the female poets of Holland, and she translated the great poem of Tasso. They were women of universal accomplishment, graceful manners, and singular beauty; and their company attracted to the house of Roemer Visscher all the most gifted youths of the time, several of whom were suitors, but in vain, for the hand of Anna or of Tesselschade.

Hooft. Of this Amsterdam school, the first to emerge into public notice was Pieter Cornelissen Hooft (1581–1647). He belonged to a patrician family, and became a member at a very early age of the chamber of the Eglantine. When he was only eighteen he produced, before this body, his tragedy of *Achilles and Polyxena* (1598), which displayed a precocious ease in the use of rhetorical artifices of style. His intellectual character, however, was formed by a journey into Italy which he took in 1598, where he steeped himself for three years in the best Italian literature, both prose and verse. He returned to Holland in 1601, with his head full of schemes for the creation of a Dutch school of belles lettres. In 1605 he produced his pastoral drama of *Granida*, in which he proved himself a pupil of Guarini. During the remainder of his life he dedicated himself chiefly to history and tragedy. In the latter field he produced *Baeto* and *Geraad van Velsen*; in history he published in 1626 his *Life of Henry the Great*, while from 1628 to 1642 he was engaged upon his master-work, the *History of Holland*. Hooft desired to be a severe purist in style, and to a great extent he succeeded, but, like most of the writers of his age, he permitted himself too many Latinisms. In his poetry, especially in the lyrical and pastoral verse of his youth, he is full of Italian reminiscences both of style and matter; in his noble prose work he has set himself to be a disciple of Tacitus. Mr Motley has spoken of Hooft as one of the greatest historians, not merely of Holland, but of Europe. His influence in purifying the language of his country, and in enlarging its sphere of experience, can hardly be overrated.

Brederôo. Very different from the long and prosperous career of Hooft was the brief, painful life of the greatest comic dramatist that Holland has produced. Gerbrand Adriaanssen Brederôo (1585-1618) was the son of an Amsterdam shoemaker. He knew no Latin; he had no taste for humanism; he was a simple growth of the rich humour of the people. His life was embittered by a hopeless love for Tesselschade, to whom he dedicated his dramas, and whose beauty he celebrated in a whole cycle of love songs. His ideas on the subject of drama were at first a mere development of the mediæval "Abelespelen." He commenced by dramatizing the romance of *Roderick and Alphonsus*, in 1611, and *Griane* in 1612, but in the latter year he struck out a new and more characteristic path in his *Farce of the Cow*. From this time until his death he continued to pour out comedies, farces, and romantic dramas, in all of which he displayed a coarse, rough genius not unlike that of Ben Jonson, whose immediate contemporary he was. His last and best piece was *Jerolimo, the Spanish Brabanter*, a satire upon the exiles from the south who filled the halls of the Amsterdam chambers of rhetoric with their pompous speeches and preposterous Burgundian phraseology. Brederôo was closely allied in genius to the dramatists of the Shakespearian age, but he founded no school, and stands almost as a solitary figure in the literature of Holland.

Coster. The only individual at all clearly connected with Brederôo in talent was Dr Samuel Coster, whose dates of birth and death are unknown. He is chiefly remembered for having been the first to take advantage of the growing dissension in the body of the old chamber of the Eglantine to form a new institution. In 1617 Coster founded what he called the "First Dutch Academy." This was in fact a theatre, where, for the first time, dramas could be publicly acted under the patronage of no chamber of rhetoric. Coster himself had come before the world in 1612 with his farce of *Teuwis the Boor*, and he continued this order of composition in direct emulation of Brederôo, but with less talent. In 1615 he began a series of "blood-and-thunder" tragedies with his horrible *Itys*, and he continued this coarse style of tragic writing for several years. He survived at least until after 1648 as a supreme authority in Amsterdam upon all dramatic matters.

Vondel. The greatest of all Dutch writers, Joost van der Vondel (1587-1679), was born at Cologne on the 17th of November 1587. In 1612 he brought out his first work, *Het Pascha*, a tragedy or tragi-comedy on the exodus of the children of Israel, written, like all his succeeding dramas, on the recognized Dutch plan, in alexandrines, in five acts, and with choral interludes between the acts. There is comparatively little promise in *Het Pascha*. It was much inferior dramatically to the plays just being produced by Brederôo, and metrically to the clear and eloquent tragedies and pastorals of Hooft; but it secured the young poet a position inferior only to theirs. Yet for a number of years he made no attempt to emphasize the impression he had produced on the public, but contented himself during the years that are the most fertile in a poet's life with translating and imitating portions of Du Bartas's popular epic. The short and brilliant life of Brederôo, his immediate contemporary and greatest rival, burned itself out in a succession of dramatic victories, and it was not until two years after the death of that great poet that Vondel appeared before the public with a second tragedy, the *Jerusalem laid Desolate*. Five years later, in 1625, he published what seemed an innocent study from the antique, his tragedy of *Palamedes, or Murdered Innocence*. All Amsterdam discovered, with smothered delight, that under the name of the hero was thinly concealed the figure of Barneveldt, whose execution in 1618 had been a triumph of the hated Calvinists. Thus, at the age of forty-one, the obscure Vondel became in a week the most famous writer in Holland. For the next twelve years, and till the accession of Prince Frederick Hendrick, Vondel had to maintain a hand-to-hand combat with the "Saints of Dort." This was the period of his most resolute and stinging satires; Cats took up the cudgels on behalf of the counter-Remonstrants, and there raged a war of pamphlets in verse. A purely fortuitous circumstance led to the next great triumph in Vondel's slowly developing career. The Dutch Academy, founded in 1617 almost wholly as a dramatic guild, had become so inadequately provided with stage accommodation that in 1638, having coalesced with the two chambers of the "Eglantine" and the "White Lavender," it ventured on the erection of a large public theatre, the first in Amsterdam. Vondel, as the greatest poet of the day, was invited to write a piece for the first night; on the 3d of January 1638 the theatre was opened with the performance of a new tragedy out of early Dutch history, the famous *Gysbreght van Aemstel*. The next ten years were rich in dramatic work from Vondel's hand; he supplied the theatre with heroic Scriptural pieces, of which the general reader will obtain the best idea if we point to the *Athalie* of Racine. In 1654, having already attained an age at which poetical production is usually discontinued by the most energetic of poets, he brought out the most exalted and sublime of all his works, the tragedy of *Lucifer*. Very late in life, through no fault of his own, financial ruin fell on the aged poet, and from 1658 to 1668—that is, from his seventieth to his eightieth year—this venerable and illustrious person, the main literary glory of Holland through her whole history, was forced to earn his bread as a common clerk in a bank, miserably paid, and accused of wasting his masters' time by the writing of verses. The city released him at last from this wretched bondage by a pension, and the wonderful old man went on writing odes and tragedies almost to his ninetieth year. He died at last in 1679, of no disease, having outlived all his contemporaries and almost all his friends, but calm, sane, and good-humoured to the last, serenely conscious of the legacy he left to a not too grateful country. Vondel is the typical example of Dutch intelligence and imagination at their highest development. Not merely is he to Holland all that Camoens is to Portugal and Michiewicz to Poland, but he stands on a level with these men in the positive value of his writings.

Starter. Lyrical art was represented on its more spontaneous side by the songs and ballads of Jan Janssen Starter (b. 1594), an Englishman by birth, who was brought to Amsterdam in his thirteenth year. Very early in life he was made a member of the "Eglantine," and he worked beside

Brederôo for two years; but in 1614 he wandered away to Leeuwarden, in Friesland, where he founded a literary guild, and brought out, in 1618, his tragi-comedies of *Timbre de Cardone* and *Daraida*. But his great contribution to literature was his exquisite collection of lyrics, entitled the *Friesche Lusthof*, or Frisian Pleasance. He returned to Amsterdam, but after 1625 we hear no more of him, and he is believed to have died as a soldier in Germany. The songs of Starter are in close relation to the lyrics of the English Elizabethans, and have the same exquisite simplicity and audacity of style.

While the genius of Holland clustered around the circle of Amsterdam, a school of scarcely less brilliance arose in Middelburg, the capital of Zealand. The ruling spirit of this school was the famous Jakob Cats (1577–1660). In this voluminous writer, to whom modern criticism almost denies the name of poet, the genuine Dutch habit of thought, the utilitarian and didactic spirit which we have already observed in Houwaert and in Boendale, reached its zenith of fluency and popularity. Cats was a man of large property and high position in the state, and his ideas never rose above the horizon of wealth and easy domestic satisfaction. Between 1609 and 1621, that is, during early middle life, he produced the most important of his writings, his pastoral of *Galathea*, and his didactic poems, the *Maechdenplicht* and the *Sinne- en Minne-Beelden*. In 1624 he removed from Middelburg to Dort, where he soon after published his tedious ethical work called *Houwelick*, or Marriage; and this was followed from time to time by one after another of his monotonous moral pieces. Cats is an exceedingly dull and prosaic writer, whose alexandrines roll smoothly on without any power of riveting the attention or delighting the fancy. Yet his popularity with the middle classes in Holland has always been immense, and his influence extremely hurtful to the growth of all branches of literary art. Among the disciples of Cats, Jakob Westerbaen (1599–1670) was the most successful. The Jesuit Adriaen Poirters (1606–1675) closely followed Cats in his remarkable *Masquer of the World*. A poet of Amsterdam, Jan Hermansz Krul, preferred to follow the southern fashion, and wrote didactic pieces in the Catsian manner.

A poet of dignified imagination and versatile form was Sir Constantijn Huygens (1596–1687), the diplomatist. Though born and educated at the Hague, he threw in his lot with the great school of Amsterdam, and became the intimate friend and companion of Vondel, Hooft, and the daughters of Roemer Visscher. His famous poem in praise of the Hague, *Batava Tempe*, appeared in 1621, and was, from a technical point of view, the most accomplished and elegant poem till that time produced in Holland. His collected poems, *Otiorum Libri Sex*, were printed in 1625. *Oogentroost*, or Eye Consolation, was the fantastic title of a remarkable poem dedicated in 1647 to his blind friend, Lucretia van Trello. He printed in 1654 a topographical piece describing his own mansion, *Hofwijck*. Huygens represents the direction in which it would have been desirable that Dutch literature, now completely founded by Hooft and Vondel, should forthwith proceed, while Cats represents the tame and mundane spirit which was actually adopted by the nation. Huygens had little of the sweetness of Hooft or of the sublimity of Vondel, but his genius was eminently bright and vivacious, and he was a consummate artist in metrical form. The Dutch language has never proved so light and supple in any hands as in his, and he attempted no class of writing, whether in prose or verse, that he did not adorn by his delicate taste and sound judgment. A blind admiration for our own John Donne, whose poems he translated, was the greatest fault of Huygens, who, in spite of his conceits, remains one of the most pleasing of Dutch writers. In addition to all this he comes down to us with the personal recommendation of having been "one of the most lovable men that ever lived."

Three Dutchmen of the 17th century distinguished themselves very prominently in the movement of learning and philosophic thought, but the illustrious names of Hugo Grotius (1583–1645) and of Baruch Spinoza (1632–1677) can scarcely be said to belong to Dutch literature. Balthasar Bekker (1634–1698), on the contrary, a Reformed preacher of Amsterdam, was a disciple of Descartes, who deserves to be remembered as the greatest philosophical writer who has used the Dutch language. His masterpiece, *Betoverde Wereld*, or the World Bewitched, appeared in 1691–1693. Bekker is popularly remembered most honourably by his determined attacks upon the system of a penal code for witchcraft.

From 1600 to 1650 was the blossoming time in Dutch literature. During this period the names of greatest genius were first made known to the public, and the vigour and grace of literary expression reached their highest development. It happened, however, that three men of particularly commanding talent survived to an extreme old age, and under the shadow of Vondel, Cats, and Huygens there sprang up a new generation which sustained the great tradition until about 1680, when the final decline set in. Jan Vos (d. 1667) gained one illustrious success with his tragedy of *Aaron and Titus* in 1641, and lost still more in the same year by his obscene farce of *Oene*. His second tragedy of *Medea*, in 1665, and his collected poems in 1662, supported his position as the foremost pupil of Vondel. Geeraerdt Brandt (1626–1685) deserves remembrance less as a tragic dramatist than as a consummate biographer, whose lives of Vondel and of De Ruyter are among the masterpieces of Dutch prose. Johan Antonides van der Goes (1647–1684) followed Vos as a skilful imitator of Vondel's tragical manner. His Chinese tragedies, *Trazil* (1665) and *Zungchin* (1666), scarcely gave promise of the brilliant force and fancy of his *Ijstroom*, a poem in praise of Amsterdam, 1671. He died suddenly, in early life, leaving unfinished an epic poem on the life of St Paul. Reyer Anslo (1626–1669) marks the decline of taste and vigour; his once famous descriptive epic, *The Plague at Naples*, is singularly tame and rococo in style. Joachim Oudaen (1628–1692) wrote in his youth two promising tragedies, *Johanna Gray* (1648) and *Konradyn* (1649). The Amsterdam section of the school of Cats produced Jeremias de Decker (1609–1646) and Joannes Vollenhove (1631–1708), voluminous writers of didactic verse. The engraver Jan Luiken (1649–1708) published in 1671 a very remarkable volume of poems. In lyrical poetry Starter had a single disciple, Daniel Jonctijs (1600–1652), who published a volume of love songs in 1639 under the affected and untranslatable title of *Rooselijns oochjens ontleed*. None of these poets, except in some slight degree Luiken, set before themselves any more ambitious task than to repeat with skill the effects of their predecessors.

Meanwhile the romantic and voluminous romances of the French school of Scudéry and Honoré d'Urfé had invaded Holland and become fashionable. Johan van Heemskerk (1597–1656), a councillor of the Hague, set himself to reproduce this product in native form, and published in 1637 his *Batavian Arcadia*, the first original Dutch romance, in which a party of romantic youths journey from the Hague to Katwijk, and undergo all sorts of romantic adventures. This book was excessively popular, and was imitated by Hendrik Zoeteboom in his *Zaanlandsche Arcadia* (1658), and by Lambertus Bos in his *Dordtsche Arcadia* (1662). A far more spirited and original romance is the *Mirandor* of Nikolaes Heinsius, the younger (b. 1655), a book which resembles *Gil Blas*, and precedes it by forty years. It was written when the author was only twenty years of age, and gave promise of very great talent in the future; but unfortunately Heinsius committed a murder only two years afterwards, and, escaping to Paris, was never heard of again.

Gallican dramatists. The drama fell into Gallicized hands at the death of Vondel and his immediate disciples. Lodewijck Meijer translated Corneille, and brought out his plays on the stage at Amsterdam, where he was manager of the national theatre or Schouwburg after Jan Vos. In connexion with Andries Pels, author of the tragedy of *Dido's Death*, Meijer constructed a dramatic club, entitled "Nil Volentibus Arduum," the great object of which was to inflict the French taste upon the public. Pels furthermore came forward as the censor of letters and satirist of barbarism in *Horace's Art of Poetry expounded*, in 1677, and in his *Use and Misuse of the Stage*, in 1681. Willem van Focquenbroch (1640–1679) was the most voluminous comic writer of this period. The close of the century saw the rise of two thoroughly Gallican dramatists, Johan van Paffenrode and Pieter Bernagie, who may not unfairly be compared respectively to our own Farquhar and Shadwell. Thomas Asselijn (1630–1695) was a writer of more considerable talent and more homely instincts. He attempted to resist the dictatorship of Pels, and to follow the national tradition of Brederôo. He is the creator of the characteristic Dutch type, the comic lover, Jan Klaaszen, whom he presented on the stage in a series of ridiculous situations. Abraham Alewijn, author of *Jan Los* (1721), possessed a coarse vein of dramatic humour; he lived in Java, and his plays were produced in Batavia. Finally Pieter Langendijk claims notice among the dramatists of this period, although he lived from 1683 to 1756, and properly belongs to the next century. With him the tradition of native comedy expired.

Decline of poetry. The Augustan period of poetry in Holland was even more blank and dull than in the other countries of Northern Europe. Of the names preserved in the history of literature there are but very few that call for repetition here. Arnold Hoogvliet (1687–1763) wrote a passable poem in honour of the town of Vlaardingen, and a terrible Biblical epic, in the manner of Blackmore, on the history of Abraham. Hubert Cornelissen Poot (1689–1733) showed an unusual love of nature and freshness of observation in his descriptive pieces. Sybrand Feitama (1694–1758), who translated Voltaire's *Henriade*, and wrote much dreary verse of the same class himself, is less worthy of notice than Dirk Smits (1702–1752), the mild and elegiac singer of Rotterdam. Tragic drama was more or less capably represented by Lucretia Wilhelmina van Merken (1722–1789), wife of the very dreary dramatist Nicholaas Simon van Winter (1718–1795).

Van Effen. In the midst of this complete dissolution of poetical style, a writer arose who revived an interest in literature, and gave to Dutch prose the classical grace of the 18th century. Justus van Effen (1684–1735) was born at Utrecht, fell into poverty early in life, and was thrown very much among the company of French émigrés, in connexion with whom he began literary life in 1713 by editing a French journal. Coming to London just when the *Tatler* and *Spectator* were in their first vogue, Van Effen studied Addison deeply, translated Swift and Defoe into French, and finally determined to transfer the beauties of English prose into his native language. It was not, however, until 1731, after having wasted the greater part of his life in writing French, that he began to publish his *Hollandsche Spectator*, which his death in 1735 soon brought to a close. Still, what he composed during the last four years of his life, in all its freshness, manliness, and versatility, constitutes the most valuable legacy to Dutch literature that the middle of the 18th century left behind it.

The brothers Van Haren. The supremacy of the poetical clubs in every town produced a very weakening and Della-Cruscan effect upon literature, from which the first revolt was made by the famous brothers Van Haren, so honourably known as diplomatists in the history of the Netherlands. Willem van Haren (1710–1768) wrote verses from his earliest youth, while Onno Zwier van Haren (1713–1779), strangely enough, did not begin to do so until he had passed middle life. They were friends of Voltaire, and they were both ambitious of success in epic writing, as understood in France at that period. Willem published in 1741 his *Gevallen van Friso*, an historical epos, and a long series of odes and solemn lyrical pieces. Onno, in a somewhat lighter strain, wrote *Piet and Agnietje, or Pandora's Box*, and a long series of tragedies in the manner of Voltaire. The Baroness Juliana Cornelia de Lannoy (1738–1782) was a writer of considerable talent, also of the school of Voltaire; her poems were highly esteemed by Bilderdijk, and she has a neatness of touch and clearness of penetration that give vivacity to her studies of social life. Jakobus Bellamy (1757–1786) was the son of a Swiss baker at Flushing; his pompous odes struck the final note of the false taste and Gallic pedantry that had deformed Dutch literature now for a century, and were for a short time excessively admired.

Baroness de Lannoy.

The ladies Wolff and Dekken. The year 1777 has been mentioned as the turning-point in the history of letters in the Netherlands. It was in that year that Betjen Wolff (1738–1804), a widow lady in Amsterdam, persuaded her friend Aagjen Deken (1741–1804), a poor but extremely intelligent governess, to throw up her situation and live with her. For nearly thirty years these women continued together, writing in combination, and when the elder friend died on the 5th of November 1804, her companion survived her only nine days. Madame Wolff had appeared as a poetess so early as 1762, and again in 1769 and 1772, but her talent in verse was by no means very remarkable. But when the friends, in the third year of their association, published their *Letters on Divers Subjects*, it was plainly seen that in prose their talent was very remarkable indeed. Since the appearance of Heinsius's *Mirandor* more than a century had passed without any fresh start in novel-writing being made in Holland. In 1782 the ladies Wolff and Deken, inspired partly by contemporary English writers, and partly by Goethe, published their first novel, *Sara Burgerhart*. In spite of the close and obvious following of Richardson, this was a masterly production, and it was enthusiastically received. Another novel, *Willem Leevend*, followed in 1785, and *Cornelia Wildschut* in 1792. The ladies were residing in France at the breaking-out of the Revolution, and they escaped the guillotine with difficulty. After this they wrote no more, having secured for themselves by their three unrivalled romances a place among the foremost writers of their country.

The last years of the 18th century were marked in Holland by a general revival of intellectual force. The romantic movement in Germany made itself deeply felt in all branches of Dutch literature, and German lyricism took the place hitherto held by French classicism. Pieter Nieuwland (1764–1794) was a feeble forerunner of the revival, but his short life and indifferent powers gave him no chance of directing the transition that he saw to be inevitable. The real precursor and creator of a new epoch in letters was the famous Willem Bilderdijk (1756–1831). This remarkable man, whose force of character was even greater than his genius, impressed his personality on his generation so indelibly that to think of a Dutchman of the beginning of the present century is to think of Bilderdijk. He was born at Amsterdam on the 7th of September 1756, and through an accident in early childhood was obliged to rest almost constantly, thus attaining habits of long and

Nieuwland.

Bilderdijk.

concentrated study. His parents were zealous in the cause of the house of Orange, and the youth grew up violently monarchical and Calvinistic, as Da Costa says, "anti-revolutionary, anti-Barneveldtian, anti-Loevesteinish, anti-liberal." In poetry his taste was strictly national and didactic; he began as a disciple of Cats, nor could he to the end of his life tolerate what he called "the puerilities of Shakespeare." His early love-songs, collected in 1781 and 1785, gave little promise of talent, but in his epic of *Elias* in 1786, he showed himself superior to all the Dutch poets since Huygens in mastery of form. For twenty years he lived a busy, eventful life, writing great quantities of verse, and then commenced his most productive period with his didactic poem of *The Disease of the Learned*, in 1807; in 1808 he imitated Pope's *Essay on Man*, and published *Floris V.*, and in 1809 commenced the work which he designed to be his master-piece, the epic of *De Ondergang der eerste Wereld* (The Destruction of the First World), which he never finished, and which appeared as a fragment in 1820. His long and fretful life ceased on the 18th of December 1831. To the foreign student Bilderdijk is a singularly uninviting and unpleasing figure. He unites in himself all the unlovely and provincial features which deform the worst of his countrymen. He was violent, ignorant, and dull; his view of art was confined to its declamatory and least beautiful side, and perhaps no writer of equal talent has shown so complete an absence of taste and tact. Ten Brink has summed up the character of Bilderdijk's writings in an excellent passage:—"As an artist," he says, "he can perhaps be best described in short as the cleverest versemaker of the 18th century. His admirable erudition, his power over language, more extended and more colossal than that of any of his predecessors, enabled him to write pithy and thoroughly original verses, although the general tone of his thought and expression never rose above the ceremonious, stagy, and theatrical character of the 18th century." But in spite of his outrageous faults, and partly because these faults were the exaggeration of a marked national failing, Bilderdijk has enjoyed almost to the present day an unbroken and unbounded popularity in Holland. Fortunately, however, within the last few years a sounder spirit has arisen in criticism, and the prestige of Bilderdijk is no longer preserved so religiously.

Bilderdijk's scorn for the dramas of Shakespeare was almost rivalled by that he felt for the new German poetry. Notwithstanding his opposition, however, the romantic fervour found its way into Holland, and first of all in the persons of Hieronymus van Alphen (1746–1803) and Pieter Leonard van de Kastiele (1748–1810), who amused themselves by composing funeral poems of the school of Gessner and Blair. Van Alphen at one time was extolled as a writer of verses for children, but neither in this nor in the elegiac line did he possess nearly so much talent as Rhijnvis Feith (1753–1824), burgomaster of Zwolle, the very type of a prosperous and sentimental Dutchman. In his *Julia* (1783), a prose romance, Feith proved himself as completely the disciple of Goethe in *Werther* as Wolff and Deken had been of Richardson in their *Sara Burgerhart*. In Johannes Kinker (1764–1845) a comic poet arose who, at the instigation of Bilderdijk, dedicated himself to the ridicule of Feith's sentimentalities. The same office was performed with more dignity and less vivacity by Baron W. E. van Perponcher (1741–1819), but Feith continued to hold the popular ear, and achieved an immense success with his poem *The Grave*, in 1792. He then produced tragedies for a while, and in 1803 published *Antiquity*, a didactic epic. But his popularity waned before his death, and he was troubled by the mirth of such witty scoffers as Arend Fokke Simons (1755–1812), the disciple of Klopstock, and as P. de Wacker van Zon (1758–1818), who, in a series of very readable novels issued under the pseudonym of Bruno Daalberg, sharply ridiculed the sentimental and funereal school.

Feith.

Under the Batavian republic an historian of great genius arose in the person of Johannes Henricus van der Palm (1763–1840), whose brilliant and patriotic *Gedenkschrift van Nederlands Herstelling* (1816) has somewhat obscured his great fame as a politician and an Orientalist. The work commenced by Van der Palm in prose was continued in verse by Cornelis Loots (1765–1834) and Jan Frederik Helmers (1767–1813). Loots, in his *Batavians of the Time of Cæsar* (1805), read his countrymen a lesson in patriotism, which Helmers far exceeded in originality and force by his *Dutch Nation* in 1812. Neither of these poets, however, had sufficient art to render their pieces classical, or, indeed, enough to protect them during their lifetime from the sneers of Bilderdijk. Other political writers, whose lyrical energies were stimulated by the struggle with France, were Maurits Cornelis van Hall (1768–1858), Samuel Iperuszoon Wiselius (1769–1845), and Jan ten Brink (1771–1839), the second of whom immortalized himself and won the favour of Bilderdijk by ridiculing the pretensions of such frivolous tragedians as Shakespeare and Schiller.

Van der Palm. Loots. Helmers.

The healthy and national spirit in which the ladies Wolff and Deken had written was adopted with great spirit by a novelist in the next generation, Adriaan Loosjes (1761–1818), a bookseller at Haarlem. His romantic stories of mediæval life, especially his *Charlotte van Bourbon*, are curiously like shadows cast forward by the Waverley Novels, but he has little of Sir Walter Scott's historical truth of vision. His production was incessant and his popularity great for many years, but he was conscious all through that he was at best but a disciple of the authoresses of *Sara Burgerhart*. Another disciple whose name should not be passed over is Maria Jacoba de Neufville (1775–1856), author of *Little Duties*, an excellent story somewhat in the manner of Mrs Opie.

Loosjes.

A remarkable poet whose romantic genius strove to combine the power of Bilderdijk with the sweetness of Feith is Hendrik Tollens (1780–1856), whose verses have shown more vitality than those of most of his contemporaries. He struck out the admirable notion of celebrating the great deeds of Dutch history in a series of lyrical romances, many of which possess a lasting charm. Besides his folk-songs and popular ballads, he succeeded in a long descriptive poem, *A Winter in Nova Zembla*, 1819. He lacks the full accomplishment of a literary artist, but his inspiration was natural and abundant, and he thoroughly deserved the popularity with which his patriotic ballads were rewarded. Willem Messchert (1790–1844), a friend and follower of Tollens, pushed the domestic and familiar tone of the latter to a still further point, especially in his genre poem of the *Golden Wedding*, 1825. Both these writers were natives and residents of Rotterdam, which also claims the honour of being the birthplace of Adrianus Bogaers (1795–1870), the most considerable poetical figure of the time. Without the force and profusion of Bilderdijk, Bogaers has more truth to nature, more sweetness of imagination, and a more genuine gift of poetry than that clamorous writer, and is slowly taking a higher position in Dutch literature as Bilderdijk comes to take a lower one. Bogaers printed his famous poem *Jochebed* in 1835, but it had then been in existence more than thirteen years, so that it belongs to the second period of imaginative revival in Europe, and connects the name of its author with those of Byron and Heine. Still more beautiful was his *Voyage of Heemskerk to Gibraltar* (1836), in which he rose to the highest level of his genius. In 1846 he privately printed his *Romances and Ballads*. Bogaers had a great objection to publicity,

Tollens. Messchert. Bogaers.

and his reputation was long delayed by the secrecy with which he circulated his writings among a few intimate friends. A poet of considerable talent, whose powers were awakened by personal intercourse with Bogaers and Tollens, was Antoni Christiaan Winand Staring (1767–1840), who first at the age of fifty-three came before the world with a volume of *Poems*, but who continued to write till past his seventieth year. His amorous and humorous lyrics recall the best period of Dutch song, and are worthy to be named beside those of Starter and Vondel.

Since 1830 Holland has taken a more prominent position in European thought than she could claim since the end of the 17th century. In scientific and religious literature her men of letters have shown themselves cognizant of the newest shades of opinion, and have freely ventilated their ideas. The language has resisted the pressure of German from the outside, and from within has broken through its long stagnation and enriched itself, as a medium for literary expression, with a multitude of fresh and colloquial forms. At the same time, no very great genius has arisen in Holland in any branch of literature, and all that a foreign critic can do in such space as is here at his command is to chronicle the names of a few of the most prominent writers of the past and present generations. The vast labours of Jakobus van Lennep (1802–68) consist of innumerable translations, historical novels, and national romances, which have gained for him the title of the leader of the Dutch romantic school. Reinier Cornelis Bakhuizen van den Brink (1810–65) was the chief critic of the romantic movement, and Everhard Johannes Potgieter (1808–75) its mystical philosopher and esoteric lyrical poet. The genius and influence of Potgieter were very considerable, but they were exceeded by the gifts of Nicolaes Beets, author of the famous *Camera Obscura* (1836), a masterpiece of humour and character. Johannes Pieter Hasebroek, who has been called the Dutch Charles Lamb, wrote in 1840 an admirable collection of essays entitled *Truth and Dreams*. A poet of unusual power and promise was lost in the early death of Pieter Augustus de Genestet (1830–1861). Criticism has been represented by W. J. A. Jonckbloet, C. Busken Huet, and Jan ten Brink. With Isaac de Costa (1798–1860), W. J. van Zeggelen, and J. J. L. Ten Kate, the domestic tendency of Cats and Bilderdijk has overpowered the influence of romanticism. An independent writer of great power and charm both in prose and verse is C. Vosmaer, author of a life of Rembrandt, and of a translation of the *Iliad* into Dutch hexameters. E. Douwes Dekker, in his novel of *Max Havelaar*, and Marcellus Emants, in his poem of *Lilith*, have displayed talents of a very modern and cosmopolitan order, but it yet remains to be seen whether they have sufficient power to sustain their promise.

Revival of Flemish literature.

Flemish literature has again come into being since the independence of Belgium, and has produced two writers of very remarkable talent, the popular poet Karel Ledeganck (1805–47), and the still more popular novelist Hendrik Conscience. But the general use of the French language, although Flemish exercises are encouraged by the Government, has prevented any considerable cultivation of Flemish by modern writers of ambition.

Authorities.—Dr W. J. A. Jonckbloet, *Geschiedenis der Nederlandsche Letterkunde*, 2d ed., 1873; Dr J. ten Brink, *Kleine Geschiedenis der Nederlandschen Letteren*, Haarlem, 1877; Dr J. van Vloten, *Schets van de Geschiedenis der Nederlandschen Letteren*, 1879. (E. W. G.)

HOLLAND, or Holland and West Friesland, was the second province of the republic of the United Netherlands, and consisted of the old countship of Holland, with the addition of the lordship of Voorne. In 1801, after the erection of the Batavian republic, very nearly the same area was included in the "department" of Holland; but when in June 1806 Holland became the name of the new kingdom, it ceased to be applied to any of the administrative divisions. On the establishment of the kingdom of the Netherlands in 1814 the province of Holland was restored, with its ancient limits only slightly modified. A few further alterations were made in 1815, 1819, and 1820. It was the only province that had two governors, one for the north and another for the south, and the provincial states met alternately at the Hague and at Haarlem. In 1840 this bipartite arrangement was carried to its logical conclusion by the erection of two distinct provinces called respectively North and South Holland.

1. North Holland (*Noordholland*), the fourth province of the kingdom of the Netherlands, lies between the German Ocean and the Zuyder Zee, and on the land side is bounded by the provinces of South Holland and Utrecht. The area—which in 1855 was increased by the commune of Haarlemmermeer, and in 1864 was diminished by the larger part of Leimuiden—is estimated at 744,554 acres, exclusive of the newly won lands of the Y. The amount of available ground has been augmented by the draining not only of the Haarlemmermeer but also of more than a score of lesser lakes. In 1840 the population was returned at 443,334, in 1850 at 477,079, in 1860 at 521,125, and in 1875 at 620,890. In 1870, when the total was 577,436, there were 382,607 Protestants, 157,971 Roman Catholics, 2723 Old Catholics, and 32,953 Jews. Amsterdam is the largest city, with a population in 1876 of 296,200; and next in order as communes follow Haarlem, 34,797; Helder, 22,030; Haarlemmermeer, 13,171; Zaandam, 12,772; Alkmaar, 12,245; Nieuweramstel, 11,502; Hoorn, 9763; Hilversum, 7805; Texel, 6383; Enkhuizen, 5560; and Edam, 5361. There are besides 36 communes with more than 2000 inhabitants.

2. South Holland (*Zuidholland*) is the third province of the kingdom of the Netherlands. On the W. it is bounded by the German Ocean, on the N. by North Holland, on the E. by Utrecht and Guelderland, on the S.E. by North Brabant, and on the S. by Zealand. The area is estimated at 823,851 acres. In 1850 the population was returned at 564,000, in 1860 at 617,699, and in 1876 at 748,162. In 1870, when the total was 688,254, there were 508,132 Protestants, 166,219 Roman Catholics, and 12,152 Jews. The largest city is Rotterdam, with a population in 1876 of 136,230; and next in order as communes follow the Hague, 101,095; Leyden, 41,298; Dort, 26,576; Delft, 24,511; Schiedam, 21,880; Gouda, 17,070; Kralingen, 10,313; Delfshaven, 10,042; and Gorinchem, 9301. There are besides 74 communes with more than 2000 inhabitants.

HOLLAND, Sir Henry (1788–1873), physician and author, was born at Knutsford, Cheshire, on the 27th October 1788. He could claim relationship to three persons who have attained eminence in careers entirely different both from one another and from his own: his maternal grandmother was the sister of Josiah Wedgwood, whose grandson was Charles Darwin; and his paternal aunt was the mother of Mrs Gaskell. After spending some years at a private school at Knutsford, he was sent to a school at Newcastle-on-Tyne, whence after four years he was transferred to Dr Estlin's school near Bristol. There he at once took the position of head boy, in succession to John Cam Hobhouse, afterwards Lord Broughton, an honour which required to be maintained by physical prowess. On leaving school he became articled clerk to a mercantile firm in Liverpool, but, as the privilege was reserved to him of passing two sessions at Glasgow university, he at the close of his second session sought relief from his articles, and in 1806 began the study of medicine in the university of Edinburgh, where he graduated in 1811. After several years spent in foreign travel, he began practice in 1816 as a physician in London,—according to his own statement, "with a fair augury of success speedily and completely fulfilled." This "success," he adds, "was materially aided by visits for four successive years to Spa, at the close of that which is called the London season." It must also, however, be in a great degree attributed to his happy temperament and his gifts as a conversationalist—qualities the influence of which, in the majority of cases belonging to his class of practice, is often of more importance than direct medical treatment. In 1816 he was elected a fellow of the Royal Society, and in 1828 a fellow of the Royal College of Physicians. He became physician in ordinary to Prince Albert in 1840, and was appointed in 1852 physician in ordinary to the Queen. In April 1853 he was created a baronet. He was also a D.C.L. of Oxford and a member of the principal learned societies of Europe. He was twice married, his second wife being a daughter of Sydney Smith, a lady of considerable literary talent, who published a biography of her father. Sir Henry Holland at an early period of his practice resolved to devote to his professional duties no more of his time than was necessary to secure an income of £5000 a-year, and also to spend two months of every year solely in foreign travel. By the former resolution he secured leisure for a wide acquaintance with general literature, and for a more than superficial cultivation of several branches of science; and the latter enabled him, besides visiting, "and most of them repeatedly, every country of Europe," to make extensive tours in the other three continents, journeying often to places little frequented by European travellers. As, moreover, he procured an introduction to nearly all the eminent personages in his line of travel, and knew many of them in his capacity of physician, his acquaintance with "men and cities" was of a species without a parallel. The *London Medical Record*, in noticing his death, which took place on his eighty-fifth birthday, October 27, 1873, remarked that it "had occurred under circumstances highly characteristic of his remarkable career." On his return from a journey in Russia he was present, on Friday, October 24th, at the trial of Marshal Bazaine in Paris, dining with some of the judges in the evening. He reached London on the Saturday, took ill the following day, and died quietly on the Monday afternoon.

Sir Henry Holland was the author of *General View of the Agriculture of Cheshire*, 1807; *Travels in the Ionian Isles, Albania, Thessaly, and Greece*, 1812-13, 2d ed., 1819; *Medical Notes and Reflections*, 1839; *Chapters on Mental Physiology*, 1852; *Essays on Scientific and other Subjects contributed to the Edinburgh and Quarterly Reviews*, 1862; and *Recollections of Past Life*, 1872, which is less interesting than it might have been, owing to the reticence of the author in regard to personal details and characteristics.

HOLLAND, PHILEMON (1551-1636), usually styled, in the words of Thomas Fuller, "the translator-general of his age," was born in 1551 at Chelmsford, in Essex, the son of a clergyman, John Holland, who had been obliged to take refuge abroad during the Marian persecution. Having become a fellow of Trinity College, Cambridge, and passed M.A. at Oxford in 1587, he further took the degree of M.D. at Cambridge in 1591. In 1612 he was sworn freeman of the city of Coventry, and in 1617, dressed in a suit which cost £11, 1s. 11d., he had the honour of reading, as the recorder's deputy, an oration to King James I. In 1628 he was appointed head master of the free school of Coventry, but, owing probably to advancing old age, he held office only for eleven months. His latter days were oppressed by poverty, partly relieved by the generosity of the common council of Coventry, which in 1632 assigned him £3, 6s. 8d. for three years, "if he should live so long." He died February 9, 1636, survived by only one of his seven sons. The fame of Philemon Holland is due solely to his activity as a translator; Livy, Pliny's *Natural History*, Plutarch's *Morals*, Suetonius, Ammianus Marcellinus, and Xenophon's *Cyropædia* successively employed him; and he also published an English version of Camden's *Britannia*. Pope's allusion to his voluminousness is well known—

"De Lyra there his dreadful front extends,
And here the groaning shelves Philemon bends."

Henry Holland, his surviving son, became a London bookseller, and is known to bibliographers for his *Baziliωlogia; a Booke of Kings, beeing the true and liuely Effigies of all our English Kings from the Conquest* (London, 1618), and his *Herωologia Anglica, hoc est clariss. et doctiss. aliquot Anglorum viuæ Effigies, Vitæ et Elogia* (1620).

See Colvile's *Worthies of Warwickshire* (Warwick, 1869), and Lowndes's *Bibliographical Manual*.

HOLLAND, HENRY RICHARD VASSALL FOX, THIRD BARON (1773-1840), nephew of Charles James Fox and only son of Stephen Fox, second Lord Holland, was born at Winterslow House, Wiltshire, 21st November 1773. Of his ancestry an account is given in the article FOX (CHARLES JAMES). Not long after his birth he was with difficulty saved from the flames which destroyed the splendid family mansion in which he was born. When little more than a year old he succeeded, through the death of his father, to the peerage. On the death of his mother in his fifth year, the care of his early education nominally devolved upon her brother, the earl of Upper Ossory, but the character of his early training and studies was determined chiefly by his uncle Charles James Fox, of whom he wrote—"He seemed to take pleasure in awakening my ambition, and directing it both by conversation and correspondence, and yet more by talking to me of my studies and inspiring me with a love of poetry both ancient and modern." After spending eight or nine years at Eton, where he had as contemporaries J. Hookham Frere, Mr Canning, and Frederick Howard, fifth earl of Carlisle, he in 1790 entered Christ Church College, Oxford. Though the years of his early manhood were occupied more in amusement than in study, he acquired at school and the university a taste for classical literature which he more fully cultivated in after life. Before taking his seat in the House of Lords, he made two tours on the Continent,—in 1791, while still a student at Oxford, visiting Paris about the time when Louis XVI. accepted the revolutionary constitution; and in 1793 making a prolonged stay in Spain, where he began the study of its language and literature. Thence he went in 1795 to Italy; and at Florence he formed the acquaintance of Lady Webster, wife of Sir Godfrey Webster, whom after her divorce from her husband —who received £6000 damages in the action against Lord Holland—he married in 1797. After the marriage he assumed his wife's family name of Vassall, but its use was discontinued by his son, the fourth and last Lord Holland.

Lord Holland's early inheritance of a peerage must be regarded rather as a misfortune than an advantage, for it debarred him from a career in the House of Commons which might have proved as brilliant as that of his uncle Charles Fox, and raised him to an assembly, not only more listless and much less numerous, but where at the time he entered it the Whig party, of whose principles the influence of his uncle had induced him to become a strenuous supporter, could muster only a minority of six or seven in a house of eighty or ninety. He began his political career by a motion against the Assessed Tax Bill, and though his speech had, as was to be expected, no influence on the division, it proved that he had inherited the oratorical abilities of his family, and pointed him out as the leader of his uncle's supporters in the Upper House. As his disapproval of most of the proceedings of the House of Lords was recorded by protests, his copiousness in this species of composition has perhaps never been equalled. These protests were afterwards collected and published by D. C. Moylan under the title *The Opinions of Lord Holland as recorded in the Journals of the House of Lords, from* 1797 *to* 1841 (London, 1841), and, besides constituting, as they necessarily do, a full though condensed account of his political views and opinions, form one of the most authentic and original records of the course of Whig policy during the years to which they refer. After the peace of Amiens in 1802 Lord Holland proceeded to Paris, whence he went to Spain, staying in that country until the declaration of war in January 1805, when he returned to England. Of this second visit to Spain he doubtless took advantage for the purpose of acquiring a more complete mastery of the Spanish language and literature, and the fruit of this was seen by the publication in 1807 of *The Life and Writings of Lope Felix de Vega Carpio*, and in 1808 of *Three Comedies from the Spanish*. When the ministry of "All the Talents" came into office in 1806, Lord Holland was made a privy councillor, and was appointed along with Lord Auckland to negotiate with the American plenipotentiaries that treaty the refusal of whose ratification by Mr Jefferson resulted in the subsequent war with America. On the death of Mr Fox, 15th October following, Lord Holland received the privy seal, holding office till the dismissal of the ministry in 1807. When the Spaniards rebelled against the French yoke in 1808, Lord Holland's interest in the country induced him to pay it a third visit. He landed at Corunna almost simultaneously with the division of the British army under Sir David Baird, and did not return to England till the close of 1809. During the long period when the Whigs were excluded from power Lord Holland continued to afford them his strenuous and steady support. He did not join the Canning ministry of 1827, but when the Whigs were recalled in 1830 he became chancellor of the duchy of Lancaster, an office which, with the exception of two short intervals when his party were temporarily excluded from power, he continued to hold till his death at Holland House, 22d October 1840.

Although Lord Holland for the greater period of his life had to lead the forlorn hope of his party in the House of Lords, his influence on the politics of his country was of an importance far beyond what was manifest at the time, and without his persistent support in parliament and his aid in maintaining his party's courage and discipline, the triumph of many of the measures he advocated would in all probability not have been so speedy and complete. Few have been more closely identified with all the great political changes of the first half of the present century, more especially the extension of the suffrage, the abrogation of Catholic disabilities, the abolition of the Test and Corporation Acts, the repeal of the corn laws, and the repression of the slave trade. A sympathizer with the French Revolution, he differed from his party in his admiration and esteem for Napoleon, against whose imprisonment he protested as an outrageous violation both of good faith and of what was due to fallen greatness. The character of Lord Holland's oratory very closely resembled that of his uncle Charles Fox, and was inferior to it only perhaps because his natural indolence was not counteracted by the stimulus of a popular assembly encouraging him to a more careful study of the art of eloquence, and affording him more adequate opportunities for its display. He excelled principally in close reasoning rendered clear and easy of apprehension by copious illustration, and—as was to be expected from the fact that he trusted little to previous preparation—was more happy in reply than in original statement. The effect of the best passages of his speeches was often marred by a more aggravated form of that tendency to hesitation which was one of the principal oratorical defects of Fox, the rush of ideas seeming to be too rapid to permit him to select with ease from his copious vocabulary the word most appropriate for his purpose. According to Lord Brougham—"The same delicate sense of humour which distinguished Mr Fox he also showed, and much of the exquisite Attic wit which formed so large and so effective a portion of that great orator's argumentation, never uselessly introduced, always adapted nicely to the occasion, always aiding and as it were directing the reasoning." The language both of his spoken and written style was graceful, pure, flowing, and vigorous, and entirely devoid of extravagance, singularity, or affectation. In addition to his poetical translations, he was the author of fugitive verses of some elegance. Two of his works were published posthumously by his son Henry Edward, fourth Lord Holland —*Foreign Reminiscences* (1850), and *Memoirs of the Whig Party during my Time* (2 vols. 1852-54).

It is, however, as the restorer of Holland House, and as the host of the brilliant company which he there assembled, that Lord Holland in all probability will be chiefly remembered by posterity. Though his temper was quick and excitable, his amiable disposition rendered his manners in private uniformly cordial and engaging. His conversation, easy, unconstrained, and of great variety both as to manner and matter, was enlivened by a peculiarly genial wit, and a never-failing supply of racy anecdote to which his powers of mimicry gave additional point and zest. The width of his sympathies and his manifold acquirements enabled him to enjoy the society of persons of every species of intellectual eminence. Holland House, which owes its name to Henry Rich, first earl of Holland,—who was no relation of the Fox family,—and which had been afterwards the home of Addison and of other tenants of various kinds of distinction, was restored by Lord Holland in a manner worthy of the company of European statesmen, artists, and men of letters, of which it became the common meeting-place. Much of the attraction of these brilliant gatherings was due to the management and personal influence of Lady Holland, who had the peculiar gift of making herself both feared and fascinating at the same time. Of her the Princess Liechtenstein writes—"Beautiful, clever, and well-informed, she exercised a natural authority over those around her. But a habit of contradiction—which, it is fair to add, she did not mind being reciprocated upon herself—occasionally lent animation, not to say animosity, to the arguments in which she engaged. It is easy for some natures to say a disagreeable thing, but it is not always easy to carry a disagreeable thing off cleverly. This Lady Holland could do."

See Macaulay's *Essays*; Brougham's *Statesmen of the Time of George III. and IV.*; Hayward's *Essays*; Sir Henry Holland's *Recollections*; and *Holland House*, by Princess Marie Liechtenstein, 2 vols., 1874.

HOLLAR, WENZEL or WENCESLAUS (1607-1677), a celebrated etcher, was born at Prague on July 13, 1607, and died in Westminster, being buried at St Margaret's church on March 28, 1677. His family was ruined by the capture of Prague in the Thirty Years' War, and young Hollar, who had been destined for the law, determined to become an artist. The earliest of his works that have come down to us are dated 1625 and 1626; they are small plates, and one of them is a copy of a Virgin and Child by Dürer, whose influence upon Hollar's work was always great. In 1627 he was at Frankfort, working under Matthew Merian, an etcher and engraver; thence he passed to Strasburg and thence, in 1633, to Cologne. It was there that he attracted the notice of the famous amateur Thomas, earl of Arundel, then on an embassy to the imperial court; and with him Hollar travelled to Vienna and Prague, and finally came in 1637 to England, destined to be his home for many years. Though he lived in the household of Lord Arundel, he seems to have worked not exclusively for him, but to have begun that slavery to the publishers which was afterwards the normal condition of his life. In his first year in England he made for Stent, the printseller, the magnificent View of Greenwich, nearly a yard long, and received thirty shillings for the plate,—perhaps a twentieth part of what would now be paid for a single good impression. Afterwards we hear of his fixing the price of his work at fourpence an hour, and measuring his time by a sandglass. The civil war had its effect on his fortunes, but none on his industry. Lord Arundel left England in 1642, and Hollar passed into the service of the duke of York, taking with him a wife and two children. With other royalist artists, notably Inigo Jones and Faithorne, he stood the long and eventful siege of Basing House; and as we have some hundred plates from his hand dated during the years 1643 and 1644 he must have turned his enforced leisure to good purpose. Taken prisoner, he escaped or was released, and joined Lord Arundel at Antwerp, and there he remained eight years, the prime of his working life, when he produced his finest plates of every kind, his noblest views, his miraculous "muffs" and "shells," and the superb portrait of the duke of York. In 1652 he returned to London, and lived for a time with Faithorne the engraver near Temple Bar. During the following years were published many books which he illustrated:—Ogilby's *Virgil* and *Homer*, Stapylton's *Juvenal*, and Dugdale's *Warwickshire*, *St Paul's*, and *Monasticon* (part i.). The booksellers continued to impose on the simple-minded foreigner, pretending to decline his work that he might still further reduce the wretched price he charged them. Nor did the Restoration improve his position. The court did nothing for him, and in the great plague he lost his young son, who, we are told, might have rivalled his father as an artist. After the great fire he produced some of his famous "Views of London"; and it may have been the success of these plates which induced the king to send him, in 1668, to Tangier, to draw the town and forts. During his return to England occurred the desperate and successful engagement fought by his ship the "Mary Rose," under Captain Kempthorne, against seven Algerine men-of-war,—a brilliant affair which Hollar etched for Ogilby's *Africa*. He lived eight years after his return, still working for the booksellers, and retaining to the end his wonderful powers; witness the large plate of Edinburgh (dated 1670), one of the greatest of his works. He died in extreme poverty, his last recorded words being a request to the bailiffs that they would not carry away the bed on which he was dying.

Hollar has been called by a recent critic "the most accurate delineator and the most ingenious illustrator of his time, and as to technic the most able etcher." His variety was boundless; his plates number some 2740, and include views, portraits, ships, religious subjects, heraldic subjects, landscapes, and still life in a hundred different forms. No one that ever lived has been able to represent fur, or shells, or a butterfly's wing, as he has done. His architectural drawings, such as those of Antwerp and Strasburg cathedrals, and his views of towns, are mathematically exact, but they are pictures as well. He could reproduce the decorative works of other artists quite faultlessly, as in the famous chalice after Mantegna's drawing. His *Theatrum Mulierum* and similar collections reproduce for us with literal truth the outward aspects of the people of his day; and his portraits, a branch of art in which he has been unfairly disparaged, are of extraordinary refinement and power. His genius is wholly unlike that of his great contemporary Rembrandt; it aims rather at the delicate rendering of details than at the truth of character and the mystery of light and shade. But in his own way Hollar is as perfect as Rembrandt.

Almost complete collections of Hollar's works exist in the British Museum and in the library at Windsor Castle. Two admirable catalogues of his plates have been made, one in 1745 (2d ed., 1759), by George Vertue, and one in 1853 by Parthey. The latter, published at Berlin, is a model of German thoroughness and accuracy, and leaves very little to be added by future research.

HOLLY, *Ilex*, L., a genus of trees and shrubs of the natural order *Ilicineæ* or *Aquifoliaceæ*, containing some one hundred and fifty species, of which several occur in the temperate northern hemisphere, North-West America excepted, by far the larger number in tropical Asia and America, and very few in Africa and Australia. In Europe, where *I. Aquifolium* is the sole surviving species, the genus was richly represented during the Miocene period by forms at first South American and Asiatic, and later North American in type (Schimper, *Paléont. Végét.*, iii. 204, 1874). The leaves are generally coriaceous and evergreen, and are alternate and stalked; the flowers are commonly diœcious, are in axillary cymes, fascicles, or umbellules, and have a persistent four- to five-lobed or parted calyx, a white, rotate four- or rarely five- or six-cleft corolla, with the four or five stamens adherent to its base in the male, sometimes hypogynous in the female flowers, and a two- to twelve-celled ovary; and the fruit is a globose, very seldom ovoid, and usually red drupe, containing two to sixteen one-seeded stones.

The Common Holly, or Hulver (apparently the κήλαστρος of Theophrastus;[1] Ang.-Sax., *holen* or *holegn*; Mid. Eng., *holyn* or *holin*, whence *holm* and *holmtree*;[2] Welsh, *celyn*; Germ., *Stechpalme*, *Hülse*, *Hulst*; Old Fr., *houx*; and Fr., *houlx*),[3] *I. Aquifolium*, L., is an evergreen shrub or low tree, having smooth, ash coloured bark, and wavy, pointed, smooth, and glossy leaves, 2 to 3 inches long, with a spinous margin, raised and cartilaginous below, or, as commonly on the upper branches of the older trees, entire—a peculiarity alluded to by Southey in his poem *The Holly Tree*. The flowers, which appear in May, are ordinarily diœcious, as in all the best of the cultivated varieties in nurseries (*Gard. Chron.*, 1877, i. 149). Darwin (*Diff. Forms of Flow.*, p. 297, 1877) says of the holly: "During several years I have examined many plants, but have never found one that was really hermaphrodite." Shirley Hibberd, however (*Gard. Chron.*, 1877, ii. 777), mentions the occurrence of "flowers bearing globose anthers well furnished with pollen, and also perfect ovaries." In his opinion, *I. Aquifolium* changes its sex from male to female with age. In the female flowers the stamens are destitute of pollen, though but slightly or not at all shorter than in the male flowers; the latter are

[1] *Hist. Plant.*, i. 9. 3, iii. 3. 1, and 4. 6, *et passim*. On the *aquifolium* or *aquifolia* of Latin authors, commonly regarded as the holly, see A. de Grandsagne, *Hist. Nat. de Pline*, bk. xvi., "Notes," pp. 199, 206.

[2] The term "holm," as indicative of a prevalence of holly, is stated to have entered into the names of several places in Britain. From its superficial resemblance to the holly, the tree *Quercus Ilex*, L., the evergreen oak, received the appellation of "holm-oak."

[3] Skeat (*Etymolog. Dict.*, 1879) with reference to the word holly remarks: "The form of the base KUL (=Teutonic HUL) is probably connected with Lat. *culmen*, a peak, *culmus*, a stalk; perhaps because the leaves are 'pointed.'" Grimm (*Deut. Wört-rb.*, Bd. iv.) suggests that the term *Hulst*, as the O.H.G. *Hulis*, applied to the butcher's broom, or knee-holly, in the earliest times used for hedges, may have reference to the holly as a protecting (*hüllender*) plant.

more numerous than the female, and have a smaller ovary, and a larger corolla, to which the filaments adhere for a greater length. The corolla in male plants falls off entire, whereas in fruit-bearers it is broken into separate segments by the swelling of the young ovary (M'Nab). The holly occurs in Britain, north east Scotland excepted, and in western and southern Europe, from as high as 62° N. lat. in Norway to Turkey and the Caucasus, and in western Asia. It is found generally in forest glades or in hedges, and does not flourish under the shade of other trees. In England it is usually small, probably on account of its destruction for timber, but it may attain to 60 or 70 feet in height, and Loudon mentions one tree at Claremont, in Surrey, of 80 feet. Some of the trees on Bleak Hill, Shropshire, are asserted to be 14 feet in girth at some distance from the ground (*N. and Q.*, 5th ser., xii. 508). The holly is abundant in France, especially in Britanny. It will grow in almost any soil not absolutely wet, but flourishes best in rather dry than moist sandy loam. Beckmann (*Hist. of Invent.*, i. 193, 1846) says that the plant which first induced J. di Castro to search for alum in Italy was the holly, which is there still considered to indicate that its habitat is aluminiferous. The holly is propagated by means of the seeds, which do not normally germinate until their second year (see ARBORICULTURE, vol. ii. p. 322), by whip-grafting and budding, and by cuttings of the matured summer shoots, which, placed in sandy soil and kept under cover of a hand-glass in sheltered situations, generally strike root in spring. Transplantation should be performed in damp weather in September and October, or, according to some writers, in spring or on mild days in winter, and care should be taken that the roots are not dried by exposure to the air. It is rarely injured by frosts in Britain, where its foliage and bright red berries in winter render it a valuable ornamental tree. The yield of berries has been noticed to be less when a warm spring, following on a wet winter season, has promoted excess of growth. There are numerous varieties of the holly. Some trees have yellow, and others white or even black fruit. In the fruitless variety *laurifolia*, "the most floriferous of all hollies" (Hibberd), the flowers are highly fragrant; the form known as *femina* is, on the other hand, remarkable for the number of its berries. The leaves in the unarmed varieties *aureo-marginata* and *albo-marginata* are of great beauty, and in *ferox* they are studded with sharp prickles. The holly is of importance as a hedge-plant (see ARBORICULTURE, vol. ii. p. 319), and is patient of clipping, which is best performed by the knife. Evelyn's holly hedge at Say's Court, Deptford, was 400 feet long, 9 feet high, and 5 feet in breadth. To form fences, for which Evelyn recommends the employment of seedlings from woods, the plants should be 9 to 12 inches in height, with plenty of small fibrous roots, and require to be set 1 to 1½ feet apart, in well-manured and weeded ground, and thoroughly watered.

The wood of the holly is even-grained and hard, especially when from the heartwood of large trees, and almost as white as ivory, except near the centre of old trunks, where it is brownish. It is employed in inlaying and turning, and, since it stains well, in the place of ebony, as for tea-pot handles. For engraving it is inferior to box. When dry it weighs about 47½ lb per cubic foot. From the bark of the holly bird-lime is manufactured. From the leaves are obtainable a colouring matter named *ilixanthin*, *ilicic acid*, and a bitter principle, *ilicin*, which has been variously described by different analytical chemists. The leaves have been used in rheumatism, and were at one time, on account of their taste, supposed to be of value in intermittent fever. A. Lonicerus (*Kreuterb.*, Th. 1, p. xxxviii., Frankf., 1582, fol.) speaks of their decoction as a remedy for pain in the side. They are eaten by sheep and deer, and in parts of France serve as a winter fodder for cattle. The berries provoke in man violent emesis and catharsis, but are eaten with immunity by thrushes and other birds. The larvæ of the moths *Sphinx ligustri*, L., and *Phoxopteryx nævana*, Hb., have been met with on holly. The leaves are mined by the larva of a fly, *Phytomyza ilicis*, and both on them and the tops of the young twigs occurs the plant-louse *Aphis ilicis*, Kalt. (Kaltenbach, *Pflanzenfeinde*, p. 427, 1874). The custom of employing holly and other plants for decorative purposes at Christmas is one of considerable antiquity, and has been regarded as a survival of the usages of the Roman Saturnalia, or of an old Teutonic practice of hanging the interior of dwellings with evergreens as a refuge for sylvan spirits from the inclemency of winter. A Border proverb defines an habitual story-teller as one that "lees never but when the hollen is green." Several popular superstitions exist with respect to holly. In the county of Rutland it is deemed unlucky to introduce it into a house before Christmas Eve. In some English rural districts the prickly and non-prickly kinds are distinguished as "he" and "she" holly; and in Derbyshire the tradition obtains that according as the holly brought at Christmas into a house is smooth or rough, the wife or the husband will be master. Holly that has adorned churches at that season are in Worcestershire and Herefordshire much esteemed and cherished, the possession of a small branch with berries being supposed to bring a lucky year; and Lonicerus (*op. cit.*) mentions a notion in his time vulgarly prevalent in Germany that consecrated twigs of the plant hung over a door are a protection against thunder.

Among the North American species of *Ilex* are *I. opaca*, Ait., which resembles the European tree, and the Inkberry, *I.* (*Prinos*) *glabra*, L., and the American Black Alder, or Winterberry, *I.* (*Prinos*) *verticillata*, L. Hooker (*Fl. of Brit. India*, i. 598,606) enumerates twenty-four Indian species of Ilex. The Japanese *I. crenata*, Thb., and *I. latifolia*, Thb., a remarkably hardy plant, and the North American *I. Dahoon*, Walt., are among the species cultivated in Britain. The leaves of several species of *Ilex* are used by dyers. The member of the genus most important economically is *I. paraguayensis*, St.-Hil., the prepared leaves of which constitute Paraguay tea, or MATÉ (*q.v.*). Knee Holly is the species *Ruscus aculeatus*, L.; Sea Holly, *Eryngium maritimum*, L.; and the Mountain Holly of America, *Nemopanthes canadensis*, D. C.

HOLLYHOCK (from M.E. *holi*—doubtless because brought from the Holy Land, where it is indigenous (Wedg.)—and A.-S. *hoc*, a mallow), *Althæa rosea*, L., a perennial plant of the natural order *Malvaceæ* and tribe *Malveæ*, a native of the East, has been cultivated in Great Britain for about three centuries. The ordinary hollyhock is single-blossomed, but the florists' varieties have all double flowers, of white, yellow, rose, purple, violet, and other tints, some being almost black. The plant is in its prime about August, but by careful management examples may be obtained in blossom from July to as late as November. Hollyhocks are propagated from seed, or by division of the root, or by planting out in rich sandy soil, in a close frame, with a gentle bottom heat, single eyes from wood-shoots, or cuttings from outgrowths of the old stock or of the lateral offsets of the spike. The seed may be sown in October under cover, the plants obtained being potted in November, and kept under glass till the following April, or, if it be late-gathered, in May or June, in the open ground, whence, if required, the plants are best removed in October or April. Seedlings may also be raised in February or March, by the aid of a gentle heat, in a light and rich moist soil; they should not be watered till they have made their second leaves, and when large enough for handling should be pricked off in a cold frame; they are subsequently transferred to the flower-bed. Hollyhocks thrive best in a well-trenched and manured sandy loam. The spikes as they grow must be staked; and water and, for the finest blossoms, liquid manure should be liberally supplied to the roots. Plants for exhibition require pruning of side growths; and it is recommended, when the flowering is over, and the stalks have been cut off 4 to 6 inches above the soil, to earth up the crowns with sand. Some of the finest double-flowered kinds of hollyhock will not bloom well in Scotland. The plant is susceptible of great modification under cultivation. The forms now grown are due to the careful selection and crossing of varieties, first by Mr Charles Baron, a shoemaker at Saffron-Walden, and afterwards by Mr Paul of Cheshunt, Messrs R. B. Bircham, W. Chater, Downie & Laird, John Laing, Anthony Parsons, and other well-known floriculturists. It is found that the most diverse varieties may be raised with certainty from plants growing near together. Darwin from the seed of 11 out of 18 varieties procured 62 plants, all perfectly true to their kind, and from the seed of the remaining 7 varieties 49 plants, half true and half false. Mr Masters of Canterbury, he relates, saved seed from a great bed of 24 named varieties planted in closely adjoining rows, each of which faithfully reproduced itself, with only sometimes a shade of difference in tint. Since the abundant pollen of the hollyhock becomes ripe, and is for the most part shed, before the stigma of the flower affording it is ready for its reception, the preservation of the individuality of different varieties flourishing side by side, in spite of the frequent visits of bees (unless, as suggested by Mr Turner of Slough, those insects be debarred access to the pollen and stigmas by the doubleness of the flowers), would appear to be due to the prepotency of the pollen of each variety on its own stigma over that of all other plants. The hollyhock is very liable to the attacks of slugs, and to a disease occasioned by a fungus, *Puccinia malvacearum*, which, originally from South America, attained notoriety in the Australian colonies, and finally, reaching Europe, threatened the extermination of the hollyhock, the soft parts of the leaves of which it destroys, leaving the venation only remaining. It has been found especially hurtful to the plant in dry seasons. Wild mallows, upon which also it is parasitic, do not appear to be very injuriously affected by it. As means of getting rid of this pest the following expedients have been resorted to:—the application of a weak aqueous solution of Condy's fluid, which in killing it turns its natural light grey colour to a rusty black, or of a strong solution of soft soap with sulphur ("Gishurst compound"); the destruction of the plants, and their replacement by healthy stocks; and, as practised by Mr Chater, cultivation in highly-manured trenches, with all possible exposure to the open air, and mulching during summer.

Berkeley, *Fungi: their Nature, Influence, and Uses*, p. 230, 1875; *Florist*, 1875; *Floral World*, 1877 and 1879; *Gardener's Chron.*, 1877, i. 114, and 1878, i. 766, and ii. 478; and, for fig. of pollen of hollyhock, BOTANY, vol. iv. p. 139.

HOLMAN, JAMES (*c.* 1787–1857), the "Blind Traveller," was born about 1787. He entered the British navy in 1798 as first-class volunteer, and was appointed lieutenant in April 1807. In 1810 he was invalided by an illness which resulted in the total and hopeless deprivation of sight. In consideration of his helpless circumstances he was in 1812 appointed one of the royal knights of Windsor, but the dulness and seclusion of such a life harmonized so ill with his active habits and his keen interest in the outside world that he requested leave of absence that he might go abroad. This being granted, he in 1819, 1820, and 1821 journeyed through France, Italy, Switzerland, the parts of Germany bordering on the Rhine, Belgium, and the Netherlands. In 1822 he published a narrative of his journey. His enjoyment in his travels was derived from the love of locomotion and the attendant exercise, the varieties of company and of topics of conversation, and the information and descriptions he obtained from eye-witnesses, which constantly supplied him with new materials on which to exercise his imagination. He again set out in 1822 with the design of making the circuit of the world, but after travelling through Russia into Siberia, he was arrested when he had managed to penetrate 1000 miles beyond Smolensk, and after being conducted to the frontiers of Poland, returned home by Austria, Saxony, Prussia, and Hanover. The pretext for arresting him was the suspicion of his being a spy, but the probability is that the authorities wished to prevent him from persevering in what they must have regarded as, to one in his helpless condition, a foolish and hazardous adventure. An account of his journey was published in 1825. Shortly afterwards he again set out to accomplish by a somewhat different method the design which had been frustrated by the Russian authorities; and an account of his remarkable achievement was published in four volumes in 1834–35, under the title of *A Voyage round the World, including Travels in Africa, Asia, Australasia, America, &c., from* 1827 *to* 1832. His last journeys were through Spain, Portugal, Wallachia, Moldavia, Montenegro, Syria, and Turkey; and he was engaged in preparing his journals of this tour for the press when he died at London, 29th July 1857. The works of Holman, besides the interest attaching to them from his incidental references to the peculiarities of his circumstances arising from his physical defect, and to his methods of triumphing over his difficulties, occupy a unique place in literature as products of very extraordinary energy and perseverance, while, on account of the variety of their information and their frequently graphic descriptions, they are of considerable value as books of travel.

HOLSTEIN. See SCHLESWIG-HOLSTEIN.

HOLT, SIR JOHN (1642–1710), lord chief-justice of the Court of King's Bench in the reigns of William III. and Anne, was born at Thame, Oxfordshire, December 30, 1642. His father, Sir Thomas Holt, possessed a small patrimonial estate, but in order to supplement his income had adopted the profession of law, in which he was not very successful, although he became sergeant in 1677, and afterwards for his political services to the "Tories" was rewarded with knighthood. After attending for some years the free school of the town of Abingdon, of which his father was recorder, young Holt in his sixteenth year entered Oriel College, Oxford. He is said to have spent a very dissipated youth, and even to have been in the habit of taking purses on the highway, but after entering Gray's Inn about 1660 he completely renounced his old habits and applied himself with exemplary diligence to the study of law. He was called to the bar in 1663, and, although his youth hindered his immediate success, when once he had an opportunity of manifesting his talent he speedily acquired a lucrative practice. An ardent supporter of civil and religious liberty, he distinguished himself in the state trials which were then so common by the able and courageous manner in which he supported the pleas of the defendants. In February 1666 he was appointed recorder of London, and on the 22d of April he was made king's sergeant and received the honour of knighthood. His giving a decision adverse to the pretensions of the king to exercise martial law in time of peace led to his dismissal from the office of recorder, but he was continued in the office of king's sergeant in order to prevent him from becoming counsel for accused persons. Having been one of the judges who acted as assessors to the peers in the Convention parliament, he took a leading part in arranging the constitutional change by which William III. was called to the throne, and after his accession he was appointed lord chief-justice of the king's bench. His merits as a judge are the more apparent and the more remarkable when contrasted with the qualities displayed by his unworthy predecessors in office. In judicial fairness, legal knowledge and ability, clearness of statement, and unbending integrity he has had few if any superiors on the English bench. Over the civil rights of his countrymen he exercised a jealous watchfulness, more especially when presiding at the trial of state prosecutions, and he was especially careful that all accused persons should be treated with fairness and respect. He is, however, best known for the firmness with which he upheld his own prerogatives in opposition to the authority of the Houses of Parliament. On several occasions his physical as well as his moral courage was tried by extreme tests. Having been requested to supply a number of police to help the soldiery in quelling a riot, he assured the messenger that if any of the people were shot he would have the soldiers hanged, and proceeding himself to the scene of riot he was successful in preventing bloodshed. A still more signal proof of his courage is said to have been given in the Aylesbury case. He declared in favour of the Aylesbury burgesses, who had been committed to Newgate for complaining about the non-registry of their votes. On this account his commitment was moved by the Tories, but the result of the motion is uncertain. There is a tradition, however, which whether true or not is equally a tribute to his integrity, that the House of Commons summoned him to appear before them, and that when, on his disregarding the summons, the speaker himself made his appearance, Holt told him that unless he returned to his chair within five minutes he would have him sent to Newgate. While steadfast in his sympathies with the Whig party, Holt maintained on the bench entire political impartiality, and always held himself aloof from political intrigue. On the retirement of Somers from the chancellorship in 1700 he was offered the great seal, but declined it. His death took place 3d March 1710, and he was buried in the chancel of Redgrave church, where a fine monument in white marble was erected by his brother to his memory.

Reports of Cases determined by Sir John Holt, 1681-1710, appeared at London in 1738; and *The Judgments delivered in the case of Ashby v. White and others, and in the case of John Paty and others, printed from original MSS.*, at London, 1837. See Burnet's *Own Times*; *Tatler*, No. xiv.; a Life, published in 1764; Welsby, *Lives of Eminent English Judges of the 17th and 18th Centuries*, 1846; and Campbell's *Lives of the Lord Chief Justices*.

HÖLTY, LUDWIG HEINRICH CHRISTOPH (1748–1776), German poet, and one of the founders of the "Hainbund," was born at Mariensee in Hanover, December 21, 1748. His father, who was a pastor, was three times married, and Hölty was the eldest of his ten children. His second wife, Hölty's mother, died in 1758, and her children were tenderly brought up by the third wife, together with her own large family. In his ninth year, Hölty, till then a beautiful and lively child, was smitten with smallpox, and was for some time nearly blind. On his recovery, his features and disposition were altered, and he was through life plain, silent, and awkward. From an early age he was an inveterate lover of solitude and books. He was taught at home by his father, besides the ordinary school branches, Latin, French, and Hebrew, and at the age of sixteen was sent to the public school of Celle. On leaving Celle three years later, he went as a theological student to Göttingen, where, however, he devoted his leisure hours to the study of the English and Italian poets, and began his own literary career. The appearance of some of his verses in a Göttingen weekly paper, especially those on the death of Münchhausen, brought his name before the public, and he was shortly afterwards admitted as a member of the "German Society." He now made the acquaintance of Bürger, Miller, Voss, Boie, the brothers Stolberg, and other poets, in conjunction with whom he formed in 1772 the famous poetical brotherhood known as the "Hainbund." The next two years were spent by Hölty in this brilliant and enthusiastic company; and, with the assistance of a scholarship and a post in the philological seminary in Göttingen, he succeeded in making a scanty livelihood by teaching English and Greek and by making translations. In 1774, having abandoned the intention of entering the church, he accompanied his friend Miller to Leipsic, where he remained for a year in the hopes of obtaining a private tutorship. The penniless young poet had for some time been silently attached to a lady, who about this time married some more eligible suitor. His health now began to cause him anxiety, and symptoms of consumption, inherited from his mother, made their appearance. His prospects were further altered by the death of his father in 1775; and Hölty found himself not only thrown entirely on his own resources, but obliged in some measure to assist his family. Towards the end of 1775 he settled in Hanover, to be near his physician Zimmermann and his friend Boie, and there he died in his twenty-eighth year, September 1, 1776. Hölty was a writer of ballads, idylls, elegies, and odes. His conceptions, if not lofty, are always graceful, his style finished, his language and rhythm faultless. He was from the first one of the shining lights of the "Hainbund," and during his short career became one of the most popular of German lyric poets. Many of his songs have become folk-songs, and his ballads have been ranked with those of Bürger.

Hölty was engaged when he died in collecting and revising his poems for the press; and after his death his friends Boie and Voss undertook the charge of their publication. In 1782, however, an incorrect edition of his works appeared edited by Geissler, which contained many poems not by Hölty. The correct edition was first published by Voss and Stolberg in 1783, and again, revised, in 1804. An edition of his *Gedichte*, with a biographical introduction and notes by Karl Halm, was published by Brockhaus in the *Bibliothek der Deutschen Nationalliteratur* (1870).

HOLYHEAD (Welsh, *Caer-Gybi*, the fort of Gybi), a market-town and parliamentary borough of Anglesey, North Wales, is situated on a small island on the western extremity of the county and at the terminus of the Chester and Holyhead Railway, 24 miles from Bangor. It is connected with the mainland by an embankment three-quarters of a mile long, over which pass both the railway and the coach road. Underneath the bridge in the centre the tide rushes with great velocity. The town, formerly a small fishing village, has since the reign of William III. acquired importance as the station of the mail packets for Dublin, and it now possesses a magnificent harbour of refuge begun in 1847, and formally opened in September 1873. The original plan included the erection of a north breakwater 5360 feet in length from the coast-line, and also of an east breakwater 2000 feet in length, but the scheme of the east breakwater, of which the chief object was to cover the Platter's and Skinner's Rocks, was subsequently abandoned, and their positions were marked instead by buoys. On account of the number of vessels which began to take advantage of the shelter that was being provided for them it was also resolved to lengthen the northern breakwater in a north-easterly direction by 2000 feet, and subsequently by 500 feet more, making its total length 7860 feet. By these additions a sheltered roadstead of 400 acres in extent was obtained, besides the enclosed area of 267 acres. The breakwater consists of a rubble mound, upon which is erected a solid central wall of massive masonry rising to a height of 38 feet 9 inches above low water. On the wall there is a promenade sheltered on the sea side by a parapet. The breakwater is terminated by a head 150 feet long and 50 feet wide, on which is erected a lighthouse. The whole cost of the works was £1,479,538. In 1873 works were commenced by the railway company for extending the old harbour and increasing the length of the quay to 4000 feet. They were opened by the prince of Wales in June 1880. The cost has been nearly half a million sterling. Upon the pier of the old harbour there is an arch of Mona marble, commemorative of the visit of George IV. in 1821 on his way to Ireland. The church, an old embattled building, is said to occupy the site of an ancient monastery founded by St Gybi about 610; and in the south porch there is a rude figure of the patron saint under a canopy. The churchyard is surrounded by a wall 6 feet thick, supposed by some to be of Roman construction.

Holyhead Harbour.

The town possesses assembly-rooms and baths. On the rock south of the harbour is an obelisk erected in memory of Captain Skinner, commander of the steam packet, who in 1833 lost his life by being washed overboard. About 2 miles from the town, Pen-Caer-Gybi, or the hill of Holyhead, rises perpendicularly from the sea to the height of 700 feet, affording a fine view of the town and harbour, and the irregularities of the rock-bound coast. On the sides of the hill there are traces of an extensive British fortification, and on the summit are remains of a circular building, which in all probability was a Roman watch-tower. The inhabitants are chiefly engaged in the coasting trade and in shipbuilding. Holyhead unites with Beaumaris in returning a member to parliament. The population of the parliamentary borough in 1871 was 8131.

HOLY ISLAND, or LINDISFARNE, an irregularly shaped island in the North Sea, 10 miles S.S.E. of Berwick, and 2 miles from the coast of Northumberland, in which county it is included. It is joined to the mainland at low water by flat sands, over which a track, marked by wooden posts and practicable for vehicles, leads to the island. The parish of Holy Island includes Fenham and Goswick townships on the mainland, and had in 1871 a population of 876. The area of the island is about 1000 acres, of which about 400 are under cultivation, producing abundant crops of barley, oats, turnips, carrots, and potatoes. The northern part consists chiefly of barren sand-hills on which rabbits and eider-ducks breed. There are several fresh springs on the island, and in the north-east is a lake of 6 acres. Lime, quarried and burned on the island, is exported chiefly to Dundee. Four vessels are engaged in the trade. Rabbits, fish, cattle, corn, and potatoes are also exported. At the south-west angle is the little fishing village, formerly much larger, which is now a favourite summer watering-place. Salmon, cod, haddocks, crabs, lobsters, and herrings are the principal fish taken. There are two churches and a national school on the island. The population of the island proper in 1871 was 553.

Holy Island derives its name from a monastery founded on it in 635 by Oswald, king of Northumbria, which, after being plundered and destroyed by the Danes in the three preceding centuries, was restored by the Normans in 1082 as a cell of the Benedictine monastery at Durham. Its ruins, still extensive and now carefully preserved, justify Scott's description of it as a "solemn, huge, and dark-red pile." Holy Island was also an episcopal see (finally transferred to Durham), of which St Cuthbert was consecrated bishop in 685. The castle, situated to the east of the village, on a basaltic rock about 90 feet high, dates from a very early period. In 1646 it was garrisoned by parliament, and in 1715 an abortive attempt was made by two Jacobites to hold it for the Pretender.

HOLYOKE, a city of Hamden county, Massachusetts, is situated on the west bank of the Connecticut river, crossed there by a bridge, and on the Connecticut River railroad and the Holyoke and Westfield branch of the New Haven and Northampton line, 8 miles north of Springfield. It is well supplied with schools and churches, and has three hotels and a public library. It was a small village until 1849, when the construction of a dam across the river supplied it with water-power for its manufactories, which now include paper-mills, cotton-mills both for spinning and weaving, woollen-mills, planing-mills, a flour-mill, a wire-mill, and machine works. Originally the village was a part of Springfield, and in 1786 it was incorporated with West Springfield under the name of Ireland parish. It was incorporated into a town in 1850, and in 1873 it was made a city. The population, which in 1870 was 10,733, was 21,915 in 1880.

HOLY WATER (*aqua benedicta*, *lustralis*, *exorcizata*, *aspersoria* or *aspersionis*, ἁγιασμός, ὕδωρ εὐλογίας), in Roman Catholic ritual, is a specially exorcized and consecrated mixture of salt and water, believed to possess, when duly sprinkled, peculiar potency as a remedy for sickness, mental or bodily, and as a protection to property. According to present usage prescribed in the *Missal*, it is prepared in the sacristy on Sunday by the priest who is to celebrate high mass (or by some other on whom the duty is devolved): robed in alb and superpelliceum and wearing his stole, he first exorcizes the salt and the water separately; next he mixes the two in the name of Father, Son, and Holy Ghost; and finally he pronounces the prayer of consecration over the mixture. Thereupon he assumes his pluvial, goes to the altar, and takes from the deacon the aspergillum, with which he sprinkles the altar, himself, his assistants, and the congregation, meanwhile repeating the words of Ps. li. 7. The faithful who desire it are afterwards permitted to carry a supply home with them for application to the sick and for similar purposes. Holy water is solemnly used, not only in the consecration of sacred objects, such as churches, churchyards, bells, images, vestments, and the like, but also on various domestic occasions such as marriages and funerals. A holy-water stoup is placed at every church door and the faithful are expected to make use of it both on entering and on leaving the building.

The present Occidental usage with regard to holy water admits of being traced substantially, without a break, back to the Carolingian period. In the pseudo-Isidorian decretals, Alexander, bishop of Rome (*c.* 109 A.D.), commenting on Heb. ix. 13, is represented as applying that text to prove the purifying power of consecrated salt and water;[1] and in a genuine charge to his clergy Leo IV. (847 A.D.) says, "Every Lord's day before mass bless water wherewith the people may be sprinkled, and for this have a proper vessel." Hincmar of Rheims to a similar injunction adds permission to all who may wish to carry some of the water home in their own clean vessels, and sprinkle it "over their dwellings and fields and vineyards, over their cattle also and their provender, and likewise over their own meat and drink." In Gratian the decree runs —"We bless water sprinkled with salt, that all being therewith besprinkled may be sanctified and purified. Which also we recommend to be done by all priests."[2] But from the Ordo Romanus (i. 42) we learn that, in Rome, if not elsewhere in the West, a peculiar sacredness and magical efficacy were attributed, to baptismal water at least, two centuries before the publication of the forged decretals. After the usual consecration of the font on Easter eve, "the whole people, whoever wished, took a blessing in their vessels of the water itself, before the children were baptized in it, to sprinkle about their houses and vineyards and fields and fruits." We learn from Chrysostom (*De Bapt. Chr.*) that in the East a similar custom prevailed even in his time, while the *Apostolical Constitutions* (viii. 29) show that at a somewhat later period (probably in the 5th century) it had become usual also to bless water and oil without any reference to baptismal uses. An indication of later Oriental practice is gathered from Theodore Balsamon (*c.* 1200), according to whom, by immemorial custom, holy water was in his day consecrated in Greek churches at the beginning of every lunar month. The use of holy water at the church door can be traced back to pre-Christian practice, both Jewish and pagan. The laver in front of the altar (Exod. xxx. 18–21) in the old ritual of Israel had its analogue in the vessels with consecrated water (περιῤῥαντήρια or ἀποῤῥαντήρια) at the entrance of the peribolos of the Greek temple; from these the entrants used to sprinkle themselves, or to be sprinkled by the priests, to symbolize the purity required of those who sought to enter the sanctuary of God. There is evidence that, as early as Tertullian (*De Orat.*, 11) at least, it was customary to place outside Christian places of worship in the atrium (αἴθριον) a fountain or cistern of water (κρήνη, φιάλη, φρέαρ, ἐμβάτης, κολυμβεῖον, λεοντάριον, nymphaeum, cantharus) in which persons about to enter were expected to wash their hands and (perhaps) also the face. The vessel was not taken into the church and placed near the entrance of the nave until after the 8th century. It is not evident at what date it became customary within the Christian Church to mix salt with the water employed for sacramental or quasi-sacramental purposes; this practice also, however, must be traced to pre-Christian usage (see *Iliad* i. 314; Aristoph., *Plut.*, 656; and *cf.* Tzetzes, *Schol. in Lycoph.*, 135—τὸ ἁλικὸν καὶ θαλάσσιον ὕδωρ καθαρτικώτερον φύσει τῶν γλυκέων).

HOLY WEEK (ἑβδομὰς μεγάλη, ἁγία or τῶν ἁγίων, ξηροφαγίας, ἄπρακτος, also ἡμέραι παθημάτων, ἡμέραι σταυρώσιμαι; *hebdomas* [or *septimana*] *major*, *sancta*, *authentica* [*i.e.*, *canonizata*, Du Cange], *ultima*, *pœnosa*, *luctuosa*, *nigra*, *inofficiosa*, *muta*, *crucis*, *lamentationum*, *indulgentiæ*), in the ecclesiastical year the week immediately preceding that of Easter. The earliest allusion to the custom of marking this week as a whole with special observances is to be found in the *Apostolical Constitutions* (v. 18, 19), dating from the latter half of the 3d century A.D. Abstinence from wine and flesh is there commanded for all the days, while for the Friday and Saturday an absolute fast is enjoined. Dionysius Alexandrinus also, in his canonical epistle (260 A.D.), refers to the six fasting days (ἑξ τῶν νηστειῶν ἡμέραι) in a manner which implies that the observance of them had already become an established usage in his time. There is some doubt about the genuineness of an ordinance attributed to Constantine, in which abstinence from public business was enforced for the seven days immediately preceding Easter Sunday, and also for the seven which followed it; the *Codex Theodosianus*, however, is explicit in ordering that all actions at law should cease, and the doors of all courts of law be closed during those fifteen days (l. ii. tit. viii.). Of the particular days of the "great week" the earliest to emerge into special prominence was naturally that which commemorated the supreme crisis of the passion; next came the Sabbatum Magnum (Holy Saturday or Easter Eve) with its vigil, which in the early church was associated with an expectation that the second advent would occur on an Easter Sunday. The Dominica Palmarum or in Palmis (ἑορτὴ τῶν βαΐων) was, as we learn from Chrysostom, known and observed under that name in his day; for the fact of its observance in the Western Church, however, probably our earliest authority is the Venerable Bede. Maundy Thursday (ἡ μεγάλη πέμπτη, feria quinta paschæ) is referred to both by Chrysostom and by Augustine as having been in their time marked by a general and solemn celebration of the sacrament of the supper; the latter writer also (*Ep.* 118, *Ad Januarium*) alludes to a partial observance of the pedilavium or footwashing which in later centuries became the most conspicuous feature in the church services of the day. For details of the elaborate ceremonial observed in the Roman Catholic Church during this week, reference must be made to the *Missal* and *Breviary*. In the Eastern Church the week is marked by similar practices, but with less elaboration and differentiation of rite. See also EASTER and GOOD FRIDAY.

HOLYWELL (Welsh, *Treffynnon*, the town of the well), a parliamentary borough and market-town of Flintshire, North Wales, is beautifully situated on an eminence near the left bank of the estuary of the Dee, and about 2 miles from the station on the Chester and Holyhead line, 17 miles from Chester. The streets are irregular, but spacious and well-paved, while many of the buildings are substantial and elegant, and give the town an air of prosperity and opulence. The parish church, dedicated to St Winifred, and erected in 1769, but retaining some columns of a more ancient structure, is a plain edifice with a strong embattled tower. Near the railway station are the remains of Basingwerk abbey, partly Saxon and partly Early Pointed. Of the old fort called Basingwerk castle scarcely any traces now remain. Until the commencement of the present century the size of Holywell was inconsiderable, but since then its prosperity has been uninterruptedly increasing, owing to the lead quarries and the lead, copper, and zinc mines of the vicinity. The town possesses lead smelting works, a shot manufactory, and copper, brass, and zinc works. The population of the parliamentary borough in 1871 was 7961.

The well of St Winifred, from which the town takes its name, long considered one of the wonders of Wales, is a spring of water which rushes up at the rate of 21 tons a minute. Its temperature is higher than that of ordinary spring water, and varies very little with the different seasons. The stones at the bottom of the well have a slightly reddish colouring due to vegetable substances, a fact which doubtless suggested the legend according to which the spring gushed up on the spot where rested the head of the virgin Winifred, who had been decapitated by a lover offended at her constancy to her monastic vows. The well is covered by a fine Gothic building said to have been erected by Margaret, countess of Richmond, mother of Henry VII., but having some portions which are of earlier date. The exquisite chapel above has been restored, and is used for public service. Many Roman Catholics still visit the well, and swimming-baths have been erected for general use.

HOLZMINDEN, the chief town of a circle in the duchy of Brunswick, Germany, is situated on the right bank of the Weser, at the foot of the Sollinger mountains, and on the railway from Kreiensen to Altenbeken, 56 miles south-west of Brunswick. It is the seat of a circle administration, of a circle and common court, and of a general superintendent. The educational establishments include a gymnasium and an architectural school, the latter attended by upwards of 1000 scholars. The prosperity of the town

[1] Nam si cinis vitulæ adspersus sanguine populum sanctificabat atque mundabat, multo magis aqua sale adspersa divinisque precibus sacrata populum sanctificat atque mundat.

[2] Gratian, *De Cons.*, d. iii. c. 20; Labbe, *Conc.*, viii. 37; comp. Baluze, *Append. ad. lib. Reginonis de Eccl. Discipl.*, pp. 503–9.

depends chiefly on agriculture and the manufacture of iron and steel-wares, but weaving and the making of pottery are also carried on, and there are baryta mills and polishing-mills for sandstone. By means of the Weser it carries on a lively trade. Holzminden obtained town rights from Count Otto of Eberstein in 1245. In 1410 it came into the possession of Brunswick. The population in 1875 was 6887.

HOMAGE (from *homo*, through the Low Latin *hominaticum*, which occurs in a document of 1035) was one of the ceremonies used in the granting of a fief, and indicated the submission of a vassal to his lord. It could be received only by the suzerain in person. With head uncovered the vassal humbly requested to be allowed to enter into the feudal relation; he then laid aside his sword and spurs, ungirt his belt, and kneeling before his lord uttered words to this effect:—"I become your man from this day forth, of life and limb, and will hold faith to you for the lands I claim to hold of you." The oath of fealty, which could be received by proxy, followed the act of homage; then came the ceremony of investiture, either directly on the ground or by the delivery of a turf, a handful of earth, a stone, or some other symbolical object. Homage was done not only by the vassal to whom feudal lands were first granted but by every one in turn by whom they were inherited, since they were not granted absolutely but only on condition of military and other service. An infant might do homage, but he did not thus enter into full possession of his lands. The ceremony was of a preliminary nature, securing that the fief would not be alienated; but the vassal had to take the oath of fealty, and to be formally invested, when he reached his majority. The obligations involved in the act of homage were more general than those associated with the oath of fealty, but they provided a strong moral sanction for more specific engagements. They essentially resembled the obligations undertaken towards a Teutonic chief by the members of his "comitatus" or "gefolge," one of the institutions from which feudalism directly sprang. Besides *homagium ligeum*, there was a kind of homage which imposed no feudal duty; this was *homagium per paragium*, such as the dukes of Normandy rendered to the kings of France, and as the dukes of Normandy received from the dukes of Britanny. The act of liege homage to a particular lord did not interfere with the vassal's allegiance as a subject to his sovereign, or with his duty to any other suzerain of whom he might hold lands.

HOMBERG, Wilhelm (1652-1715), an eminent natural philosopher, born at Batavia, January 8, 1652, was educated in Holland, studied law at Jena and Leipsic, and became an advocate at Magdeburg in 1674. In that town he interested himself in botany and astronomy, and made the acquaintance of Otto von Guericke, under whose influence, renouncing his profession, he finally devoted himself exclusively to the natural sciences. Having travelled in Italy, France, and England, and profited by the instructions of the anatomist Graaf in Holland, he took the degree of doctor of medicine at Wittemberg; and, after visiting Germany, Hungary, Bohemia, and Sweden, he in 1685 settled in Rome, where he practised physic with great success. At Paris, whither he repaired in 1691, he was elected a member of the Academy of Sciences, and became (1702) teacher of physics and (1705) private physician to the duke of Orleans. He died at Paris, September 24, 1715. In 1702 Homberg discovered boracic acid, termed at first the *sal sedativum Hombergi*, the true nature of which was ascertained by Bergman in 1775. What is known as "Homberg's phosphorus" is a mixture of calcium chloride and lime, which, after heating in a sealed tube and exposure to sunlight, phosphoresces in the dark. Numerous treatises by Homberg, chiefly chemical, were published in the *Recueil de l'Académie des Sciences*, 1692, &c. See Chauffepié, *Dictionnaire*, and Chemistry, vol. v. p. 461.

HOMBURG-vor-der-Höhe, chief town of the circle of Obertaunus in the Wiesbaden government district of the Prussian province of Hesse-Nassau, is prettily situated on a small stream at the foot of a spur of the Taunus mountains, about 11 miles north of Frankfort-on-the-Main, with which it is connected by rail. Homburg consists of an old and a new town, the latter, founded by the landgrave Frederick II., being regular and well-built. Besides the palatial edifices erected in connexion with the mineral water-cure, the most important buildings are the theatre, the synagogue, and the various churches, schools, and benevolent institutions. On a neighbouring hill stands the castle of the former landgraves, built in 1680, and subsequently enlarged and improved. The White Tower, 183 feet in height, is said to date from Roman times, and certainly existed under the lords of Eppstein, who held the district in the 12th century. The castle is surrounded by extensive grounds, laid out in the manner of an English park. The woollen and linen manufactures of Homburg are unimportant, the prosperity of the town being almost entirely due to the annual influx

of visitors, which in the season lasting from May to October inclusive averages 9000 or 10,000. The five mineral springs which form the chief attraction to strangers are very saline, and contain a considerable proportion of carbonate of lime. Their use is beneficial for diseases of the stomach and intestines, and externally for diseases of the skin and rheumatism. The population of the town in 1875, including the garrison, was 8294.

Homburg first came into repute as a watering-place in 1834, and owing to its gambling tables, which were set up soon after, it rapidly became one of the favourite and most fashionable health-resorts of the Continent. In 1849 the town was occupied by Austrian troops for the purpose of enforcing the imperial decree against gambling establishments, but immediately on their withdrawal the bank was again opened, and play continued unchecked till 1872, when the Prussian Government refused to renew the lease for gambling purposes which then expired. As the capital of the former landgraviate of Hesse-Homburg the town shared the vicissitudes of that state.

See Schudt's *Homburg und seine Umgebungen*, 11th ed., 1875.

HOME, Henry. See Kames, Lord.

HOME, John (1722-1808), a Scottish dramatic poet, was born on 20th September 1722 at Leith, where his father, Alexander Home, filled the office of town-clerk. He was educated at the grammar school of his native town, and at the university of Edinburgh, where he graduated as M.A. in 1742. Though in his youth he was distinguished for vivacity, and showed a fondness for the profession of arms, he ultimately studied divinity, and was licensed by the presbytery of Edinburgh in 1745. In the same year he joined as a volunteer against the Pretender, and was taken prisoner at the battle of Falkirk. Along with many others he was carried to the castle of Doune, from which, however, he soon effected his escape. In July 1746 Home was presented to the parish of Athelstaneford in Haddingtonshire, vacant by the death of Robert Blair, the author of *The Grave.* There he devoted himself to dramatic literature, and his first production, *The Tragedy of Agis*, was finished in 1749. He took it to London and submitted it to Garrick for representation at Drury Lane, but it was rejected as unsuitable for the stage. Being but little disappointed, he projected a new work, and having heard a lady sing the ballad of Gil Morice, he formed the idea of *The Tragedy of Douglas*, which after five years' labour he completed, and took to London for Garrick's opinion. It also was rejected, but on his return to Edinburgh his friends resolved that it should be brought out in that city, where it met with overwhelming success, in spite of the opposition of the clergy, who suspended one member of the presbytery for a month for having attended its representation. As the author of the tragedy might count on being dealt with yet more severely, Home resigned his charge in 1757, and shortly afterwards he was appointed lecturer in a Presbyterian chapel in Silver Street, London. In 1758 he became private secretary to Lord Bute, then secretary of state; and three years later his patron's influence procured him a pension of £300 per annum. *A Letter from a Blacksmith to the Ministers and Elders of the Church of Scotland*, in which the manner of public worship in that church is considered, published in 1759, has been attributed to his pen. In 1760 Home brought out another tragedy, *The Siege of Aquileia*, which was put on the stage, Garrick taking the part of Æmilius. In 1763 he was appointed to the sinecure office of conservator of Scots privileges at Campvere. In 1769 Home's tragedy of *The Fatal Discovery* had a run of nine nights; *Alonzo* also (1773) had fair success in the representation; but his last tragedy, *Alfred* (1778), was so coolly received that he gave up writing for the stage. From 1767 he resided either at Edinburgh or at a villa which he built at Kilduff near his former parish. It was at this time that he wrote his *History of the Rebellion of* 1745, which appeared in 1802. Home died at Merchiston Bank, near Edinburgh, in 1808, in his eighty-sixth year. He was a man of great amiability of character, and numbered among his friends most of the Scottish literati of the last century. His writings, while they display fervid feeling, and have less artificiality than the works of the poets of his time, are now, with the exception of *Douglas*, comparatively little known.

The works of Home were collected and published by Henry Mackenzie in 1822 (3 vols. 8vo), but several of his smaller poems seem to have escaped the editor's observation. These are—"The Fate of Cæsar," "Verses upon Inveraray," "Epistle to the Earl of Eglintoun," "Prologue on the Birthday of the Prince of Wales, 1759," and several "Epigrams," which are printed in vol. ii. of *Original Poems by Scottish Gentlemen*, 1762.

HOMEL, or GOMEL, a town of Russia in Europe, in the government of Mohileff, 132 miles S. of Mohileff, on the highway to Tchernigoff, and on the right bank of the Sosh, which joins the Dnieper about 45 miles further down. It is a place of considerable importance, possessing (according to the *St Petersburg Calendar* for 1878) a population of 13,030, the suburb of Bielitsa being included. Most of the houses are of wood, but there are a good number of churches, several hospitals, and public schools. Three of the Orthodox churches were built by Rumantzeff, who lies buried in St Peter's. The sugar-refineries are the most important of the industrial establishments. A good trade is carried on in the agricultural produce of the surrounding district, partly with Warsaw and partly with Riga. In 1860, when the population amounted to 13,659, there were 3637 Raskolniks (separatists) and 6518 Jews.

Homel, which appears in the older documents as Gomie or Gomi and Gom, is mentioned for the first time in 1142, when it belonged to the Tchernigoff principality. The first inhabitants were Rodimitchians. In the 12th century we find Izyaslaff Daviditch taking refuge at Homel on his expulsion from Kieff. Along with Tchernigoff the town passed under the power of Lithuania; but in the 15th century Simeon, son of John of Mozhaisk, to whom it had been entrusted by King Alexander, entered the service of John III. of Moscow, and it was not till 1537 that it was recovered for Sigismund Augustus by Prince Radzivill and a body of Crim Tatars. The bailiwick was granted to the Polish grandees; and by the last of these—Prince Tcharovizhski—a strong oaken castle was erected. In 1648 the town suffered from the invasion of Bogudan Khmelnitzki, who put to death 1500 Roman Catholics and Jews. In 1655 it passed voluntarily to the side of the insurgent Cossacks, but at the peace of Andrusoff it remained with Poland. It was not incorporated with White Russia till the reign of Catherine II., who assigned it to Field-Marshal Rumantzeff Zadunaiski. In 1834 it was purchased by Prince Paskevitch, and in 1852 it was made the chief town of a district.

HOMER (Ὅμηρος) was by the general consent of antiquity the first and greatest of poets. Many of the works once attributed to him are lost; those which remain are the two great epics, the *Iliad* and the *Odyssey*, about thirty *Hymns*, a mock epic (the *Battle of the Frogs and Mice*), and some pieces of a few lines each (the so-called *Epigrams*).

Ancient Accounts of Homer.—Of the date of Homer probably no record, real or pretended, ever existed. Herodotus (ii. 53) maintains that Hesiod and Homer lived not more than 400 years before his own time, consequently not much before 850 B.C. From the controversial tone in which he expresses himself it is evident that others had made Homer more ancient; and accordingly the dates given by later authorities, though very various, generally fall within the 10th and 11th centuries B.C. It is needless to go into the questions raised by these statements, none of which has any claim to the character of external evidence.[1]

The extant lives of Homer (edited in Westermann's *Vitarum Scriptores Græci minores*) are eight in number, including the piece called the *Contest of Hesiod and Homer.* The longest is written in the Ionic dialect, and bears the name of Herodotus, but is certainly spurious. According to Joh. Schmidt (in the *Dissertationes philologicæ Halenses*, vol. ii. pp. 97–219), it belongs to the time which was fruitful beyond all others in literary forgeries, viz., the 2d century of our era. The other lives are probably not more ancient. They contain a strange medley, ranging from the simplest outgrowth of popular fancy to the frigid inventions of the age which would not confess itself ignorant of the name of Hecuba's mother. Thus the story that Homer was the son of the Meles (the river on which Smyrna is situated) and the nymph Critheis is evidently a local legend. Another story of a primitive cast describes the manner of Homer's death in the island of Ios. Seeing some young fishermen on the beach with their nets, he asked them—

"Fishermen sprung of Arcadia, have we aught?"

To which they answered in a riddle—

"What we caught we left behind,
What we caught not we bear with us."

Homer could not explain this, and then he remembered an oracle which had told him to beware of the young men's riddle. He wrote an epitaph for himself, and died on the third day after. This story comes from a lost work of Aristotle. On the other hand, when we are told in the Herodotean life that Critheis was a daughter of Melanopus, one of the colonists who came to Cyme from Magnesia, that being found to be with child she was sent with the fresh

[1] See Lauer, *Gesch. der Homer. Poesie*, pp. 115–30; Sengebusch, *Homerica dissertatio posterior*, p. 77.

colony that founded Smyrna, that she there brought forth Homer on the banks of the Meles, whence he was called Melesigenes,—in this form of the story it is easy to recognize the hand of the critic. There is an evident desire to get rid of the primitive supernatural element, and also to reconcile the claims of two cities, Cyme and Smyrna, to the envied distinction of giving birth to Homer. There are other incidents in the Herodotean life which seem devised merely to fit certain of the minor characters in the Homeric poems. Phemius, we are told, was a schoolmaster of Smyrna, who was kind to the young Melesigenes, and was accordingly immortalized as the singer in the *Odyssey*; the original of Mentor was a man of Ithaca, who entertained Homer and tended him in illness; and so on.

The chief value of these "Lives," and especially of the Herodotean life, lies in the curious short poems which they have preserved. These poems are the *Epigrams* which used to be printed at the end of Homer, but are banished by the somewhat inconvenient purism of modern editors. One of them (*Epigr.* iv.) is put in the mouth of a native of "Æolian Smyrna," whose poetical aid has been spurned by the people of Cyme, and who is accordingly departing to some other city. *Epigr.* vi. is a prayer to Poseidon for safe arrival at Erythræ; *Epigr.* vii. describes the rocky soil of that place. There is also an Epigram addressed to the people of Neonteichos (*Epigr.* i.), and another which brings in the pine woods of Mount Ida and the iron-mines of that district (*Epigr.* x.). Besides these pieces, the interest of which is topographical, there is an interesting little poem addressed to potters, beginning—

"If you give me hire I will sing, O potters,"

and another called Εἰρεσιώνη, which, according to the author of the life, was sung by the children in Samos when they went round begging at the festival of Apollo; also certain verses addressed to sailors (viii., ix.), to a goat-herd (xi.), &c. All these short poems have a common character. They are "rhymes" such as every country possesses in greater or less number, treasured by the people as a kind of proverbs. Some of them may be fragments of longer poems, but they are certainly not the work of any one poet. The circumstance that they are ascribed to Homer merely shows that his name had gained such a hold on the imagination of the Ionian and Æolian Greeks as to draw to itself all ancient and popular verse.

Such being the true character of the *Epigrams*, it follows that, so far from being "occasional verses," suggested by moments in Homer's life, they are really the original documents, to which the narrative was afterwards adjusted. Even the leading incident of the Herodotean life—the birth of Homer at Smyrna—may have been originally derived from *Epigr.* iv. The epithet "Æolian" indicates high antiquity; for Smyrna (according to Herodotus) was lost by the Æolians about 688 B.C. Similarly, the claim of Cyme was doubtless supported (not quite so logically) by the mention of that place in *Epigr.* iv. and i.

The same line of argument may be extended to the *Hymns*, and even to some of the lost works of the "Cyclic" poets; with the result of making it probable that most of the traditions about Homer rest ultimately on poems commonly ascribed to him. Thus—

1. The hymn to the Delian Apollo ends with an address of the poet to his audience. When any stranger comes and asks who is the sweetest singer, they are to answer with one voice, the "blind man that dwells in rocky Chios; his songs deserve the prize for all time to come." Thucydides, who quotes this passage to show the ancient character of the Delian festival, seems to have no doubt of the Homeric authorship of the hymn. Hence we may most naturally account for the belief that Homer was a Chian. That it was a general belief is shown by a passage (interesting as the earliest express quotation from Homer) in which Simonides calls him simply the "man of Chios" (fr. 85):—

Ἓν δὲ τὸ κάλλιστον Χῖος ἔειπεν ἀνήρ,
Οἵη περ φύλλων γενεή, τοίη δε καὶ ἀνδρῶν.

It was also supported by the Chian family or gens of Homeridæ, of whom more will be said hereafter.

2. The *Margites*—a humorous poem which kept its ground as the reputed work of Homer down to the time of Aristotle—began with the words, "There came to Colophon an old man, a divine singer, servant of the Muses and Apollo." Hence doubtless the claim of Colophon to be the native city of Homer—a claim supported in the early times of Homeric learning by the Colophonian poet and grammarian Antimachus.

3. The poem called the *Cypria* was said to have been given by Homer to Stasinus of Cyprus as a daughter's dowry. The connexion with Cyprus appears further in the predominance given in the poem to Aphrodite. From the argument preserved by Proclus it is evident that Aphrodite held the same place in the *Cypria* which Athene has in the *Odyssey*.

4. The *Little Iliad* and the *Phocaïs*, according to the Herodotean life, were composed by Homer when he lived at Phocæa with a certain Thestorides, who carried them off to Chios and there gained fame by reciting them as his own. The name Thestorides occurs in *Epigr.* v.

These indications make it probable that the stories connecting Homer with different cities and islands do not rest upon any better foundation than supposed allusions in poems, none of which, to all appearance, can make good the claim to Homeric authorship. And this result is confirmed by the want of positive authority in favour of any one version. The number of opinions is proverbial, and most of them are supported by relatively ancient testimony.

It is plain that the contention for Homer began at a time when his real history had been lost. And since the inevitable legend found no clue in the *Iliad* and *Odyssey*, it was driven to seek for one in poems of secondary value.

A singular exception is formed by Miletus, one of the greatest of Ionian cities, for which no legend claims even a visit from Homer. Yet Arctinus of Miletus is said to have been a "disciple of Homer," and his *Æthiopis* was a continuation of the *Iliad*. Another equally exceptional fact is that no poem of Arctinus is ever ascribed to Homer. Are we to suppose that the authorship of the poems of Arctinus never fell into doubt? If so, it is a confirmation, from the negative side, of the theory advanced above, viz., that the stories of Homer's connexion with different places are suggested for the most part by the poems which came to be assigned to him in popular belief.

Recitation of the Poems.—The recitation of epic poetry was called in historical times "rhapsody" (ῥαψῳδία). The word ῥαψῳδός is post-Homeric, but occurs in Pindar, who gives two different explanations of it—"singer of stitched verse" (ῥαπτῶν ἐπέων ἀοιδοί), and "singer with the wand" (ῥαβδός). Of these the first is etymologically correct (except that it should rather be "stitcher of verse"); the second agrees with the fact, for which there is early evidence, that the reciter was accustomed to hold a wand in his hand—perhaps, like the sceptre in the Homeric assembly, as a symbol of the right to a hearing.[1]

The first notice of rhapsody meets us at Sicyon, in the reign of Clisthenes (600–560 B.C.), who, as Herodotus tells us (v. 67), "put down the rhapsodists on account of the poems of Homer, because they are all about Argos and the Argives." This description applies very well to the *Iliad*, in which Argos and Argives occur on almost every page. It may have suited the *Thebaid* still better, but there is no

[1] Compare the branch of myrtle at an Athenian feast (Aristoph., *Nub.*, 1364).

need to understand it only of that poem, as Mr Grote does (Part i. c. 21). In any case the incident shows that the poems of the Ionic Homer had gained in the 6th century B.C., and in the Doric parts of the Peloponnesus, the ascendency, the national importance, and the almost canonical character which they ever afterwards retained.[1]

At Athens there was a law that the Homeric poems should be recited (ῥαψῳδεῖσθαι) on every occasion of the Panathenæa. This law is appealed to as an especial glory of Athens by the orator Lycurgus (*Leocr.*, 102). Perhaps therefore the custom of public recitation was exceptional, and unfortunately we do not know when or by whom it was introduced. The Platonic dialogue *Hipparchus* attributes it to Hipparchus, son of Pisistratus. This, however, is part of the historical myth, in the Platonic style, of which the dialogue mainly consists. The choice of a member of the tyrant family as the type of an enlightened despot was evidently made, not on grounds of evidence, but merely as a sign of reaction against popular sentiment. Moreover, the author of the dialogue makes (perhaps wilfully) all the historical mistakes which Thucydides notices in a well-known passage (vi. 54–59). In one point, however, his testimony is valuable. He tells us that the law required the rhapsodists to recite "taking each other up in order (ἐξ ὑπολήψεως ἐφεξῆς), as they still do." This recurs in a different form in the statement of Diogenes Laertius (i. 2, 57) that Solon made a law that the poems should be recited "with prompting" (so we must understand ἐξ ὑποβολῆς). The question as between Solon and Hipparchus cannot be settled; but it is at least clear that a due order of recitation was secured by the presence of a person charged to give the rhapsodists their cue (ὑποβάλλειν). It was necessary, of course, to divide the poem to be recited into parts, and to compel each contending rhapsodist to take the part assigned to him. Otherwise they would choose favourite or show passages.

The practice of poets or rhapsodists (we cannot always tell which) contending for the prize at the great religious festivals is of considerable antiquity, though apparently post-Homeric. It is brought vividly before us in the Hymn to Apollo (see the passage mentioned above), and in two Hymns to Aphrodite (v. and ix.). The latter of these may evidently be taken to belong to Salamis in Cyprus and the festival of the Cyprian Aphrodite, in the same way that the hymn to Apollo belongs to Delos and the Delian gathering. The germ of such contests may, however, be found in the story of Thamyris, the Thracian singer, who boasted that he could conquer even the Muses in song (*Il.* ii. 594 *ff.*).

Much has been made in this part of the subject of a family or clan (γένος) of Homeridæ in the island of Chios. On the one hand, it seemed to follow from the existence of such a family that Homer is a mere "eponymus," or mythical ancestor; on the other hand, it became easy to imagine the Homeric poems handed down orally in a family whose hereditary occupation it was to recite them, possibly to add new episodes from time to time, or to combine their materials in new ways, as their poetical gifts permitted. But, although there is no reason to doubt the existence of a family of "Homeridæ," it is far from certain that they had anything to do with Homeric poetry. The word occurs first in Pindar (*Nem.* 2, 2), who applies it to the rhapsodists (Ὁμηρίδαι ῥαπτῶν ἐπέων ἀοιδοί). On this a scholiast says that "Homeridæ" denoted originally the descendants of Homer, who sang his poems in succession, but afterwards the rhapsodists who did not claim descent from him. He adds that there was a famous rhapsodist, Cynæthus of Chios, who was said to be the author of the Hymn to Apollo, and to have first recited Homer at Syracuse about the 69th Olympiad. Nothing here connects the Homeridæ with Chios. Our knowledge of Chian Homeridæ comes chiefly from the lexicon of Harpocration, where we are told that Acusilaus and Hellanicus said that they were so called from the poet, but that Seleucus pronounced this to be an error. Strabo, also, says that the Chians put forward the Homeridæ as an argument in support of their claim to Homer. These Homeridæ, then, belonged to Chios, but there is no indication of their being rhapsodists. On the contrary, Plato uses the word to include interpreters and admirers—in short, the whole "spiritual kindred"—of Homer (*Rep.*, 599 E; *Phædr.*, 252 B; *Ion*, 530 D). And although we hear of "descendants of Creophylus" as in possession of the Homeric poems, there is no similar story about descendants of Homer himself. Such is the evidence on which so many inferences are based.

The result of the notices now collected is to show that the early history of epic recitation consists of (1) passages in the Homeric hymns showing that poets contended for the prize at the great festivals, (2) the passing mention in Herodotus of rhapsodists at Sicyon, and (3) a law at Athens, of unknown date,[2] regulating the recitation at the Panathenæa. Let us now compare these data with the account given in the Homeric poems. The word "rhapsode" does not yet exist; we hear only of the "singer" (ἀοιδός), who does not carry a wand or laurel-branch, but the lyre (φόρμιγξ), with which he accompanies his "song." In the *Iliad* even the epic "singer" is not met with, but Achilles himself sings the stories of heroes (κλέα ἀνδρῶν) in his tent, and Patroclus is waiting apparently to take up the song in his turn (*Il.* ix. 191). Again we do not hear of poetical contests (except in the story of Thamyris already mentioned) or of recitation of epic poetry at festivals. The *Odyssey* gives us pictures of two great houses, in Ithaca and in Phæacia; and each has its singer. The song is on a subject taken from the Trojan war, at some point chosen by the singer himself, or by his hearers. Thus Phemius pleases the suitors by singing of the calamitous return of the Greeks; Demodocus sings of a quarrel between Ulysses and Achilles, and then, on being asked to change the theme, of the wooden horse and the capture of Troy.

It may be granted that the author of the *Odyssey* can hardly have been just such a singer as he himself describes. The songs of Phemius and Demodocus are too short, and have too much the character of improvisations. Nor is it necessary to suppose that epic poetry, at the time to which the picture in the *Odyssey* belongs, was confined to the one type represented. Yet in several respects the conditions under which the singer finds himself in the house of a chief like Odysseus or Alcinous are more in harmony with the character of Homeric poetry than those of the later rhapsodic contests. The subdivision of a poem like the *Iliad* or *Odyssey* among different and necessarily unequal performers must have been injurious to the effect. The highly theatrical manner of recitation which was fostered by the spirit of competition, and by the example of the stage, cannot have done justice to the even movement of the epic style. It is not certain indeed that the practice of reciting a long poem by the agency of several competitors was ancient, or that it prevailed elsewhere than at Athens; but as rhapsodists were numerous, and popular favour throughout Greece became more and more confined to one or two great works, it must have become almost a

[1] We may compare the exclamation of the Spartan envoys to Hiero, ἦ κε μέγ' οἰμώξειεν ὁ Πελοπίδης Ἀγαμέμνων, &c.,—showing that the glories of the early Achæan empire, with Homer for its *vates sacer*, were adopted without reserve by the Dorian conquerors.

[2] For the assertions of the Platonic *Hipparchus* and of Diogenes Laertius are contradictory. The orators Lycurgus and Isocrates give no date. The question is complicated by the stories about Pisistratus.

necessity. That it was the mode of recitation contemplated by the author of the *Iliad* or *Odyssey* it is impossible to believe.

The difference made by substituting the wand or branch of laurel for the lyre of the Homeric singer is a slighter one, though not without significance. The recitation of the Hesiodic poems was from the first unaccompanied by the lyre,[1] *i.e.*, they were confessedly *said*, not *sung*; and it was natural that the example should be extended to Homer. For it is difficult to believe that the Homeric poems were ever "sung" in the strict sense of the word. We can only suppose that the lyre in the hands of the epic poet or reciter was in reality a piece of convention, a "survival" from the stage in which narrative poetry had a lyrical character. Probably the poets of the Homeric school—that which dealt with war and adventure—were the genuine descendants of minstrels whose "lays" or "ballads" were the amusement of the feasts in an earlier heroic age; whereas the Hesiodic compositions were non-lyrical from the first, and were only in verse because that was the universal form of literature.

It seems, then, that if we imagine Homer as a singer in a royal house of the Homeric age, but with more freedom regarding the limits of his subject, and a more tranquil audience than is allowed him in the rapid movement of the *Odyssey*, we shall probably not be far from the truth.

Time and Place of Homer.—The oldest direct references to the *Iliad* and *Odyssey* are in Herodotus, who quotes from both poems (ii. 53). The quotation from the *Iliad* is of interest because it is made in order to show that Homer supported the story of the travels of Paris to Egypt and Sidon (whereas the Cyclic poem called the *Cypria* ignored them), and also because the part of the *Iliad* from which it comes is cited as the "Aristeia of Diomede." This was therefore a recognized part of the poem.[2]

The earliest mention of the name of Homer is found in a fragment of the philosopher Xenophanes (of the 6th century B.C., or possibly earlier), who complains of the false notions implanted through the teaching of Homer (ἐξ ἀρχῆς καθ' Ὅμηρον ἐπεὶ μεμαθήκασι πάντες). The passage shows, not merely that Homer was well known at Colophon in the time of Xenophanes, but also that the great advance in moral and religious ideas which forced Plato to banish Homer from his republic had made itself felt in the days of the early Ionic philosophers.

Failing external testimony, the time and place of the Homeric poems can only be determined (if at all) by internal evidence. This is of two main kinds:—(1) evidence of history, consisting in a comparison of the political and social condition, the geography, the institutions, the manners, arts, and ideas of Homer with those of other times; (2) evidence of language, consisting in a comparison with later dialects, in respect of grammar and vocabulary. To these may be added, as occasionally of value, (3) evidence of the direct influence of Homer upon the subsequent course of literature and art.

(1) The political condition of Greece in the earliest times known to history is separated from the Greece of Homer by an interval which can hardly be overestimated. The great national names are different: instead of Achæans, Argives, Danai, we find Hellenes, Dorians, Ionians, Æolians—names either unknown to Homer, or mentioned in terms more significant than silence. Mycenæ is no longer the centre of empire; new empires, polities, and civilizations have grown up,—Sparta with its military discipline, Delphi with its religious supremacy, Miletus with its commerce and numberless colonies, Æolis and Ionia, Sicily and Magna Græcia.

While the political centre of Homeric Greece is Mycenæ, the real centre is evidently Bœotia. The Catalogue of the Ships begins with Bœotia; the list of Bœotian towns is much the longest; and they sail, not from the bay of Argos, but from the Bœotian harbour of Aulis. This position is not due to its chiefs, who are all of inferior rank. The importance of Bœotia for civilization is further shown by the ancient worship of the Muses on Mount Helicon, and the fact that the oldest poet whose birthplace is known was the Bœotian Hesiod. Next to Bœotia and the neighbouring countries, Phocis, Locris, Athens, it appears that the Peloponnesus, Crete, and Thessaly are the most important seats of Greek population.

In the Peloponnesus the face of things was completely altered by the Dorian conquest, no trace of which is found in Homer. The only Dorians known in Homer are those that the *Odyssey* (xix. 177) places in Crete. It seems difficult to connect them with the Dorians of history.

The eastern shores of the Ægean, which the earliest historical records represent to us as the seat of a brilliant civilization, giving way before the advance of the great military empires (Lydia and afterwards Persia), are almost a blank in Homer's map. The line of settlements can be traced in the Catalogue from Crete to Rhodes, and embraces the neighbouring islands of Cos and Calymnos. The colonization of Rhodes by Tlepolemus is related (*Il.* ii. 661 *ff.*), and seems to mark the furthest point reached in the Homeric age. Between Rhodes and the Troad the only name is Miletus, and that is still in the hands of "barbarous speaking" Carians. Even the Cyclades—Naxos, Paros, Melos—are unknown to the Homeric world. The disposition of the Greeks to look to the west for the centres of religious feeling appears in the mention of Dodona and the Dodonæan Zeus, put in the mouth of the Thessalian Achilles.

To the north we find the Thracians, known from the stories of Thamyris the singer (*Il.* ii. 595), and Lycurgus, the enemy of the young god Dionysus (*Il.* vi. 130). Here the Trojan empire begins. It does not appear, however, that the Trojans are thought of as people of a different language. As this is expressly said of the Carians, and of the Trojan allies who were "summoned from afar," the contrary rather is implied regarding Troy itself.

The mixed type of government described by Homer—consisting of a king guided by a council of elders, and bringing all important resolutions before the assembly of the fighting men—does not seem to have been universal in Indo-European communities, but to have grown up in many different parts of the world under the stress of similar conditions. The king is the commander in war, and the office probably owed its existence to military necessities. It is not surrounded with any special sacredness. There were ruling families, laying claim to divine descent, from whom the king was naturally chosen, but his own fitness is the essence of his title. The aged Laertes is set aside; the young Telemachus does not succeed as a matter of course. Nor are any very definite rights attached to the office. Each tribe in the army before Troy was commanded by its own king (or kings); but Agamemnon was supreme, because he was "more a king" (βασιλεύτερος) than any other. The assembly is summoned on all critical occasions, and its approval is the ultimate sanction. A king there-

[1] So Pausanias (ix. 30, 2), who supports his opinion from Hesiod, *Theog.*, 30-32. And so Aristophanes (*Nub.*, 1355-64) distinguishes between *singing* an ode from Simonides and *saying* (λέξαι) a piece of Æschylus. In the second case the myrtle branch is taken instead of the lyre.

[2] The difficulty which has been made because the title Διομήδους Ἀριστεία is given in the MSS. to the fifth book, whereas the quotation in question comes from the sixth, is due to an oversight. Putting aside the modern division into books, and looking to the narrative, we see that the Aristeia of Diomede extends from the beginning of Book v. to ver. 311 in Book vi. See the *Journal of Philology*, vol. ii. p. 214.

fore stands in almost as much need of oratory as of warlike skill and prowess. Even the division of the spoil is not made in the *Iliad* by Agamemnon, but by "the Achæans" (*Il.* i. 162, 368). The taking of Briseïs from Achilles was an arbitrary act, and against all rule and custom. The council is more difficult to understand. The "elders" (γέροντες) of the *Iliad* are the same as the subordinate "kings"; they are summoned by Agamemnon to his tent, and form a small council of nine or ten persons. In Troy we hear of elders of the people (δημογέροντες) who are with Priam, and are men past the military age. So in Ithaca there are elders who have not gone to Troy with the army. It would seem therefore that the meeting in Agamemnon's tent was only a copy or adaptation of the true constitutional "council of elders," which indeed was essentially unfitted for the purposes of military service.

Priesthood in Homer is found in the case of particular temples, where an officer is naturally wanted to take charge of the sacred inclosure and the sacrifices offered within it. It is perhaps an accident that we do not hear of priests in Ithaca. Agamemnon performs sacrifice himself, not because a priestly character was attached to the kingly office, but simply because he was "master in his own house."

The conception of "law" is foreign to Homer. The later words for it (νόμος, ῥήτρα) are unknown, and the terms which he uses (δίκη and θέμις) mean merely "custom." Judicial functions are in the hands of the elders, who "have to do with suits" (δικασπόλοι), and "uphold judgments" (θέμιστας εἰρύαται). On such matters as the compensation in cases of homicide, it is evident that there were no rules, but merely a feeling, created by use and wont, that the relatives of the slain man should be willing to accept payment. The sense of anger which follows a violation of custom has the name of "Nemesis"—righteous displeasure.

As there is no law in Homer, so there is no morality. That is to say, there are no general principles of action, and no words which indicate that acts have been classified as good or bad, right or wrong. Moral *feeling*, indeed, existed, and was denoted by "Aidos"; but the numerous meanings of this word—shame, veneration, pity—show how rudimentary the idea was. And when we look to practice we find that cruel and even treacherous deeds are spoken of without the least sense that they deserve censure. The heroes of Homer are hardly more moral agents than the giants and enchanters of a fairy tale.[1]

The religious ideas of Homer differ in some important points from those of later Greece. The Apollo of the *Iliad* has the character of a local deity—"ruler of Chryse and goodly Cilla and Tenedos." He may be compared with the Clarian and the Lycian god, but he is unlike the Apollo of Dorian times, the "deliverer" and giver of oracles. Again, the worship of Dionysus, and of Demeter and Persephone, is mainly or wholly post-Homeric. The greatest difference, however, lies in the absence of hero-worship from the Homeric order of things. Castor and Polydeuces, for instance, are simply brothers of Helen who died before the expedition to Troy (*Il.* iii. 243).

The military tactics of Homer belong to the age when the chariot was the principal engine of warfare. Cavalry is unknown, and the battles are mainly decided by the prowess of the chiefs. The use of the trumpet is also later. It has been supposed indeed that the art of riding was known in Homer's own time, because it occurs in comparisons. But the riding which he describes (*Il.* xv. 679) is a mere exhibition of skill, such as we may see in a modern circus. And though he mentions the trumpet (*Il.* xviii. 219), there is nothing to show that it was used, as in historical times, to give the signal for the charge. The chief industries of Homeric times are those of the carpenter (τέκτων), the worker in leather (σκυτοτόμος), the smith or worker in metal (χαλκεύς),—whose implements are the hammer and pincers,—and the potter (κεραμεύς); also spinning and weaving, which were carried on by the women. The fine arts are represented by sculpture in relief, carving in wood and ivory, embroidery. Statuary is later; it appears to have come into existence in the 7th century, about the time when casting in metal was invented by Rhœcus of Samos. In general, as has been well shown by Mr A. S. Murray,[2] Homeric art does not rise above the stage of *decoration*, applied to objects in common use; while in point of style it is characterized by a richness and variety of ornament which is in the strongest contrast to the simplicity of the best periods. It is the work, in short, not of artists but of skilled workmen; the ideal artist is "Dædalus," a name which implies mechanical skill and intricate workmanship, not beauty of design. Mr Murray further shows (following Professor Brunn of Munich) that the Greek art of the Homeric period is identical in origin with contemporary Assyrian work. The sculptures on the shield of Achilles, in particular, are quite Assyrian in type: and the same may be said of the work which has the best claim to equal antiquity with the Homeric poems—the lions sculptured in flat relief over the gate of Mycenæ.

One art of the highest importance remains. The question whether writing was known in the time of Homer was raised in antiquity, and has been debated with especial eagerness ever since the appearance of Wolf's *Prolegomena*. In this case we have to consider not merely the indications of the poems, but also the external evidence which we possess regarding the use of writing in Greece. This latter kind of evidence is much more considerable now than it was in Wolf's time. It will be found in a very convenient form in A. Kirchoff's *Studien zur Geschichte des griechischen Alphabets* (Berlin, 1877).

The oldest known stage of the Greek alphabet appears to be represented by inscriptions of the islands of Thera, Melos, and Crete, which are referred to the 40th Olympiad (620 B.C.). The oldest specimen of a distinctively Ionian alphabet is the famous inscription of the mercenaries of Psammetichus, in Upper Egypt, as to which the only doubt is whether the Psammetichus in question is the first or the second, and consequently whether the inscription is to be dated Ol. 40 or Ol. 47. Considering that the divergence of two alphabets (like the difference of two dialects) requires both time and familiar use, we may gather from these facts that writing was well known in Greece early in the 7th century B.C.[3]

The rise of prose composition in the 6th century B.C. has been thought to mark the time when memory was practically superseded by writing as a means of preserving literature,—the earlier use of letters being confined to short documents, such as lists of names, treaties, laws, &c. This conclusion, however, is by no means necessary. It may be that down to comparatively late times poetry was not commonly read, but was recited from memory. But the question is—From what time are we to suppose that the preservation of long poems was generally secured by the existence of written copies? Now, without counting the Homeric

[1] "The incidents which, as we read them in Homer, touch us as we are touched by a fairy tale" (Conington's *Virgil*, ii. p. 11). This subject is well treated by Mr Mahaffy in his *Social Life of Greece*, ch. ii.

[2] *Contemporary Review*, vol. xxiii. p. 218 *ff.*

[3] The fact that the Phœnician Vau (Ϝ) was retained in the Greek alphabets, and the vowel υ added, shows that when the alphabet was introduced the sound denoted by Ϝ was still in full vigour. Otherwise Ϝ would have been used for the vowel υ, just as the Phœnician consonant Yod became the vowel ι. But in the Ionic dialect the sound of Ϝ died out soon after Homer's time, if indeed it was still pronounced then. It seems probable therefore that the introduction of the alphabet is not later than the composition of the Homeric poems.

poems—which doubtless had exceptional advantages in their fame and popularity—we find a body of literature dating from the 8th century B.C. to which the theory of oral transmission is wholly inapplicable. In the Trojan cycle alone we know of the two epics of Arctinus, the *Little Iliad* of Lesches, the *Cypria*, the *Nostoi*. The Theban cycle is represented by the *Thebaid* (which Callinus, who was of the 7th century, ascribed to Homer) and the *Epigoni*. Other ancient epics—ancient enough to have passed under the name of Homer—are the *Taking of Œchalia*, and the *Phocaïs*. Again, there are the numerous works attributed to Hesiod and other poets of the didactic and the quasi-historical schools,—Eumelus of Corinth, Cinæthon of Sparta, Agias of Trœzen, and many more. The preservation of this vast mass is not explained by any of the various considerations which have been brought to bear on the Homeric poems—national interest, families of rhapsodists, public recitation, &c. It can only be attributed to writing, which must therefore have been in use for two centuries or more before there was any considerable prose literature. Nor is this in itself improbable. On the contrary, when we see how gradual and tentative progress is, and how great is the influence of an established literary form, we must feel it to be probable that the art of writing had been applied to the existing kinds of literature long before it led to the creation of a new type.

The further question, whether the *Iliad* and *Odyssey* were originally written, is much more difficult. External evidence does not reach back so far, and the internal evidence is curiously indecisive. The only passage which can be interpreted as a reference to writing occurs in the story of Bellerophon, told by Glaucus in the sixth book of the *Iliad*. Prœtus, king of Corinth, sent Bellerophon to his father-in-law the king of Lycia, and gave him "baneful tokens, scratching on a folded tablet many spirit-destroying things, and bade him show this to his father-in-law, that he might perish." The king of Lycia asked duly (on the tenth day from the guest's coming) for a token (ᾔτεε σῆμα ἰδέσθαι), and then knew what Prœtus wished to be done.[1] In this account there is nothing to show exactly how the message of Prœtus was expressed. The use of writing for the purpose of the token between "guest-friends" (*tessera hospitalis*) is certainly very ancient. Mommsen (*Röm. Forsch.*, i. p. 338 *ff.*) aptly compares the use in treaties, which are the oldest species of public documents. But we may suppose that tokens of some kind—like the marks which the Greek chiefs make on the lots (*Il.* vii. 175 *ff.*)—were in use before writing was known. In any system of signs there were doubtless means of recommending a friend, or giving warning of the presence of an enemy. There is no difficulty, therefore, in understanding the message of Prœtus without alphabetical writing. But, on the other hand, there is no reason for so understanding it.

If the language of Homer is so ambiguous where the use of writing would naturally be mentioned, we cannot expect to find more decisive references elsewhere. Arguments have been founded upon the descriptions of the blind singers in the *Odyssey*, with their songs inspired directly by the Muse; upon the appeals of the poet to the Muses, especially in such a place as the opening of the Catalogue; upon the Catalogue itself, which is a kind of historical document put into verse to help the memory; upon the shipowner in the *Odyssey*, who has "a good memory for his cargo," &c. It may be answered, however, in the first place, that much of this is traditional, handed down from the time when all poetry was unwritten, and in the second place that the form of poetry is determined by the manner in which it is used,—the recitation or performance, if we may give a wide meaning to that term,—not by the manner in which it is composed or preserved. And the "performance" of epic poetry still depended upon the power of memory long after written copies were in existence. In short, it is one thing to recognize that a literature is essentially oral in its form, characteristic of an age which was one of hearing rather than of reading, and quite another to hold that the same literature was preserved entirely by oral transmission. And finally, if writing was used in Homeric times, the absence of all mention of it may be connected with the peculiar silence—imposed doubtless by the tradition of his art—which the poet observes regarding himself and his circumstances.

The result of these various considerations seems to be that the age which we may call the Homeric—the age which is brought before us in vivid outlines in the *Iliad* and *Odyssey*—lies beyond the earliest point to which history enables us to penetrate. And so far as we can draw any conclusion as to the author (or authors) of the two poems, it is that the whole debate between the cities of Æolis and Ionia was wide of the mark. The author of the *Iliad*, at least, was evidently a European Greek who lived before the colonization of Asia Minor; and the claims of the Asiatic cities mean no more than that in the days of their prosperity these were the chief seats of the fame of Homer.[2]

This is perhaps the place to consider whether the poems are to be regarded as possessing in any degree the character of historical record. The question is one which in the absence of satisfactory criteria will generally be decided by taste and predilection. A few suggestions, however, may be made.

1. The events of the *Iliad* take place in a real locality, the general features of which are kept steadily in view. There is no doubt about Sigeum and Rhœteum, or the rivers Scamander and Simois, or the islands Imbros, Lemnos, and Tenedos. It is at least remarkable that a legend of the national interest of the "tale of Troy" should be so definitely localized, and that in a district which was never famous as a seat of Greek population.

2. The discoveries of Schliemann prove that the Homeric Troy (which can hardly be other than Hissarlik, see TROY) was an ancient seat of pre-Hellenic population. This circumstance perhaps adds something to the probability that the legend was founded on fact.

3. The story of the *Iliad* is singularly free from the exaggerated and marvellous character which belongs to most legends. The apple of discord, the arrows of Philoctetes, the invulnerability of Achilles, and similar fancies, are the additions of later poets. This sobriety, however, belongs not to the whole *Iliad*, but to the events and characters of the war. Such figures as Bellerophon, Niobe, the Amazons, which are thought of as traditions from an earlier generation, show the marvellous element at work.

4. Certain persons and events in the story have a distinctly mythical stamp. Helen is a figure of this kind. There was another story according to which she was carried off by Theseus, and recovered by her brothers the Dioscuri. There are even traces of a third version, in which the Messenian twins, Idas and Lynceus, appear.

5. The analogy of the French epic, the *Chanson de Roland*, favours the belief that there was some nucleus of fact. The defeat of Roncevaux was really suffered by a part of Charlemagne's army. But the Saracen army is purely mythical, the true enemy having been the Gascons. Thus the element of fact is found in the *place* where the battle was fought, and the *name* of the great emperor. If similarly we leave, as historical, the plain of Troy, and the name Agamemnon, we shall perhaps not be far wrong.

(2) The dialect of Homer is properly to be called Old Ionic: that is to say, it is the dialect of which the New Ionic of Herodotus and the Attic are varieties, but it is in a much earlier stage of development. The proof of this proposition is to be obtained chiefly by comparing the grammatical formation and the syntax of Homer with those of Attic. The comparison of the vocabulary is in the nature of things less conclusive on the question of date. It would be impossible to give the evidence in full without writing a Homeric grammar, but a few specimens may be of interest.

[1] The word σῆμα means the whole message or document. Hence σήματα λυγρά are not "baneful marks" or "characters," but "a token which" (instead of being one of friendly recommendation, as it purported to be) "was a message of death."

[2] On this point, see Mr Gladstone's *Homeric Synchronism*, ch. iii.

1. The first aorist in Greek being a "weak" tense, *i.e.*, formed by a suffix (-σᾰ), whereas the second aorist is a "strong" tense, distinguished by the form of the root-syllable, we expect to find a constant tendency to diminish the number of second aorists in use. No new second aorists, we may be sure, were formed any more than new "strong" tenses, such as *came* or *sang*, can be formed in English. Now in Homer there are upwards of 80 second aorists (not reckoning aorists of "Verbs in μι," such as ἔστην, ἔβην), whereas in all Attic prose not more than 30 are found. In this point therefore the Homeric language is manifestly older. In Attic poets, it is true, the number of such aorists is much larger than in prose. But here again we find that they bear witness to Homer. Of the poetical aorists in Attic the larger part are also Homeric. Others are not really Attic at all, but borrowed from earlier Æolic and Doric poetry. It is plain, in short, that the later poetical vocabulary was separated from that of prose mainly by the forms which the influence of Homer had saved from being forgotten.

2. While the whole class of "strong" aorists diminished, certain smaller groups in the class disappeared altogether. Thus we find in Homer—

(*a.*) The second aorist middle without the "thematic" ε or ο: as ἔβλη-το, *was struck*; ἔφθι-το, *perished*; ἆλ-το, *leaped*.

(*b.*) The aorist formed by reduplication: as δέδαεν, *taught*; λελαβέσθαι, *to seize*. These constitute a distinct formation, generally with a "causative" meaning; the solitary Attic specimen is ἤγαγον.

3. Another "exception," which is really a survival from a former rule, is seen in the short syllable of the plural of οἶδα (ἴσμεν, in Homer ἴδ-μεν, ἴστε, &c.). Other examples occur in Homer, both in the indicative and in the participle, as ἀρηρώς, fem. ἀρᾰρυῖα; so μεμακυῖα, ἰδυῖα, &c.). But this variation of the stem in different parts of a single tense is exactly one of the complexities from which language is ever striving to free itself; and accordingly in Attic it has all but disappeared.

4. It had long been known that the subjunctive in Homer often takes a short vowel (*e.g.*, in the plural, -ομεν, -ετε instead of -ωμεν, -ητε, and in the Mid. -ομαι, &c., instead of -ωμαι, &c.). This was generally said to be done by "poetic licence," or *metri gratia*. In fact, however, the Homeric subjunctive is almost quite "regular," though the rule which it obeys is a different one from the Attic. It may be summed up by saying that the subjunctive takes ω or η when the indicative has ο or ε, and not otherwise. Thus Homer has ἴ-μεν, *we go*, ἴ-ο-μεν, *let us go*. The later ἴ-ω-μεν was at first a solecism, an attempt to conjugate a "verb in μι" like the "verbs in ω." It will be evident that under this rule the perfect and first aorist subjunctive should always take a short vowel; and this accordingly is the case, with very few exceptions.

5. The article (ὁ, ἡ, τό) in Homer is chiefly used as an independent pronoun (*he*, *she*, *it*), a use which in Attic appears only in a few combinations (such as ὁ μὲν .... ὁ δέ, *the one .... the other*). This difference is parallel to the relation between the Latin *ille* and the article of the Romance languages.

6. The prepositions offer several points of comparison. What the grammarians called "tmesis," the separation of the preposition from the verb with which it is compounded, is peculiar to Homer. The true account of the matter is that in Homer the place of the preposition is not rigidly fixed, as it was afterwards. Again "with" is in Homer σύν (with the dative), in Attic prose μετά with the genitive. Here Attic poetry is intermediate; the use of σύν is retained as a piece of poetical tradition.

7. In addition to the particle ἄν, Homer has another, κεν, hardly distinguishable in meaning. The Homeric uses of ἄν and κεν are different in several respects from the Attic, the general result being that the Homeric syntax is more elastic. Thus ἄν and κεν are used in Homer with the future, and with the subjunctive in simple sentences (οὐκ ἄν τοι χραίσμῃ, *shall not avail thee*). Again in clauses introduced by the relative, or by εἰ, *if*, the subjunctive is found both with and without ἄν or κεν; whereas in Attic (except in a few poetical instances) ἄν is always found (ὅς ἄν, ἐάν). And yet the Homeric syntax is perfectly definite and precise. Homer uses no constructions loosely or without corresponding differences of meaning. His rules are equally strict with those of the later language, but they are not the same rules. And they differ chiefly in this, that the less common combinations of the earlier period were disused altogether in the later.

8. In the vocabulary the most striking difference is that many words appear from the metre to have contained a sound which they afterwards lost, viz., that which is written in some Greek alphabets by the "digamma" ϝ. Thus the words ἄναξ, ἄστυ, ἔργον, ἔπος, and many others must have been written at one time ϝάναξ, ϝάστυ, ϝέργον, ϝέπος. This letter, however, died out earlier in Ionic than in most dialects, and there is no proof that the Homeric poems were ever written with it.

The points that have been mentioned, to which many others might be added, make it clear that the Homeric and Attic dialects are separated by differences which affect the whole structure of the language, and require a considerable time for their development. At the same time there is hardly one of these differences which cannot be accounted for by the natural growth of the language. It has been thought indeed that the Homeric dialect was a mixed one, containing Æolic and even Doric forms, but the proof of this is scanty and doubtful. There are doubtless many Homeric forms which were unknown to the later Ionic and Attic, and which are found in Æolic or other dialects. In general, however, these are *older* forms, which must have existed in Ionic at one time, and may very well have belonged to the Ionic of Homer's time. So too the digamma is called "Æolic" by grammarians, and is found on Æolic and Doric inscriptions. But the letter was one of the original alphabet, and was retained universally as a numeral. It can only have fallen into disuse by degrees, as the sound which it denoted ceased to be pronounced. The fact that there are so many traces of it in Homer is a strong proof of the antiquity of the poems, but no proof of admixture with Æolic.

There is one sense, however, in which an admixture of dialects may be recognized. It is clear that the variety of forms in Homer is too great for any actual spoken dialect. To take a single instance: it is impossible that the genitives in -οιο and in -ου should both have been in everyday use together. The form in -οιο must have been poetical or literary, like our *-eth* of the third person singular, or like *ye* for *you*, *whoso* for *whoever*, and the like. The origin of such double forms is not far to seek. The effect of dialect on style was always recognized in Greece, and the dialect which had once been adopted by a particular kind of poetry was ever afterwards adhered to. The Epic of Homer was doubtless formed originally from a spoken variety of Ionic, but became literary and conventional with time. It is Homer's own testimony that all the Greeks spoke one language (*Il.* iv. 437),—that is to say, that they understood one another, in spite of the inevitable local differences. In these circumstances experience shows that some one dialect gains a literary supremacy to which the whole nation yields. So Tuscan became the type of Italian, and Anglian of English. But as soon as the dialect is adopted, it begins to diverge from the colloquial form. Just as modern poetical Italian uses many older grammatical forms peculiar to itself, so the language of poetry, even in Homeric times, had formed a deposit (so to speak) of archaic grammar. There were doubtless poets before Homer, as well as brave men before Agamemnon; and indeed the formation of a conventional dialect such as the Homeric must have been the work of several generations.

The use of Ionic (instead of Æolic) by the Bœotian poet Hesiod, in a kind of poetry which was not of the Homeric type, tends to confirm the conclusion that the literary ascendency of Ionic was anterior to the *Iliad* and *Odyssey*. It follows that the choice of Ionic as the language of the Homeric poems is no argument for the Ionian birth of their author (or authors).

The argument for the antiquity of Homer founded upon the traces of Homeric influence in later poetry cannot be profitably discussed without going into details which would be out of place here. When a phrase or idea is found in Homer, and again in a later author, we have to inquire whether it may not belong to the common stock from which the poet of the *Iliad* or *Odyssey* himself drew, and then whether it proves anything as to the antiquity of the poems *in their present form*. Hence it is seldom that such considerations yield a satisfactory proof.[1] The case is

[1] This is not the place to notice the argument which has been founded upon the differences between Homer and later poets. It may be observed, however, that, while agreement between poets widely separated by time calls for notice and explanation, difference is only what we expect.

somewhat different with the arguments derived from the early epic poems called "cyclic." The fragments of these poems, indeed, are so scanty that we cannot compare them with Homer in respect of style or language, but enough is known of their subjects to indicate that they presuppose an *Iliad* and *Odyssey* of something like their present form and extent. The *Æthiopis* of Arctinus (who was of the 8th century) took up the story of the Trojan war at the point where the *Iliad* leaves it, and similarly the *Telegoneia* of Eugammon (fl. 568 B.C.) is a mere continuation of the *Odyssey*.

Study of Homer.—The Homeric Question.—The critical study of Homer began in Greece almost with the beginning of prose writing. The first name is that of Theagenes of Rhegium, contemporary of Cambyses (525 B.C.), who is said to have founded the "new grammar" (the older "grammar" being the art of reading and writing), and to have been the inventor of the allegorical interpretations by which it was sought to reconcile the Homeric mythology with the morality and speculative ideas of the 6th century B.C. The same attitude in the "ancient quarrel of poetry and philosophy" was soon afterwards taken by Anaxagoras; and after him by his pupil Metrodorus of Lampsacus, who explained away all the gods, and even the heroes, as elementary substances and forces (Agamemnon as the upper air, &c.).

The next writers on Homer of the "grammatical" type were Stesimbrotus of Thasos (contemporary with Cimon) and Antimachus of Colophon, himself an epic poet of mark. The *Thebaid* of Antimachus, however, was not popular, and seems to have been a great storehouse of mythological learning rather than a poem of the Homeric school.

Other names of the pre-Socratic and Socratic times are mentioned by Xenophon, Plato, and Aristotle. These were the "ancient Homerics" (οἱ ἀρχαῖοι Ὁμηρικοί), who busied themselves much with the hidden meanings of Homer; of whom Aristotle says, with his profound insight, that they see the small likenesses and overlook the great ones (*Metaph.*, xii.).

The text of Homer must have attracted some attention when Antimachus came to be known as the "corrector" (διορθωτής) of a distinct edition (ἔκδοσις). Aristotle is said himself to have made a recension for the use of Alexander the Great. His remarks on Homer (in the *Poetics* and elsewhere) show that he had made a careful study of the structure and leading ideas of the poems, but do not throw much light on the text.

The real work of criticism became possible only when great collections of manuscripts began to be made by the princes of the generation after Alexander, and when men of learning were employed to sift and arrange these treasures. In this way the great Alexandrian school of Homeric criticism began with Zenodotus, the first chief of the Museum, and was continued by Aristophanes and Aristarchus. In Aristarchus ancient philology culminated, as philosophy had done in Socrates. All earlier learning either passed into his writings, or was lost; all subsequent research turned upon his critical and grammatical work.

The means of forming a judgment of the criticism of Aristarchus are scanty. The literary form which preserved the works of the great historians was unfortunately wanting, or was not sufficiently valued, in the case of the grammarians. Abridgments and newer treatises soon drove out the writings of Aristarchus and other founders of the science. Moreover, a recension could not be reproduced without new errors soon creeping in. Thus we find that Didymus, writing in the time of Cicero, does not quote the readings of Aristarchus as we should quote a *textus receptus*. Indeed, the object of his work seems to have been to determine what those readings were. Enough, however, remains to show that Aristarchus had a clear notion of the chief problems of philology (except perhaps those concerning etymology). He saw, for example, that it was not enough to find a meaning for the archaic words (the γλῶσσαι, as they were called), but that common words (such as πόνος, φόβος) had their Homeric uses, which were to be gathered by due induction. In the same spirit he looked upon the ideas and beliefs of Homer as a consistent whole, which might be determined from the evidence of the poems. He noticed especially the difference between the stories known to Homer and those given by later poets, and made many comparisons between Homeric and later manners, arts, and institutions. Again, he was sensible of the paramount value of manuscript authority, and appears to have introduced no readings from mere conjecture. The frequent mention in the Scholia of "better" and "inferior" texts may indicate a classification made by him. His use of the "obelus" to distinguish spurious verses, which made so large a part of his fame in antiquity, has rather told against him with modern scholars.[1] It is chiefly interesting as a proof of the confusion in which the text must have been before the Alexandrian times; for it is impossible to understand the readiness of Aristarchus to suspect the genuineness of verses unless the state of the copies had pointed to the existence of numerous interpolations. On this matter, however, we are left to mere conjecture. The quotations from Homer in pre-Alexandrian authors are so inaccurate as to throw little or no light on the text which they used. It is at least clear that our manuscripts are much more trustworthy than the recollection of these ancient writers.[2]

Our knowledge of Alexandrian criticism is derived almost wholly from a single document, the famous *Iliad* of the library of St Mark in Venice (*Codex Venetus*, or *Ven. A*), first published by the French scholar Villoison in 1788 (*Scholia antiquissima ad Homeri Iliadem*). This manuscript, written in the 10th century, contains (1) the best text of the *Iliad*, (2) the critical marks of Aristarchus, and (3) Scholia, consisting mainly of extracts from four grammatical works, viz., Didymus (contemporary of Cicero) on the recension of Aristarchus, Aristonicus (fl. 24 B.C.) on the critical marks of Aristarchus, Herodian (fl. 16 A.D.) on the accentuation, and Nicanor (fl. 127 A.D.) on the punctuation, of the *Iliad*.

These extracts present themselves in two distinct forms. One series of scholia is written in the usual way, on a margin reserved for the purpose. The other consists of brief scholia, written in very small characters (but of the same period) on the narrow space left vacant round the text. Occasionally a scholium of this kind gives the substance of one of the longer extracts; but as a rule they are distinct. It would seem, therefore, that after the manuscript was finished the "marginal scholia" were discovered to be extremely defective, and a new series of extracts was added in a form which interfered as little as possible with the appearance of the book.[3]

The mention of the Venetian Scholia leads us at once to the Homeric controversy; for the immortal *Prolegomena* of Wolf[4] appeared a few years after Villoison's publication, and was founded in great measure upon the fresh and abundant materials which it furnished. Not that the "Wolfian theory" of the Homeric poems is directly supported by anything in the Scholia; the immediate object of the *Prolegomena* was not to put forward that theory, but to elucidate the new and remarkable conditions under which the text of Homer had to be settled, viz., the discovery of an *apparatus criticus* of the 2d century B.C. The questions regarding the original structure and early history of the poems were raised (forced upon him, it may be said) by the critical problem; but they were really originated by facts and ideas of a wholly different order.

The 18th century, in which the spirit of classical correctness had the most absolute dominion, did not come to an end before a powerful reaction set in, which affected not only literature but also speculation and politics. In this movement the leading ideas were concentrated in the word Nature. The natural condition of society, natural law, natural religion, the morality of feeling, the poetry of nature, gained a singular hold, first on the English philosophers from Hume onwards, and then (through Rousseau chiefly) on the general drift of thought and action in Europe. In literature the effect of these ideas was to set up a false opposition between nature and art. As political writers imagined a patriarchal innocence prior to codes of law, so men of letters sought in popular unwritten poetry the freshness and simplicity which were wanting in the prevailing styles. The blind minstrel was the counterpart of the noble savage. The supposed discovery of the poems of Ossian fell in with this train of sentiment, and created an enthusiasm for the study of early popular poetry. Homer was soon drawn into the circle of inquiry. Blackwell (Professor of Greek at Aberdeen) had insisted, in a book published in 1735, on the "naturalness" of Homer; and Wood (*Essay on the Original Genius of Homer*, London, 1769) was the first who maintained that Homer composed without the help of writing,

---

[1] See the chapter in Cobet's *Miscellanea Critica*, pp. 225–239.

[2] For example, Æschines says that the words φήμη δ' ἐς στρατὸν ἦλθε occur repeatedly in the *Iliad*, whereas they never occur there. Had Æschines lived two centuries earlier, how decisive this would have seemed against the antiquity of "our Homer!" As it is, it only proves the weakness of all such arguments. On the Homeric quotations in Aristotle, see Cope's edition of Aristotle's *Rhetoric*, vol. iii. p. 48.

[3] The existence of two groups of the Venetian Scholia was first noticed by Professor La Roche, and they were first distinguished in the edition of W. Dindorf (Oxford, 1875). There is also a group of Scholia, chiefly exegetical, a collection of which was published by Villoison from a second Venetian MS. in his edition of 1788, and has been again edited by W. Dindorf (Oxford, 1877). The most important collection of this group is contained in the *Codex Townleianus* of the British Museum, which is still unedited, though a MS. probably copied from it, the *Codex Victorianus* at Munich, was used by Bekker for his edition of the Scholia (Berlin, 1825). The vast commentary of Eustathius (of the 12th century) marks a third stage in the progress of ancient Homeric learning.

[4] *Prolegomena ad Homerum, sive de operum Homericorum prisca et genuina forma variisque mutationibus et probabili ratione emendandi*, scripsit Frid. Aug. Wolfius. Volumen i.

and supported his thesis by ancient authority, and also by the parallel of Ossian. Both these books were translated into German, and their ideas passed into the popular philosophy of the day. Everything in short was ripe for the reception of a book that brought together, with masterly ease and vigour, the old and the new Homeric learning, and drew from it the historical proof that Homer was no single poet, writing according to art and rule, but a name which stood for a golden age of the true spontaneous poetry of genius and nature.

The part of the *Prolegomena* which deals with the original form of the Homeric poems occupies pp. xl.–clx. (in the first edition). Wolf shows how the question of the date of writing meets us on the threshold of the textual criticism of Homer, and accordingly enters into a full discussion, first of the external evidence, then of the indications furnished by the poems. Having satisfied himself that writing was unknown to Homer, he is led to consider the real mode of transmission, and finds this in the Rhapsodists, of whom the Homeridæ were an hereditary school. And then comes the conclusion to which all this has been tending: "the die is cast"—the *Iliad* and *Odyssey* cannot have been composed in the form in which we know them without the aid of writing. They must therefore have been, as Bentley had said, "a sequel of songs and rhapsodies," "loose songs not collected together in the form of an epic poem till about 500 years after." This conclusion he then supports by the character attributed to the "Cyclic" poems (whose want of unity showed that the structure of the *Iliad* and *Odyssey* must be the work of a later time), by one or two indications of imperfect connexion, and by the doubts of ancient critics as to the genuineness of certain parts. These, however, are matters of conjecture. "Historia loquitur." The voice of antiquity is unanimous in declaring that "Pisistratus first committed the poems of Homer to writing, and reduced them to the order in which we now read them."

The appeal of Wolf to the "voice of all antiquity" is by no means borne out by the different statements on the subject. According to Heraclides Ponticus (pupil of Plato), the poetry of Homer was first brought to the Peloponnesus by Lycurgus, who obtained it from the descendants of Creophylus (*Polit.*, fr. 2). Plutarch in his *Life of Lycurgus* (c. 4) repeats this story, with the addition that there was already a faint report of the poems in Greece, and that certain detached fragments were in the possession of a few persons (ἐκέκτηντο δὲ οὐ πολλοὶ μέρη τινὰ σπο ράδην τῆς ποιήσεως ὡς ἔτυχε διαφερομένης). Again, the Platonic dialogue *Hipparchus* (which though not genuine is probably earlier than the Alexandrian times) asserts that Hipparchus, son of Pisistratus, first brought the poems to Athens, and obliged the rhapsodists at the Panathenæa to follow the order of the text, "as they still do," instead of reciting portions chosen at will. The earliest authority for attributing any work of the kind to Pisistratus is the well known passage of Cicero (*De Orat.*, 3, 34: "Quis doctior eisdem temporibus illis, aut cujus eloquentia litteris instructior fuisse traditur quam Pisistrati? qui primus Homeri libros, confusos antea, sic disposuisse dicitur ut nunc habemus"). To the same effect Pausanias (vii. p. 594) says that the change of the name Donoessa to Gonoessa (in *Il.* ii. 573) was thought to have been made by "Pisistratus or one of his companions," when he collected the poems, which were then in a fragmentary condition (διεσπασμένα τε καὶ ἄλλα ἀλλαχοῦ μνημονευόμενα ἤθροιζε). Finally, Diogenes Laertius (i. 57) says that Solon made a law that the poems should be recited with the help of a prompter (ἐξ ὑποβολῆς), so that each rhapsodist should begin where the last left off; and he argues from this that Solon did more than Pisistratus to make Homer known. The argument is directed against a certain Dieuchidas of Megara, who appears to have maintained that the verses about Athens in the Catalogue (*Il.* ii. 546–556) were interpolated by Pisistratus. The passage is unfortunately corrupt, but it is at least clear that in the time of Solon, according to Diogenes, there were complete copies of the poems, such as could be used to control the recitations. Hence the account of Diogenes is quite irreconcilable with the notices on which Wolf relied.

It is needless to examine the attempts which have been made to harmonize these accounts. Such attempts usually start with the tacit assumption that each of the persons concerned—Lycurgus, Solon, Pisistratus, Hipparchus—must have done *something* for the text of Homer, or for the regulation of the rhapsodists. But we have first to consider whether any of the accounts come to us on such evidence that we are bound to consider them as containing a nucleus of truth.

In the first place, the statement that Lycurgus obtained the poems from descendants of Creophylus must be admitted to be purely mythical. But if we reject it, have we any better reason for believing the parallel assertion in the Platonic *Hipparchus*? It is true that Hipparchus is undoubtedly a real person. On the other hand it is evident that the Pisistratidæ soon became the subject of many fables. Thucydides notices as a popular mistake the belief that Hipparchus was the eldest son of Pisistratus, and that consequently he was the reigning "tyrant" when he was killed by Aristogiton. The Platonic *Hipparchus* follows this erroneous version, and may therefore be regarded as representing (at best) mere local tradition. We may reasonably go further, and see in this part of the dialogue a piece of historical romance, designed to put the "tyrant" family in a favourable light, as patrons of literature and learning.

Again, the account of the *Hipparchus* is contradicted by Diogenes Laertius, who says that Solon provided for the due recitation of the Homeric poems. The only good authorities as to this point are the orators Lycurgus and Isocrates, who mention the law prescribing the recitation, but do not say when or by whom it was enacted. The inference seems a fair one, that the author of the law was really unknown.

With regard to the statements which attribute some work in connexion with Homer to Pisistratus, it was noticed by Wolf that Cicero, Pausanias, and the others who mention the matter do so *nearly in the same words*, and therefore appear to have drawn from a common source. This source was in all probability an epigram quoted in two of the short lives of Homer, and there said to have been inscribed on the statue of Pisistratus at Athens. In it Pisistratus is made to say of himself that he "collected Homer, who was formerly sung in fragments (ὃς τὸν Ὅμηρον ἤθροισα σποράδην τὸ πρὶν ἀειδόμενον), for the golden poet was a citizen of ours, since we Athenians founded Smyrna." The other statements repeat these words with various minor additions, chiefly intended to explain how the poems had been reduced to this fragmentary condition, and how Pisistratus set to work to restore them. Thus all the authority for the work of Pisistratus "reduces itself to the testimony of a single anonymous inscription" (Nutzhorn, p. 40). Now, what is the value of that testimony? It is impossible of course to believe that a statue of Pisistratus was set up at Athens in the time of the free republic. The epigram is almost certainly a mere literary exercise. And what exactly does it say? Only that Homer was *recited in fragments* by the rhapsodists, and that these partial recitations were made into a continuous whole by Pisistratus; which does not necessarily mean more than that Pisistratus did what other authorities ascribe to Solon and Hipparchus, viz., regulated the recitation.

Against the theory which sees in Pisistratus the author of the first complete text of Homer we have to set the absolute silence of Herodotus, Thucydides, the orators, and the Alexandrian grammarians. And it can hardly be thought that their silence is accidental. Herodotus and Thucydides seem to tell us all that they know of Pisistratus. The orators Lycurgus and Isocrates make a great deal of the recitation of Homer at the Panathenæa, but know nothing of the poems having been collected and arranged at Athens, a fact which would have redounded still more to the honour of the city. Finally, the Scholia of the *Ven. A* contain no reference or allusion to the story of Pisistratus. As these Scholia are derived in substance from the writings of Aristarchus, it seems impossible to believe that the story was known to him. The circumstance that it is referred to in the later *Scholia Victoriana*, and in Eustathius, gives additional weight to this argument.

The result of these considerations seems to be that nothing rests on good evidence beyond the fact that Homer was recited by law at the Panathenaic festival. The rest of the story is probably the result of gradual expansion and accretion. It was inevitable that later writers should speculate about the authorship of such a law, and that it should be attributed with more or less confidence to Solon or Pisistratus or Hipparchus. The choice would be determined in great measure by political feeling. It is probably not an accident that Dieuchidas, who attributed so much to Pisistratus, was a Megarian. The author of the *Hipparchus* is evidently influenced by the anti-democratical tendencies in which he only followed Plato. In the times to which the story of Pisistratus can be traced, the 1st century B.C., the substitution of the "tyrant" for the legislator was extremely natural. It was equally natural that the importance of his work as regards the text of Homer should be exaggerated. The splendid patronage of letters by the successors of Alexander, and especially the great institutions which had been founded at Alexandria and Pergamus, had made an impression on the imagination of learned men which was reflected in the current notions of the ancient despots. It may even be suspected that anecdotes in praise of Pisistratus and Hipparchus were a delicate form of flattery addressed to the reigning Ptolemy. Under these influences the older stories of Lycurgus bringing Homer to the Peloponnesus, and Solon providing for the recitation at Athens, were thrown into the shade.

In the later Byzantine times it was believed that Pisistratus was aided by seventy grammarians, of whom Zenodotus and Aristarchus were the chief. The great Alexandrian grammarians had become figures in a new mythology. It is true that Tzetzes, one of the writers from whom we have this story, gives a better version, according to which Pisistratus employed four men, viz., Onomacritus, Zopyrus of Heraclea, Orpheus of Croton, and one whose name is corrupt (written ἐπικόγκυλος). Many scholars (among them Ritschl) accept this account as probable. Yet it rests upon no better evidence than the other.

The effect of the *Prolegomena* was so overwhelming that, although a few protests were made at the time, the true Homeric controversy did not begin till after the death of Wolf (1824). His speculations were thoroughly in harmony with the ideas and sentiment of the time, and his historical arguments, especially his long array of testimonies to the work of Pisistratus, were hardly challenged.

The first considerable antagonist of the Wolfian school was G. W. Nitzsch, whose writings cover the space 1828-1862, and deal with every side of the controversy. In the earlier part of his *Meletemata* (1830) he took up the question of written or unwritten literature, on which Wolf's whole argument turned, and showed that the art of writing must be anterior to Pisistratus. In the later part of the same series of discussions (1837), and in his chief work (*Die Sagenpoesie der Griechen*, 1852), he investigated the structure of the Homeric poems, and their relation to the other epics of the Trojan cycle. These epics had meanwhile been made the subject of a work which for exhaustive learning and delicacy of artistic perception has few rivals in the history of philology, the *Epic Cycle* of F. G. Welcker. The confusion which previous scholars had made between the ancient post-Homeric poets (Arctinus, Lesches, &c.) and the learned mythological writers (such as the "scriptor cyclicus" of Horace) was first cleared up by Welcker. Wolf had argued that if the cyclic writers had known the *Iliad* and *Odyssey* which we possess, they would have imitated the unity of structure which distinguishes these two poems. The result of Welcker's labours was to show that the Homeric poems had influenced both the form and the substance of epic poetry.

In this way there arose a conservative school who admitted more or less freely the absorption of pre-existing lays in the formation of the *Iliad* and *Odyssey*, and also the existence of considerable interpolations, but assigned the main work of formation to prehistoric times, and to the genius of a great poet. Whether the two epics were by the same author remained an open question; the tendency of this group of scholars was decidedly towards separation. Regarding the use of writing too they were not unanimous. K. O. Müller, for instance, maintained the view of Wolf on this point, while he strenuously combated the inference which Wolf drew from it.

The *Prolegomena* bore on the title page the words "Volumen I."; but no second volume ever appeared, nor was any attempt made by Wolf himself to carry his theory further. The first important steps in that direction were taken by Gottfried Hermann, chiefly in two dissertations, *De interpolationibus Homeri* (Leips., 1832), and *De iteratis Homeri* (Leips., 1840), called forth by the writings of Nitzsch. As the word "interpolation" implies, Hermann did not maintain the hypothesis of a congeries of independent "lays." Feeling the difficulty of supposing that all the ancient minstrels sang of the "wrath of Achilles" or the "return of Ulysses" (leaving out even the capture of Troy itself), he was led to assume that two poems of no great compass dealing with these two themes became so famous at an early period as to throw other parts of the Trojan into the background, and were then enlarged by successive generations of rhapsodists. Some parts of the *Iliad*, moreover, seemed to him to be older than the poem on the wrath of Achilles; and thus in addition to the "Homeric" and "post-Homeric" matter he distinguished a "pre-Homeric" element.

The conjectures of Hermann, in which the Wolfian theory found a modified and tentative application, were presently thrown into the shade by the more trenchant method of Lachmann, who (in two papers read to the Berlin Academy in 1837 and 1841) sought to show that the *Iliad* was made up of sixteen independent "lays," with various enlargements and interpolations, all finally reduced to order by Pisistratus. The first book, for instance, consists of a lay on the anger of Achilles (1-347), and two continuations, the return of Chryseis (430-492) and the scenes in Olympus (348-429, 493-611). The second book forms a second lay, but several passages, among them the speech of Ulysses (278-332), are interpolated. In the third book the scenes in which Helen and Priam take part (including the making of the truce) are pronounced to be interpolations; and so on. Regarding the evidence on which these sweeping results are founded, opinions will vary. The degree of smoothness or consistency which is to be expected on the hypothesis of a single author will be determined by taste rather than argument. The dissection of the first book, for instance, turns partly on a chronological inaccuracy which might well escape the poet as well as his hearers. In examining such points we are apt to forget that the contradictions by which a story is shown to be untrue are quite different from those by which a confessedly untrue story would be shown to be the work of different authors.

Structure of the Iliad.—The subject of the *Iliad*, as the first line proclaims, is the "anger of Achilles." The manner in which this subject is worked out will appear from the following summary, in which we distinguish (1) the plot, *i.e.*, the story of the quarrel, (2) the main course of the war, which forms a sort of underplot, and (3) subordinate episodes.

I.	Quarrel of Achilles with Agamemnon and the Greek army—Agamemnon, having been compelled to give up his prize Chryseis, takes Briseis from Achilles—Thereupon Achilles appeals to his mother Thetis, who obtains from Zeus a promise that he will give victory to the Trojans until the Greeks pay due honour to her son—Meanwhile Achilles takes no part in the war.
II.	Agamemnon is persuaded by a dream sent from Zeus to take the field with all his forces.
	His attempt to test the temper of the army nearly leads to their return.
	Catalogue of the army.
	Trojan muster—Trojan catalogue.
III.	Meeting of the armies—Paris challenges Menelaus—Truce made.
	"Teichoscopy," Helen pointing out to Priam the Greek leaders.
	The duel—Paris is saved by Aphrodite.
IV.	Truce broken by Pandarus.
	Advance of the armies—Battle.
V.	Aristeia of Diomede—his combat with Aphrodite
VI.	—Meeting with Glaucus—Visit of Hector to
(1-311)	the city, and offering of a peplus to Athene.
(312-529)	Visit of Hector to Paris—to Andromache.
VII.	Return of Hector and Paris to the field.
	Duel of Ajax and Hector.
	Truce for burial of dead.
	The Greeks build a wall round their camp.
VIII.	Battle—The Trojans encamp on the field.
IX.	Agamemnon sends an embassy by night, offering Achilles restitution and full amends—Achilles refuses.
X.	Doloneia—Night expedition of Odysseus and Diomede.
XI.	Aristeia of Agamemnon—he is wounded—Wounding of Diomede and Odysseus.
	Achilles sends Antilochus to inquire about Machaon.
XII.	Storming of the wall—the Trojans reach the ships.
XIII.	Zeus ceases to watch the field—Poseidon secretly comes to the aid of the Greeks.
XIV.	Sleep of Zeus, by the contrivance of Here.
XV.	Zeus awakened—Restores the advantage to the Trojans—Ajax alone defends the ships.
XVI.	Achilles is persuaded to allow Patroclus to take the field.
	Patroclus drives back the Trojans—kills Sarpedon—is himself killed by Hector.
XVII.	Battle for the body of Patroclus—Aristeia of Menelaus.
XVIII.	News of the death of Patroclus is brought to Achilles—Thetis comes with the Nereids—promises to obtain new armour for him from Hephæstus.
	The shield of Achilles described.
XIX.	Reconciliation of Achilles—His grief and desire to avenge Patroclus.
XX.	The gods come down to the plain—Combat of Achilles with Æneas and Hector, who escape.
XXI.	The Scamander is choked with slain—rises against Achilles, who is saved by Hephæstus.
XXII.	Hector alone stands against Achilles—his flight round the walls—he is slain.
XXIII.	Burial of Patroclus—Funeral games.
XXIV.	Priam ransoms the body of Hector—his burial.

Such is the "action" (πρᾶξις) which in Aristotle's opinion showed the superiority of Homer to all later epic poets. But the proof that his scheme was the work of a great poet does not depend merely upon the artistic unity which excited the wonder of Aristotle. A number of separate "lays" might conceivably be arranged and connected by a man of poetical taste in a manner that would satisfy all requirements. In such a case, however, the connecting passages would be slight and weak. Now, in the *Iliad* these passages are the finest and most characteristic. The element of connexion and unity is the story of the "wrath of Achilles"; and we have only to look at the books which give the story of the wrath to see how essential they are. Even if the ninth book is rejected (as Grote proposed), there remain the speeches of the first, sixteenth, and nineteenth books. These speeches form the cardinal points in the action of the *Iliad*—the framework into which everything else is set; and they have also the best title to the name of Homer.

The further question, however, remains,—What shorter narrative piece fulfilling the conditions of an independent poem has Lachmann succeeded in disengaging from the existing *Iliad*? It must be admitted that when tried by this test his "lays" generally fail. The "quarrel of the chiefs," the "muster of the army," the "duel of Paris and Menelaus," &c., are excellent beginnings, but have no satisfying conclusion. And the reason is not far to seek. The *Iliad* is not a history, nor is it a series of incidents in the history, of the siege. It turns entirely upon a single incident, occupying a few days only. The several episodes of the poem are not so many distinct stories, each with an interest of its own. They are only parts of a single main event. Consequently the type of epic poem which would be produced by an aggregation of shorter lays is not the type which we have in the *Iliad*. Rather the *Iliad* is itself a single lay which has grown with the growth of poetical art to the dimensions of an epic.

But the original nucleus and parts of the incidents may be the work of a single great poet, and yet other episodes may be of different authorship, wrought into the structure of the poem in later times. Various theories have been based on this supposition. Grote in particular held that the original poem, which he called the Achilleïs, did not include books ii.–vii., ix., x., xxiii., xxiv. Such a view may be defended somewhat as follows.

Of the books which relate the events during the absence of Achilles from the Greek ranks (ii.–xv.), the last five are directly related to the main action. They describe the successive steps by which the Greeks are driven back, first from the plain to the rampart, then to their ships. Moreover three of the chief heroes, Agamemnon, Diomede, and Ulysses are wounded, and this circumstance, as Lachmann himself admitted, is steadily kept in mind throughout. It is otherwise with the earlier books (especially ii.–vii.). The chief incidents in that part of the poem—the panic rush to the ships, the duels of Paris and Menelaus, and of Hector and Ajax, the Aristeia of Diomede—stand in no relation to the mainspring of the poem, the promise made by Zeus to Thetis. It is true that in the thirteenth and fourteenth books the purpose of Zeus is thwarted for a time by other gods; but in books ii.–vii. it is not so much thwarted as ignored. Further, the events follow without sufficient connexion. The truce of the third book is broken by Pandarus, and Agamemnon passes along the Greek ranks with words of encouragement, but without a hint of the treachery just committed. The Aristeia of Diomede ends in the middle of the sixth book; he is uppermost in all thoughts down to ver. 311, but from this point, in the meetings of Hector with Helen and Andromache, and again in the seventh book when Hector challenges the Greek chiefs, his prowess is forgotten. Once more, some of the incidents seem to belong properly to the beginning of the war. The joy of Menelaus on seeing Paris, Priam's ignorance of the Greek leaders, the speeches of Agamemnon in his review of the ranks (in book iv.), the building of the wall—all these are in place after the Greek landing, but hardly in the ninth year of the siege.

On the other hand, it may be said, the second book opens with a direct reference to the events of the first, and the mention of Achilles in the speech of Thersites (ii. 239 *ff.*) is sufficient to keep the main course of events in view. The Catalogue is connected with its place in the poem by the lines about Achilles (686-694). When Diomede is at the height of his Aristeia Helenus says (*Il.* vi. 99), "We did not so fear even Achilles." And when in the third book Priam asks Helen about the Greek captains, or when in the seventh book nine champions come forward to contend with Hector, the want of the greatest hero of all is sufficiently felt. If these passages do not belong to the period of the wrath of Achilles, how are we to account for his conspicuous absence?

Further, the want of smoothness and unity which is visible in this part of the *Iliad* may be due to other causes than difference of date or authorship. A national poet such as the author of the *Iliad* cannot always choose or arrange his matter at his own will. He is bound by the traditions of his art, and by the feelings and expectations of his hearers. The poet who brought the exploits of Diomede into the *Iliad* doubtless had his reasons for doing so, which were equally strong whether he was the poet of the Achilleis or a later Homerid or rhapsodist. And if some of the incidents (those of the third book in particular) seem to belong to the beginning of the war, it must be considered that poetically, and to the hearers of the *Iliad*, the war opens in the third book, and the incidents are of the kind that is required in such a place. The truce makes a pause which heightens the interest of the impending battle; the duel and the scene on the walls are effective in bringing some of the leading characters on the stage, and in making us acquainted with the previous history. The story of Paris and Helen especially, and the general position of affairs in Troy, is put before us in a singularly vivid manner. The book in short forms so good a *prologue* to the action of the war that we can hardly be wrong in attributing it to the genius which devised the rest of the *Iliad*.

The case against the remaining books is of a different kind. The ninth and tenth seem like two independent pictures of the night before the great battle of xi.–xvii. Either is enough to fill the space in Homer's canvas; and the suspicion arises (as when two Platonic dialogues bear the same name) that if either had been genuine, the other would not have come into existence. If one of the two is to be rejected it must be the tenth, which is certainly the less Homeric. It relates a picturesque adventure, conceived in a vein more approaching that of comedy than any other part of the *Iliad*. Moreover, the language in several places exhibits traces of post-Homeric date. The ninth book, on the other hand, was rejected by Grote, chiefly on the grounds that the embassy to Achilles ought to have put an end to the quarrel, and that it is ignored in later passages, especially in the speeches of Achilles (xi. 609; xvi. 72, 85). His argument, however, rests on an assumption which we are apt to bring with us to the reading of the *Iliad*, but which is not borne out by its language, viz., that there was some definite atonement demanded by Achilles, or due to him according to the custom and sentiment of the time. But in the *Iliad* the whole stress is laid on the anger of Achilles, which can only be satisfied by the defeat and extreme peril of the Greeks.[1] He is influenced by his own feeling, and by nothing else. Accordingly, in the ninth book, when they are still protected by the rampart (see 348 *ff.*), he rejects gifts and fair words alike; in the sixteenth he is moved by the tears and entreaties of Patroclus, and the sight of the Greek ships on fire; in the nineteenth his anger is quenched in grief. But he makes no conditions, either in rejecting the offers of the embassy or in returning to the Greek army. And this conduct is the result, not only of his fierce and inexorable character, but also (as the silence of Homer shows) of the want of any general rules or principles, any code of morality or of honour, which would have required him to act in a different way.

Finally, Grote objected to the two last books that they prolong the action of the *Iliad* beyond the exigencies of a coherent scheme. Of the two, the twenty-third could more easily be spared. In language, and perhaps in style and manner, it is akin to the tenth; while the twenty-fourth is in the pathetic vein of the ninth, and like it serves to bring out new aspects of the character of Achilles.

[1] On this point see a paper by Professor Packard in the *Trans. of the American Philological Association*, 1876.

A recent writer (Dr E. Kammer) has given some strong reasons for doubting the genuineness of the passage in book xx. describing the duel between Achilles and Æneas (79–352). The incident is certainly very much out of keeping with the vehement action of that part of the poem, and especially with the moment when Achilles returns to the field, eager to meet Hector and avenge the death of his friend. The interpolation (if it is one) is probably due to local interests. It contains the well-known prophecy that the descendants of Æneas are to rule over the Trojans,—pointing to the existence of an Ænead dynasty in the Troad. So, too, the legend of Anchises in the Hymn to Aphrodite is evidently local; and Æneas becomes more prominent in the later epics, especially the *Cypria* and the Ἰλίου πέρσις of Arctinus.

Structure of the Odyssey.—In the *Odyssey*, as in the *Iliad*, the events related fall within a short space of time. The difficulty of adapting the long wanderings of Ulysses to a plan of this type is got over by the device—first met with in the *Odyssey*—of making the hero tell the story of his own adventures. In this way the action is made to begin almost immediately before the actual return of Ulysses. Up to the time when he reaches Ithaca it moves on three distinct scenes: we follow the fortunes of Ulysses, of Telemachus on his voyage in the Peloponnesus, and of Penelope with the suitors. The art with which these threads are woven together was recognized by Wolf himself, who admitted the difficulty of applying his theory to the "admirabilis summa et compages" of the poem. Of the comparatively few attempts which have been made to dissect the *Odyssey*, the most moderate and attractive is that of Professor A. Kirchoff of Berlin.[1]

According to Kirchoff, the *Odyssey* as we have it is the result of additions made to an original nucleus. There was first of all a "Return of Odysseus," relating chiefly the adventures with the Cyclops, Calypso, and the Phaeacians; then a continuation, the scene of which lay in Ithaca, embracing the bulk of books xiii.–xxiii. The poem so formed was enlarged at some time between Ol. 30 and Ol. 50 by the stories of books x.–xii. (Circe, the Sirens, Scylla, &c.), and the adventures of Telemachus. Lastly, a few passages were interpolated in the time of Pisistratus.

The proof that the scenes in Ithaca are by a later hand than the ancient "Return" is found chiefly in a contradiction discussed by Kirchoff in his sixth dissertation (pp. 135 *ff.*, ed. 1869). Sometimes Ulysses is represented as aged and worn by toil, so that Penelope, for instance, cannot recognize him; sometimes he is really in the prime of heroic vigour, and his appearing as a beggarly old man is the work of Athene's wand. The first of these representations is evidently natural, considering the twenty eventful years that have passed; but the second, Kirchoff holds, is the Ulysses of Calypso's island and the Phaeacian court. He concludes that the aged Ulysses belongs to the "continuation" (the change wrought by Athene's wand being a device to reconcile the two views), and hence that the continuation is the work of a different author.

Ingenious as this is, there is really very slender ground for Kirchoff's thesis. The passages in the second half of the *Odyssey* which describe the appearance of Ulysses do not give *two* well-marked representations of him. Sometimes Athene disguises him as a decrepit beggar, sometimes she bestows on him supernatural beauty and vigour. It must be admitted that we are not told exactly how long in each case the effect of these changes lasted. But neither answers to his natural appearance, or to the appearance which he is imagined to present in the earlier books. In the palace of Alcinous, for instance, it is noticed that he is vigorous but "marred by many ills" (κακοῖσι συνέρρηκται πολέεσσι, *Od.* viii. 137); and this agrees with the scenes of recognition in the latter part of the poem.

The arguments by which Kirchoff seeks to prove that the stories of books x.–xii. are much later than those of book ix. are not more convincing. He points out some resemblances between these three books and the Argonautic fables, among them the circumstance that a fountain Artacia occurs in both. In the Argonautic story this fountain is placed in the neighbourhood of Cyzicus, and answers to an actual fountain known in historical times. Kirchoff argues that the Artacia of the Argonautic story must have been taken from the real Artacia, and the Artacia of the Odyssey again from that of the Argonautic story. And as Cyzicus was settled from Miletus, he infers that both sets of stories must be comparatively late. It is more probable, surely, that the name Artacia occurred independently (as most geographical names are found to occur) in more than one place. Or it may be that the Artacia of the *Odyssey* suggested the name to the colonists of Cyzicus, whence it was adopted into the later versions of the Argonautic story. The further argument that the *Nostoi* recognized a son of Calypso by Ulysses but no son of Circe, consequently that Circe was unknown to the poet of the *Nostoi*, rests (in the first place) upon a conjectural alteration of a passage in Eustathius, and moreover has all the weakness of an argument from silence, in addition to the uncertainty arising from our very slight knowledge of the author whose silence is in question. Finally, when Kirchoff finds traces in books x.–xii. of their having been originally told by the poet himself instead of being put in the mouth of his hero, we feel that inaccuracies of this kind are apt to creep in whenever a fictitious story is thrown into the form of an autobiography.

Inquiries conducted with the refinement which characterizes those of Kirchoff are always instructive, and his book contains very many just observations; but it is impossible to admit his main conclusions. And perhaps we may infer that no similar attempt can be more successful. It does not indeed follow that the *Odyssey* is free from interpolations. The Νέκυια of book xi. may be later (as Lauer maintained), or it may contain additions, which could easily be inserted in a description of the kind. And the last book is probably by a different hand, as the ancient critics believed. But the unity of the *Odyssey* as a whole is apparently beyond the reach of the existing weapons of criticism.

Chorizontes.—When we are satisfied that each of the great Homeric poems is either wholly or mainly the work of a single poet, a question remains which has been matter of controversy in ancient as well as modern times—Are they the work of the same poet? Two ancient grammarians, Xeno and Hellanicus, were known as the separators (οἱ χωρίζοντες); and Aristarchus appears to have written a treatise against their heresy. In modern times some of the greatest names have been on the side of the "Chorizontes."

If, as has been maintained in the preceding pages, the external evidence regarding Homer is of no value, the problem now before us may be stated in this form:—Given two poems of which nothing is known except that they are of the same school of poetry, what is the probability that they are by the same author? We may find a fair parallel by imagining two plays drawn at hazard from the works of the great tragic writers. It is evident that the burden of proof would rest with those who held them to be by the same hand.

The arguments used in this discussion have been of very various calibre. The ancient Chorizontes observed that the messenger of Zeus is Iris in the *Iliad*, but Hermes in the *Odyssey*; that the wife of Hephæstus is one of the Charites in the *Iliad*, but Aphrodite in the *Odyssey*; that the heroes in the *Iliad* do not eat fish; that Crete has a hundred cities according to the *Iliad*, and only ninety according to the *Odyssey*; that προπάροιθε is used in the *Iliad* of place, in the *Odyssey* of time, &c. Modern scholars have added to the list, especially by making careful comparisons of the two poems in respect of vocabulary and grammatical forms. Nothing is more difficult than to assign the degree of weight to be given to such facts. The difference of subject between the two poems is so great that it leads to the most striking differences of detail, especially in the vocabulary. For instance, the word φόβος, which in Homer means "flight in battle" (not "fear"), occurs thirty-nine times in the *Iliad*, and only once in the *Odyssey*; but then there are no battles in the *Odyssey*. Again, the verb ῥήγνυμι, "to break," occurs forty-eight times in the *Iliad*, and once in the *Odyssey*,—the reason being that it is constantly used of breaking the armour of an enemy, the gate of a city, the hostile ranks, &c. Once more, the word σκότος, "darkness," occurs fourteen times in the *Iliad*, once in the *Odyssey*. But in every one of the fourteen places it is used of "darkness" coming over the sight of a fallen warrior. On the other side, if words such as ἀσάμινθος, "a bath," χέρνιψ, "a basin for the hands," λέσχη, "a place to meet and talk," &c., are peculiar to the *Odyssey*, we have only to remember that the scene in the *Iliad* is hardly ever laid

[1] *Die Composition der Odyssee*, Berlin, 1869. A full discussion of this book is given by Dr E. Kammer, *Die Einheit der Odyssee*, Leipsic, 1873.

within any walls except those of a tent. These examples will show that mere statistics of the occurrence of words prove little, and that we must begin by looking to the subject and character of each poem. When we do so, we at once find ourselves in the presence of differences of the broadest kind. The *Iliad* is much more historical in tone and character. The scene of the poem is a real place, and the poet sings (as Ulysses says of Demodocus) as though he had been present himself, or had heard from one who had been. The supernatural element is confined to an interference of the gods, which to the common eye hardly disturbs the natural current of affairs. The *Odyssey*, on the contrary, is full of the magical and romantic—"speciosa miracula," as Horace called them. Moreover, these marvels—which in their original form are doubtless as old as anything in the *Iliad*, since in fact they are part of the vast stock of popular tales (*Märchen*) diffused all over the world—are mixed up in the *Odyssey* with the heroes of the Trojan war. This has been especially noticed in the case of the story of Polyphemus, one that is found in many countries, and in versions which cannot all be derived from Homer. W. Grimm has pointed out that the behaviour of Ulysses in that story is senseless and foolhardy, utterly beneath the wise and much-enduring Ulysses of the Trojan war. The reason is simple; he is not the same Ulysses, but a being of the same world as Polyphemus himself—the world of giants and ogres. The question then is—How long must the name of Ulysses have been familiar in the legend (*Sage*) of Troy before it made its way into the tales of giants and ogres (*Märchen*), where the poet of the *Odyssey* found it?

Again, the Trojan legend has itself received some extension between the time of the *Iliad* and that of the *Odyssey*. The story of the Wooden Horse is not only unknown to the *Iliad*, but is of a kind which we can hardly imagine the poet of the *Iliad* admitting. The part taken by Neoptolemus seems also to be a later addition. The tendency to amplify and complete the story shows itself still more in the Cyclic poets. Between the *Iliad* and these poets the *Odyssey* often occupies an intermediate position.

This great and significant change in the treatment of the heroic legends is accompanied by numerous minor differences (such as the ancients remarked) in belief, in manners and institutions, and in language. These differences bear out the inference that the *Odyssey* is of a later age. The progress of reflexion is especially shown in the higher ideas entertained regarding the gods. The turbulent Olympian court has almost disappeared. Zeus has acquired the character of a supreme moral ruler; and although Athene and Poseidon are adverse influences in the poem, the notion of a direct contest between them is scrupulously avoided. The advance of morality is shown in the more frequent use of terms such as "just" (δίκαιος), "piety" (ὁσίη), "insolence" (ὕβρις), "god-fearing" (θεουδής), "pure" (ἁγνός); and also in the plot of the story, which is distinctly a contest between right and wrong. In matters bearing upon the arts of life it is unsafe to press the silence of the *Iliad*. We may note, however, the difference between the house of Priam, surrounded by distinct dwellings for his many sons and daughters, and the houses of Ulysses and Alcinous, with many chambers under a single roof. The singer, too, who is so prominent a figure in the *Odyssey* can hardly be thought to be absent from the *Iliad* merely because the scene is laid in a camp.

Style of Homer.—A few words remain to be said on the style and general character of the Homeric poems, and on the comparisons which may be made between Homer and analogous poetry in other countries.

The cardinal qualities of the style of Homer have been pointed out once for all by Mr Matthew Arnold. "The translator of Homer," he says, "should above all be penetrated by a sense of four qualities of his author—that he is eminently rapid; that he is eminently plain and direct, both in the evolution of his thought and in the expression of it, that is, both in his syntax and in his words; that he is eminently plain and direct in the substance of his thought, that is, in his matter and ideas; and finally, that he is eminently noble" (*On Translating Homer*, p. 9).

The peculiar rapidity of Homer is due in great measure to his use of the hexameter verse. It is characteristic of early literature that the evolution of the thought—that is, the grammatical form of the sentence—is guided by the structure of the verse; and the correspondence which consequently obtains between the rhythm and the grammar—the thought being given out in lengths, as it were, and these again divided by tolerably uniform pauses—produces a swift flowing movement, such as is rarely found when the periods have been constructed without direct reference to the metre. That Homer possesses this rapidity without falling into the corresponding faults—that is, without becoming either "jerky" or monotonous—is perhaps the best proof of his unequalled poetical skill. The plainness and directness, both of thought and of expression, which characterize Homer were doubtless qualities of his age; but the author of the *Iliad* (like Voltaire, to whom Mr Arnold happily compares him) must have possessed the national gift in a surpassing degree. The *Odyssey* is in this respect perceptibly below the level of the *Iliad*.

Rapidity or ease of movement, plainness of expression, and plainness of thought, these are not the distinguishing qualities of the great epic poets—Virgil, Dante, Milton. On the contrary, they belong rather to the humbler epico-lyrical school for which Homer has been so often claimed. The proof that Homer does not belong to that school—that his poetry is not in any true sense "ballad-poetry"—is furnished by the higher artistic structure of his poems (already discussed), and as regards style by the fourth of the qualities distinguished by Mr Arnold—the quality of *nobleness*. It is his noble and powerful style, sustained through every change of idea and subject, that finally separates Homer from all forms of "ballad-poetry" and "popular epic."[1]

But while we are on our guard against a once common error, we may recognize the historical connexion between the *Iliad* and *Odyssey* and the "ballad" literature which undoubtedly preceded them in Greece. It may even be admitted that the swift-flowing movement, and the simplicity of thought and style, which we admire in the *Iliad* are an inheritance from the earlier "lays"—the κλέα ἀνδρῶν such as Achilles and Patroclus sang to the lyre in their tent. Even the metre—the hexameter verse—may be assigned to them. But between these lays and Homer we must place the cultivation of epic poetry as an art.[2] The pre-Homeric lays doubtless furnished the elements of such a poetry—the alphabet, so to speak, of the art; but they must have been refined and transmuted before they formed poems like the *Iliad* and *Odyssey*.

A single example will illustrate this. In the scene on the walls of Troy, in the third book of the *Iliad*, after Helen has pointed out Agamemnon, Ulysses, and Ajax in answer to Priam's questions, she goes on unasked to name Idomeneus. Lachmann, whose mind is full of the ballad manner, fastens upon this as an irregularity. "The unskil-

[1] "As a poet Homer must be acknowledged to excel Shakespeare in the truth, the harmony, the sustained grandeur, the satisfying completeness of his images" (Shelley, *Essays*, &c., vol. i. p. 51, ed. 1852).

[2] "The old English balladist may stir Sir Philip Sidney's heart like a trumpet, and this is much; but Homer, but the few artists in the grand style, can do more—they can refine the raw natural man, they can transmute him" (*On Translating Homer*, p. 61).

ful transition from Ajax to Idomeneus, about whom no question had been asked," he cannot attribute to the original poet of the lay (*Betrachtungen*, p. 15, ed. 1865). But, as has lately been pointed out,[1] this is exactly the variation which a *poet* would introduce to relieve the primitive *ballad-like* sameness of question and answer; and moreover it forms the transition to the lines about the Dioscuri by which the scene is so touchingly brought to a close.

Analogies.—The development of epic poetry (properly so called) out of the oral songs or ballads of a country is a process which in the nature of things can seldom be observed. It seems clear, however, that the hypothesis of epics such as the *Iliad* and *Odyssey* having been formed by putting together or even by working up shorter poems finds no support from analogy.

Narrative poetry of great interest is found in several countries (such as Spain and Servia), in which it has never attained to the epic stage. In Scandinavia, in Lithuania, in Russia, according to M. Gaston Paris (*Histoire poétique de Charlemagne*, p. 9), the national songs have been arrested in a form which may be called intermediate between contemporary poetry and the epic. The true epics are those of India, Persia, Greece, Germany, Britain, and France. Most of these, however, fail to afford any useful points of comparison, either from their utter unlikeness to Homer, or because there is no evidence of the existence of anterior popular songs. The most instructive, perhaps the only instructive, parallel is to be found in the French "chansons de geste," of which the *Chanson de Roland* is the earliest and best example. These poems are traced back with much probability to the 10th century. They are epic in character, and were recited by professional *jongleurs* (who may be compared to the ἀοιδοί of Homer). But as early as the 7th century we come upon traces of short lays (the so-called cantilènes) which were in the mouths of all, and were sung in chorus. It has been held that the chansons de geste were formed by joining together "bunches" of these earlier cantilènes, and this was the view taken by M. Léon Gautier in the first edition of his great work, *Les Épopées françaises*, published in 1865. In the second edition, of which the first volume appeared in 1878, he has abandoned this theory. He still believes that the epics were generally composed under the influence of earlier songs. "Our first epic poets," he now says, "did not actually and materially patch together pre-existent cantilènes. They were only inspired by these popular songs; they only borrowed from them the traditional and legendary elements. In short, they took nothing from them but the ideas, the spirit, the life; they 'found' (ils ont trouvé) all the rest" (p. 80). But he admits that "some of the old poems may have been borrowed from tradition, without any intermediary" (*ibid.*); and when it is considered that the traces of the "cantilènes" are slight, and that the degree in which they inspired the later poetry must be a matter of impression rather than of proof, it does not surprise us to find other scholars (notably M. Paul Meyer) attaching less importance to them, or even doubting their existence.[2]

When M. Léon Gautier shows how history passes into legend, and legend again into romance, we are reminded of the difference noticed above between the *Iliad* and the *Odyssey*, and between Homer and the early Cyclic poems. And as has been recently pointed out, the peculiar degradation of Homeric characters which appears in some poets (especially Euripides) finds a parallel in the later chansons de geste.[3]

The comparison of Homer with the great literary epics calls for more discursive treatment than would be in place here. Some external differences have been already indicated. Like the French epics, Homeric poetry is indigenous, and is distinguished by this fact, and by the ease of movement and the simplicity which result from it, from poets such as Virgil, Dante, and Milton. It is also distinguished from them by the comparative absence of underlying motive or sentiment. In Virgil's poetry a sense of the greatness of Rome and Italy is the leading motive of a passionate rhetoric, partly veiled by the "chosen delicacy" of his language. Dante and Milton are still more faithful exponents of the religion and politics of their time. Even the French epics are pervaded by the sentiment of fear and hatred of the Saracens. But in Homer the interest is purely dramatic. There is no strong antipathy of race or religion; the war turns on no political event; the capture of Troy lies outside the range of the *Iliad*. Even the heroes are not the chief national heroes of Greece. The interest lies wholly (so far as we can see) in the picture of human action and feeling.

Bibliography.—A complete bibliography of Homer would fill volumes. The following list is intended to include those books only which are of first-rate importance, or which would be found of use to a student at the present time.

The *editio princeps* of Homer, published at Florence in 1488, by Demetrius Chalcondylas, and the Aldine editions of 1504 and 1517, have still some value beyond that of curiosity. The chief modern critical editions are those of Wolf (Halle, 1794-95; Leipsic, 1804-7), Spitzner (Gotha, 1832-36), Bekker (Berlin, 1843; Bonn, 1858), and La Roche (*Odyssey*, 1867-68; *Iliad*, 1873-76, both at Leipsic). The commentaries of Barnes, Clarke, and Ernesti are practically superseded; but Heyne's *Iliad* (Leipsic, 1802), and Nitzsch's commentary on the *Odyssey* (books i.-xii., Hanover, 1826-40) are still useful. Nägelbach's *Anmerkungen zur Ilias* (A, B 1-483, Γ) is of great value, especially the third edition (by Autenrieth, Nuremberg, 1864). The school editions of Faesi, Ameis, and La Roche should be added to the corresponding English books. The unique *Scholia Veneta* on the *Iliad* were first made known by Villoison (*Homeri Ilias ad veteris codicis Veneti fidem recensita, Scholia in eam antiquissima ex eodem codice aliisque nunc primum edidit, cum Asteriscis, Obeliscis, aliisque signis criticis, Joh. Baptista Caspar d'Ansse de Villoison*, Venice, 1788); reprinted, with many additions from other MSS., by Bekker (*Scholia in Homeri Iliadem*, Berlin, 1825-26). A new edition is being published by the Oxford Press (*Scholia Græca in Homeri Iliadem*, ed. Gul. Dindorfius); four volumes have appeared (1875-77). The vast commentary of Eustathius was first printed at Rome in 1542; the last edition is that of Stallbaum (Leipsic, 1827). The Scholia on the *Odyssey* were published by Buttmann (Berlin, 1821), and with greater approach to completeness by W. Dindorf (Oxford, 1855). Although Wolf at once perceived the value of the Venetian Scholia on the *Iliad*, the first scholar who thoroughly explored them was K. Lehrs (*De Aristarchi studiis Homericis*, Königsberg, 1833; 2d ed. Leipsic, 1865). Of the studies in the same field which have appeared since, the most important are:—Aug. Nauck, *Aristophanis Byzantii fragmenta* (Halle, 1848); L. Friedländer, *Aristonici* περὶ σημείων Ἰλιάδος *reliquiæ* (Göttingen, 1853); M. Schmidt, *Didymi Chalcenteri fragmenta* (Leipsic, 1854); L. Friedländer, *Nicanoris* περὶ Ἰλιακῆς στιγμῆς *reliquiæ* (Berlin, 1857); Aug. Lentz, *Herodiani Technici reliquiæ* (Leipsic, 1867); J. La Roche, *Die homerische Textkritik im Alterthum* (Leipsic, 1866), and *Homerische Untersuchungen* (Leipsic, 1869); Ad. Römer, *Die Werke der Aristarcheer im Cod. Venet. A.* (Munich, 1875).

The literature of the "Homeric Question" begins practically with Wolf's *Prolegomena* (Halle, 1795). Of the earlier books

[1] By A. Römer, *Die Exegetischen Scholien der Ilias*, p. vii.

[2] "On comprend que des chants populaires nés d'un événement éclatant, victoire ou défaite, puissent contribuer à former la tradition, à en arrêter les traits; ils peuvent aussi devenir le centre de légendes qui se forment pour les expliquer; et de la sorte leur substance au moins arrive au poëte épique qui l'introduit dans sa composition. Voilà ce qui a pu se produire pour de chants très-courts, dont il est d'ailleurs aussi difficile d'affirmer que de nier l'existence. Mais on peut expliquer la formation des chansons de geste par une autre hypothèse" (Meyer, *Recherches sur l'Épopée française*, p. 65). "Ce qui a fait naître la théorie des chants 'lyrico-épiques' ou des cantilènes, c'est le système de Wolf sur les poëmes homériques, et de Lachmann sur les *Nibelungen*. Mais, au moins en ce qui concerne ce dernier poëme, le système est détruit. . . . On tire encore argument des romances espagnoles, qui, dit-on, sont des 'cantilènes' non encore arrivées à l'épopée. . . . Et c'est le malheur de cette théorie: faute de preuves directes, elle cherche des analogies au dehors; en Espagne, elle trouve des 'cantilènes,' mais pas d'épopée; en Allemagne, une épopée, mais pas de cantilènes!" (*Ibid.*, p. 66).

[3] A. Lang, *Contemporary Review*, vol. xvii., n.s., p. 588.

Wood's *Essay on the Original Genius and Writings of Homer* is the most interesting. Wolf's views were skilfully popularized in W. Müller's *Homerische Vorschule* (2d. ed., Leipsic, 1836). G. Hermann's dissertations *De interpolationibus Homeri* (1832) and *De iteratis apud Homerum* (1840) are reprinted in his *Opuscula*. Lachmann's two papers (*Betrachtungen über Homer's Ilias*) were edited together by M. Haupt (2d ed., Berlin, 1865). Besides the somewhat voluminous writings of Nitzsch, and the discussions contained in the histories of Greek literature by K. O. Müller, Bernhardy, Ulrici, and Th. Bergk, and in Grote's *History of Greece*, the chief books are:—Welcker, *Der epische Cyclus oder die homerischen Dichter* (Bonn, 1835–49); Lauer, *Geschichte der homerischen Poesie* (Berlin, 1851); Sengebusch, two dissertations prefixed to the two volumes of W. Dindorf's *Homer* in the Teubner series (1855–56); Friedländer, *Die Homerische Kritik von Wolf bis Grote* (Berlin, 1853); Nutzhorn, *Die Entstehungsweise der Homerischen Gedichte, mit Vorwort von J. N. Madvig* (Leipsic, 1869); E. Kammer, *Zur homerischen Frage* (Königsberg, 1870); A. Kirchoff, *Die Composition der Odyssee* (Berlin, 1869); Volkmann, *Geschichte und Kritik der Wolf'schen Prolegomena* (Leipsic, 1874). The interest taken in the question by English students is sufficiently shown in the writings of Mr Gladstone, Professor Blackie, Mr Paley, Dr Hayman (in the Introduction to his *Odyssey*), and Professor Geddes.

The Homeric dialect must be studied in the books (such as those of G. Curtius) that deal with Greek on the comparative method. The best special work is the *Griechische Formenlehre* of H. L. Ahrens (Göttingen, 1852). On Homeric syntax the chief book is B. Delbrück's *Syntactische Forschungen* (Halle, 1871–79), especially vols. i. and iv.; on metre, &c., Hartel's *Homerische Studien* (i.–iii., Vienna), and Knös, *De digammo Homerico quæstiones* (Upsala, 1872–73–78). The papers reprinted in Bekker's *Homerische Blätter* (Bonn, 1863–72) and Cobet's *Miscellanea Critica* (Leyden, 1876) are of the highest value. Hoffmann's *Quæstiones Homericæ* (Clausthal, 1842) is a useful collection of facts. Buttmann's *Lexilogus*, as an example of method, is still worth study.

The antiquities of Homer—using the word in a wide sense—may be studied in the following books:—Völcker, *Ueber Homerische Geographie und Weltkunde* (Hanover, 1830); Nägelsbach's *Homerische Theologie* (2d ed., Nuremberg, 1861); H. Brunn, *Die Kunst bei Homer* (Munich, 1868); W. W. Lloyd, *On the Homeric Design of the Shield of Achilles* (London, 1854); Buchholz, *Die homerischen Realien* (Leipsic, 1871–73).

Among other aids should be mentioned the *Index Homericus* of Seber (Oxford, 1780); Mr Prendergast's *Concordance to the Iliad* (London, 1875); Autenrieth's *Homeric Dictionary* (London, 1877); and the *Lexicon Homericum*, edited by H. Ebeling (in the course of publication). (D. B. M.)

HOMESTEAD

THE laws of the United States give to every citizen who is the head of a family, or who has arrived at the age of twenty-one years, the right to a homestead of 160 acres, to be selected at will from any of the surveyed and otherwise unappropriated public lands, without cost, except entry fees. The tract thus taken as a homestead must be located in a compact body, upon land which is agricultural in character, and must conform to the legal subdivisions established by the official survey. It is set apart from the general estate of the householder as a sacred provision for the family, and is protected from alienation by the householder, and from execution for his general debts. The administration of the homestead and other land laws is committed to the general land office, a bureau of the interior department of the National Government at Washington, presided over by a commissioner, the secretary of the interior having appellate jurisdiction. For the convenience of applicants, the States and Territories where the public lands are still to be found are divided into districts, in each of which there is established a local land office, in charge of a registrar and a receiver, whose duty it is to attend to the disposal of the public lands.

To obtain a homestead the applicant must make an affidavit before the registrar or receiver that he is over the age of twenty-one years, or the head of a family; that he is a citizen of the United States, or has declared his intention to become such; and that the entry is made for his exclusive use and benefit, and for actual settlement and cultivation. A homestead entry thus made vests in the settler an inceptive right only. He has a "claim" to the land which no one can dispute so long as he complies with the law requiring him to live upon and cultivate it for five years; but he has no title which he can convey. If he abandons the land, or remains absent from it for a period of more than six months, his entry may be contested and cancelled; and then the tract will be open to the first legal applicant. In such a case the original claimant will not be permitted to make another entry, as the law allows but one homestead privilege. It is essential that the person making a homestead entry should know that no one else has located upon the land and begun improvements as the foundation of a claim under the pre-emption laws, for such a claim would antedate his own. Having resided upon and cultivated his claim for five years, the settler is allowed two years more, but no longer, in which to make his "final proof." Final proof consists in the affidavit of the settler and that of two disinterested witnesses, showing that the claimant is a citizen of the United States, that he has made actual settlement upon and cultivated the land in good faith for the time required, and that he has never perfected or abandoned an entry made under the homestead laws. This proof is then transmitted to the commissioner of the general land office at Washington, and if the entry is found to be in all respects lawful, a patent is forwarded to the settler, who thus acquires a permanent and absolute title to his homestead.

The public lands are held by the Government at the minimum price of $1.25 per acre; but where alternate sections have been granted to railroads or other works of internal improvement, the reserved sections are held at $2.50. Of this $2.50 or "double minimum" land, formerly only soldiers and sailors of the War of the Rebellion were allowed to enter as homestead claimants of 160 acres, other citizens being restricted to 80 acres. By the acts of March 3d and July 1st 1879, the privilege of entering 160 acres was extended to all citizens and made general; but there are still some portions of Alabama, Mississippi, and other States where no more than 80 acres of $2.50 land can be taken.

Where homestead entries are made by soldiers and sailors who served ninety days or more in the United States army or navy during the War of the Rebellion, the period of their service, or, if they were discharged on account of wounds or disability incurred in the line of duty, the entire term of enlistment, not to exceed four years, is deducted from the five years' residence required by law. But no one can receive a title to his homestead under any circumstances without having lived upon it at least one year.[1]

For homestead entries on lands in Michigan, Wisconsin, Iowa, Missouri, Minnesota, Kansas, Nebraska, Dakota, Alabama, Mississippi, Louisiana, Arkansas, and Florida, commissions and fees are to be paid according to the following table:—

---

[1] A settler who under former laws was restricted in his entry to less than 160 acres is now permitted, except in a few localities, to enter other lands adjoining his original homestead, as an "additional entry," to an amount sufficient to make with his first entry 160 acres; and in this case the time of his residence on the tract originally entered will be deducted from the five years, so that in making his final proof he need show occupancy and cultivation of his additional homestead for one year only. Entries of this class are made without payment of fees and commissions. Instead of making such an additional entry the settler may surrender his existing entry to the Government, and make another of 160 acres. Soldiers and sailors of the War of the Rebellion, who prior to June 22, 1874, had made homestead entries of less than 160 acres, have the further privilege of selecting their additional entries from any unoccupied lands, whether adjoining their original homesteads or not.

Acres.	Price per Acre.	Commissions.		Fee.	Total of Fee and Commissions.
		Payable when Entry is made.	Payable when final Proof is made.	Payable when Entry is made.	
160	$2 50	$8 00	$8 00	$10 00	$26 00
80	2 50	4 00	4 00	5 00	13 00
40	2 50	2 00	2 00	5 00	9 00
160	1 25	4 00	4 00	10 00	18 00
80	1 25	2 00	2 00	5 00	9 00
40	1 25	1 00	1 00	5 00	7 00

On lands in California, Nevada, Oregon, Colorado, and in the Territories of Arizona, Idaho, Montana, New Mexico, Utah, Washington, and Wyoming, the commissions are 50 per cent. greater, but the fees are as given above.

If the settler does not wish to remain five years upon his land, the law permits him to pay for it with cash, military bounty land warrants, or agricultural college, private claim, or certain other scrip, upon making proof of residence and cultivation for a period of not less than six months from date of entry. Scrip is a paper issued by the Government, either as a gratuity, or in lieu of a claim for lands, and made receivable by the land bureau in payment for other lands. When the land is paid for in this way the homestead becomes virtually a "pre-emption." Every person qualified to make a homestead entry is also a qualified pre-emptor, provided he is already the owner of 320 acres of land in the United States, and does not abandon a residence on his own land, in the same State or Territory, to go upon the land he wishes to pre-empt; but only one pre-emption can be made by any citizen. Land to the extent of 160 acres may be obtained by actual settlers under the pre-emption laws, by purchase (sections 2257 to 2288, U. S. Revised Statutes). A residence of at least six months, with cultivation and improvement of the land, is required. Pre-emption claims may be initiated upon unsurveyed lands, although in such a case title cannot be obtained until after the official survey has been made. The first step in securing a pre-emption right is to go upon the land and commence "improvements." When this has been done, if the land is "offered"—that is, if at some time it has been offered at public sale by proclamation of the president, or otherwise—the applicant, within thirty days from date of his settlement, must file with the district land office a declaratory statement setting forth his claim; and within one year from date of settlement he must appear before the registrar and receiver, and make proof of actual residence on and cultivation of the tract. He will then be permitted to obtain title to the land, by locating upon it land warrants or scrip, or by paying for it with cash at the rate of $1.25 per acre, or, if within the limits of a public improvement grant, at the rate of $2.50 per acre. In case the land has not been offered at public sale, the applicant has three months after settlement within which to file his declaratory statement with the local land officers, and thirty-three months from settlement within which to make final proof and payment for the land. If the land is unsurveyed when the settlement is made, the claimant must file his declaratory statement within three months from the date of the receipt at the district land office of the approved plat of survey of the township embracing the tract. Where compliance with the requirements of the homestead or pre-emption laws is rendered difficult or impossible in consequence of the destruction of crops by grasshoppers, an absence of one year is allowed, during which time no adverse right can accrue. Public notice by advertisement must be given, under direction of the registrar, before final proof can be made in homestead and pre-emption entries.

Under the homestead laws the land is virtually a gift to the settler by the Government, in consideration of settlement and cultivation, the fees charged being about sufficient to cover the cost of entry and conveyance. Under the pre-emption laws the right of purchase is conceded to the actual settler only. With regard to the value of improvements which must be put upon the land in order to entitle the claimant to make final proof and obtain a patent, nothing is definitely stated in the laws themselves, and no absolute rule has been laid down by the general land office; it can only be said generally that homestead and pre-emption improvements must be sufficient to satisfy the land officers that settlement has been made in good faith. A habitable house, which must be used as the home of the settler, with his family, if he is the head of a family, is always required, and a part of the claim must be brought under cultivation.

It will be noted that under the homestead laws none but citizens of the United States, native or naturalized, can make final proof and receive a patent, while a pre-emption entry may be made and consummated by a settler who has declared his intention to become a citizen, whether or not he has taken out his final citizenship papers. After a settler has exercised his right of pre-emption, and obtained title to his claim, there is nothing in the laws or in the regulations of the department to prevent him from proceeding to settle upon another tract under the homestead law; and he may also, during the time he is residing upon his pre-emption or homestead claim, make entry of 160 acres under the "timber culture act." It is possible for a settler in this way to acquire title to an aggregate quantity of 480 acres; and this is frequently done. The privileges of the land laws of the United States are extended equally to male and female citizens. Lands entered under the homestead and pre-emption laws are exempt from taxation during the term of residence necessary to acquire title; and in a majority of the States such lands are not taxable until a patent has been issued. Upon the death of a claimant under the homestead, pre-emption, or timber culture laws, any rights he may have acquired accrue to his heirs.

Large portions of the unoccupied public lands of the United States are devoid of timber. "To encourage the growth of timber on the western prairies" the following privileges are granted by the Act of March 3, 1873, and subsequent amendments. Any person who is the head of a family or over twenty-one years of age, and who is a citizen of the United States, or has declared his intention to become such, may enter as a "timber culture" claim one-quarter section (160 acres) of prairie land, upon making affidavit to the fact that he desires for his own benefit to plant and cultivate timber upon the tract. The section of land in which such an entry is made must be naturally devoid of timber, and only one-quarter of any one section can be entered. A person making an entry of 160 acres is required to break or plough 5 acres during the first year and 5 acres in addition during the second year. The 5 acres broken or ploughed during the first year he is required to cultivate during the second year, and to plant in timber, seeds, or cuttings during the third year. The 5 acres broken or ploughed during the second year he is required to cultivate during the third year, and to plant in timber, seeds, or cuttings during the fourth year. Land embraced in entries of a less quantity than one-quarter section must be cultivated and planted during the same periods and in the same proportion, viz., to the amount of one-sixteenth of the area claimed. The trees must be such as are suitable for timber, the cultivation of fruit trees and shrubbery not being sufficient. Provision is made under the act for an extension of time in case the trees, seeds, or cuttings planted should be destroyed by grasshoppers or by extreme and unusual drought. If, at the expiration of eight years from the date of entry, or at any time within five years thereafter, the claimant shall prove by two credible witnesses that he has successfully cultivated the required amount of timber for not less than eight years, according to the provisions of the act of June 14, 1878, he will be entitled to a patent for the land embraced in the entry. At any time after one year from the date of entry, if the applicant fails to comply with any of the requirements of the act, his claim becomes liable to contest, and, upon due proof of such failure, the entry will be cancelled and the land become again subject to entry under the homestead laws, or by some other person, under the Act of June 14, 1878. The fees for timber culture entries are $10 if the tract applied for is more than 80 acres, and $5 if it is 80 acres or less. The commissions on all entries are $4 at the date of entry, and $4 at the date of final proof.

The foregoing statements refer to public lands which are agricultural in character. There are special laws for the disposal of desert lands, mineral lands, town sites on the public domain, and lands which are unfit for cultivation, and valuable chiefly for timber or stone.

By desert lands is meant a class of lands which will not, without irrigation, "produce any agricultural crop." Title to such lands in any of the following States and Territories may be acquired under Act of Congress of March 3, 1877:—the States of California, Oregon, and Nevada, and the Territories of Washington, Idaho, Montana, Utah, Wyoming, Arizona, New Mexico, and Dakota. Any person desiring to avail himself thereof must file with the registrar and receiver of the proper land office a declaration, under oath, setting forth that the applicant is a citizen of the United States or that he has declared his intention to become such, that he has made no other declaration for desert lands, and that he intends to reclaim the tract applied for, not exceeding one section, by conducting water thereon within three years from the date of his declaration; and he must show by the testimony of at least two disinterested and credible witnesses that the tract applied for is desert land. After this proof has been made to the satisfaction of the district officers, 25 cents per acre will be received from the applicant as a preliminary payment for the land. At any time within three years after the date of the filing of his declaration the claimant may offer proof that he has conducted water upon the land, which proof must consist of the testimony of at least two disinterested and credible witnesses. When such proof is satisfactory to the district officers, the final payment of $1 per acre may be made, and the papers will be forwarded to the general land office at Washington, as the basis for a patent.

The laws extending the homestead, pre-emption, timber culture, and desert land entry privileges make *bona fide* settlement or improvement of the land a condition precedent to obtaining title. The United States Government does not offer at public sale any of its lands in the western or north-western States or Territories; but in the States of Florida, Arkansas, Alabama, Mississippi, and Louisiana there are still large tracts of land which may be bought at the minimum price of $1.25, or at the double minimum price of $2.50 per acre.

The laws providing for the reservation and sale of town sites on the public lands are found in title 32, chapter 8, of the revised statutes of the United States. Persons who desire to found a city or town may acquire title by purchase to the extent of the tract occupied for town purposes, depending upon the number of occupants, viz., 100 to 200 inhabitants, 320 acres; 200 to 1000 inhabitants, 640 acres; 1000 inhabitants, 1280 acres; and 320 acres for each additional 1000 inhabitants, not exceeding 5000 in all. If the town be incorporated, the entry must be made by its mayor or legal representative—if unincorporated, by the county court acting as trustee—for the use and benefit of the several occupants. The patent is issued to the mayor or judge in trust for the purchaser, and the State or Territorial legislature must provide the mode of distribution of the lots.

Mineral lands are subject to exploration, occupation, and purchase by citizens or those who have made declaration of intention to become citizens of the United States. Indefinite occupation, without purchase, is secured under some circumstances by certain annual expenditures upon a mining claim. There is no restriction by United States laws of the number of locations one man may make or own by purchase from other locators.

The present area of vacant surveyed Government lands in the United States is about 134,600,000 acres, the area unsurveyed being 1,080,000,000 acres.

The public lands referred to in this article are found only in the States of Alabama, Arkansas, California, Colorado, Florida, Iowa, Kansas, Louisiana, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, Oregon, Wisconsin, and the Territories of Arizona, Dakota, Idaho, Montana, New Mexico, Utah, Washington, and Wyoming. Throughout these States and Territories the land laws are uniform. When Texas was admitted into the Union the disposal of its public lands was reserved to the State, and it has therefore a land system of its own, which, although rather complicated, does not differ essentially from the land policy of the United States as indicated above. Under the laws of Texas, every person who is the head of a family and without a homestead may acquire title to 160 acres of land, by living upon it and cultivating it for three years; and every single man over the age of eighteen years may so acquire title to 80 acres. "Every person over the age of eighteen years, who is a citizen of the State of Texas, and who shall hereafter in good faith settle upon and occupy any part of the unappropriated public domain, not exceeding 160 acres, shall have the right to purchase the same at the sum of $1 per acre." But this right of pre-emption is not conceded to any one who is the owner of 160 acres of land in Texas, or who abandons a residence on his own land in that State to take up a residence on the public lands. The extensive school lands of Texas are purchasable by actual settlers in tracts of 80 to 160 acres at their actual value, to be determined by appraisement, "but in no case for a less price than $1.50 per acre." (E. P. H.)

HOMEYER, Karl Gustav (1795-1874), was born August 13, 1795, at Wolgast, a small town in Pomerania, which at that time was still Swedish territory. After a four years' stay in Sweden, whither his father, a merchant, had taken him in 1806, and where he may have laid the foundation of that knowledge of the languages and laws of the North which is so conspicuous in his later works, he was in 1810 received into the house of his uncle Rühs, the learned historian, who had just been called to the professorship of history at the newly-founded university of Berlin. He subsequently went through the course of law study at the universities of Berlin, Göttingen, and Heidelberg (1813–1817). It was in Berlin especially that he was introduced to the principles of the so-called historical school of the science of law by Savigny and Eichhorn, who were his principal teachers. In 1821 he settled as a privat-docent at the university of Berlin, where he was promoted to an extraordinary professorship in 1824, and to the ordinary German law chair in 1827. His principal works are his edition of the *Sachsenspiegel* (in 3 vols., containing also some other important sources of Saxon or Low German law), which is still unsurpassed in accuracy and sagacity of research, and his book on *Die Haus- und Hofmarken* (1870), in which he has given a history of the use of trade-marks among all the Teutonic nations of Europe, and which is full of important elucidations of the history of law and also contains valuable contributions to the history of art and civilization. In 1850 Homeyer was elected a member of the Berlin Academy of Sciences, in the *Transactions* of which he published various papers exhibiting profound learning ("Ueber die Heimath," 1852; "Genealogie der Handschriften des Sachsenspiegels," 1859; "Die Stadtbücher des Mittelalters," 1860; "Der Dreissigste," 1864, &c.). He died October 20, 1874.

HOMICIDE, in law, is the act of killing a human being, whether such act be criminal or not. Blackstone distinguishes three kinds of homicide—(1) justifiable, (2) excusable, and (3) felonious.

The most important case of justifiable homicide is the execution of a criminal in due course of public justice. This condition is most stringently interpreted. "To kill the greatest of malefactors deliberately, uncompelled, and extra-judicially is murder. . . . And further, if judgment of death be given by a judge not authorized by lawful commission, and execution is done accordingly, the judge is guilty of murder" (Stephen's *Commentaries*, book vi. c. iv.). The execution must be carried out by the proper officer or his deputy: any person executing the sentence without such authority, were it the judge himself, would be guilty of murder. And the sentence must be strictly pursued: to execute a criminal by a kind of death other than that to which he has been judicially condemned is murder.

Homicide committed by an officer of justice in the course of carrying out his duty, as such, is also justifiable; *e.g.*, where a person resists a legal arrest and is killed in the struggle; where officers in dispersing a riotous assemblage kill any of the mob, &c. In these cases the homicide must be shown to have been absolutely necessary. Again, homicide committed for the prevention of forcible and heinous crime, such as violent robbery, or murder, or house-breaking during the night, is justifiable.

Excusable homicide is homicide committed either by misadventure or in self-defence. In the former case, where a man in the course of doing some lawful work, accidentally and without intention kills another, the homicide is excused; *e.g.*, shooting at a mark and undesignedly hitting and killing a man. The act must be strictly lawful, and death by misadventure in unlawful sports is not a case of excusable homicide. Homicide in self-defence is excusable when the slayer is himself in immediate danger of death, and has done all he could to avoid the assault. Accordingly, if he strikes and kills his assailant after the assault is over, this is not excusable homicide. And if the assault has been premeditated, as in the case of a duel, the death of either antagonist is murder, and not excusable homicide. The excuse of *se defendendo* covers the case in which a person in defence of others whom it is his duty to protect—children, wife, master, &c.—kills an assailant. It has been considered doubtful whether the plea of self-defence is available to one who has himself provoked a fray, in the course of which he is so pressed by his antagonist that his only resource is to kill him.

The distinction between excusable and justifiable homicides refers back to a period in the history of the law when the former were considered to carry with them some taint of guilt, and to require some kind of punishment or expiation. In early law homicide, however innocent, subjects the slayer to the lawful vengeance of the kindred of the dead man. We have a good example of this feeling in the Jewish institution of cities of refuge, to which innocent manslayers might flee from the avenger of blood. The case mentioned in Deut. xix. 5 is a typical instance of what we should call excusable homicide:—"A man goeth into the wood with his neighbour to hew wood, and his hand fetcheth a stroke with the axe to cut down the tree, and the head slippeth from the helve, and lighteth upon his neighbour, that he die." In English law, the same feeling long remained. Excusable homicide involved at least forfeiture of goods, which, however, might be recovered as a matter of course by the innocent criminal obtaining a pardon and writ of restitution. Afterwards judges appear to have been in the habit of directing an acquittal in such cases. It is only by a statute so recent as 9 Geo. IV. c. 31 that the innocence of excusable homicide is expressly declared.

Felonious homicide includes SUICIDE, MANSLAUGHTER, and MURDER—the law relating to which is discussed under the different headings. These distinctions of the English law correspond generally to those of other systems. The chief difficulty is the definition of murder—the distinction between the highest and second degree of criminal homicide. In English law the element of malice aforethought chiefly distinguishes murder from manslaughter. In Scotland the term culpable homicide is the equivalent of the manslaughter of English law.

HOMILY, HOMILIARIUM, BOOKS OF HOMILIES. The word ὁμιλία from ὁμιλεῖν (ὁμοῦ, εἴλω), meaning communion, intercourse, and especially interchange of thought and feeling by means of words (conversation), was early employed in classical Greek to denote the instruction which a philosopher gave to his pupils in familiar talk (Xen., *Mem.*, I. ii. 6, 15). This usage of the word was long preserved (Ælian, *V. H.*, iii. 19); and the ὁμιλήσας of Acts xx. 11 may safely be taken to assign not only a free and informal but also a didactic character to the apostle Paul's discourse in the upper chamber at Troas, when "he talked a long while, even till break of day." That the "talk" on that occasion partook of the nature of the "exposition" (דְּרָשָׁה) of Scripture, which, undertaken by a priest, elder, or other competent person, had become a regular part of the service of the Jewish synagogue,[1] may also with much probability be assumed. The custom of delivering expositions or comments more or less extemporaneous on the lessons of the day at all events passed over soon and readily into the Christian Church, as may be gathered from the first *Apology* (c. 67) of Justin Martyr, where we read that, in connexion with the practice of reading portions from the collected writings of the prophets and from the memoirs of the apostles, it had by that time become usual for the presiding minister to deliver a discourse in which "he admonishes the people, stirring them up to an imitation of the good works which have been brought before their notice." This discourse, from its explanatory character, and from the easy conversational manner of its delivery, was for a long time called ὁμιλία rather than λόγος; it was regarded as part of the regular duty of the bishop, but he could devolve it, if he thought fit, on a presbyter, or deacon, or even on a layman. An early and well-known instance of such delegation is that mentioned by Eusebius (*H. E.*, vi. 19) in the case of Origen (216 A.D.).[2] In course of time the exposition of the lesson for the day came more frequently to assume a more elaborate character, and to pass into the category of a λόγος or even φιλοσοφία or φιλοσόφημα; but when it did so the fact was as far as possible denoted by a change of name, the word ὁμιλία being reserved for the expository or exegetical lecture as distinguished from the pulpit oration or sermon.[3] While the church of the 3d and 4th centuries could point to a brilliant succession of great preachers, whose discourses were wont to be taken down in short hand and circulated among the Christian public as edifying reading, it does not appear that the supply of ordinary homiletical talent kept pace with the rapidity of her extension throughout the Roman empire. In the smaller and remoter communities it not uncommonly happened that the minister was totally unqualified to undertake the work of preaching; and though, as is curiously shown by the case of Rome (Sozom., *H. E.*, vii. 19), the regular exposition of the appointed lessons was by no means regarded as part of the necessary business of a church, it was generally felt to be advisable that some provision should be made for the public instruction of congregations. Even in Jerome's time (*De Vir. Ill.*, c. 115), accordingly, it had become usual to read, in the regular meetings of the churches which were not so fortunate as to possess a competent preacher, the written discourses of celebrated fathers; and at a considerably later period we have on record the canon of at least one provincial council (that of Vaux, probably the third, held in 529 A.D.), positively enjoining that if the presbyter through any infirmity is unable himself to preach, "homilies of the holy fathers" (homiliæ sanctorum patrum) are to be read by the deacons. Thus the finally fixed meaning of the word homily as an ecclesiastical term came to be a written discourse (generally possessing the sanction of some great name) read in church by or for the officiating clergyman when from any cause he was unable to deliver a sermon of his own. As the standard of clerical education sank during the dark ages, the habit of using the sermons of others became almost universal. Among the authors whose works were found specially serviceable in this way may be mentioned the Venerable Bede, who is credited with no fewer than 140 homilies in the Basel and Cologne editions of his works, and who certainly was the author of many *Homiliæ de Tempore* which were much in vogue during the 8th and following centuries. Prior to Charlemagne it is probable that several other collections of homilies had obtained considerable popularity, but in the time of that emperor these had suffered so many mutilations and corruptions that an authoritative revision was felt to be imperatively necessary. The result was the well-known *Homiliarium*, prepared by Paul Warnefrid, otherwise known as Paulus Diaconus.[4] It consists of 176 homilies arranged in order for all the Sundays and festivals of the ecclesiastical year; and probably was completed before the year 780. Though written in Latin, its discourses were doubtless intended to be delivered in the vulgar tongue; the clergy, however, were often too indolent or too ignorant for this, although by more than one provincial council they were enjoined to exert themselves so that they might be able to do so.[5] Hence an important form of literary activity came to be the translation of the homilies approved by the church into the vernacular. Thus we find Alfred the Great translating the homilies of Bede; and in a similar manner arose

---

[1] See Philo, *Quod omnis probus liber*, sec. 12 (ed. Mangey, ii. 458; *cf.* ii. 630).

[2] Sozomen (*H. E.* vii. 19) mentions that in Alexandria in his day the bishop alone was in the custom of preaching; but this, he implies, was a very exceptional state of matters, dating only from the time of Arius.

[3] To the more strictly exegetical lectures the names ἐξηγήσεις, ἐξηγήματα, ἐξηγητικά, ἐκθέσεις, were sometimes applied. But as no popular discourse delivered from the pulpit could ever be exclusively expository and as on the other hand every sermon professing to be based on Scripture required to be more or less "exegetical" and "textual," it would obviously be sometimes very hard to draw the line of distinction between ὁμιλία and λόγος. It would be difficult to define very precisely the difference in French between a "conférence" and a "sermon;" and the same difficulty seems to have been experienced in Greek by Photius, who says of the eloquent pulpit orations of Chrysostom, that they were ὁμιλίαι rather than λόγοι.

[4] It was first printed at Spires in 1482. In the Cologne edition of 1530 the title runs—*Homiliæ seu mavis sermones sive conciones ad populum, præstantissimorum ecclesiæ doctorum Hieronymi, Augustini, Ambrosii, Gregorii, Origenis, Chrysostomi, Bedæ, &c., in hunc ordinem digestæ per Alchuinum levitam, idque injungente ei Carolo M. Rom. Imp. cui a secretis fuit.* Though thus attributed here to Alcuin, who is known to have revised the Lectionary or *Comes Hieronymi*, the compilation of the *Homiliarium* is in the emperor's own commission entrusted to Paul, to whom it is assigned in the earlier printed editions also.

[5] Neander, *Church History*, v. 174 (Eng. transl. of 1851).

Ælfric's Anglo-Saxon *Homilies* and the German *Homiliarium* of Ottfried of Weissenburg. Such *Homiliaria* as were in use in England down to the end of the 15th century were at the time of the Reformation eagerly sought for and destroyed, so that they are now extremely rare, and the few copies which have been preserved are generally in a mutilated or imperfect form.[1]

The *Books of Homilies* referred to in the 35th Article of the Church of England originated at a convocation in 1542, at which it was agreed "to make certain homilies for stay of such errors as were then by ignorant preachers sparkled among the people." Certain homilies accordingly, composed by dignitaries of the lower house, were in the following year produced by the prolocutor; and after some delay a volume was published in 1547 entitled *Certain sermons or homilies appointed by the King's Majesty to be declared and read by all parsons, vicars, or curates every Sunday in their churches where they have cure.* In 1563 a second Book of Homilies was submitted along with the 39 Articles to convocation; it was issued the same year under the title *The second Tome of Homilies of such matters as were promised and instituted in the former part of Homilies, set out by the authority of the Queen's Majesty, and to be read in every Parish Church agreeably.* Of the twelve homilies contained in the first book, four (the 1st, 2d, 3d, and 4th) are probably to be attributed to Cranmer, and one (the 12th) possibly to Latimer; one (the 6th) is by Bonner; another (the 2d) is by Harpsfield, archdeacon of London, and a third (the 11th) by Becon, one of Cranmer's chaplains. The authorship of the 8th and 10th is quite unknown; and Becon and Ridley have been only doubtfully conjectured as the authors of the 7th and 9th respectively. The second book consists of twenty-two homilies, of which the 1st, 2d, 3d, 7th, 8th, 9th, 16th, and 17th have been assigned to Jewel, the 4th to Grindal, the 5th and 6th to Pilkington, and the 18th to Parker. See the critical edition by Griffiths, Oxford, 1869. For *The Clementine Homilies* see Apostolic Fathers, vol. ii. p. 196.

HOMŒOPATHY (from ὁμοιοπάθεια, a similarity of feeling or condition) as a distinctive system of medicine owes its origin to Hahnemann, a German physician (see Hahnemann). It is customary to regard homœopathy as a mere system of therapeutics, having reference only to the question how and on what principle is disease to be treated. But a careful student of Hahnemann or of his *Organon* will soon discover that the system with which his name is fundamentally associated is one not merely of therapeutics but of pathology, and that any complete exposition of it must embrace an account of Hahnemann's views of the ultimate nature and cause of disease, as well as of the remedies by which it is to be combated, and the principles or principle on which these are to be selected.

Hahnemann taught that disease is to be regarded as consisting essentially of the symptoms of it as experienced and expressed by the patient, or as detected by the physician; in other words, that the chief symptoms, or the "totality of the symptoms," constitute the disease, and that disease is in no case caused by any material substance, but is only and always a peculiar, virtual, dynamic derangement of the health. "Diseases" (Introduction to the *Organon*, p. 17) "will not cease to be spiritual dynamic derangements of our spiritual vital principle." He says on page 3 of the *Organon*, "For as far the greatest number of diseases are of dynamic (spiritual) origin and dynamic (spiritual) nature, their cause is therefore not perceptible to the senses;" and at page 18, referring "to small-pox, a disease accompanied by almost general suppuration," he asks, "is it possible to entertain the idea of a material morbific matter being introduced into the blood?" He held that the psoric miasm, of which the itch is the outward and visible and comparatively harmless sign, was at the root of nearly all chronic disease, viz., of all chronic disease that was not due to syphilis or sycosis. He tells us in a note to the 80th section of the *Organon* that he spent twelve years in the investigations which led to the discovery of that great source of chronic disease and of its remedies (antipsoric remedies). It was a very essential part of Hahnemann's teaching that nature is a bad physician, and not to be much trusted; that drugs are the real curative agents provided by the beneficence of the Almighty; that drugs given to healthy persons have a power of producing symptoms of disease. The ascertainment of the symptoms produced by drugs in healthy persons is called technically "proving," and the record of such provings constitutes a large part of the literature of homœopathy. This power of drugs he perpetually refers to as their "pathogenetic power." His great therapeutical doctrine, for formulating which his followers call him, with doubtful taste, "the Messiah of Medicine," was to this effect, that there is a correspondence between the symptoms produced by any given drug administered to a healthy person and its power of curing any given disease, and that the remedy for any given disease, that is, for any set of symptoms "in their totality," is that drug which, given to any healthy person, will produce the most perfect imitation of the said set of symptoms; in other words, *Similia similibus curantur.* Further, the dose of medicine is to be so attenuated as to cure the disease without hurting the patient. This attenuation of medicines constitutes, not only the most popular note of the system of Hahnemann, but that feature of it which is most characteristic of his own views and practice, and which in well-known words he declared to be established beyond the reach of cavil from future experience either of allopaths or of practitioners of the "new mongrel system made up of a mixture of allopathic and homœopathic processes." He gives minute directions as to the processes by which this attenuation is to be achieved, the principal of which are trituration, succussion, and dilution. These processes developed what he called the "spiritual power which lies hid in the inner nature of medicines" (20th section of the *Organon*). Hahnemann held that medicines became, for curative purposes, more powerful as they became more attenuated; in his last edition of the *Organon* (1833), and in its last pages, he gave the most expressive evidence of his belief in the virtue of attenuation by saying that he could scarcely name one disease which in the last year he and his assistants had not treated with the most happy results, solely by means of "olfaction"; and he added that a patient even destitute of the sense of smell may expect an equally perfect action and cure from the medicine by olfaction. He condemned strongly the administration simultaneously of a number of medicines, and insisted that only one should be given at a time. Finally, it would be unjust to him not to bear in mind that he claimed to base his views and practice on experience and sound experiment. Some points of his system were borrowed by Hahnemann from previous writers—as, indeed, he himself, though imperfectly, admits. Not to mention others, he was anticipated by Hippocrates, and especially by Paracelsus (1495–1541), in his doctrine of *Similia similibus curantur*, if not in its exclusive application. These identical words occur in the Geneva edition (1658) of the works of Paracelsus, as a marginal heading to one of the paragraphs; and in the "Fragmenta Medica," *Op. Omnia*, vol. i. 168, 169, occurs the following passage:—

[1] An ancient English metrical homiliarium exists in the library of the university of Cambridge, of which earlier versions have existed, and a portion of perhaps the earliest copy, dating from about the middle of the 13th century, was published in 1862 by Mr J. Small, librarian to the university of Edinburgh.

Simile similis cura; non contrarium.

"Quisquis enim cum laude agere Medicum volet, is has nugas longe valere jubeat. Nec enim ullus unquam morbus calidus per frigida sanatus fuit, nec frigidus per calida. Simile autem suum simile frequenter curavit, scilicet Mercurius sulphur, et sulphur Mercurium; et sal illa, velut et illa sal. Interdum quidem cum proprietate junctum frigidum sanavit calidum; sed id non factum est ratione frigidi, verum ratione naturæ alterius, quam a primo illo omnino diversam facimus."

It is very remarkable that in Hahnemann's enumeration of authors who anticipated him in regard to the doctrine of *Similia*, he makes no mention of the views of Paracelsus, though the very words seem to be taken from the works of that physician. The other point in Hahnemann's doctrine—that medicines should be tried first on healthy persons—he admits to have been enunciated by Haller. Roughly it has been acted on by physicians in all ages, but certainly more systematically since Hahnemann's time, though the result is often not such as to support his theory in regard to the action of medicine on the diseased as compared with the healthy body.

In the most characteristic feature of Hahnemann's practice—"the potentizing," "dynamizing," of medicinal substances—he appears to have been original. It has been generally affirmed that he was led to adopt his doctrine of "attenuation" by the fact that the medicines he administered produced similar effects to those of the disease, and that in any gross quantity, as he admitted, they would aggravate matters. But another and a chief reason is to be found in his views of the "spiritual," "immaterial," "dynamic" origin of disease, and his resentment against the old modes of practice of medicine.

The followers of Hahnemann are true to him in making light comparatively of pathological facts, and giving their main attention to therapeutics. They are still concerned mainly with medicines, and one very large American encyclopædia is devoted exclusively to a record of "Provings"; it is edited by Dr Timothy Allen, professor of materia medica and therapeutics in the New York Homœopathic Medical College. For some years Hahnemann's disciples continued pretty faithful to the doctrine of *Similia similibus curantur*, but they were not long in making some changes in it. We can only notice a few of the leading deviations. Dr Sharp, of Rugby, who has striven hard to overcome objectors, while admitting the doctrine of *Similia*, requires that it have regard, not to mere symptoms, but to the seat and pathology of the case; that the drug used be one which shall affect the organ at fault. Homœopathy cannot become a science till it is founded on what he calls Organopathy, or a much more careful consideration of the seat of disease than is involved in Hahnemann's views, who, he complains, passionately rejected pathology and morbid anatomy. Recently a leading homœopathist has published a book, the very title of which contradicts the doctrine of his master. Hahnemann maintains that cures never were effected in any other manner than by means of medicines of homœopathic power (*Organon*, p. 100), and that, whenever cures were wrought by those who did not understand homœopathy, it was in virtue of the homœopathic law, "the only law consonant to nature." But in 1878 Dr Kidd, the leading consultant among homœopathic practitioners in London, published a book on the *Laws of Therapeutics*. It is true that he does not carry the pluralizing far: he only substitutes two for Hahnemann's one law; but it is not the less a very remarkable departure. He is still faithful to the idea of a relationship between the action of medicines on the healthy and their curative value in sickness; but the law of *Similia* is sadly compromised. "In most cases that relationship is either of *similarity* or of *contrariety*." "Looking," says he, "to the observation of facts apart from theoretic speculations, two primary laws of therapeutics unfold themselves. Those two laws of therapeutics may well be called Galen's law, founded upon the rule of *contraria contrariis*, and Hahnemann's or the homœopathic law, founded upon the relationship of similars." This is certainly a comprehensive if a rather unphilosophical generalization. The practice of Hahnemann as to the use of highly attenuated doses of medicine is evidently not more closely adhered to than his doctrine of *Similia*. This fact is the subject of complaint in homœopathic journals. The *Medical Investigator*, in 1876, says reprovingly: "How many claiming to be homœopaths are daily entirely disregarding the law of *Similia*. It is getting to be quite a rare thing to hear of a homœopathic practitioner conducting a serious case from beginning to end without using as such cathartics, sudorifics, diuretics, &c., in direct opposition to our law; not only are these drugs used in this way, but there are some also go so far as to say that they cannot be dispensed with." Dr Wyld, the vice-president of the British Homœopathic Society, in a letter to Dr W. B. Richardson, published in the *Lancet* of June 2, 1877, arguing for an abolition of the schism of the profession on this question, thus sums up the admissions which he as a somewhat representative man was prepared to make:—"*First*, that the views expressed by Hahnemann are often extravagant and incorrect; *Secondly*, that Hippocrates was right when he said some diseases are best treated by similars and some by contraries, and therefore it is unwise and incorrect to assume the title of homœopathist; *Thirdly*, that although many believe that the action of the infinitesimal in nature can be demonstrated, its use in medicine is practically by a large number in this country all but abandoned." It must not, however, be supposed that there are not many true believers in Hahnemann's doctrines both of *Similia*, &c., and of infinitesimal doses, extending even to olfactions. In fact, one recent writer goes beyond Hahnemann. In the *Homœopathic Observer*, after many years of anxious experimenting, he claims to have discovered decided results from olfaction, or the smelling of medicines, but more especially by means of medicines contained in *closed* vessels held in the hand. Mons. Granier, of Nîmes, carries the dynamic theory of Hahnemann farther than its author. "Medicines," he says, "are fluidic powers, they are beings (*êtres*) that man may create at his will. I wish I could say they are occult powers, forming the chain of fluidic connection between the world and the tomb; but I am convinced in my own mind that, placed on the limits of *fluidic dynamism*, our observation might cast its scrutinizing glance into the unseen world."

Homœopathy has a considerable number of adherents in Great Britain, in the United States, and on the continent of Europe. In order to ascertain the esteem accorded to it in the land of its origin, inquiries have been made of neutral and unbiassed authorities, and the general result is that it has no scientific recognition, but that many of the public believe in it, and consult practitioners who profess to practise it. The system has no place in any of the universities of Germany, nor does it seem to have a single school of its own in the entire German empire. It is universally condemned in Germany by men who have anything to do with biological science, and even in the lectures on therapeutics it is not mentioned at all. In Great Britain the Medical Act of 1858 gives power to the Privy Council severely to prohibit attempts by any examining body to impose restrictions as to any theory of medicine or surgery on candidates for examination. There is a homœopathic hospital with 100 beds in London, to which is attached a homœopathic school (see Dr Wyld in *Lancet*, June 2, 1877). Homœopathy is not strong in England. There are said to be 105 homœopathic practitioners in London. In Great Britain and Ireland, with a population of thirty-five millions, there are but 275 homœopathic physicians. Liverpool and Glasgow, each with about half a million of population, have respectively fifteen and five homœopathic doctors. The somewhat weak and failing condition of homœopathy in Britain is thus contrasted by a writer in the monthly *Homœopathic Review* for January 1880 with its condition in America: in four chief American cities there are 462 homœopathic doctors, in four English towns 139; in New York city the homœopathic physicians are to the allopathic as 1 to 6, in London the proportion is 1 to 20. The writer attributes the lower condition of homœopathy in England to the fact "that it has ceased to be a novelty, that it has revolutionized orthodox medicine, and that many of our own men (homœopathic practitioners) abjure the minute doses which served so well in the hands of Hahnemann and many of his earlier disciples." But all these facts or factors must obtain equally in America. It is probable that the different system of medical education and qualification in the two countries has something to do with the difference. In the United States homœopathy has naturally had freer scope than in Europe. Some have estimated the proportion of homœopathic practitioners in the States as being one-eighth of the whole number of legally qualified practitioners. Every State determines for itself the conditions of qualification in medicine; and there is thus a vast number of separate medical schools giving both education and diplomas. Consequently there is a serious inequality in the severity of medical education and examination. In some States, as in that of Michigan, the legislature has engrafted on the university a department for teaching its youth the principles and therapeutics of homœopathy; and very lately the same legislature has provided a hospital for the homœopathic treatment of disease.

In all countries the doctrine of homœopathy is still without broad scientific recognition; and certainly in England its chief representatives are anxious to cease their existence as a distinctive school, and have, by their avowed departure from Hahnemann's law of *Similia*, and his mode of attenuating and administering medicines, brought themselves under the severest condemnation of their master's few faithful followers, amongst whom are still included men of high character. We need not discuss in detail the individual doctrines of Hahnemann, especially those just referred to, as they are scarcely fought for by those who now represent what remains of the homœopathic school. Hahnemann's fundamental views of disease deserve more attention. He despised any deep study of disease, and theorized about it instead. Had he carefully inquired into the nature and natural history of disease as Hippocrates did, or as he himself inquired into the sensations of those who took infinitesimal doses, he would have done more for the world and his own reputation. Hahnemann was easily captivated by theories, and not very sound in his reasoning. But underlying all his system, as we have seen, was the idea that the causes of disease were impalpable, immaterial, spiritual, dynamic. And this great foundation was rotten. Modern medicine is doing some of its best work in showing the material and the visible character of the causes of many of the commonest diseases, and suggests this in many cases where it has not as yet been demonstrated. The cause of many diseases is shown to be a living germ or particle which can be discerned under the microscope, can be carried on a lancet or in a tube, and inserted under the skin so as to produce its peculiar disease. This is true of small-pox, Hahnemann notwithstanding. The germ can be preserved or it can be killed, and thus disease can be propagated or prevented. The close air of workshops, which generates consumption in such amount, can be shown to be full of impurities, chemical or organic. The causes of other diseases are often, not merely visible under a microscope, but coarsely visible. We have been lately told on high authority that to produce certain forms of blood-poisoning one or two ounces at least of septic fluid are necessary. So with other forms of common disease. Alcohol does not destroy a liver or kidney in any dynamic or immaterial form, but in coarse quantities diligently repeated. The lead which paralyses the painter's wrist is not a "spiritual" thing. It is an accumulation of matter in the wrong place, and enters his body in palpable quantities, and, what is more, can be recovered in similar quantities from his body. So with the uric acid or its salts in the blood of a person who has inherited his father's gout, and perhaps his port wine. It is not a "spiritual" affair at all, but can be demonstrated chemically and under the microscope. The itch, to whose mysterious workings Hahnemann attributed two-thirds of the internal diseases of the body, including mania, cancer, gout, &c., is easily demonstrated to be dependent on an ugly crab-like insect, which can be destroyed in a few hours with sulphur, when there is an end both of it and of the itch. We are aware of the euphemistic form which is given to Hahnemann's views of the psoric or itch disease; and we are partly disposed to admit, with the late Professor Henderson, the ablest and wisest of Hahnemann's supporters in England, that Hahnemann was unfortunate in the exposition of his own views of this subject. But Hahnemann's fine but fundamental theories about the spiritual and dynamic origin of disease are all exploded by the revelations of modern pathology, and their demolition only completes that of his therapeutical theories which rested on them.

Still it does not follow that homœopathy has been of no use. Hahnemann deserves the credit of being the first to break decidedly with the old school of medical practice, in which, forgetful of the teachings of Hippocrates, nature was either overlooked or rudely opposed by wrong and ungentle methods. He was so dissatisfied with this system that he gave up practice. We can scarcely now estimate the force of character and of courage which was implied, eighty years back, in abandoning the common lines of medicine. More than this, he and his followers showed results in the treatment of disease which compared very favourably with the results of orthodox practice. But they entirely missed the right conclusion from their experience. Let us take, for example, the statistics of the treatment of inflammation of the lung (pneumonia), adduced, not by Hahnemann,—for it is one of his very weak points that he did not record cases,—but, after his death, by Dr Fleischmann of Vienna. Dr Henderson quotes these and other homœopathic statistics with great satisfaction, and undoubtedly and properly they produced a great effect, showing a mortality of 1 in 21 cases only, which was a much higher percentage of success than under the ordinary treatment. But these statistics have since been entirely eclipsed by the minute and historical record of cases treated in the Edinburgh Infirmary, where the late Dr Hughes Bennett treated 105 cases of acute pneumonia, extending over sixteen years, without one death. Still we must admit that Fleischmann's results were greatly better than the old ones, and that but for the homœopathic practice, which most practitioners regarded as a negation, tantamount to leaving the disease to nature, the emancipation from traditional methods of treatment would have been much slower than it was.

Besides this, homœopathy may be credited with two other services. It has given prominence to the therapeutical side of medicine, and has done much to stimulate the study of the physiological action of drugs. No doubt Hahnemann completely erred in despising nature, and in magnifying medicines in the cure of disease. But his very methods showed, unintentionally on his part, what nature could do;

and his devotion and that of his school to therapeutics has acted as a somewhat deserved rebuke to those physicians who get so absorbed in the study of disease as to forget that the great interest of mankind in it is to have it cured with as little delay as possible. It may be admitted that homœopathy has done some service in directing more special attention to various powerful drugs, such as aconite, nux vomica, belladonna, and to the advantage of giving them in simpler forms than were common before the days of Hahnemann.

Hahnemann's errors were great. His doctrine of specifics was highly retrograde and unscientific, and his disparagement of the principle of *tolle causam* and of those who aimed at discovering the causes of disease (*Organon*, p. 3) was unphilosophical. He was fanciful and theoretical to a very high degree. He led his followers far out of the track of sound views of disease and the methods by which it can best be prevented and cured. But, with all his defects, it must be admitted that he had the great merit of disturbing and discrediting indefensible modes of practice. (J. G. G.)

HONDA, or San Bartolommeo de Honda, a town of the republic of Colombia, in the state of Cundinamarca, on the left bank of the river Magdalena, about 575 miles from the sea, in 5° 11′ 42″ N. lat. and 74° 41′ 6″ W. long. It is regular and well-built, but none of its public edifices—churches, convents, or hospitals—call for special remark. Situated at the spot where the upward navigation of the Magdalena is stopped by a series of rapids, Honda was formerly the seat of a very considerable trade, and it still retains a certain amount of commercial importance. Goods and passengers for Bogotá, the capital of Colombia, are now disembarked at Caracoli about 2 miles further down. The population of Honda is stated at 4000 or 5000. See Colombia, vol. vi. p. 153.

HONDECOETER, Melchior d' (*c.* 1636–1695), painter, was born at Utrecht, it is said, about 1636, and died at Amsterdam, April 3, 1695. Old historians say that, being the grandson of Gillis and son of Gisbert d'Hondecoeter, as well as nephew of J. B. Weenix, he was brought up by the last two to the profession of painting. Of Weenix we know that he married one Josina d'Hondecoeter in 1638. Melchior was, therefore, related to Weenix, who certainly influenced his style. As to Gillis and Gisbert some points still remain obscure, and it is difficult to accept the statement that they stood towards each other in the relation of father and son, since both were registered as painters at Utrecht in 1637. Both it appears had practised art before coming to Utrecht, but where they resided or what they painted is uncertain. Unhappily pictures scarcely help us to clear up the mystery. In the Fürstenberg collection at Donaueschingen there is a Concert of Birds dated 1620, and signed with the monogram G. D. H.; and we may presume that G. D. H. is the man whose Hen and Chickens in a Landscape in the gallery of Rotterdam is inscribed "G. D. Hondecoeter, 1652;" but we ask, Is the first letter of the monogram to stand for Gillis or Gisbert? In the museums of Dresden and Cassel landscapes with sportsmen are catalogued under the name of Gabriel de Heusch (?), one of them dated 1529, and certified with the monogram G. D. H., challenging attention by resemblance to a canvas of the same class inscribed G. D. Hond. in the Berlin Museum. The question here is also whether G. means Gillis or Gisbert. Obviously there are two artists to consider, one of whom paints birds, the other landscapes and sportsmen. Perhaps the first is Gisbert, whose son Melchior also chose birds as his peculiar subject. Weenix too would naturally teach his nephew to study the feathered tribe. Melchior, however, began his career with a different specialty from that by which he is usually known. Mr de Stuers affirms that he produced sea-pieces. One of his earliest works is a Tub with Fish, dated 1655, in the gallery of Brunswick. But Melchior soon abandoned fish for fowl. He acquired celebrity as a painter of birds only, which he represented not exclusively, like Fyt, as the gamekeeper's perquisite after a day's shooting, or stock of a poulterer's shop, but as living beings with passions, joys, fears, and quarrels, to which naturalists will tell us that birds are subject. Without the brilliant tone and high finish of Fyt, his Dutch rival's birds are full of action; and, as Bürger truly says, Hondecoeter displays the maternity of the hen with as much tenderness and feeling as Raphael the maternity of Madonnas. But Fyt was at home in depicting the coat of deer and dogs as well as plumage. Hondecoeter cultivates a narrower field, and seldom goes beyond a cock-fight or a display of mere bird life. Very few of his pictures are dated, though more are signed. Amongst the former we should note the Jackdaw deprived of his Borrowed Plumes (1671), at the Hague, of which Earl Cadogan has a variety; or Game and Poultry and a Spaniel hunting a Partridge (1672), in the gallery of Brussels; or a Park with Poultry (1686) at the Hermitage of St Petersburg. Hondecoeter, in great favour with the magnates of the Netherlands, became a member of the painters' academy at the Hague in 1659. William III. employed him to paint his menagerie at Loo, and the picture, now at the Hague museum, shows that he could at a pinch overcome the difficulty of representing India's cattle, elephants, and gazelles. But he is better in homelier works, with which he adorned the royal chateaus of Bensberg and Oranienstein at different periods of his life (Hague and Amsterdam). In 1488 Hondecoeter took the freedom of the city of Amsterdam, where he resided till his death. His earliest works are more conscientious, lighter, and more transparent than his later ones. At all times he is bold of touch and sure of eye, giving the motion of birds with great spirit and accuracy. His masterpieces are at the Hague and at Amsterdam. But there are fine examples in private collections in England, and in the public galleries of Berlin, Caen, Carlsruhe, Cassel, Cologne, Copenhagen, Dresden, Dublin, Florence, Glasgow, Hanover, London, Lyons Montpellier, Munich, Paris, Rotterdam, Rouen, St Petersburg, Stuttgardt, and Vienna.

HONDURAS

HONDURAS, a republic of Central America, formerly a province of the kingdom of Guatemala, deriving its name from the Spanish *honduras*, depths, in allusion, it is said, to the difficulty experienced by its original explorers in finding anchorage off its coast. See Pla[te] III. vol. xi. It is bounded on the N. and E. by the Bay of Honduras and the Caribbean Sea, extending from the mouth of the Rio Tinto, 15° 45′ N. lat. and 88° 30′ W. long., to the mouth of the Rio Wanks or Segovia, in 14° 59′ N. lat. and 83° 11′ W. long., having a coast-line of about 400 miles. On the S. it is bounded by Nicaragua, the line of division following the Rio Wanks for about two-thirds of its length, thence deflecting to the sources of the Rio Negro, which flows into the Gulf of Fonseca; it has on this gulf a coast line of about 60 miles, embracing also the islands of Tigre, Sacate Grande, and Gueguensi. Upon the W. and S.W. it is bounded by San Salvador and Guatemala; the line of separation there is irregular, commencing on the Gulf of Fonseca, at the mouth of the Rio Goascoran, and ending at the mouth of the Rio Tinto, on the Bay of Honduras. The republic is therefore entirely between 83° 20′ and 89° 30′ W. long. and 13° 10′ and 16° N. lat., and comprises about 40,000 square miles. The large island of Roatan, with Guanaja or Bonacca, Utila, Helena, Barbaretta, and Morat are naturally dependent on Honduras.

Mountains.—The general aspect of the country is mountainous; it is traversed by ranges of mountains and hills radiating from the common base of the Cordilleras. That chain does not, in this republic, approach within 50 or 60 miles of the Pacific; nor does it throughout maintain its general character of an unbroken range, but sometimes turns back on itself, forming interior basins or valleys, within which are collected the headwaters of the streams that traverse the country in the direction of the Atlantic Ocean. Nevertheless, viewed from the Pacific, it presents the appearance of a great natural wall, with a lower range of mountains, bristling with volcanic peaks, intervening between it and the western sea. It would almost seem that at one time the Pacific broke at the foot of the great mountain barrier, and that the subordinate coast range was subsequently thrust up by volcanic forces. The northern and eastern coasts of the republic present several bold groups of mountains, which are the ends of the ranges radiating north and east from the Cordilleras, and which, striking the coast diagonally, and overlapping each other, seem to form an unbroken range, and are sometimes represented as such on the maps. The Cordilleras proper traverse the state in the general direction of north-west and south-east, but it is throughout serpentine, and at one point is interrupted by a great transverse valley or plain, known as the plain of Comayagua, having an extreme length of about 40 miles, with a width of from 5 to 15 miles, from which, extending due north to the Atlantic, is the valley of the river Humuya, and due south, to the Pacific, the valley of the river Goascoran, collectively constituting a great transverse valley reaching from sea to sea, which was pointed out soon after the conquest as an appropriate course for inter-oceanic communication. Topographically the country has great diversity of surface and elevation; broad alluvions, fertile valleys, wide and elevated plains, and mountains terraced to their summits, collectively affording almost every variety of climate, soil, and production, from oranges and pine apples in the valleys to peaches and pears on the table-lands.

Hydrography.—The rivers of Honduras are numerous, and some of them of large size and navigable. The largest is the Ulua, which drains a wide expanse of territory, comprehending nearly one-third of the entire state, and probably discharges a greater amount of water into the sea than any other river of Central America, the Wanks or Segovia, perhaps, excepted. It may be navigated by steamers of light draught for the greater part of its course. The soil on its banks is of extreme fertility. The Rio Aguan or Roman is a large stream falling into the sea near Truxillo, with a total length of about 120 miles. Its largest tributary is the Rio Mangualil, celebrated for its gold washings, and it may be ascended by boats of light draft for 80 miles. Rio Tinto, Negro, or Black River, called also Poyer or Poyas, is a considerable stream, said to have a length of 120 miles; it is navigable by small vessels for from 40 to 60 miles. Some English settlements were made on its banks during the last century. The Poyas Indians have a number of establishments on its upper tributaries. The Rio Wanks or Segovia is the longest, if not the largest, river in Central America, rising within 50 miles of the Bay of Fonseca, and flowing into the Caribbean Sea at Cape Gracias á Dios, constituting for the greater part of its length the boundary between Honduras and Nicaragua, and having a length of 350 miles. For 251 miles above its mouth it flows through an almost unbroken wilderness, among high mountains and over a very broken and rocky bed. It is nevertheless occasionally navigated by canoes to within a few leagues of the town of Ocotal or Nueva Segovia in Nicaragua. Three considerable rivers flow into the Pacific,—the Goascoran, Nacaome, and Choluteca, the last-named having a length of about 150 miles. The Goascoran, which almost interlocks with the Humuya, in the plain of Comayagua, has a length of about 80 miles. The Lake of Yojoa or Taulébe is the only lake of note in Honduras, and is about 25 miles in length, by from 6 to 8 in breadth. Its surface is 2050 feet above the sea. It has two outlets on the south, the rivers Jaitique and Sacapa, which unite about 15 miles from the lake; and it is drained on the north by the Rio Blanco, a narrow, deep stream falling into the Ulua. It has also a feeder on the north, in the form of a subterranean stream of beautiful clear water, which here comes to the surface.

Harbours and Islands.—The Bay of Fonseca or Conchagua, sometimes called Amapala, is one of the finest ports, or "constellation of ports," on the entire Pacific, and on it Honduras has a larger frontage than Nicaragua or San Salvador. It is upwards of 50 miles in greatest length by about 30 miles in average width, with an entrance from the sea about 18 miles wide, between the great volcanoes of Conchagua, 3800 feet high, and Coseguina, 3000 feet high, the lofty islands of Conchaguita and Mianguiri lying between them, with a collection of rocks called "Los Farellones," dividing the entrance into four distinct channels, each of sufficient depth for the largest vessels. A channel called "El Estero Real" extends from the extreme southern point of the bay into Nicaragua for about 50 miles, reaching within 20 or 25 miles of Lake Managua. The principal islands in the bay are Sacate Grande, Tigre, Gueguensi, and Esposescion belonging to Honduras, and Martin Perez, Punta Sacate, Conchaguita, and Mianguiri belonging to San Salvador. Of these Sacate Grande is the largest, being about 7 miles long by 4 broad. The island of Tigre from its position is the most important in the bay, being about 20 miles in circumference, and rising in the form of a cone to the height of 2500 feet. The slope from the water for some distance inland is gentle, admitting of cultivation. Upon the southern and eastern shores the lava forms black rocky barriers to the waves, varying in height from 10 to 80 feet; but on the northward and eastward are a number of playas or coves, with smooth, sandy beaches. Facing one of the most considerable of these is the port of Amapala, with deep water in front, where ships of ordinary size may lie within a cable's length of the shore. This island was a favourite resort of the pirates, and it was here that Drake had his depôt during his operations in the South Sea. It exports hides, indigo, tobacco, bullion, silver and copper ores, and Brazil wood. The bay abounds in fish, oysters, crabs, and cray fish, and water-fowl swarm along its shores. The whole region around it is eminently productive, and adapted to the production of every tropical commodity. The savannas back from the shores are fitted for grazing, while wheat, potatoes, and other products of the temperate zone may be cultivated on the plateaus and slopes of the mountains in the interior, where oaks and pines are abundant. The silver and gold mining districts of Tabanco, Aramacina, San Martyn, and Corpus all lie within from 10 to 40 miles of this bay. Limestone is also found near by, with a fine rose-coloured sandstone. Extensive beds of coal exist in the valley of the river Lempa. Puerto Caballos, on the northern coast, in 15° 49′ N. lat. and 87° 57′ W. long., was selected by Cortes during his expedition into Honduras for the settlement which he founded, with the purpose of making it the entrepôt of New Spain; he called it Natividad. For more than two centuries it was the principal establishment on the coast; but, during the time of the buccaneers, the settlement was removed to Omoa, a few miles to the east, because of the large size of the bay, which could only be adequately defended by the construction of several forts, while a single work, still extant and formidable, was sufficient for Omoa. The port or rather bay is about 9 miles in circumference, with a depth throughout the greater part of its area of from 4 to 12 fathoms, with secure holding ground. Towards the northern shore the depth of water is greatest; there suitable docks have been constructed, and the largest ocean steamers may enter and tie up, the rise and fall of the tide being scarcely perceptible. The prevailing winds are from the north-east, north, and north by west, from all which points the port is perfectly protected. The port of Omoa, in 15° 47′ N. lat. and 88° 3′ W. long., is small but secure, and is defended by a strong work, "El Castillo de San Fernando." The anchorage is good, in from 2 to 6 fathoms. The population in 1876 was about 600, most of the inhabitants having removed to San Pedro, 37 miles inland, where the business of the port is transacted. The exports of these ports consist of bullion, tobacco, indigo, sarsaparilla, hides, &c. A large number of cattle are shipped annually to supply the markets of Cuba and the mahogany establishments of Belize. There is an abundant supply of fish, turtle, and wild fowl from the quays and waters in its vicinity. Puerto Sal is a small harbour a few miles to the eastward of Puerto Caballos. Truxillo is an ancient port, in 15° 55′ N. lat. and 86° W. long., situated on the western shore of a noble bay, formed by the projecting land of Punta Castilla. Its trade is chiefly with Olancho, of which department it may be considered the port. There are some mines of gold in its vicinity. Triunfo de la Cruz is a large bay, commencing at Puerto Sal, bending thence inward and terminating at Cabo Triunfo, with a coastline of upwards of 20 miles. To the northward of Honduras, in the bay of the same name, distant from 30 to 50 miles, is a cluster of islands, sometimes called the Bay Islands, consisting of Roatan, Guanaja or Bonacca, Utila, Barbaretta, Helena, and Morat. They have a good soil, fine climate, and an advantageous position. Roatan, the largest, is about 30 miles long by 9 miles broad, with mountains rising to the height of 900 feet, covered with valuable woods, and abounding with deer and wild hogs. Its trade is chiefly with New Orleans in plantains, cocoa-nuts, pine apples, &c. Guanaja, discovered by Columbus, is 9 miles long by 5 miles broad; it lies 15 miles north-east of Roatan, has interior highlands thickly wooded, with beds of limestone, and, it is said, ores of zinc. Wild hogs are numerous. The other islands are comparatively small, and may be regarded as detached parts of Roatan, with which they are connected by reefs.

Minerals.—In respect to mineral resources, Honduras ranks first among the states of Central America; the working of the mines, however, has been conducted on a very small scale, and in a very rude manner, and as a consequence most of them have been abandoned and have filled with water, and have thus or otherwise been allowed to go to ruin. Silver ores are most abundant and valuable. They are chiefly found on the Pacific ranges or groups of mountains, while the gold washings, if not the gold mines proper, are most numerous on the Atlantic slope. The silver is found in various combinations with iron, lead, and copper, and in a few instances with antimony. Chlorides of silver are not uncommon, and rank among the richest ores in the country. The principal supply of gold is from the washings of Olancho, which are exceedingly productive. There are also rich mines of copper, the ores, in all cases, containing a considerable proportion of silver. Iron ores are common, most of them magnetic, and some so rich that they can be worked without smelting. Antimony, zinc, and tin also exist. Lignite has been discovered in various localities, and large beds exist in the department of Gracias, in which opals are also abundant.

Animals.—The domestic animals of the country are much the same as those of England and the United States. Cattle are everywhere abundant, and form one of the great sources of wealth in the country. Of late great numbers have been taken to Cuba, where there is a large and increasing demand for them. The forests are frequented by the ocelot or American tiger, and the peccary and deer; the tapir is found near the sea, and the manatee in the northern creeks. Monkeys are numerous and of many varieties; the raccoon, squirrel, opossum, ant-eater, and armadillo abound. The alligator is found in all the rivers and lagoons on both coasts. Of lizards there are numberless varieties, including the iguana. Serpents are very rare, and of but two or three varieties, of which one only is venomous. Tortoise and turtle are everywhere numerous, and of several kinds. Oysters of two varieties are plentiful, namely, the bank and mangrove oyster. Vast beds of the first are found in the Bay of Fonseca. Crustaceans of various kinds and sizes, from the largest lobster to the smallest crab, are abundant. The lagoons and creeks of the coast abound in endless varieties of fish, as do also the waters of the interior. Several varieties of honey bees also are found. Mosquitoes are almost unknown in the interior, and are found at but few points on the coast. The woodtick and flea are common everywhere. The insect most dreaded is the "langosta" or "chapulin," which at intervals afflicts the entire country, vast columns passing from one end to the other, darkening the air, and destroying every green thing in their course. The parrot, macaw, and toucan are found everywhere. Hawks, vultures, owls, and sea eagles are among the birds of prey. The crow, blackbird, Mexican jay, ricebird, swallow, rainbird, and humming-bird are common. There is a very great variety of water birds. The wild turkey, quail, and pigeon are numerous in the interior.

Inhabitants.—The inhabitants of Honduras are principally of the Indian or aboriginal type. In the eastern portion of the state, between the Rio Roman and Cape Gracias á Dios and Segovia river, the country is almost exclusively occupied by native Indian tribes, known under the general names of Xicaques and Poyas. Portions of all of these tribes have accepted the Catholic religion, and live in peaceful neighbourhood and good understanding with the white inhabitants. There are, however, considerable numbers who live among the mountains, and still conform closely to the aboriginal modes of life. They all cultivate the soil, and are good and industrious labourers. A small portion of the coast, above Cape Gracias, is occupied by the Sambos, a mixed race of Indians and negroes, which, however, is fast disappearing. Spreading along the entire north coast are the Caribs, a vigorous race, descendants of the Caribs of St Vincent, one of the Windward Islands, who were deported in 1796, by the English, to the number of 5000, and landed on the island of Roatan. They still retain their native language, and are active, industrious, and provident, forming the chief reliance of the mahogany cutters on the coast. A portion of them, who have a mixture of negro blood, are called the Black Caribs. They profess the Catholic religion, but retain many of their native rites and superstitions. In the departments of Gracias, Comayagua, and Choluteca are many purely Indian towns, with industrious, peaceable inhabitants, retaining many of their primitive habits and their ancient language. The aggregate population, in the absence of trustworthy data, can only be estimated approximately. Attempts were made under the crown and subsequently under the republic to effect a complete census, but with very unsatisfactory results, since it has always been found that the ignorant masses of the people, and especially the Indians, avoid a census as in some way connected with military conscription or taxation. The bulk of the Spanish population exists on the Pacific slope of the continent, while on the Atlantic declivity the country is uninhabited or but sparsely occupied by Indian tribes, of which the number is wholly unknown. Nevertheless, from the imperfect data which are accessible, the population of Honduras may fairly be estimated at about 400,000, 6000 to 7000 being whites, and the balance Indians and the mixed races.

Departments.—Honduras is divided politically into seven departments, viz., Comayagua, Gracias, Choluteca, Tegucigalpa, Olancho, Yoro, and Santa Barbara.

That of *Comayagua* lies in the very centre of the state. It contains the capital of the same name (see COMAYAGUA). The trade of the town is small, but the plain around it is very fertile, and capable of sustaining, as formerly, a large and flourishing population. Numerous monuments of antiquity are scattered over the plain, consisting of large, pyramidal, terraced structures, conical mounds of earth, and walls of stone.[1] Pine and oak are abundant on the hills, and mahogany, cedar, and lignum vitæ, as well as other useful woods, are found in the valleys. The nopal, cultivated in Guatemala and Mexico as the food of the cochineal insect, is indigenous.

[1] The most remarkable of these are the ruins of Tenampua, situated on a high hill, 20 miles to the south-east of Comayagua. The hill is of the prevailing soft sandstone, about 1600 feet high. At the accessible points are heavy stone walls, terraced on the inner side for convenience in defence. At various points are traces of towers, and remains of water reservoirs. Most of the mounds occur in groups, arranged with obvious design in respect to each other, from 20 to 30 feet square, and of several stages. The principal enclosure is in the very midst of the ruins, at a point conspicuous from every portion of the hill, and is 300 feet long by 80 feet broad, but now elevated only a few feet above the ground, on which are indications of buildings. Great quantities of fragments of pottery are found here, painted and ornamented. Altogether there are the remains of between 300 and 400 truncated, terraced pyramids of various sizes. The whole served probably for defensive and religious purposes.

Coffee and the other staples of semi-tropical regions also flourish here.

The department of *Gracias* lies in the north-western portion of the state, touching on Guatemala and Salvador, and its territory is in many respects the most interesting in Central America, of which it may be regarded as an epitome. On the north are many beautiful valleys, among them that of Copan, celebrated for its ancient monuments. Among its mountains is found the *quetzal*, the royal and sacred bird of the aborigines. Peaches, apples, and plums flourish here, and the blackberry is indigenous among the hills. The vegetable products, actual and possible, exhaust the list of productions of the tropics and the temperate zones. Wheat, barley, rye, and the potato grow on the mountains, while sugar cane, indigo, cotton, coffee, cocoa, oranges, and plantains flourish in the valleys. Pine covers the hills, and there is much mahogany, cedar, and granadillo, also Brazil wood, &c., for dyeing and manufacture. Copal balsam and liquidambar are among the common gums, while the tobacco has a wide and deserved celebrity. Gold and silver mines are numerous and rich, although but little worked. Bituminous coal, in beds of from 8 to 10 feet in thickness, is found in the plain of Sensenti, and asbestos, cinnabar, and platinum in various localities. Opals are frequent, principally in the vicinty of Erandique, where as many as sixteen mines have been "denounced" in a single year. Amethysts are reported to have been found near Campuca.

Choluteca is the extreme southern department of the state, lying along the Bay of Fonseca. It is extremely diversified in surface. Its alluvions, fronting the bay, are remarkably fertile, and are capable of producing all the staples of the tropics. As the country rises, which it does by a series of terraces, the savannas become broad and numerous, affording vast pastures for herds of cattle, which at present constitute the chief wealth of the department. Apart from its agricultural wealth, it is rich in minerals, chiefly in mines of silver.

Tegucigalpa, to the north of Choluteca, is the smallest but relatively the most populous department. It is a vast interior basin or plateau, with an average elevation of not less than 3000 feet above the sea. Its soil is not so productive as that of some of the other departments, and is essentially a mining district, rich in gold and silver. Tegucigalpa is the largest and finest city of the state, and is at present the capital, alternating with Comayagua as the seat of government.

The department of *Olancho* joins Tegucigalpa on the east, and has an area of about 11,300 square miles. Its people are industrious, and the department is comparatively the richest in the state. Its exports are bullion, cattle, hides and deer skins, sarsaparilla, and tobacco. Next to its herds of cattle, its principal sources of wealth are its gold washings. Nearly all of its streams carry gold of a fine quality in their sands.

The department of *Yoro* comprehends all the northern part of Honduras, with an area of 15,000 square miles, being the largest in size and the smallest in population. The valleys of all the streams abound in precious woods, and comprise the great mahogany district of Central America. The inhabitants are chiefly mahogany cutters by occupation. The mountains of Pija and Sulaco are said to contain great mineral wealth, but they have never been adequately explored.

The department of *Santa Barbara* lies between Gracias and Comayagua and the Bay of Honduras. It is traversed by several large streams. The great plain of Sula is the distinguishing feature of this department, which has a frontage of between 60 and 70 miles on the Bay of Honduras, and reaches inland upwards of 50 miles, comprising an area of not less than 1500 square miles. Its products are cotton, rice, sugar, cocoa, and all the great staples of the tropics.

Administration.—The government is republican in form, based on a constitution promulgated in November 1865. The chief executive consists of a president elected every four years, assisted by a council of state, consisting of two ministers appointed by the president, a senator elected by congress, and a judge of the supreme court. The legislature consists of a senate and chamber of deputies.

Public Debt.—The public debt of the republic in 1876 was $29,950,540, held in London and Paris, having been issued in three different loans in those cities, at high rates of interest and at a low valuation to make them attractive to capitalists. Since that time the accumulated interest, which has never been paid, has considerably swollen the amount. This debt, which is of a very questionable origin, was contracted for the alleged purpose of building the "Honduras Interoceanic Railway" between Port Caballos on the Bay of Honduras and the Gulf of Fonseca on the Pacific, a distance of 148 geographical miles. The road was first proposed by Mr E. G. Squier of New York, in 1854, who made the preliminary survey of the line, finding it perfectly feasible, and had it been built then it no doubt would have proved a financial success, and a great benefit to the commerce of the world. But the breaking out of the American war put a stop to the enterprise for the time, and the completion of the Union Pacific Railway in the United States has done away with the necessity for such a road as a highway for the nations. Still it would be a great benefit to the interior country should it at any time be completed. It is graded, and has a narrow guage track laid to San Pedro, 37 miles from Port Cortez.

Trade.—The total trade of the country for 1876 is given below:—

Exports from the Bay Islands, Truxillo, Omoa, and Puerto Caballos during the year 1876.

To United States	$230,503
To other countries	114,337
Total	344,840
From the port of Amapala, of which $208,646 was gold and silver	250,000
Grand total	$594,840

Imports into the Bay Islands, Truxillo, and Puerto Caballos for 1876.

From the United States	$230,184
From other countries	109,959
Total	340,143
Into the port of Amapala, estimated value	300,000
Total imports for 1876	640,143
Total foreign commerce foi 1876	$1,234,983

A number of small sailing vessels engaged in the fruit trade ply between the Bay Islands and New Orleans: Cocoa-nuts are in demand both in New Orleans and New York, and the inhabitants of the mainland, as well as those of the islands, have planted the fruit extensively, so that the entire north coast will soon be bordered by cocoa-nut plantations.

History.—It was in Honduras that Columbus first planted his feet on the continent of America. In 1502, while on his fourth voyage, he discovered the island of Guanaja or Bonacca, whence he saw the high mountains of the mainland; and on the 14th of August he landed on the continent at a point which he called *Punta de Cassinas*, now Cabo de Honduras, and took possession of the country on behalf of the crown of Spain. He subsequently coasted to the eastward, and after many delays and dangers reached a point where the coast abruptly trends to the southward, forming a cape, to which, in gratitude for his safety, he gave the name of *Cabo Gracias á Dios*, Cape Thanks to God. Less than twenty years afterwards, Hernando Cortes, inspired by accounts of great and populous empires to the southward of the then prostrate empire of the Montezumas, undertook an expedition into Honduras, which for length and difficulties encountered and overcome stands unprecedented in the history of martial adventure. He entered the vast and unbroken wilderness, and after two years of struggle and endurance reached the point where Columbus first landed. Without giving the history of Spanish power in Honduras, suffice it to say that as early as 1540, sixty years before Jamestown in Virginia was founded, and nearly a hundred years before Hudson entered the Bay of New York, Honduras had its large and flourishing cities. After throwing off the Spanish yoke, Honduras in 1823 joined the union of Central America. In 1839 that union was dissolved, but the liberal party in the now independent state made repeated attempts to restore a federative union with the neighbouring republics of Nicaragua and San Salvador. These efforts even led to unsuccessful hostilities with Guatemala, but President Cabaños in 1855 being defeated and exiled, his successor General Guardiola (1856) concluded with Guatemala a treaty of peace. Six years of quiet ensued, when an insurrection broke out in 1862 among the soldiers, which cost Guardiola his life. After passing through some vicissitudes, the republic in November 1865 adopted a new constitution, under which the president is elected every four years.

See *Notes on Central America*, by E. G. Squier, New York, 1855, and *Honduras*, by same author, London, 1870. (E. G. S.)

BRITISH HONDURAS

BRITISH HONDURAS is the name given to the English establishment or colony of Belize, on the eastern shore of the peninsula of Yucatan, fronting the Bay of Honduras. It probably derives its name of Belize or Balize from the French *balise*, a beacon, as no doubt some signal or light was raised here to guide the freebooters, who at one time infested the bay, to some common rendezvous. Its boundaries, as defined by the convention between Great Britain and Carrera, president of Guatemala, in 1859, were fixed as "commencing at the mouth of the river Sarstoon, in the bay of Honduras, ascending that river to the rapids of Gracias á Dios, thence turning to the right in a straight

See Plate III. vol. xi.

line to Garbutt's Rapids in the river Belize, and thence due north to the Mexican frontier." These limits give a territory about 160 miles long by 60 miles wide at its broadest part, with an area of 7562 square miles.

The approach to the coast is through cays and coral reefs, and is both difficult and dangerous. For some miles inland the ground is low and swampy, thickly covered with mangroves and tropical jungle. Next succeeds a narrow belt of rich alluvial land, not exceeding a mile in width, beyond which, and parallel to the rivers, are vast tracts of sandy, arid land, called "pine ridges," from the red pine with which they are covered, and which are favourite resorts of wild animals. Further inland these give place to what are called "cahoon ridges," with a deep, rich soil covered with myriads of palm trees. Next come broad savannas, studded with clumps of trees, through which the streams descending from the mountains wind in every direction. The mountains themselves rise in a succession of ridges parallel to the coast. The first are the Manatee Hills, from 800 to 1000 feet high; and beyond these are the Cockscomb Mountains, which are about 4000 feet high.

No less than sixteen streams, large enough to be called rivers, descend from these mountains and crests to the sea, between the Hondo and Sarstoon. Behind the Cockscomb range there is a succession of valleys and hills, with a varied elevation of from 1200 to 3300 feet above the level of the sea. This tract, of which but little is known, consists of open, grassy lands, with interesting park-like scenery, and could no doubt support a large number of cattle, as all the conditions of climate, &c., are most favourable.

Many aboriginal remains are found, such as fortified hills, crumbling walls, and buildings subsiding into ruins. The ruins of extensive cities, with monoliths, statues, and carved stones of fine finish are said to be hidden among the yet unexplored forests. They are all, however, more or less similar to the remains found in the neighbouring states of Honduras and Yucatan, and doubtless are the work of the same race or races. The mineral resources of the colony have been but little developed. There are, however, among the hills many indications of gold, silver, and coal.

The climate generally is hot and damp, but favourably influenced by the trade winds. The mean temperature for 1878 was 79·75° Fahr.; the rainfall for the same year was 105·49 inches, which, however, was remarkably high. The country is not troubled by hurricanes, nor has it suffered from earthquakes. It has never been afflicted by epidemics, except cholera. Yellow fever occurs, but only sporadically. The climate is superior to that of Jamaica and the other West Indian Islands, and the high grounds of the interior are unquestionably healthy.

The population is mainly negro, introduced originally as slaves, whence has sprung a hybrid race from intermixture with Europeans and Indians. These are engaged in cutting mahogany and dyewoods, and in fishing. As woodmen they are most efficient, and no class or race of men has been able to excel them. A few only cultivate the soil. There are no aboriginal tribes within the limits of Belize, and of the pure Indians there are but few, belonging principally to the tribes of Yucatan. There are some Carib settlements. The scanty white population is engaged in commerce, and on the sugar plantations. The total population in 1871 was 24,710, of which 12,603 were males and 12,107 females, against a total of 25,635 in 1861, showing a decrease of 925, which can be accounted for from the fact that while the political troubles in the adjacent states caused many of their citizens to take refuge here, these, on the troubles being settled, returned to their homes.

The government is in the hands of a lieutenant-governor, with an executive and legislative council; and there are the usual judicial establishment, a lands title registry office, a public hospital, a lunatic asylum, and an alms-house. There is also an agricultural board for distributing information relative to the cultivation of suitable products, &c. The town of Belize, at the mouth of the river of the same name, has ordinarily about 6000 inhabitants; but the number is more than doubled during the Christmas holidays, when the mahogany cutters come in. The dwellings of the wealthy inhabitants are large and commodious. Besides the Government houses, court-house, barracks, and jail, there are several churches, Episcopal, Methodist, Baptist, and Presbyterian. There are also some large and costly fireproof warehouses. The place was formerly important from being the commercial entrepôt and depôt of the neighbouring Spanish states of Yucatan, Guatemala, and Honduras; but this source of prosperity has been mainly dried up, from the opening of direct communication between several of these states and the United States and Europe, and from the diversion of trade on the Pacific to Panama. The principal product of the country is mahogany, of which the export for many years was 20,000 tons annually, but the demand for it is said to be diminishing. Its logwood ranks high, and from 14,000 to 15,000 tons are exported annually. Besides these, it produces rosewood, sapodilla, Santa Maria, and numerous other woods of value. The cahoon or coyol palm is abundant, producing clusters of nuts, from which is extracted a valuable oil. Several varieties of cotton are produced, some of which are of superior quality. Sarsaparilla and vanilla are found in the interior. The animals of the country comprise many fur-bearing species, as ounces, panthers, &c., and the forests abound with various species of monkeys. Manatees and alligators are found in the lagoons and rivers. Among the birds are turkeys, ducks, macaws, parrots, pelicans, and humming-birds. There is also a small black bottle fly, whose bite is most venomous, and which, with the wood-tick, is a source of great annoyance in the forest. There are also several species of venomous snakes and scorpions. Fishes of many varieties are plentiful, as are also turtles, lobsters, and other shell-fish. Cattle and horses are kept in sufficient numbers for all needful purposes. Present statistical information indicates, instead of improvement in the colony, a considerable falling off during the past ten or fifteen years. Its sugar plantations are, however, in a flourishing condition, having increased in their yearly product from 4035 cwt. in 1860 to 38,667 cwt. in 1877. The rate of duty on the principal articles of import is an average of about 10 per cent., principally *ad valorem.* Machinery, coal, and books are imported free. The gross amount of revenue for 1877 was £41,588, against £27,398 in 1863. The public expenditure for the same year was £39,939, and the public debt £5041, the latter showing a decrease of £34,000 in nine years. The total tonnage of all kinds entered and cleared in 1877, exclusive of that employed in the coasting trade, was 73,974 tons, of which 46,168 tons were British. The value of imports, including bullion and specie, for the ten years ending 1877 was £1,781,175, and for that year £165,756, of which £84,540 came from Great Britain. The exports for 1877 amounted to £124,503, of which £94,548 worth of domestic produce went to Great Britain.

History.—"Her Majesty's Settlement in the Bay of Honduras," as the territory was formerly styled in official documents, owes its origin to logwood-cutters who frequented the coast of Yucatan and Central America, after the decline of piracy in the sea of the Antilles. Most of these had been free companions, and were well acquainted with the coast. The district was rich in dyewoods, and became a principal resort of the English cutters. Although thus industriously occupied, they so far retained their old habits as to make frequent descents on the logwood establishments of the

Spaniards, whose attempts to expel them were generally successfully resisted. The most formidable of these was made by the Spaniards in April 1754, when, in consequence of the difficulty of approaching the position from the sea, an expedition, consisting of 1500 men, was organized inland at the town of Peten. As it neared the coast, it was met by 250 English, and completely routed. The logwood-cutters were not again disturbed for a number of years, and their position had become so well established that, in the treaty of 1763, between England and Spain, the former power, while agreeing to demolish "all fortifications which English subjects had erected in the Bay of Honduras," nevertheless insisted on a clause in favour of the cutters of logwood, that "they or their workmen were not to be disturbed or molested, under any pretext whatever, in their said places of cutting and loading logwood; and for this purpose they may build without hindrance and occupy without interruption the houses and magazines necessary for their families and effects." They had also assured to them the full enjoyment of these advantages and powers in the Spanish coasts and territories. To insure the observance of this treaty, the British Government sent out Sir William Burnaby, who not only settled the limits within which the English were to confine their wood-cutting, but also drew up for their government a code of regulations or laws known as the "Burnaby Code." Successful in their contests with the Spaniards, and now strengthened by the recognition of the crown, the British settlers assumed a corresponding high tone, and, it is alleged, made fresh encroachments on the Spanish territory. The Spaniards, alarmed and indignant, and asserting that the settlers not only abused the privileges conceded to them by the treaty, but were engaged in smuggling and other illicit practices, organized a large force, and on September 15, 1779, suddenly attacked and destroyed the establishment, taking the inhabitants prisoners to Merida, and afterwards to Havana, where most of them died. The survivors were liberated in 1782, and allowed to go to Jamaica. For two or three years the establishment seems to have been abandoned, but in 1783 a part of the original settlers, with a considerable body of new adventurers, revisited the place, and were soon actively engaged in cutting woods. On September 3d of that year a new treaty was signed between Great Britain and Spain, in which it was expressly agreed that his Britannic Majesty's subjects should have "the right of cutting, loading, and carrying away logwood in the district lying between the river Wallis or Belize and Rio Hondo, taking the course of these two rivers for unalterable boundaries." These concessions "were not to be considered as derogating from the rights of sovereignty of the king of Spain" over the district in question, and all the English dispersed in the Spanish territories were to concentrate themselves within the district thus defined within eighteen months. Affairs, notwithstanding the explicit stipulations of the treaty, do not seem to have proceeded favourably; for, three years after, a new treaty was made, in which the king of Spain makes an additional grant of territory, embracing the area between the rivers Sibun or Jabon and Belize, so that collectively the grants embraced the entire coast between the river Sibun in lat. 17° 20′ on the south and the Rio Hondo in lat. 18° 30′ on the north, a coast-line of about 90 miles, with the adjacent islands and bays. But these extended limits were coupled with still more rigid restrictions. It is not to be supposed that a population composed of so wayward and lawless a set of men at a distance from England was remarkably exact in its observance of the letter or spirit of the treaty of 1786. They seem to have given great annoyance to their Spanish neighbours, who eagerly availed themselves of the breaking out of war between the two countries in 1796 to concert a formidable attack on Belize, with a view to the complete annihilation of the establishment. They concentrated a force of 2000 men at Campeachy, which, under the command of General O'Neill, set sail in thirteen vessels for Belize, and arrived off that place July 10, 1798. The settlers, in anticipation of their approach, and aided by the English sloop of war "Merlin," had strongly fortified a small island in the harbour, called St George's Cay, whence they maintained a determined and effectual resistance against the Spanish forces, which, after a contest of two days' duration, were obliged to abandon their object and retire to Campeachy. This was the last attempt to dislodge the English. The defeat of the Spanish attempt of 1798 has been adduced as an act of conquest, thereby permanently establishing British sovereignty. But those who take this view overlook the important fact that, in 1814, by a new treaty with Spain, the provisions of that of 1786 were revived. They forget also that until possibly within a few years the British Government never laid claim to any rights acquired in virtue of the successful defence; for so late as 1817–19 the Acts of Parliament relating to Belize always refer to it as "a settlement, for certain purposes, under the protection of his Majesty." After the independence of the Spanish American provinces, Great Britain sought to secure her rights by incorporating the provisions of the treaty of 1786 in all her treaties with the new states. It was, in fact, incorporated in her treaty with Mexico in 1826, in the project of a treaty which she submitted to Señor Zebadua, the representative of the republic of Central America in London in 1831, and also in the project of a treaty with New Grenada in 1825. Great Britain was, therefore, without any rights in Belize beyond those conveyed by the treaties already quoted, which define with the greatest precision the area within which these rights might be exercised. But it appears from a despatch of Sir George Grey, colonial secretary, dated in 1836, that claims had then been set up to an additional wide extent of territory, including the entire coast as far south as the river Sarstoon, and as far inland as the meridian of Garbutt's Falls on the river Belize. This anomalous state of things has no doubt had a prejudicial influence on the prosperity of Belize; but while Great Britain's right of sovereignty might be questioned, it cannot be doubted that the enterprise of her subjects has rescued a desolate coast from the savage dominion of nature, and carried industry and civilization where none existed before, and where, if left to the control of the Spanish race, none would have existed to this day. It was perhaps this consideration that induced Mr Clayton, the American secretary of state, to consent to the exclusion of Belize from the operation of the convention of 1850 between Great Britain and the United States, whereby both powers bound themselves not to occupy, fortify, or colonize any part of Central America.

Squier, New York, 1855; *A Narrative of a Journey across the Unexplored Portion of British Honduras*, by Henry Fowler, Colonial Secretary, Belize, 1879. (E. G. S.)

HONE. Under the name of hones, whetstones, or sharpening stones, a variety of finely siliceous stones are employed for whetting or sharpening edge tools, and for abrading steel and other hard surfaces. They generally are prepared in the form of flat slabs or small pencils or rods of the material, but some are made with the outline of the special instrument they are designed to sharpen. Their abrading action is due to the quartz or silica which is always present in predominating proportion, some kinds consisting of almost pure quartz, while in others the siliceous element is very intimately mixed with aluminous or calcareous matter, forming a uniform compact stone, the extremely fine siliceous particles of which impart a remarkably keen edge to the instruments for the sharpening of which they are applied. Hones are used either dry, with water, or with oil, and generally the object to be sharpened is drawn with hand pressure backward and forward over the surface of the hone; but sometimes the stone is moved over the cutting edge. The coarsest type of stone which can be included among hones is the bat or scythe stone, a porous fine-grained sandstone used for sharpening scythes and cutters of mowing machines, and for other like purposes. Next come the ragstones, which consist of quartzose mica-schist, and give a finer edge than any sandstone. Under the head of oilstones or hones proper the most famous and best-known qualities are the German razor hone, the Turkey oilstone, and the Arkansas stone. The German razor hone, used, as its name implies, chiefly for razors, is obtained from the slate mountains near Ratisbon, where it forms a yellow vein of from 1 to 18 inches in the blue slate. It is sawn into thin slabs, and these are cemented to slabs of slate which serve as a support. Turkey oilstone is a close-grained bluish stone containing from 70 to 75 per cent. of silica in a state of very fine division, intimately blended with about 20 to 25 per cent. of calcite. It is obtained only in small pieces, frequently flawed and not tough, so that the slabs must have a backing of slate or wood. It is one of the most valuable of all whetstones, abrading the hardest steel, and possessing sufficient compactness to resist the pressure required for sharpening gravers. The stone comes from the interior of Asia Minor, whence it is carried to Smyrna. Of Arkansas stones there are two varieties both found in the same district, Garland county, Arkansas, United States. The finer kind, known as Arkansas hone, is obtained in small pieces at the hot springs, and the second quality, distinguished as Washita stone, comes from Washita or Ouachita river. The hones yield on analysis 98 per cent. of silica, with small proportions of alumina, potash, and soda, and mere traces of iron, lime, magnesia, and hydrofluoric acid. They are white in colour, extremely hard and keen in grit, and not easily worn down or broken. Geologically the materials belong to the millstone grit series, and are supposed to be metamorphosed sandstone resulting from the permeation through the mass of heated alkaline siliceous waters. The finer kind is employed for fine cutting instruments, and also for polishing steel pivots of watch-wheels and similar minute work, the second and coarser quality being used for common tools. Both varieties are largely exported from the United States to all quarters in the form of blocks, slips, pencils, rods, and wheels. During the Centennial Exhibition of 1876 the comparative value of hones per lb was thus quoted—Arkansas $1·50, Washita ·35, Turkey 1·00. Among hones of less importance in general use may be noted Charnley Forest stone, a good substitute for Turkey oilstone; Water of Ayr stone, Scotch stone, or snake stone, used for tools and for polishing marble and copperplates; Idwal or Welsh oilstone, used for small articles; and cutlers' greenstone from Snowdon, very hard and close in texture, used for giving the last edge to lancets.

HONE, WILLIAM (1780–1842), a political satirist and a writer on antiquarian and miscellaneous subjects, was born at Bath, June 3, 1780. His father, a man of deep spiritual experience in that time of religious revival, brought up his children in strictness and reverence, but not without the sectarian narrowness that so frequently produces reaction. The parodist of the litany and of the Athanasian creed was taught to read from the Bible only. Hone received no systematic education. His father having removed to London in 1783, he was in 1790 placed in an attorney's office. Becoming connected with the London Corresponding Society, which was given to freethought and to political agitation, he was removed by his father to the office of a solicitor at Chatham, but after two years and a half he returned to London and became clerk to a solicitor in Gray's Inn. Having no liking for the study of the law, and apparently no hope of succeeding in it, Hone, being then married, started in 1800 a book and print shop and a circulating library in Lambeth Walk, and he soon after removed to St Martin's Churchyard, where he brought out his first publication, Shaw's *Gardener*, and suffered much loss from a fire. It was at this time that Hone matured and with a friend endeavoured to realize a plan for the establishment of popular savings banks, and even had an interview on the subject with the Right Hon. George Rose, then president of the Board of Trade. This scheme, however, fell through from lack of support. His partner in the savings bank became next his partner in a bookseller's business; but Hone's habits were not those of a tradesman, and bankruptcy was the result. After several removals, having compiled an index to Lord Berner's translation of Froissart, he was in 1811 chosen by the booksellers as auctioneer to the trade, and had an office in Ivy Lane. Independent investigations carried on by him into the condition of lunatic asylums led again to difficulties and failure, but, struggling bravely under his burdens, he took a small lodging in the Old Bailey, and kept himself and his now large family by contributions to magazines and reviews. He hired a small shop (or rather box) in Fleet Street, but this was on two separate nights broken into, and valuable books lent for show were stolen. In 1815 he started the *Traveller* newspaper, and endeavoured vainly to exculpate Eliza Fenning, a poor girl, apparently quite guiltless, executed on a charge of poisoning. From February 1 to October 25, 1817, he published the *Reformist's Register*, writing in it as the serious critic of the state abuses, to which he soon after applied the lash of satire in those political squibs and parodies that made his name known throughout the land, and that first gave notoriety to George Cruikshank, who was his artistic collaborator. In April 1817 three *ex officio* informations were filed against him by the attorney-general, Sir William Garrow, and he was seized while reading in the street and hurried to the lock-up. Three separate trials took place in the Guildhall before special juries on the 18th, 19th, and 20th of December 1817. The first, for publishing Wilkes's *Catechism of a Ministerial Member*, was before Mr Justice Abbot (afterwards Lord Tenterden); the second, for parodying the litany and libelling the prince regent, and the third, for publishing the *Sinecurist's Creed*, a parody on the Athanasian creed, were before Lord Ellenborough. The prosecuting officials, among whom we must include the judges, took the ground that the prints were calculated to injure public morals, and to bring the prayer-book and even religion itself into contempt. But there can be no doubt that the real motives of the prosecution were political; Hone had ridiculed the habits and exposed the corruption of the prince regent and of other persons in power. He went to the root of the matter when he wished the jury "to understand that, had he been a publisher of ministerial parodies, he would not then have been defending himself on the floor of that court." In spite of illness and exhaustion Hone displayed great courage, ability, dignity, and presence of mind. On each of the three days he spoke on an average seven hours. Notwithstanding the powerful prosecution and the bias of the judges, he was acquitted on each count, and the result on each occasion was received with enthusiastic cheers by immense crowds within and without the court. Soon after the trials a public meeting, in which Alderman Waithman, Sir F. Burdett, and Lord Cochrane took part, was held, and a subscription was begun, by which a large sum was soon collected to enable Hone to get over the difficulties caused by his prosecution.

Hone's most successful political satires were published within a few years after his trial. Among them we may mention *The Political House that Jack built*, *The Queen's Matrimonial Ladder* (in favour of Queen Caroline), *The Man in the Moon*, *The Political Showman*, all illustrated by Cruikshank. Many of his squibs are directed against a certain "Dr Slop," a nickname given by him to Dr (afterwards Sir John) Stoddart, a writer in the *Times*. In researches for his defence he had come upon some curious and at that time little trodden literary ground, and the results were shown by his publication in 1820 of his *Apocryphal New Testament*, and in 1823 of his *Ancient Mysteries Explained*. He proposed in 1820 to write a *History of Parody*, but this never appeared. In 1826 he published the *Every-day Book*, in 1827–8 the *Table-Book*, and in 1829 the *Year-Book*; all three were collections of curious information on manners, antiquities, and various other subjects.[1] These are the works by which Hone is best remembered. In preparing them he had the warm approval of Southey and the assistance of Charles Lamb, but pecuniarily they were not successful, and Hone was lodged in King's Bench prison for debt. Friends, however, again came to his assistance, and he was established in a coffee-house in Gracechurch Street; but this again, like most of his enterprises, ended in failure. Hone's attitude of mind had gradually changed to that of extreme devoutness, and during the latter years of his life he frequently preached in Weigh House Chapel, Eastcheap. In 1830 he edited Strutt's *Sports and Pastimes*, and, on the starting in 1832 of the *Penny Magazine*, he contributed to the first number. He was also for some years sub-editor of the *Patriot*. He died at Tottenham, 8th November 1842.

[1] According to a recent writer in *Notes and Queries* (6th S. i. 171), Hone remarked in conversation that he took the idea of the *Every-day Book* in 1814 from Defoe's *Time's Telescope*.

HONEY (Chin., *mē*; Sansk., *madhu*, mead, honey,—*cf.* A. S., *medo*, *medu*, mead; Greek, *μέλι*, in which *θ* or *δ* is changed into λ; Lat., *mel*; Fr., *miel*; A. S., *hunig*; Germ., *Honig*),[1] a sweet viscid liquid, obtained by bees chiefly from the nectaries of flowers, *i.e.*, those parts of flowers specially constructed for the elaboration of honey (see BOTANY, vol. iv. p. 134), and after transportation to the hive in the proventriculus or crop of the insects, discharged by them into the cells prepared for its reception. Whether the nectar undergoes any alteration within the crop of the bee is a point on which authors have differed. Some wasps, *e.g.*, *Myrapetra scutellaris*[2] and the genus *Nectarina*, collect honey. A honey-like fluid, which consists of a nearly pure solution of uncrystallizable sugar having the formula $C_6H_{14}O_7$ after drying in vacuo, and which is used by the Mexicans in the preparation of a beverage, is yielded by certain inactive individuals of *Myrmecocystus mexicanus*, Wesmael, the honey-ants or pouched ants (*hormigas mieleras* or *mochileras*) of Mexico.[3] The abdomen in these insects, owing to the distensibility of the membrane connecting its segments, becomes converted into a globular thin-walled sac by the accumulation within it of the nectar supplied to them by their working comrades (Wesmael, *Bull. de l'Acad. Roy. de Brux.*, v. 766, 1838). By the Rev. H. C. M'Cook, who discovered the insect in the Garden of the Gods, Colorado, the honey-bearers were found hanging by their feet, in groups of about thirty, to the roofs of special chambers in their underground nests, their large globular abdomens causing them to resemble "bunches of small Delaware grapes" (*Proc. Acad. Nat. Sci. Philad.*, 1879, p. 197). A bladder-like formation on the metathorax of another ant, *Crematogaster inflatus* (F. Smith, *Cat. of Hymenoptera*, pt. vi. pp. 136 and 200, pl. ix. fig. 1), which has a small circular orifice at each posterior lateral angle, appears to possess a function similar to that of the abdomen in the honey-ant.

It is a popular saying that where is the best honey there also is the best wool; and a pastoral district, since it affords a greater profusion of flowers, is superior for the production of honey to one under tillage.[4] Dry warm weather is that most favourable to the secretion of nectar by flowers. This they protect from rain by various internal structures, such as papillæ, cushions of hairs, and spurs, or by virtue of their position (in the raspberry, drooping), or the arrangement of their constituent parts. Dr A. W. Bennett (*How Flowers are Fertilized*, p. 31, 1873) has remarked that the perfume of flowers is generally derived from their nectar; the blossoms of some plants, however, as ivy and holly, though almost scentless, are highly nectariferous. The exudation of a honey-like or saccharine fluid, as has frequently been attested, is not a function exclusively of the flowers in all plants. A sweet material, the manna of pharmacy, *e.g.*, is produced by the leaves and stems of a species of ash, *Fraxinus Ornus*; and honey-secreting glands are to be met with on the leaves, petioles, phyllodes, stipules (as in *Vicia sativa*), or bracteæ (as in the *Marcgraviaceæ*) of a considerable number of different vegetable forms. The origin of the honey-yielding properties manifested specially by flowers among the several parts of plants has been carefully considered by Darwin, who regards the saccharine matter in nectar as a waste product of chemical changes in the sap, which, when it happened to be excreted within the envelopes of flowers, was utilized for the important object of cross-fertilization, and subsequently was much increased in quantity, and stored in various ways (see *Cross and Self Fertilization of Plants*, p. 402 *sq.*, 1876). It has been noted with respect to the nectar of the fuchsia that it is most abundant when the anthers are about to dehisce, and absent in the unexpanded flower.

Pettigrew is of opinion that few bees go more than two miles from home in search of honey. The number of blossoms visited in order to meet the requirements of a single hive of bees must be very great; for it has been found by A. S. Wilson ("On the Nectar of Flowers," *Brit. Assoc. Rep.*, 1878, p. 567) that 125 heads of common red clover, which is a plant comparatively abundant in nectar, yield but one gramme (15·432 grains) of sugar; and as each head contains about 60 florets, 7,500,000 distinct flower-tubes must on this estimate be exhausted for each kilogramme (2·204 lb) of sugar collected. Among the richer sources of honey are reckoned the apple, asparagus, asters, barberry, basswood (*Tilia americana*), and the European lime or linden (*T. europæa*), beans, bonesets (*Eupatorium*), borage, broom, buckwheat, catnip, or catmint (*Nepeta Cataria*), cherry, cleome, clover, cotton, crocus, currant, dandelion, eucalyptus, figwort (*Scrophularia*), furze, golden-rod (*Solidago*), gooseberry, hawthorn, heather, hepatica, horehound, hyacinth, lucerne, maple, mignonette, mint, motherwort (*Leonurus*), mustard, onion, peach, pear, poplar, quince, rape, raspberry, sage, silver maple, snapdragon, sour-wood (*Oxydendron arboreum*, D.C.), strawberry, sycamore, teasel, thyme, tulip-tree (more especially rich in pollen), turnip, violet, and willows, and the "honey-dew" of the leaves of the whitethorn (Bonner), oak, linden, beech, and some other trees.

Honey contains dextroglucose and lævoglucose (the former practically insoluble, the latter soluble in $\frac{1}{8}$ pt. of cold strong alcohol), cane-sugar (according to some), mucilage, water, wax, essential oil, colouring bodies, a minute quantity of mineral matter, and pollen. By a species of fermentation, the cane-sugar is said to be gradually transformed into inverted sugar (lævoglucose with dextroglucose). The pollen, as a source of nitrogen, is of importance to the bees feeding on the honey. It may be obtained for examination as a sediment from a mixture of honey and water. Other substances which have been discovered in honey are mannite (Guibourt), a free acid which precipitates the salts of silver and of lead, and is soluble in water and alcohol (Calloux), and an uncrystallizable sugar, nearly related to inverted sugar (Soubeiran, *Compt. Rend.*, xxviii. 774–75, 1849). Brittany honey contains *couvain*, a ferment which determines its active decomposition (Wurtz, *Dict. de Chem.*, ii. 430). In the honey of *Polybia apicipennis*, a wasp of tropical America, cane-sugar occurs in crystals of large size (Karsten, *Pogg. Ann.*, C. 550). Dr J. Campbell Brown ("On the Composition of Honey," *Analyst*, iii. 267, 1878) is doubtful as to the presence of cane-sugar in any one of nine samples, from various sources, examined by him. The following average percentage numbers are afforded by his analyses:—lævulose, 36·45; dextrose, 36·57; mineral matter, ·15; water expelled at 100° C., 18·5, and at a much higher temperature, with loss, 7·81: the wax, pollen, and insoluble matter vary from a trace to 2·1 per cent. The specific gravity of honey is about 1·41. The rotation of a polarized ray by a solution of 16·26 grammes of crude honey in 100 c.c. of water is generally from $-3·2°$ to $-5°$ at 60° F.; in the case of Greek honey it is nearly $-5·5°$. Almost all pure honey, when exposed for some time to light and cold, becomes more or less granular in consistency. Any liquid portion can be readily separated by straining through linen. Honey sold out of the comb is commonly clarified by heating and skimming; but according to Bonner it is always best in its natural state. The *mel depuratum* of British pharmacy is prepared by heating honey in a water-bath, and straining through flannel previously moistened with warm water.

The term "virgin-honey" (A.-S., *hunigtear*) is applied to the honey of young bees which have never swarmed, or to that which flows spontaneously from honeycomb with or

[1] The term honey in its various forms is peculiar to the Teutonic group of languages, and in the Gothic New Testament is wanting, the Greek word being there translated *melith*.

[2] See A. White, in *Ann. and Mag. Nat. Hist.*, vii. 315, pl. 4.

[3] Wetherill (*Chem. Gaz.*, xi. 72, 1853) calculates that the average weight of the honey is 8·2 times that of the body of the ant, or 0·3942 grammes.

[4] Compare Isa. vii. 15, 22, where curdled milk (A.V., "butter") and honey as exclusive articles of diet are indicative of foreign invasion, which turns rich agricultural districts into pasture lands or uncultivated wastes.

without the application of heat. The honey obtained from old hives, considered inferior to it in quality, is ordinarily darker, thicker, and less pleasant in taste and odour. The yield of honey is less in proportion to weight in old than in young or virgin combs. The far-famed honey of Narbonne is white, very granular, and highly aromatic; and still finer honey is that procured from the Corbières mountains, 6 to 9 miles to the south-west. The honey of Gâtinais is usually white, and is less odorous, and granulates less readily than that of Narbonne. Honey from white clover has a greenish-white, and that from heather a rich golden-yellow hue. What is made from honey-dew is dark in colour, and disagreeable to the palate, and does not candy like good honey. "We have seen aphide honey from sycamores," says F. Cheshire (*Pract. Bee-Keeping*, p. 74), "as deep in tone as walnut liquor, and where much of it is stored the value of the whole crop is practically *nil*." The honey of the stingless bees (*Melipona* and *Trigona*) of Brazil varies greatly in quality according to the species of flowers from which it is collected, some kinds being black and sour, and others excellent (F. Smith, *Trans. Ent. Soc.*, 3d ser., i. pt. vi., 1863). That of *Apis Peronii*, of India and Timor, is yellow, and of very agreeable flavour, and is more liquid than the British sorts. *A. unicolor*, a bee indigenous to Madagascar, and naturalized in Mauritius and the island of Réunion, furnishes a thick and syrupy, peculiarly scented green honey, highly esteemed in Western India. A rose-coloured honey is stated (*Gard. Chron.*, 1870, p. 1698) to have been procured by artificial feeding. The fine aroma of Maltese honey is due to its collection from orange blossoms. Narbonne honey being harvested chiefly from Labiate plants, as rosemary, an imitation of it is sometimes prepared by flavouring ordinary honey with infusion of rosemary flowers.

Adulterations of honey are starch, detectable by the microscope, and by its blue reaction with iodine, also wheaten flour, gelatin, chalk, gypsum, pipe-clay, added water, cane-sugar, and common syrup, and the different varieties of manufactured glucose. Honey sophisticated with glucose containing copperas as an impurity is turned of an inky colour by liquids containing tannin, as tea. Elm leaves have been used in America for the flavouring of imitation honey. Stone jars should be employed in preference to common earthenware for the storage of honey, which acts upon the lead glaze of the latter.

Honey is mildly laxative in properties. Some few kinds are poisonous, as frequently the reddish honey stored by the Brazilian wasp *Nectarina* (*Polistes*, Latr.[1]) *Lecheguana*, Shuck., the effects of which have been vividly described by Aug. de Saint-Hilaire,[2] the spring honey of the wild bees of East Nepaul, said to be rendered noxious by collection from rhododendron flowers (Hooker, *Himalayan Journals*, i. 190, ed. 1855), and the honey of Trebizond, which from its source, the blossoms, it is stated, of *Azalea pontica* and *Rhododendron ponticum* (perhaps to be identified with Pliny's *Ægolethron*), acquires the qualities of an irritant and intoxicant narcotic, as described by Xenophon (*Anab.*, iv. 8). Pliny (*Nat. Hist.*, xxi. 45) describes as noxious a livid-coloured honey found in Persia and Gætulia. Honey obtained from *Kalmia latifolia*, L., the calico bush, mountain laurel, or spoon-wood of the northern United States, and allied species, is reputed deleterious; also that of the sour-wood is by some good authorities considered to possess undeniable griping properties; and G. Bidie (*Madras Quart. Journ. Med. Sci.*, Oct. 1861, p. 399) mentions urtication, headache, extreme prostration and nausea, and intense thirst among the symptoms produced by a small quantity only of a honey from Coorg jungle. A South African species of *Euphorbia*, as was experienced by the missionary Moffat (*Miss. Lab.*, p. 32, 1846), yields a poisonous honey. The nectar of certain flowers is asserted to cause even in bees a fatal kind of vertigo. As a demulcent and flavouring agent, honey is employed in the *oxymel*, *oxymel scillæ*, *mel boracis*, *confectio piperis*, *conf. scammonii*, and *conf. terebinthinæ* of the *British Pharmacopœia*. To the ancients honey was of very great importance as an article of diet, being almost their only available source of sugar. It was valued by them also for its medicinal virtues; and in recipes of the Saxon and later periods it is a common ingredient.[3] Of the eight kinds of honey mentioned by the great Indian surgical writer Susruta, four are not described by recent authors, viz., *argha*, or wild honey, collected by a sort of yellow bee; *chhatra*, made by tawny or yellow wasps; *audálaka*, a bitter and acrid honey-like substance found in the nest of white ants; and *dála*, or unprepared honey occurring on flowers. According to Hindu medical writers, honey when new is laxative, and when more than a year old astringent (U. C. Dutt, *Mat. Med. of the Hindus*, p. 277, 1877). Ceromel, formed by mixing at a gentle heat one part by weight of yellow wax with four of clarified honey, and straining, is used in India and other tropical countries as a mild stimulant for ulcers in the place of animal fats, which there rapidly become rancid and unfit for medicinal purposes. The *Koran*, in the chapter entitled "The Bee," remarks with reference to bees and their honey: "There proceedeth from their bellies a liquor of various colour, wherein is a medicine for men" (Sale's *Koran*, chap. xvi.). Pills prepared with honey as an excipient are said to remain unindurated, however long they may be kept (*Med. Times*, 1857, i. 269). Mead, of yore a favourite beverage in England (vol. iv. p. 264), is made by fermentation of the liquor obtained by boiling in water combs from which the honey has been drained. In the preparation of sack-mead, an ounce of hops is added to each gallon of the liquor, and after the fermentation a small quantity of brandy. Metheglin, or hydromel, is manufactured by fermenting with yeast a solution of honey flavoured with boiled hops (see Cooley, *Cyclop.*). A kind of mead is largely consumed in Abyssinia (vol. i. p. 64), where it is carried on journeys in large horns (Stern, *Wanderings*, p. 317, 1862). In Russia a drink termed *lipetz* is made from the delicious honey of the linden. The *mulsum* of the ancient Romans consisted of honey, wine, and water boiled together. The *clarre*, or *piment*, of Chaucer's time was wine mixed with honey and spices, and strained till clear; a similar drink was *bracket*, made with wort of ale instead of wine. L. Maurial (*L'Insectologie Agricole* for 1868, p. 206) reports unfavourably as to the use of honey for the production of alcohol; he recommends it, however, as superior to sugar for the thickening of liqueurs, and also as a means of sweetening imperfectly ripened vintages. It is occasionally employed for giving strength and flavour to ale. In ancient Egypt it was valued as an embalming material; and in the East, for the preservation of fruit, and the making of cakes, sweatmeats, and other articles of food, it is largely consumed. Grafts, seeds, and birds' eggs, for transmission to great distances, are sometimes packed in honey. In India a mixture of honey and milk, or of equal parts of curds, honey, and clarified butter (Sansk., *madhu-parka*), is a respectful offering to a guest, or to a bridegroom on his arrival at the door of the bride's father; and one of the purificatory ceremonies of the Hindus (Sansk., *madhu-prāsana*) is the placing of a little honey in the mouth of a new-born male infant. Honey is frequently alluded to by the writers of antiquity as food for children; it is not to this, however, as already mentioned,

[1] *Mémoires du Muséum*, xi. 313, 1824.

[2] *Ib.*, xii. 293, pl. xii. fig. B, 1825. The honey, according to Lassaigne (*ib.*, ix. 319), is almost entirely soluble in alcohol.

[3] For a list of fifteen treatises concerning honey, dating from 1625 to 1868, see Waring, *Bibl. Therap.*, ii. 559, New Syd. Soc., 1879. On sundry ancient uses for honey, see Beckmann, *Hist. of Invent.*, i. 287, 1846.

that Isa. vii. 15 refers. Cream or fresh butter together with honey, and with or without bread, is a favourite dish with the Arabs.

Among the observances at the Fandròana, or New Year's Festival, in Madagascar, is the eating of mingled rice and honey by the queen and her guests; in the same country honey is placed in the sacred water of sprinkling used at the blessing of the children previous to circumcision (Sibree, *The Great African Is.*, pp. 219, 314, 1880). Honey was frequently employed in the ancient religious ceremonies of the heathen, but was forbidden as a sacrifice in the Jewish ritual (Lev. ii. 11). With milk or water it was presented by the Greeks as a libation to the dead (*Odyss.*, xi. 27; Eurip., *Orest.*, 115). A honey-cake was the monthly food of the fabled serpent-guardian of the Acropolis (Herod., viii. 41). By the aborigines of Peru honey was offered to the sun.

The Hebrew word translated "honey" in the authorized version of the English Bible is *debash*, practically synonymous with which are *ja'ar* or *ja'arith had-debash* (1 Sam. xix. 25–27; *cf.* Cant. v. 1) and *nopheth* (Ps. xix. 10, &c.), rendered "honey-comb." *Debash* denotes bee-honey (as in Deut. xxxii. 13, and Jud. xiv. 8); the manna of trees, by some writers considered to have been the "wild honey" eaten by John the Baptist (Matt. iii. 4); the syrup of dates or the fruits themselves; and probably in some passages (as Gen. xliii. 11 and Ez. xxvii. 17) the syrupy boiled juice of the grape, resembling thin molasses, in use in Palestine, especially at Hebron, under the name of *dibs* (see Kitto, *Cyclop.*, and E. Robinson, *Bibl. Res.*, ii. 81). Josephus (*B. J.*, iv. 8, 3) speaks highly of a honey produced at Jericho, consisting of the expressed juice of the fruit of palm trees; and Herodotus (iv. 194) mentions a similar preparation made by the Gyzantians in North Africa, where it is still in use. The honey most esteemed by the ancients was that of Mount Hybla in Sicily, and of Mount Hymettus in Attica (vol. iii. p. 59). Mahaffy (*Rambles in Greece*, p. 148, 2d ed., 1878) describes the honey of Hymettus as by no means so good as the produce of other parts of Greece—not to say of the heather hills of Scotland and Ireland. That of Thebes, and more especially that of Corinth, which is made in the thymy hills towards Cleonæ, he found much better (*cf.* vol. xi. p. 88). Honey and wax, still largely obtained in Corsica (vol. vi. p. 440), were in olden times the chief productions of the island. In England, in the 13th and 14th centuries, honey sold at from about 7d. to 1s. 2d. a gallon, and occasionally was disposed of by the swarm or hive, or *ruscha* (Rogers, *Hist. of Agric. and Prices in Eng.*, i. 418). At Wrexham, Denbigh, Wales, two honey fairs are annually held, the one on the Thursday next after the 1st September, and the other, the more recently instituted and by far the larger, on the Thursday following the first Wednesday in October. In Hungary the amounts of honey and of wax are in favourable years respectively about 190,000 and 12,000 cwt., and in unfavourable years, as, *e.g.*, 1874, about 12,000 and 3000 cwt. The hives there in 1870 numbered 617,407 (or 40 per 1000 of the population, against 45 in Austria). Of these 365,711 were in Hungary Proper, and 91,348 (87 per 1000 persons) in the Military Frontier (Keleti, *Uebersicht der Bevölk. Ungarns*, 1871; Schwicker, *Statistik d. K. Ungarn*, 1877). In Poland the system of bee-keeping introduced by Dolinowski has been found to afford an average of 40 lb of honey and wax and two new swarms per hive, the common peasant's hive yielding, with two swarms, only 3 lb of honey and wax. In forests and places remote from villages in Podolia and parts of Volhynia, as many as 1000 hives may be seen in one apiary. In the district of Ostrolenka, in the government of Plock, and in the woody region of Polesia, in Lithuania, a method is practised of rearing bees in excavated trunks of trees (Stanton, "On the Treatment of Bees in Poland," *Technologist*, vi. 45, 1866). When, in August, in the loftier valleys of Bormio, Italy, flowering ceases, the bees in their wooden hives are by means of spring-carts transported at night to lower regions, where they obtain from the buckwheat crops the inferior honey which serves them for winter consumption (*Ib.*, p. 38).

In Palestine, "the land flowing with milk and honey"[1] (Ex. iii. 17; Numb. xiii. 27), wild bees are very numerous, especially in the wilderness of Judæa, and the selling of their produce, obtained from crevices in rocks, hollows in trees, and elsewhere, is with many of the inhabitants a means of subsistence. Commenting on 1 Sam. xiv. 26, J. Roberts (*Oriental Illust.*) remarks that in the East "the forests literally flow with honey; large combs may be seen hanging on the trees, as you pass along, full of honey." In Galilee, and at Bethlehem and other places in Palestine, bee-keeping is extensively carried on. The hives are sun-burnt tubes of mud, about 4 feet in length and 8 inches in diameter, and, with the exception of a small central aperture for the passage of the bees, closed at each end with mud. These are laid together in long rows, or piled pyramidally, and are protected from the sun by a covering of mud and of boughs. The honey is extracted, when the ends have been removed, by means of an iron hook. (See Tristram, *Nat. Hist. of the Bible*, pp. 322 *sq.*, 2d ed., 1868). Apiculture in Turkey is in a very rude condition. The Bali-dagh, or "Honey Mount," in the plain of Troy, is so called on account of the numerous wild bees tenanting the caves in its precipitous rocks to the south. In various regions of Africa, as on the west, near the Gambia, bees abound. Cameron was informed by his guides that the large quantities of honey at the cliffs by the river Makanyazi were under the protection of an evil spirit, and not one of his men could be persuaded to gather any (*Across Africa*, i. 266). On the precipitous slopes of the Teesta valley, in India, the procuring of honey from the pendulous bees'-nests, which are sometimes large enough to be conspicuous features at a mile's distance, is the only means by which the idle poor raise their annual rent (Hooker, *Him. Journ.*, ii. 41).

To reach the large combs of *Apis dorsata* and *A. testacea*, the natives of Timor, by whom both the honey and young bees are esteemed delicacies, ascend the trunks of lofty forest trees by the use of a loop of creeper. Protected from the myriads of angry insects by a small torch only, they detach the combs from the under surface of the branches, and lower them by slender cords to the ground (Wallace, *Journ. Linn. Soc.*, Zool., vol. xi.). For additional facts concerning honey, and a sketch of the processes of apiculture usually adopted in the Old World, see the article BEE, vol. iii. pp. 484–503.

On honey, and bees and bee-keeping in general, see, besides the above-mentioned works, J. Bonner, *A New Plan for speedily increasing the number of Bee-hives in Scotland*, 1795, containing the substance of *The Bee-Master's Companion*, 1789, by the same author; V. Rendu, *Traité pratique sur les Abeilles*, 1838; Munn's *Honey Bee*, ed. by E. Bevan; J. Samuelson, *Humble Creatures*, pt. ii., 1860; H. Taylor, *The Bee-Keeper's Manual*, 6th ed., 1860; F. Cowan, *Curious Facts in the History of Insects*, pp. 174–215, 1865; A. Neighbour, *The Apiary*, 2d ed., 1866; W. E. Shuckard, *British Bees*, 1866; A. Pettigrew, *The Handy Book of Bees*, 1870; G. de Layens, *Élevage des Abeilles par les Procédés Modernes*, 1874; J. de Hidalgo Tablada, *Tratado de las Abejas*, Madr., 1875; A. J. Danyell, *The Italian System of Bee-Keeping*, 1876; and A. H. Hassall, *Food and its Adulterations*, p. 266, 1876. (F. H. B.)

HONEY-FARMING IN AMERICA.—So rapid of late years has been the development of bee-keeping in the United States, that the taking of steps to secure the fullest and most accurate details with respect to that industry has been deemed necessary by the commissioners of agriculture. It has been estimated by several intelligent bee-keepers that there are in the United States 700,000 hives of bees, owned by 35,000 people, of whom at least 30,000 are farmers possessing on an average not more than 3 hives each, the remaining 5000 being professional apiarians. Mr G. M. Doolittle, of Borodino, N.Y., on the Auburn branch of the New York Central Railway, obtained in 1877 an average of 100 lb of honey apiece from his hives, and from one of them the exceptionally large yield of 700 lb. It is not unreasonable to say that the hives in the United States afford each a net supply of about 50 lb of surplus honey, which, selling at 20 cents (10d.) per lb, returns a good profit to the owners. All American honey is classed by the apiculturist according to the plants from which it is derived. It is only in rare cases that pasturage is specially cultivated for the bees. In the States east of the Rocky Mountains there are three chief sources of honey. Those which yield the most delicately flavoured and whitest and therefore most valuable commodity (see above) are, first, the immense forests of basswood, the honey from which has perhaps a slight minty flavour, and, secondly, white clover grass, cultivated throughout the States for hay and stock pasture, which furnishes a honey pronounced by competent judges superior to that of the world-renowned Hymettus. Bees having access to both basswood and white clover frequently store the honey from each in the same cells. The third and often richest source of supply is buckwheat, which blossoms after the basswood and white clover have ceased to yield. The pungent honey obtained therefrom, though by its dark colour rendered unsuitable for the table, is greatly valued for manufacturing purposes, more especially in the brewing of fine beer, since it forms a perfectly clear solution, ferments well, and is richer in saccharine matter than the glucose commonly employed by brewers, which moreover is apt to be contaminated with the acids employed in its preparation. Buckwheat honey is also accounted a good remedy in bronchial affections, and is therefore in request for the making of cough mixtures. The day is probably not far distant when the refining of the large quantities of dark honey which are harvested will be undertaken on an extensive scale.

For the successful prosecution of bee-keeping energy and perseverance, as well as experience and considerable capital, are requisite. There are not more than four bee-keepers in the United States who own so many as 2500 or 3000 hives. The largest apiaries are the property of Mr J. S. Harbison of California. They are six in number, and situated within easy patrol distance from one another

[1] In Sanskrit, *madhu-kulyā*, a stream of honey, is sometimes used to express an overflowing abundance of good things (Monier Williams, *Sansk.-Eng. Dict.*, p. 736, 1872).

in the extreme south-west corner of the United States, in a narrow strip of country known as the "bee-belt" of California, which enjoys the soft and equable climate of the Pacific coast. Timber in this region is confined to the bottoms near running streams, and to the cañons, the valleys and hill-sides being covered with stunted brushwood and an abundant growth of white sage,—an herb similar to the garden sage, and not to be confounded with the sagebrush of Nevada and Utah, which is a species of wormwood,—sumach, and other flowering plants. These bloom nine months in the year, but are most luxuriant in May and June. The white sage affords a honey comparable to that obtained from the basswood of the eastern States. The Californian honey, owing to the innocuous nature of the flowers from which it is procured, is devoid of the colic-producing properties ascribed to some other varieties of honey. Mr Harbison employs fifteen men in his apiaries, and is reaping rich profits from very many thousands of acres useless for ordinary purposes. Active operations begin in February, and in March or April the bees swarm. The taking of the honey commences usually about May 20th. From the early part of August till as late as October the flowers provide no more honey than is just sufficient for the subsistence of the bees. When October has begun, though the air is still mild, the bees cease to work, becoming semi-dormant, except for an hour or two every eight or ten days, when they fly near their hives in the sunshine. The fact that honey until the middle of the 16th century was the only sweet in general use, and that the aggregate annual consumption of sugar is now from 2 to 2½ millions of tons, points to the conclusion that apiculture, if skilfully and extensively conducted, might ere long become productive of results of very high importance to commerce. For further information regarding American honey-farming see *The American Bee Journal*, *The Bee-Keepers' Exchange*, *Gleanings in Bee Culture*, and *The Bee-Keepers' Magazine*.

HONEY-EATER, or HONEY-SUCKER, names applied by many writers in a very loose way to a large number of birds, some of which, perhaps, have no intimate affinity; but here to be used, as before in this work (BIRDS, vol. iii. p. 739), in a more restricted sense for what, in the opinion of a good many recent authorities,[1] should really be deemed the Family *Meliphagidæ*—excluding therefrom the *Nectariniidæ* or SUN-BIRDS (which see) as well as the genera *Promerops* and *Zosterops* with whatever allies they may possess. Even with this restriction, the extent of the Family must be regarded as very indefinite, owing to the absence of materials sufficient for arriving at a satisfactory conclusion, though the existence of such a Family is probably indisputable. Making allowance then for the imperfect light in which they must at present be viewed, what are here called *Meliphagidæ* include some of the most characteristic forms of the ornithology of the great Australian Region—members of the Family inhabiting almost every part of it, and a single species only, *Ptilotis limbata*, being said to occur outside its limits. They all possess, or are supposed to possess, a long protrusible tongue with a brush-like tip, differing, it is believed, in structure from that found in any other bird,—*Promerops* perhaps excepted,—and capable of being formed into a suctorial tube, by means of which honey is absorbed from the nectary of flowers, though it would seem that insects attracted by the honey furnish the chief nourishment of many species, while others undoubtedly feed to a greater or less extent on fruits. The *Meliphagidæ*, as now considered, are for the most part small birds, never exceeding the size of a Mistletoe-Thrush; and they have been divided into more than 20 genera, containing above 200 species, of which only a few can here be particularized. Most of these species have a very confined range, being found perhaps only on a single island or group of islands in the Region, but there are a few which are more widely distributed—such as *Glycyphila rufifrons*, the White-throated[2] Honey-eater, found over the greater part of Australia and Tasmania. In plumage they vary much. Most of the species of *Ptilotis* are characterized by a tuft of white, or in others of yellow, feathers springing from behind the ear. In the greater number of the genus *Myzomela*[3] the males are recognizable by a gorgeous display of crimson or scarlet, which has caused one species, *M. sanguinolenta*, to be known as the Soldier-bird to Australian colonists; but in others no brilliant colour appears, and those of several genera have no special ornamentation, while some have a particularly plain appearance. One of the most curious forms is *Prosthemadera*—the Tui or Parson-bird of New Zealand, so called from the two tufts of white feathers which hang beneath its chin in great contrast to its dark silky plumage, and suggest a likeness to the bands worn by ministers of several religious denominations when officiating.[4] The Bell-bird of the same island, *Anthornis melanura*—whose melody excited the admiration of Cook the morning after he had anchored in Queen Charlotte's Sound—is another member of this Family, and unfortunately seems to be fast becoming extinct. But it would be impossible here to enter much further into detail, though the Wattle-birds, *Anthochæra*, of Australia have at least to be named. Mention, however, must be made of the Friar-birds, *Tropidorhynchus*, of which nearly a score of species, five of them belonging to Australia, have been described. With their stout bills, mostly surmounted by an excrescence, they seem to be the most abnormal forms of the Family, and most of them are besides remarkable for the baldness of some part at least of their head. They assemble in troops, sitting on dead trees, with a loud call, and are very pugnacious, frequently driving away Hawks and Crows. Mr Wallace (*Malay Archipelago*, ii. pp. 150–153) discovered the curious fact that two species of this genus,—*P. bourensis* and *P. subcornutus*,—respectively inhabiting the islands of Bouru and Ceram, were the object of natural "mimicry" on the part of two species of Oriole of the genus *Mimeta*, *M. bourouensis* and *M. forsteni*, inhabiting the same islands, so as to be on a superficial examination identical in appearance,—the Honey-eater and the Oriole of each island presenting exactly the same tints, —the black patch of bare skin round the eyes of the former, for instance, being copied in the latter by a patch of black feathers and even the protuberance on the beak of the *Tropidorhynchus* being imitated by a similar enlargement of the beak of the *Mimeta*. The very reasonable explanation which Mr Wallace offers is that the pugnacity of the former has led the smaller Birds-of-prey to respect it, and it is therefore an advantage for the latter, being weaker and less courageous, to be mistaken for it. (A. N.)

HONEY-GUIDE, a bird so called from its habit or supposed habit of pointing out to man and to the Ratel (*Mellivora capensis*) the nests of bees. Stories to this effect have been often told, and may be found in the narratives of many African travellers, from Bruce to Livingstone. Yet Mr Layard says (*B. South Africa*, p. 242) that the birds will not unfrequently lead any one to a leopard or a snake, and will follow a dog with vociferations,[5] so that at present judgment may perhaps be suspended on the matter, though its noisy cry and antics unquestionably have in

[1] Among them especially Mr Wallace, *Geogr. Distr. Animals*, ii. p. 275.

[2] It may be remarked that the young of this species has the throat yellow.

[3] Mr W. A. Forbes has published a careful monograph of this genus in the *Proceedings of the Zoological Society* for 1879, pp. 256–279.

[4] This bird, according to Mr Buller (*Birds of New Zealand*, p. 88), while uttering its wild notes, indulges in much gesticulation, which adds to the suggested resemblance. It has great power of mimicry, and is a favourite cage-bird both with the natives and colonists. On one occasion, says this gentleman, he had addressed a large meeting of Maories on a matter of considerable political importance, when "immediately on the conclusion of my speech, and before the old chief to whom my arguments were chiefly addressed had time to reply, a Tui, whose netted cage hung to a rafter overhead, responded in a clear emphatic way, 'Tito!' (false). The circumstance naturally caused much merriment among my audience, and quite upset the gravity of the venerable old chief Nepia Taratoa. 'Friend,' said he, laughing, 'your arguments are very good; but my *mokai* is a very wise bird, and he is not yet convinced!'"

[5] This is also a well-known habit with some *Corvidæ*—the Jays and Pies for example.

many cases the effect signified by its English name. If not its first discoverer, Sparrman, in 1777, was the first who described and figured this bird, which he met with in the Cape Colony (*Phil. Transactions*, lxvii. pp. 42-47, pl. i.), giving it the name of *Cuculus indicator*, its zygodactylous feet with the toes placed in pairs—two before and two behind—inducing the belief that it must be referred to that genus. Vieillot in 1816 elevated it to the rank of a genus, *Indicator*; but it was still considered to belong to the Family *Cuculidæ* (its asserted parasitical habits lending force to that belief) by all systematists except Blyth and Jerdon, until it was shewn by Mr Blanford (*Obs. Geol. and Zool. Abyssinia*, pp. 308, 309) and Mr Sclater (*Ibis*, 1870, pp. 176–180) that it was more allied to the Barbets, *Capitonidæ*, and, in consequence, was then made the type of a distinct Family, *Indicatoridæ*. In the meanwhile other species had been discovered, some of them differing sufficiently to warrant Sundevall's foundation of a second genus, *Prodotiscus*, of the group. The Honey-Guides are small birds, the largest hardly exceeding a Lark in size, and of plain plumage, with what appears to be a very Sparrow-like bill. Mr Sharpe, in a revision of the Family published in 1876 (*Orn. Miscellany*, i. pp. 192–209), recognizes ten species of the genus *Indicator*, to which another has since been added by Dr Reichenow (*Journ. für Ornithologie*, 1877, p. 110), and two of *Prodotiscus*. Four species of the former, including *I. sparrmani*, which was the first made known, are found in South Africa, and one of the latter. The rest inhabit other parts of the same continent, except *I. archipelagicus*, which seems to be peculiar to Borneo, and *I. xanthonotus*, which occurs on the Himalayas from the borders of Afghanistan to Bhotan. The interrupted geographical distribution of this genus is a very curious fact, no species having been found in the Indian or Malayan peninsula to connect the outlying forms with those of Africa, which must be regarded as their metropolis. (A. N.)

HONEYSUCKLE (M.E., *honysocle*, *i.e.*, any plant from which honey may be sucked,—*cf.* Ang.-Sax., *huni-suge*, privet; Germ., *Geissblatt*; Fr., Chèvrefeuille), *Lonicerus*, L., a genus of climbing, erect, or prostrate shrubs, of the natural order *Caprifoliaceæ*, so named after the German botanist Adam Lonicer. The British species are *L. Periclymenum*, the woodbine, *L. Caprifolium*, and *L. Xylosteum*. Some of the garden varieties of the woodbine are very beautiful, and are held in high esteem for their delicious fragrance; even the wild plant, with its pale flowers, compensating for its sickly looks "with never-cloying odours." The North American sub-evergreen *L. sempervirens*, with its fine heads of blossoms, commonly called the trumpet honeysuckle, is a distinct and beautiful species producing both scarlet and yellow flowered varieties, and the Japanese *L. brachypoda aureo-reticulata* is esteemed for its charmingly variegated leaves. The fly honeysuckle, *L. Xylosteum*, a hardy shrub of dwarfish erect habit, and *L. tatarica*, of similar habit, both European, are amongst the oldest English garden shrubs, and bear axillary flowers of various colours, occurring two on a peduncle. There are numerous other species, many of them introduced to our gardens, and well worth cultivating in shrubberies or as climbers on walls and bowers, either for their beauty or the fragrance of their blossoms.

Honeysuckle.

In the western counties of England, and generally by agriculturists, the name honeysuckle is applied to the meadow clover, *Trifolium pratense*. Another plant of the same leguminous family, *Hedysarum coronarium*, a very handsome hardy biennial often seen in old-fashioned collections of garden plants, is commonly called the French honeysuckle. The name is moreover applied with various affixes to several other totally different plants. Thus white honeysuckle and false honeysuckle are names for the North American *Azalea viscosa*; Australian or heath honeysuckle is the Australian *Banksia serrata*, Jamaica honeysuckle the *Passiflora laurifolia*, dwarf honeysuckle the widely spread *Cornus suecica*, Virgin Mary's honeysuckle the European *Pulmonaria officinalis*, while West Indian honeysuckle is the *Tecoma capensis*, and is also a name applied to *Desmodium*.

The wood of the fly honeysuckle is extremely hard, and the clear portions between the joints of the stems, when their pith has been removed, are stated by Linnæus to be utilized in Sweden for making tobacco-pipes. The wood is also employed to make teeth for rakes; and, like that of *L. tatarica*, it is a favourite material for walking-sticks.

HONFLEUR, a town of France, at the head of a canton in the arrondissement of Pont l'Évêque in the department of Calvados, is situated on the south side of the estuary of the Seine directly opposite Havre, and about 10 miles to the north of Pont l'Évêque and 37 miles to the north-east of Caen. With the general railway system of northern France it is connected by a line running by Pont l'Évêque to Lisieux; and a concession was granted in 1879 for another line to Pont-Audemer. As a town Honfleur has the typical aspect of a small old-fashioned seaport, equally heedless of symmetry in its plan and cleanliness in its economy. The most noteworthy of its buildings is the church of St Catherine, constructed entirely of timber work and plaster, and consisting of two parallel naves, of which the more ancient is supposed to date from the end of the 15th century. A process of restoration is at present (1880) going on under Government supervision. Within the church are several antique statues and a painting by Jordaens—Jesus in the Garden of Gethsemane. The church tower stands on the other side of a street. St Leonard's dates from the 17th century, with the exception of its fine ogival portal and rose-window belonging to the 16th, and its octagonal tower erected in the 18th. The ruins of a 16th century castle, and several houses of the same period, are the only buildings of antiquarian interest. The town-house, which contains the exchange and the commercial court, is of modern erection. On the rising ground above the town is the chapel of Notre Dame de Grâce, a shrine much resorted to by pilgrim sailors, which was founded in 1034 by Robert the Magnificent of Normandy, and rebuilt in 1606. Honfleur is the seat of a commercial college, a school of hydrography, a chamber of commerce, a custom-house, and various other Government offices, as well as of several consular establishments. The harbour, which consists of three basins, has been greatly improved between 1860 and 1875 by the extension of the pier and the formation of a new channel, which has a depth of 21 feet at neap tides and of 24 to 27 at spring-tides; and a fourth basin, decreed by the Government in 1879, will be completed by 1881. A reservoir of 120 acres in extent affords the means of sluicing the channel. In 1878 the gross returns of the shipping showed 894 vessels, of which 586 were British, 118 Norwegian, and 62 French, the total burthen amounting to 200,939 tons; and there were besides 840 French coasting vessels, with 48,000 tons. The export trade consists almost exclusively of eggs (from 10 to 12 million dozens yearly), poultry, table-fruits, nuts, butter (9 to 12 million lb), and similar produce for the London market; and the principal imports are coals, iron, wheat and oats, cement, wool, and marble, also deals from Norway, Sweden, and Russia, and oak timber from Germany. In 1879 the wheat imported from the United States amounted to 64,000 tons. Shipbuilding was formerly an extensive industry in Honfleur, most of the vessels of from 400 to 1200 tons belonging to the Havre shipowners issuing from its yards; but the number now laid on the stocks is very small. Saw-mills, oil-factories, soap-works, paper-mills, and marble-works are the main industrial establishments. The population of Honfleur, estimated at 8800 shortly before the great Revolution, was 9946 in 1872. In 1876 the census showed 9037 inhabitants in the town and 9425 in the commune.

Honfleur, Latinized as *Honflorium*, dates from the 11th century, and is thus four or five hundred years older than its greater rival Havre. During the English wars it was frequently taken and retaken, the longest English occupation being from 1430 to 1440. In 1562 the Protestant forces got possession of it only after a regular siege of the faubourg St Léonard; and though Henry IV. effected its capture in 1590 he had again to invest it in 1594 after all the rest of Normandy had submitted to his arms. In the earlier years of the 17th century Honfleur colonists founded Quebec, and Honfleur traders under Binot Paulmier established factories in Java and Sumatra. The German troops occupied the town in February 1871. Among the local celebrities are the admirals Doublet, Boitard, and Hamelin.

HONG-KONG, properly HIANG-KIANG (the place of "sweet streams"), an important British island-possession, situated off the south-east coast of China, opposite the province of Kwang-tung, on the east side of the estuary of the Chu-Kiang or Canton river, 38 miles east of Macao and 75 south-east of Canton, between 22° 9′ and 22° 1′ N. lat. and 114° 5′ and 114° 18′ E. long. It is one of a small cluster named by the Portuguese "Ladrones" or Thieves, on account of the notorious habits of their old inhabitants. Extremely irregular in outline, it has an area of 29 square miles, measuring 10½ miles in extreme length from north-east to south-west, and varying in breadth from 2 to 5 miles. From the mainland it is separated by a narrow channel, which at Hong-Kong roads, between Victoria, the island capital, and Kau-lung Point, is about one mile broad, and which narrows at Ly-ce-moon Pass to little over a quarter of a mile. The southern coast in particular is deeply indented; and there two bold peninsulas, extending for several miles into the sea, form two capacious natural harbours, namely, Deep Water Bay, with the village of Stanley to the east, and Tytam Bay, which has a safe, well-protected entrance showing a depth of 10 to 16 fathoms. An in-shore island on the west coast, called Aberdeen or Taplichan, affords protection to the Shekpywan or Aberdeen harbour, an inlet provided with a granite graving dock, the caisson gate of which is 60 feet wide, and the Hope dock, opened in 1867, with a length of 425 feet and a depth of 24 feet. Opposite the same part of the coast, but nearly 2 miles distant, rises the largest of the surrounding islands, the Lamma, whose conspicuous peak, Mount Stenhouse, attains a height of 1140 feet, and is a landmark for local navigation. On the northern shore of Hong-Kong there is a patent slip at East or Matheson Point, which is serviceable during the north-east monsoon, when sailing vessels frequently approach Victoria through the Ly-ce-moon Pass. The ordinary course for such vessels is from the westward, on which side they are sheltered by Green Island and Kellett Bank. There is good anchorage throughout the entire channel separating the island from the mainland, except in the Ly-ce-moon Pass, where the water is deep; the best anchorage is in Hong-Kong roads, in front of Victoria, where, over good holding ground, the depth is 5 to 9 fathoms. The inner anchorage of Victoria Bay, about half a mile off shore and out of the strength of the tide, is 6 to 7 fathoms. Victoria, the seat alike of government and of trade, is the chief centre of population, but in recent years a tract of 4 square miles on the mainland has been covered with public buildings and villa residences. Practically an outlying suburb of Victoria, Kau-lung (Nine Dragons), or as it is commonly called Kowloon, is free from the extreme heat of the capital, being exposed to the south-west monsoon. Numerous villas have also been erected along the beautiful western coast of the island, while Stanley, in the south, has lately been attracting attention by its excellent qualifications as a watering-place.

The island is mountainous throughout, the low granite ridges, parted by bleak, tortuous valleys, leaving in some

Hong-Kong, with adjacent Coast and Islands.

places a narrow stripe of level coast-land, and in others overhanging the sea in lofty precipices. From the sea, and especially from the magnificent harbour which faces the capital, the general aspect of Hong-Kong is one of singular beauty. With something of the rugged grandeur of the western Scottish isles, and a suggestion of Italian softness and grace, it is distinguished by unmistakable traces of a purely tropical character. Inland the prospect is wild, dreary, and monotonous. The hills have a painfully bare appearance from the want of trees. The streams, which are plentiful, are traced through the uplands and glens by a line of straggling brushwood and rank herbage. Nowhere is the eye relieved by the grateful evidences of cultivation or fertility. The mountains, which are mainly composed of granite, serpentine, and syenite, rise in irregular masses to considerable heights, the loftiest point, Victoria Peak, reaching an altitude of 1825 feet. The Peak lies immediately to the south-west of the capital, in the extreme north-west corner of the island, and is used as a station for signalling the approach of vessels. Patches of land, chiefly around the coast, have been laid under rice, sweet potatoes, and yams, but the island is hardly able to raise a home-supply of vegetables. The mango, lichen, pear, and orange are indigenous, and to these the English have added several fruits and esculents. One of the chief products is building-stone, which is quarried by the Chinese. The animals are few, comprising a land tortoise, the armadillo, a species of boa, several poisonous snakes, and some woodcock. The public works suffer from the ravages of white ants. Water everywhere abounds, and is supplied to the shipping by means of tanks. Hong-Kong acquired the name of an extremely unhealthy place at the time of settlement, but it has been found that the mortality is only high in certain seasons. It is not free from a certain malaria which, according to Montgomery Martin, is thrown off by the decomposed rocks that have been baked by a strong sun during the day. The change from the heat and rain of summer (May to October) to the refreshing temperature of the cool season tends to produce disease of the kidneys, &c. During the years 1871–75 the mean temperature was 73° Fahr. in the shade, and the range from 56° to 84°, taking the mean readings for the months. Occasionally the thermometer registers below 40°, and on 26th February 1876, when extreme cold was experienced, water was frozen to the thickness of ¼ of an inch. The annual rainfall was 99·24 inches in 1871 and 83·43 in 1875. The population, which in 1841 was only 5000, had increased to 21,514 in 1848, to 37,058 in 1852, to 123,511 in 1862, and to 139,144 in 1876. According to the census of 1872, there were of Europeans and Americans 5931, of Chinese 115,444, and of natives of India, Goa, Manila, &c., 2623. Victoria was the residence of almost all the Europeans, and of the Chinese 83,487 (14,269 women) resided there, including a boat population of 12,309, while 10,507 resided in Kau-lung and other villages, and 11,400 were scattered along the coast in boats.

Formerly an integral part of China, the island was first ceded to Great Britain in 1841, and the cession was confirmed by the treaty of Nanking in 1842, the charter bearing date 5th April 1843. Kau-lung, temporarily occupied for several years as a military sanatarium, was ceded by a treaty contracted by Lord Elgin in 1861. The colony is under a governor, and an executive council comprising the colonial secretary, the commander of the troops, the attorney-general, and the auditor-general. The legislative council, presided over by the governor, is composed of all these officials (except the commander), with the addition of four unofficial members, nominated by the crown on the recommendation of the governor. The occupation of Hong-Kong was effected at a considerable outlay, but the parliamentary vote on its behalf was reduced from £50,000 in 1845 to £9200 in 1853, and since 1855 the colony has paid its local establishments. In 1868 it extinguished its debt, which had dwindled to £15,625, and it now pays £20,000 a year as military contribution to the imperial exchequer.

The capital, situated at the north-west extremity of the island, is laid out in fine wide streets and terraces. The buildings, mostly of stone and brick, are greatly superior to those of a Chinese city. The merchants' houses are elegant and spacious, with broad verandahs and tasteful gardens. Including the Chinese town, Victoria extends for 3 miles along the bay, towards which it slopes from the base of the hills. It is lighted with gas, and supplied with water from the Pokovfulun reservoir, which impounds 74 million gallons. The main thoroughfare is protected by a massive sea-wall, and the appearance of the town has been greatly improved by the construction of public gardens. Besides several handsome Government buildings, Victoria has a large exchange, a cathedral and bishop's palace, several good hospitals, extensive barracks, and a few higher class schools. A city hall with library and museum was opened in 1876, and the public works completed in that year (the extension of public gardens, construction of many miles of mountain path, and improvement of drainage) involving an outlay of £30,867. The educational provision of the Government in 1876 comprised 54 schools, with an attendance of 3111 pupils, and of these 16 with 1816 pupils were native schools, in which the language is Chinese. At the central school (556 pupils in 1876) there is a Chinese class for Europeans, as there is also in several of the missionary and "grant-in-aid" schools. Hong-Kong publishes, in addition to 5 English newspapers (2 daily), 1 in Chinese every second day and a Portuguese weekly. The streets are guarded by a strong force of Indian sepoys, and the natives are not allowed to go abroad after 8 o'clock at night without a pass; but the general character of the town is orderly, as is attested by the police returns, from which it appears that only 68 persons were convicted before the superior courts in 1875. The common mode of street conveyance is by chairs, which are carried by coolies, while the passage across to Kau-lung is usually effected in sampans or pull-away boats. Victoria has a few slight industries, including sugar-refining, rum-distilling, and ice-making. In 1877 the introduction of a steam laundry broke the monopoly of the dhoby. There are upwards of 500 Chinese hongs of a superior class belonging to ship compradores and to dealers in fancy goods, china ware, articles in gold and silver, opium and other drugs, rice, piece goods, tea, &c.

Although formerly the central point of the great European Chinese trade and still a thriving seat of commerce, Hong-Kong owes its present importance chiefly to its financial prominence as the head-quarters of the banking interest, and to its magnificent harbour, which makes it both the station of the British fleet and an entrepôt for the custom trade of all nations. In 1877 it was the residence of 14 foreign consuls, and had 10 large banking-houses. It still imports opium more largely than any other port, and among other articles of which it is the centre of trade are sugar, flour, salt, china ware, nut-oil, amber, cotton, sandalwood, ivory, betel, live stock, granite, and ship supplies. The principal transactions in tea and silk are controlled by firms residing in Hong-Kong. As it is a free port there are no exact returns of trade, but in 1877 the imports from Great Britain alone amounted to £3,645,068 and the exports thither to £1,895,310. Chief of these exports was tea, the value of which in 1876 was £839,568. In the same year the opium imported amounted to 96,985 piculs, as compared with 69,851 piculs received at all the other treaty ports. Of 3424 chests of Bengal opium imported in February 1876, 1500 passed into the hands of local consumers and 1924 were exported; at the same date there were 4800 chests in stock as compared with 1374 at Shanghai. There is an enormous passenger traffic: between the years 1871 and 1876 there have passed through the port no fewer than 15,000 Chinese coolies, of whom the majority have gone to the United States. In the year 1876 Queensland drafted hence as many as 8325 emigrants. Large steamers go and come almost daily, the ports in regular communication with Hong-Kong including Bombay, Calcutta, Singapore, Canton, San Francisco, Yokohama, and (since 1875) Sydney. The aggregate shipping that entered the port in 1878 amounted to 3,900,891 tons. Of this 45·2 per cent. were junks, 43·7 steamers, and 11·1 European and American built sailing vessels. Exclusive of native craft there entered and cleared (1876) 4,359,616 tons, of which 3,150,952 were in British and 1,208,664 in foreign vessels. The revenue in 1878, derived from land rents, fines, licences to sell opium, and spirits, &c., amounted to £197,424, the expenditure to £189,695; there is usually a surplus of revenue. At the 31st January 1877 the bank-notes in circulation were stated at $3,536,380, and the specie in reserve at $1,295,000. Hong-Kong has a dollar of its own coining (4s. 2d.), but its mint, which entailed a cost of £9,000 a year, has ceased to operate. Other coins in circulation are the Mexican dollar, Chinese taels and cash, the American trade dollar, and Japanese silver yen. A movement is at present on foot to have the last two coins placed on an equality with the Mexican dollar. The standard of value is 1000 Mexican dollars to 717 taels by weight. In spite of the great increase in recent years of the direct trade with the various treaty ports, the progress of Hong-Kong has been steady, and there is every probability of its maintaining its peculiar position of influence in the Chinese trade. In 1871 it was placed in telegraphic communication with England, and in its recent legislative action it has shown vitality and enterprise. The gambling practices which prevailed here, as they still do in many Chinese towns, have been vigorously suppressed, and the difficulties arising from the sudden development of the coolie emigration have been overcome. The presence of Chinese revenue cruisers in Hong-Kong waters has led (February 1880) to a storm of opposition on the part of resident British merchants, who declare that this amounts to a blockade of the island; but British officials uphold the action of China as a necessary check upon the opium and salt smuggling.

Legge, "The Colony of Hong-Kong," in *The China Review* (edited by Dennys), 1872. (A. M'D.)

HONITON, a municipal borough and market-town of England, county of Devon, is pleasantly situated on a rising ground on the left bank of the Otter and on the London and South-Western Railway, 16 miles E.N.E. of Exeter. It consists of one wide street about a mile in length, crossed by a smaller one at right angles. Along the main street there runs a small stream of water. The only buildings of importance are the old parish church, on an eminence about half a mile from the town, built by Courtenay, bishop of Exeter, about 1482, and possessing a curiously carved screen; the church of St Paul's (now the parish church) in the centre of the town, in the Norman style; the dispensary; the St Margaret's charity, originally erected as a hospital for lepers, but now used as almshouses; the union workhouse, erected in 1836, with accommodation for 250 inmates; the grammar school, the national schools, and the British school opened in 1878. The town is famed for its lace manufacture; and there are also breweries, malting establishments, flour mills, tanneries, brick and tile works, and an iron foundry. The population of the municipal borough in 1871 was 3464.

Honiton is supposed to have originated in a Roman settlement at Hembury fort, about 3 miles from the town, where there are still traces of an extensive camp conjectured to be the *Moridunum* of Antoninus. The town first sent members to parliament in the reign of Edward I., but after the reign of Edward II. the privilege was suspended until 1640. In 1867 its representation was limited to one member, and in 1868 it was disfranchised. It was incorporated as a municipal borough in 1846.

HONOLULU. See HAWAIIAN ISLANDS, vol. xi. p. 531.

HONORIUS, FLAVIUS AUGUSTUS, was emperor of the West from 397 to 425 A.D. His reign of twenty-eight years was one of the most eventful in the Roman annals; the weakness and timidity of the emperor co-operated with the attacks of the Goths and Vandals in promoting the rapid disintegration of the empire. But his influence on the current of events was purely negative, and his reign will be noticed under ROMAN HISTORY.

HONORIUS I., pope from 625 to 638, succeeded Boniface V. The festival of the Elevation of the Cross is said to have been instituted during his pontificate, which was marked also by considerable missionary enterprise. Honorius in his lifetime had favoured the formula proposed by the emperor Heraclius with the design of bringing about a reconciliation between the Monophysites and the Catholics, which bore that Christ had accomplished His work of redemption by one manifestation of His will as the God-man. For this he was, more than forty years after his death, anathematized by name along with the other Monothelite heretics by the council of Constantinople (First Trullan) in 680; and this condemnation was subsequently confirmed by more than one pope, particularly by Leo II., as has been abundantly proved by unimpeachable evidence against the contentions of Baronius and Bellarmine (see Hefele, *Die Irrlehre des Honorius u. das vaticanische Lehre der Unfehlbarkeit*, 1871, who, however, has modified his view in *Conciliengeschichte*, 1877). Honorius I. was succeeded by Severinus.

HONORIUS II.[1] (Lambert of Ostia), pope from 1124 to 1130, succeeded Calixtus II. As papal legate he had been one of the framers of the concordat of Worms (1122). During his pontificate the Præmonstratensian order, and also that of the Knights Templars, received papal sanction. His successor was Innocent II.

HONORIUS III., pope from 1216 to 1227, was the successor of Innocent III., whose uncompromising policy in the struggle between the papacy and the empire he had not firmness and vigour to continue. He consented to crown Frederick II. as Holy Roman emperor in 1220, although the engagements made with his predecessor had not been fulfilled; the promises which he himself had exacted he was somewhat slow to urge, and it was left to his successor Gregory IX. to insist upon their accomplishment. He gave papal sanction to the Dominican order in 1216, and to the Franciscan in 1223; and during his pontificate also many of the tertiary orders first came into existence.

HONORIUS IV. succeeded Martin IV., and was pope for two years (1285–1287). After an uneventful pontificate he was succeeded by Nicholas IV.

[1] This name had been assumed in the previous century (1061–64) by Peter Cadalus; but he never was recognized as a legitimate pope.

HONTHEIM, JOHANN NIKOLAUS VON (1701–1790), a zealous opponent of Ultramontanism, was born at Treves, January 27, 1701. After receiving his early education at the Jesuit college of his native town, he studied jurisprudence both there and at Louvain and Leyden. On obtaining the degree of doctor of laws at Treves in 1724 he took the ecclesiastical habit, and went to Rome in order to make himself acquainted with the forms of the curia. Returning to Treves in 1728, he was appointed ecclesiastical councillor of the consistory, in 1732 professor of law, in 1741 privy councillor of the archbishop, and in 1748 suffragan of the see. In 1750 he published at Treves *Historia Trevirensis diplomatica*, and in 1763, under the pseudonym of Justinus Febronius, *De Statu ecclesiæ et legitima potestate Romani Pontificis liber singularis*, in which he maintained the Gallican theory that the supreme authority of the church was vested not in the pope but in the general council. This work he in perfect simplicity and sincerity dedicated to Pope Clement XIII., who, however, condemned it and caused it to be burned at Rome. When Hontheim was discovered to be the author he was induced to make a retractation, but in his *Febronius abbreviatus et emendatus* (Vienna, 1771) and *Febronii commentarius* (Vienna, 1781) he nevertheless gave further currency to his old views. He died at Montquintin, Luxembourg, September 2, 1790.

HONTHORST, GERARD VAN (born at Utrecht 1590, died at Utrecht 1656), was brought up as a painter at the school of Bloemart, who exchanged the style of the Franckens for that of the pseudo-Italians at the beginning of the 16th century. Infected thus early with a mania which came to be very general in Holland, Honthorst went to Italy, where he copied the naturalism and eccentricities of Michelangelo da Caravaggio. Home again about 1614, after acquiring a considerable practice in Rome, he set up a school at Utrecht which flourished exceedingly; and he soon became so fashionable that Sir Dudley Carleton, then English envoy at the Hague, recommended his works to the earl of Arundel and Lord Dorchester. At the same time the queen of Bohemia, sister of Charles I. and electress palatine, being an exile in Holland, gave him her countenance and asked him to teach her children drawing; and Honthorst, thus approved and courted, became known to Charles I., who invited him to England. There he painted several portraits, and a vast allegory, now at Hampton Court, of Charles and his queen as Diana and Apollo in the clouds receiving the duke of Buckingham as Mercury and guardian of the king of Bohemia's children. Charles I., whose taste was flattered alike by the energy of Rubens and the elegance of Van Dyck, was thus first captivated by the fanciful mediocrity of Honthorst, who though a poor executant had luckily for himself caught, as Lord Arundel said, "much of the manner of Caravaggio's colouring, then so much esteemed at Rome." It was his habit to transmute every subject into a night scene, from the Nativity, for which there was warrant in the example of Correggio, to the penitence of the Magdalen, for which there was no warrant at all. But unhappily this caprice, though "sublime in Allegri and Rembrandt," was but a phantasm in the hands of Honthorst, whose prosaic pencil was not capable of more than vulgar utterances, and art gained little from the repetition of these quaint vagaries. Sandrart gave the measure of Honthorst's popularity at this period when he says that he had as many as twenty apprentices at one time, each of whom paid him a fee of 100 florins a year. In 1623 he was president of his guild at Utrecht. After that he went to England as above stated, returning to settle anew at Utrecht, where he married. His position amongst artists was acknowledged to be important, and in 1626 he received a visit from Rubens, whom he painted as the honest man sought for and found by Diogenes Honthorst. In his home at Utrecht Honthorst succeeded in preserving the support of the English monarch, for whom he finished in 1631 a large picture of the king and queen of Bohemia "and all their children." For Lord Dorchester about the same period he completed some illustrations of the *Odyssey*, one of which survives in the Weld-Blundell collection at Ince; for the king of Denmark he composed incidents of Danish history, of which one example remains in the gallery of Copenhagen. In the course of a large practice he had painted many likenesses—Charles I. and his queen, the duke of Buckingham, and the king and queen of Bohemia. He now became court painter to the princess of Orange, settled (1637) at the Hague, and painted in succession at the Castle of Ryswick and the House in the Wood. The time not consumed in producing pictures was devoted to portraits. Even now his works are very numerous, and amply represented in English and Continental galleries. His most attractive pieces are those in which he cultivates the style of Caravaggio, those, namely which represent taverns, with players, singers, and eaters. He shows great skill in reproducing scenes illuminated by a single candle. But he seems to have studied too much in dark rooms, where the subtleties of flesh colour are lost in the dusky smoothness and uniform redness of tints procurable from farthing dips. Of great interest still, though rather sharp in outline and hard in modelling, are his portraits of the Duke of Buckingham and Family (Hampton Court), the King and Queen of Bohemia (Hanover and Combe Abbey), Mary de Medici (Amsterdam town-hall, 1628), the Stadtholders and their Wives (Amsterdam and Hague), Charles Louis and Rupert, Charles I.'s nephews (Louvre, St Petersburg, Combe Abbey, and Willin), and Lord Craven (National Portrait Gallery). His early form may be judged by a Lute-player (1614) at the Louvre, the Martyrdom of St John in S. M. della Scala at Rome, or the Liberation of Peter in the Berlin Museum; his latest style is that of the House in the Wood (1648), where he appears to disadvantage by the side of Jordaens and others. Honthorst was succeeded by his brother William, born at Utrecht in 1604, who died it is said in 1666. He lived chiefly in his native place, temporarily at Berlin. But he has left little behind except a portrait at Amsterdam, and likenesses in the Berlin Museum of William and Mary of England.

HOOCH, Pieter de, a Dutch painter of note, was born it is thought about 1632, and died it is supposed in 1681 at Haarlem. Public records testify that he was a native of Rotterdam, and wandered early to Delft, where he married in 1654 and practised till 1657. From that time onward his life is obscure; and the only proofs of his existence to which we can point are the dates on his pictures, which range from 1658 to 1670. The registry of "Pieter de Hooge's" death at Haarlem on the 28th of February 1681 is believed to refer to our artist. Though neglected by his contemporaries, De Hooch is one of the kindliest and most charming painters of homely subjects that Holland has produced. He seems to have been born at the same time and taught in the same school as Van der Meer and Maes, but his works are more harmoniously coloured than those of Maes, and more boldly touched than those of Meer. In one respect all three are alike, being disciples of the school of Rembrandt. De Hooch only once painted a canvas of any size, and that unfortunately perished in a fire at Rotterdam in 1864. But his small pieces display perfect finish and great dexterity of hand, combined with that power of discrimination which accomplishes detail whilst avoiding rapidity and smoothness. Though he sometimes paints open-air scenes, these are not his favourite subjects. He is most at home in interiors, and his delight is to contrast in one picture the different atmospheres of rooms illuminated by different lights with the radiance of day as seen through doors and windows. He thus brings together the most delicate varieties of tone, and produces chords that vibrate with harmony. The themes which he illustrates are thoroughly suited to his purpose. Sometimes he chooses the drawing-room where dames and cavaliers dance, or dine, or sing; sometimes—mostly indeed—he likes cottages or courtyards, where housewives tend their children or superintend the labours of the cook. Satin and gold are as familiar to him as camlet and fur, but the latter are his favourites; and there is no article of furniture in a Dutch house of the middle class that he does not paint with pleasure. What distinguishes him most besides subtle suggestiveness is the serenity of his pictures, whether in the open or in confined spaces. One of his most charming arrangements is a canvas in the Ashburton collection, where an old lady with a dish of apples walks with a child along a street bounded by a high wall, above which gables and a church steeple are seen. The dame is busied with the child, whilst a gentleman in a hat and cloak shows his back in the distance. The sun radiates and glitters joyfully over the whole. Fine in another way is the Mug of Beer in the Amsterdam museum, an interior where a woman is seen coming out of a pantry and giving a measure of beer to a little girl. The light flows in here from a small closed window. But through the door to the right we look into a drawing-room, and through the open sash of that room we see the open air. The three lights are managed with supreme cunning. In such masterpieces as these we discern the models familiar to later artists such as Boursse and Koedijk, and a delicate gradation of tints which Maes and Meer might have envied. Beautiful for its lighting again is the Mother peeling Apples, whilst her child looks on supported in leading strings by a nurse, the sun shining through the casement to the left, a gem in the Speck collection at Lütschena near Leipsic. More subtly suggestive, in the museum of Berlin, is the Mother seated near a Cradle, whilst a child totters away into a lobby on the right. The mother looks into the depths of the cradle with a smile, thus betraying to us the presence of the baby which we cannot see. A Card Party, dated 1658, at Buckingham Palace is a good example of De Hooch's drawing-room scenes, counterpart as to date and value of a Woman and Child in the National Gallery, and a Smoking Party belonging to Lord Enfield. Other pictures later onward in the master's career are—the Lady and Child in a Courtyard, of 1665, in the National Gallery, and the Lady receiving a Letter, of 1670, in the Van der Hoop collection at Amsterdam. It is possible to bring together between fifty and sixty examples of De Hooch, but not more. There are eight at St Petersburg alone, three in Buckingham Palace, three in the National Gallery, five, or at least four of undoubted genuineness, in the Hoop collection at Amsterdam, some in the Louvre, at Munich, and Darmstadt; the rest are chiefly in private galleries in England. For England was the first to recognize the merit of De Hooch, who only began to be valued in Holland in the middle of last century. A celebrated picture at Amsterdam, sold for 450 florins in 1765, fetched 4000 in 1817, and now even that price is thought a bagatelle, since the Berlin museum gave £6000 for a De Hooch at the Schneider sale in 1876.

HOO-CHOW-FOO, a city of China, in the province of Che-Keang, lies a little to the south of Lake Tai-hoo, in the midst of the central silk district. According to Chinese authorities, it is 6 miles in circumference, and contains about 100,000 families; but Fortune thinks it is not more than 3 or 4 miles round. A broad stream or canal crosses the city from south to north, and forms the principal highway for boat traffic. The main trade of the place is in raw silk, but some silk fabrics, such as flowered crape (*tchoisha*), are also manufactured. Silk is largely worn even by the lowest classes of the inhabitants.

HOOD, ROBIN. See ROBIN HOOD.

HOOD, THOMAS (1789-1845), humorist and poet, born 23d May 1789, was the son of Mr Hood, bookseller, of the firm of Vernor & Hood, a man of intelligence, and the author of two novels. "Next to being a citizen of the world," writes Thomas Hood in his *Literary Reminiscences*, "it must be the best thing to be born a citizen of the world's greatest city." The best incident of his boyhood was his instruction by a schoolmaster who appreciated his talents, and, as he says, "made him feel it impossible not to take an interest in learning while he seemed so interested in teaching." Under the care of this "decayed dominie," whom he has so affectionately recorded, he earned a few guineas—his first literary fee—by revising for the press a new edition of *Paul and Virginia*. Admitted soon after into the counting-house of a friend of his family, he "turned his stool into a Pegasus on three legs, every foot, of course, being a dactyl or a spondee;" but the uncongenial profession affected his health, which was never strong, and he was transferred to the care of a relation at Dundee. He has graphically described his unconditional rejection by this inhospitable personage, and the circumstances under which he found himself in a strange town without an acquaintance, with the most sympathetic nature, anxious for intellectual and moral culture, but without guidance, instruction, or control. This self-dependence, however, suited the originality of his character: he became a large and indiscriminate reader, and before long contributed humorous and poetical articles to the provincial newspapers and magazines. As a proof of the seriousness with which he regarded the literary vocation, it may be mentioned that he used to write out his poems in printed characters, believing that that process best enabled him to understand his own peculiarities and faults, and probably unconscious that Coleridge had recommended some such method of criticism when he said he thought "print settles it."

His modest judgment of his own abilities, however, deterred him from literature as a profession, and on his return to London he applied himself assiduously to the art of engraving, in which he acquired a skill that in after years became a most valuable assistant to his literary labours, and enabled him to illustrate his various humours and fancies by a profusion of quaint devices, which not only repeated to the eye the impressions of the text, but, by suggesting amusing analogies and contrasts, added considerably to the sense and effect of the work.

In 1821 Mr John Scott, the editor of the *London Magazine*, was killed in a duel, and that periodical passed into the hands of some friends of Hood, who proposed to him to take a part in its publication. His installation into this congenial post at once introduced him to the best literary society of the time; and in becoming the associate of such men as Charles Lamb, Cary, De Quincey, Allan Cunningham, Proctor, Talfourd, Hartley Coleridge, the peasant-poet Clare, and other contributors to that remarkable miscellany, he gradually developed his own intellectual powers, and enjoyed that happy intercourse with superior minds for which his cordial and genial character was so well adapted, and which he has described in his best manner in several chapters of *Hood's Own*. *Odes and Addresses*—his first work—were written about this time, in conjunction with his brother-in-law Mr J. H. Reynolds, the friend of Keats; and it is agreeable to find Sir Walter Scott acknowledging the gift of the work with no formal expressions of gratification, but "wishing the unknown author good health, good fortune, and whatever other good things can best support and encourage his lively vein of inoffensive and humorous satire." *Whims and Oddities*, *National Tales*, *Tylney Hall*, a novel, and *The Plea of the Midsummer Fairies* followed. In these works the humorous faculty not only predominated, but expressed itself with a freshness, originality, and power which the poetical element could not claim. There was much true poetry in the verse, and much sound sense and keen observation in the prose of these works; but the poetical feeling and lyrical facility of the one, and the more solid qualities of the other, seemed best employed when they were subservient to his rapid wit, and to the ingenious coruscations of his fancy. This impression was confirmed by the series of the *Comic Annual*, a kind of publication at that time popular, which Hood undertook and continued, almost unassisted, for several years. Under that somewhat frivolous title he treated all the leading events of the day in a fine spirit of caricature, entirely free from grossness and vulgarity, without a trait of personal malice, and with an under-current of true sympathy and honest purpose that will preserve these papers, like the sketches of Hogarth, long after the events and manners they illustrate have passed from the minds of men. But just as the agreeable jester rose into the earnest satirist, one of the most striking peculiarities of his style became a more manifest defect. The attention of the reader was distracted, and his good taste annoyed, by the incessant play upon words, of which Hood had written in his own vindication—

"However critics may take offence,
A double meaning has double sense."

Now it is true that the critic must be unconscious of some of the subtlest charms and nicest delicacies of language who would exclude from humorous writing all those impressions and surprises which depend on the use of the diverse sense of words. The history, indeed, of many a word lies hid in its equivocal uses; and it in no way derogates from the dignity of the highest poetry to gain strength and variety from the ingenious application of the same sounds to different senses, any more than from the contrivances of rhythm or the accompaniment of imitative sounds. But when this habit becomes the characteristic of any wit, it is impossible to prevent it from degenerating into occasional buffoonery, and from supplying a cheap and ready resource, whenever the true vein of humour becomes thin or rare. Artists have been known to have used the left hand in the hope of checking the fatal facility which practice had conferred on the right; and if Hood had been able to place under some restraint the curious and complex machinery of words and syllables which his fancy was incessantly producing, his style would have been a great gainer, and much real earnestness of object, which now lies confused by the brilliant kaleidoscope of language, would have remained definite and clear. He was probably not unconscious of this danger; for, as he gained experience as a writer, his diction became more simple, and his ludicrous illustrations less frequent. In another annual called the *Gem* appeared the poem on the story of "Eugene Aram," which first manifested the full extent of that poetical vigour which seemed to advance just in proportion as his physical health declined. He started a magazine in his own name, for which he secured the assistance of many literary men of reputation and authority, but which was mainly sustained by his own intellectual activity. From a sick-bed, from which he never rose, he conducted this work with surprising energy, and there composed those poems, too few in number, but immortal in the English language, such as the "Song of the Shirt," the "Bridge of Sighs," and the "Song of the Labourer," which seized the deep human interests of the time, and transported them from the ground of social philosophy into the loftier domain of the imagination. They are no clamorous expressions of anger at the discrepancies and contrasts of humanity, but plain, solemn pictures of conditions of life, which neither the politician nor the moralist can deny to exist, and which they are imperatively called upon to remedy. Woman, in her wasted life, in her hurried death, here stands appealing to the society that degrades her, with a combination of eloquence and poetry, of forms of art at once instantaneous and permanent, and with a metrical energy and variety of which perhaps our language alone is capable. Prolonged illness brought on straitened circumstances; and application was made to Sir Robert Peel to place Hood's name on the pension list with which the British state so moderately rewards the national services of literary men. This was done readily and without delay, and the pension was continued to his wife and family after his death, which occurred on the 3d of May 1845. Nine years after, a monument, raised by public subscription, in the cemetery of Kensal Green, was inaugurated by Mr Monckton Milnes (Lord Houghton) with a concourse of spectators that showed how well the memory of the poet stood the test of time. Artisans came from a great distance to view and honour the image of the popular writer whose best efforts had been dedicated to the cause and the sufferings of the workers of the world; and literary men of all opinions gathered round the grave of one of their brethren whose writings were at once the delight of every boy and the instruction of every man who read them. Happy the humorist whose works and life are an illustration of the great moral truth that the sense of humour is the just balance of all the faculties of man, the best security against the pride of knowledge and the conceits of the imagination, the strongest inducement to submit with a wise and pious patience to the vicissitudes of human existence. This was the lesson that Thomas Hood left behind him, and which his countrymen will not easily forget. (H.)

HOOD, Tom (1835–1874), son of Thomas Hood, and the inheritor of similar though less brilliant literary talents, was born at Lake House, Wanstead, January 19, 1835. After attending University College School and Louth Grammar School he entered Pembroke College, Oxford, where he passed all the examinations for the degree of B.A., but did not graduate. At Oxford he also wrote his first work, *Pen and Pencil Pictures*, which appeared in 1854–55. This was followed in 1861 by *The Daughters of King Daker, and other Poems*, after which he published a number of amusing books for children. His serious novels were not so successful, and are now almost wholly forgotten. He also wielded the pencil with considerable facility, among his illustrations being those of several of his father's comic verses. Having become editor of the comic paper *Fun* in 1865, he succeeded in acquiring for it a wide popularity, principally as a depictor of the humours and eccentricities of middle-class life. Privately his lightsomeness, geniality, and sincere friendliness secured him the affection and esteem of his wide circle of acquaintance. He died 20th November 1874.

HOOD, Samuel Hood, First Viscount (1724–1816), English admiral, was born in 1724 at Butleigh in Somersetshire, where his father was rector. Entering the navy at sixteen years of age, he quickly obtained promotion, becoming lieutenant in 1746 and commander in 1754. In 1757 he captured a French ship of equal size with his own, and in 1759 he repeated the achievement. After holding successively the appointments of chief commander of the Boston naval station and commissioner of the dockyards at Portsmouth, he was in 1780 promoted to the rank of rear-admiral, and sent to co-operate with Sir George Rodney in the West Indies, where he fought some indecisive actions with the Comte de Grasse. In July of the following year he succeeded Rodney in the supreme command, shortly after which the fleet set sail for America. Although in January 1782 Hood failed to hold the island of St Christopher's against the superior forces of the French, he succeeded in very difficult circumstances in preserving his fleet intact until the arrival of Rodney, when he so distinguished himself in the action of the 9th April and the more important one of the 12th, that for his services he was created a peer of Ireland with the title of Baron Hood of Catherington. On Rodney's return home he was again promoted to the chief command, which he held till peace was proclaimed in 1783. In 1784 Lord Hood successfully opposed Charles Fox as parliamentary candidate for Westminster, and, though he lost his seat on being made a lord of the admiralty in 1788, he regained it in 1790. On the outbreak of war with France, after the Revolution, in 1793, he was appointed to the command of the fleet in the Mediterranean, where he received the surrender of Toulon from the French royalists. Before evacuating it to Napoleon on December 18th, Hood burned the arsenal, and destroyed fifteen sail of the line besides carrying off eight. In the following year he succeeded, after a stubborn resistance, in expelling the French from Corsica; and after his return home he was in 1796 appointed governor of Greenwich Hospital and raised to the English peerage with the title of Viscount Hood of Whitley. In 1799 he was promoted to the rank of admiral, and in 1804 he received the grand cross of the bath. He died at Bath 27th June 1816. The achievements of Lord Hood, though not of so brilliant a character as those of a Blake or a Nelson, were the result of thorough seamanship, and of a rare union of courage and decision with coolness and caution.

HOOFT, Pieter Cornelissen (1581–1647), Dutch poet and historian, was born at Amsterdam on the 16th of March 1581. His father was one of the leading citizens of Holland, both in politics and in the patronage of letters, and for some time burgomaster of Amsterdam. As early as 1598 the young man was made a member of the chamber of rhetoric of the Eglantine, and produced before that body his tragedy of *Achilles and Polyxena*, not printed until 1614. In June 1598 he left Holland and proceeded to Paris, where on the 10th of April 1599 he saw the body of Gabrielle d'Estrées lying in state. He went a few months later to Venice, Florence, and Rome. In 1600 he proceeded to Naples, and during all this Italian sojourn he made a deep and fruitful study of the best literature of Italy. In July 1600 he sent home to the Eglantine a very fine letter in verse, which is considered to mark an epoch in the development of Dutch poetry. He returned through Germany, and after an absence of three years and a half found himself in Amsterdam again on the 8th of May 1601. He soon after brought out his second tragedy, the *Ariadne*, in 1602. In 1605 he completed his beautiful pastoral drama *Granida*, not published until 1615. He studied law at Leyden from 1606 to 1609, and in June of the latter year received from the prince of Orange the appointment of steward of Minden, bailiff of Gooiland, and lord of Weesp, a joint office of great emolument. He occupied himself with repairing and adorning the decayed castle of Minden, which was his residence during the remainder of his life. In August 1610 he married the famous botanist, Christina van Erp. In 1612 Hooft produced, and in 1613 printed, his national tragedy of *Geeraerdt van Velsen*, a story of the reign of Count Floris V. In 1614 was performed at Coster's academy Hooft's comedy of *Ware-nar*, an adaptation of the *Aulularia* of Plautus, first printed in 1617. In 1616 he wrote another tragedy, *Baeto, or the Origin of the Dutch*, not printed until 1626. It was in 1618 that he abandoned poetry for history, and in 1626 he published the first of his great prose works, the

History of Henry the Great (Henry IV. of France). His next production was his *Miseries of the Princes of the House of Medici*, printed in 1638. In 1642 he published the masterpiece of his life, his *Dutch History*, a magnificent performance, to the perfecting of which he had given fifteen years of labour. Hooft died on a visit to Prince Frederick Henry at the Hague on the 21st of May 1647, and was buried in the New Church at Amsterdam.

Hooft is one of the most brilliant figures that adorn Dutch literature at its best period. He was the first writer to introduce a modern and European tone into belles lettres, and the first to refresh the sources of native thought from the springs of antique and Renaissance poetry. His lyrics and his pastoral of *Granida* are strongly marked by the influence of Tasso and Sannazaro; his later tragedies belong more exactly to the familiar tone of his native country. But high as Hooft stands among the Dutch poets, he stands higher, he holds perhaps the highest place, among writers of Dutch prose. His historical style has won the warmest eulogy from so temperate a critic as Motley, and his letters are the most charming ever published in the Dutch language. After Vondel, he may on the whole be considered the most considerable author that Holland has produced.

Hooft's poetical and dramatic works were collected in two volumes, 1871, 1875, by P. Leendertz. Many editions exist of his prose works.

HOOGEVEEN (*i.e.*, High Fen or Moor), a village and commune of the Netherlands in the province of Drenthe, about 12 miles north-east of Meppel on the railway opened in 1870 between that town and Groningen. The village contains a Reformed church, erected in 1652 and restored in 1766 and 1801, a small but handsome synagogue, a poorhouse dating from 1810, and a library belonging to the local branch of the society *Tot nut van 't Algemeen*; and among the industrial establishments of the commune are timber yards, sail factories, block factories, tanneries, brick-works, gin distilleries, and breweries. Hoogeveen was founded in 1625 by Baron van Eichten, and in the following year it was erected into a lordship which lasted till 1795. The population of the commune, which was 7339 in 1840, had risen to 10,763 in 1874.

HOOGHLY, or Húglí. The Hooghly river is the most westerly and commercially the most important channel by which the Ganges enters the Bay of Bengal. It takes its distinctive name near the town of Sántipur, about 120 miles from the sea. The stream now known as the Hooghly represents three western deltaic distributaries of the Ganges —viz., (1) the Bhágirathí, (2) the Jalangi, and (3) part of the Mátábhángá. The Bhágirathí and Jalangi unite at Nadiyá, above the point of their junction with the lower waters of the Mátábhángá, which has taken the name of the Churní before the point of junction and thrown out new distributaries of its own These three western distributaries are known as "The Nadiyá Rivers," and are important, not only as great highways for internal traffic, but also as the headwaters of the Hooghly. Like other deltaic distributaries, they are subject to sudden changes in their channels, and to constant silting up. The supervising and keeping open of the Nadiyá rivers has, therefore, formed one of the great tasks of fluvial engineering in Bengal. Proceeding south from Sántipur, with a twist to the east, the Hooghly river divides Murshidábád from Hooghly district, until it touches the district of the Twenty-Four Parganás in 22° 57′ 30″ N. lat. and 88° 27′ 15″ E. long. It then proceeds almost due south to Calcutta, next twists to the south-west, and finally turns south, entering the Bay of Bengal in 21° 41′ N. lat. and 88° E. long.

In the 40 miles of its course that are above Calcutta, the channels of the Hooghly are under no supervision, and the result is that they have silted up and shifted to such an extent as to be no longer navigable for sea-going ships. Yet it was upon this upper section that all the famous ports of Bengal lay in olden times. From Calcutta to the sea (about 80 miles) the river is a record of engineering improvement and success. A minute supervision, with steady dredging and constant readjustment of buoys, now renders it a safe waterway to Calcutta for ships of the largest tonnage. Much attention has also been paid to the port of Calcutta. For its trade, shipping, and administration, see CALCUTTA.

The tide runs rapidly on the Hooghly, and produces a remarkable example of the fluvial phenomenon known as a "bore." This consists of the headwave of the advancing tide, hemmed in where the estuary narrows suddenly into the river, and often exceeds 7 feet in height. It is felt as high up as Calcutta, and frequently sinks small boats or dashes them to pieces on the bank. The difference from the lowest point of low-water in the dry season to the highest point of high-water in the rains is reported at 20 feet 10 inches. The greatest mean rise of tide, about 16 feet, takes place in March, April, or May,—with a declining range during the rainy season to a mean of 10 feet, and a minimum during freshets of 3 feet 6 inches. The scenery on the banks of the Hooghly varies greatly. The sea approach presents nothing to view but sandbanks, succeeded by mean-looking mud formations covered with coarse grass. As the river narrows, however, the country improves. Trees and rice fields and villages are common, and at length a section is reached where the banks are high, and lined with hamlets buried under evergreen groves. Then come long tiers of shipping, with the stately painted mansions of Garden Reach on the margin in the foreground, the fort rising from the great plain on the bank higher up, and the domes, steeples, and noble public buildings of Calcutta beyond,—all gradually unfolding their beauties in a long panorama.

HOOGHLY, a British district in the lieutenant-governorship of Bengal, lying between 22° 13′ 45″ and 23° 13′ 15″ N. lat., and between 87° 47′ and 88° 33′ E. long. The area, including the magistracy of Howrah, amounted in 1878 to 1467 square miles. It forms the south-eastern portion of the Bardwán division, and is bounded N. by the district of Bardwán, E. by the Hooghly river, separating it from the districts of Nadiyá and the Twenty-Four Parganás; S. by the Rúpnáráyan, separating it from Midnapur; and W. by the same river, separating it from Midnapur, and by Bardwán district.

The district is flat, with a gradual ascent to the north and north-west. The scenery along the high-lying bank of the Hooghly has a quiet beauty of its own, presenting the appearance of a connected series of orchards and gardens, interspersed with factories, villages, and temples. The principal rivers are the Hooghly, the Dámodar, and the Rúpnáráyan. The Dámodar is the only large river which intersects the district. As in other deltaic districts, the highest land lies nearest the rivers, and the lowest levels are found midway between two streams. There are in consequence considerable marshes both between the Hooghly and the Damodar and between the latter river and the Rúpnáráyan.

The first regular census of the district (1872) showed a population of 1,488,556 persons, of whom 722,856 were males and 765,700 females. Of these 813 were Non-Asiatics, the great majority of them Europeans, and 557 were of mixed races (Eurasians). The Hindus numbered 1,186,435; Mahometans, 299,025; and the Christian community, 2583. Seven municipalities contain a population of over 5000 each, viz., Howrah, 97,784; Hooghly and Chinsurah given as one town, 34,761; Serampur, 24,448; Baidyabati, 13,332; Bansbáriá, 7861; Bhadreswar, 7417; and Kotrang, 6811. HOWRAH (*q.v.*) is the largest and most important town in the district. Amongst other places of interest are—Tribeni, a place of great sanctity, and the scene of many religious gatherings; Panduah, now a small village, but in ancient times the fortified seat of a Hindu rájá; Tarakeswar, a village containing a large and richly endowed shrine of great holiness, visited at all times of the year by crowds of pilgrims. The total revenue in 1870–71 was £239,452, and the expenditure £84,989. In 1870 there were 16 magisterial and 35 civil and revenue courts, with 8 covenanted English officers. The regular police force of Hooghly and Howrah consisted (1871) of 1140 men, maintained at a cost of £20,726. There was also in 1870 a municipal force (exclusive of Howrah) of 583 men, costing £4475, and a rural police of 7068 men, costing £17,856. The number of Government-aided schools in

1877–78 was 625, attended by 22,666 pupils. The principal educational institution in the district is the Hooghly College, attended in 1872 by 3142 students, on which the expenditure was £5143.

Rice forms the staple crop of the district, occupying about thirteen-sixteenths of the cultivated area; the other cereals are barley, wheat, and Indian corn. The other crops consist of pease, pulses, oil-seeds, vegetables, jute, hemp, cotton, sugar-cane, indigo, mulberry, tobacco, and *pán*. Blights occasionally visit Hooghly and Howrah, but they have not affected any crop throughout the entire district. An exceptional case was that of the "Bombay sugar-cane," which was totally destroyed by blight in 1860. Droughts caused by deficiency of rainfall sometimes occur, but not to any serious extent. Floods are rare. The trade of the district is chiefly carried on by means of permanent markets. The principal exports are—fine rice, silk, indigo, jute, cotton cloth, and vegetables; the chief imports are common rice, English piece goods, lime, timber, &c. The chief manufactures are silk and cotton. In 1870 there were 400 miles of road in Hooghly district, maintained at a cost of £4000. The East Indian Railway has its principal terminus at Howrah, and runs through the district for about 45 miles; there are 10 stations in the district. There are six canals in Hooghly district used for water-carriage, of a total length of 33 miles.

The climate does not differ from that of Lower Bengal generally. The average maximum temperature is 92° F., the minimum 68° F., and the average annual rainfall about 70 inches. The diseases of the district are fever, cholera, dysentery, &c. An epidemic malarious fever has raged at intervals, and is said to have carried off more than half the population and to have almost depopulated certain villages. There are 7 hospitals and dispensaries.

From an historical point of view the district possesses as much interest as any in Bengal, or indeed in India. In the early period of the Mahometan rule Sátgáon was the seat of the governors of Lower Bengal and a mint town. It was also a place of great commercial importance. In consequence of the silting up of the Saraswatí, the river on which Sátgáon was situated, the town became inaccessible to large ships, and the Portuguese moved to Hooghly. In 1632 the latter place, having been taken from the Portuguese by the Mahometans, was made the royal port of Bengal; and all the public offices and records were withdrawn from Sátgáon, which rapidly fell into decay. In 1640 the East India Company established a factory at Hooghly. This was the first English settlement in Lower Bengal. In 1685, a dispute having taken place between the English factors and the nawáb of Bengal, the town was bombarded and burned to the ground. This was not the first time that Hooghly had been the scene of a struggle deciding the fate of a European power in India. In 1629, when held by the Portuguese, it was besieged for three months and a half by a large Mahometan force sent by the emperor Sháh Jahán. The place was carried by storm; more than 1000 Portuguese were killed, upwards of 4000 prisoners taken, and of 300 vessels only 3 escaped. But Hooghly district possesses historical interest for other European nations besides England and Portugal. The Dutch established themselves at Chinsurah in the 17th century, and held the place till 1825, when it was ceded to Great Britain in exchange for the island of Java. The Danes settled at Serampur, where they remained till 1825, when all Danish possessions in India were transferred to the East India Company. Chandarnagar became a French settlement in 1683. The English captured this town twice, but since 1816 it has remained in the possession of the French.

HOOGHLY, the administrative headquarters of the above district, is a town situated on the right or west bank of the Hooghly, 22° 54′ 44″ N. lat. and 88° 26′ 28″ E. long. Hooghly and Chinsurah form one municipality, and the two towns were treated as one in the enumeration of 1872. Population, 34,761, viz., 17,114 males and 17,647 females:—Hindus, 27,429; Mahometans, 6952; Christians, 328; "others," 52. Hooghly is a station on the East Indian Railway, 25 miles from Calcutta. The principal building is a handsome "imámbárá," constructed out of funds which had accumulated from an endowment originally left for the purpose by a wealthy Shiá gentleman, Muhammad Mohsin. The town is said to have been founded by the Portuguese in 1537, on the decay of Sátgáon, the royal port of Bengal. Upon establishing themselves they built a fort at a place called Gholghat (close to the present jail), vestiges of which are still visible in the bed of the river. This fort gradually grew into the town and port of Hooghly. (W. W. H.)

HOOGSTRATEN, SAMUEL DIRKSZ VAN, was born, it is said, in 1627 at the Hague, and died at Dort, October 19, 1678. This artist, who was first a pupil of his father, lived at the Hague and at Dort till about 1640, when on the death of Dirk Hoogstraten he changed his residence to Amsterdam and entered the school of Rembrandt. A short time afterwards he started as a master and painter of portraits, set out on a round of travels which took him (1651) to Vienna, Rome, and London, and finally retired to Dort, where he married in 1656, and held an appointment as "provost of the mint." Hoogstraten's works are scarce; but a sufficient number of them has been preserved to show that he strove to imitate different styles at different times. In a portrait dated 1645 in the Lichtenstein collection at Vienna he imitates Rembrandt; and he continues in this vein as late as 1653, when he produced that wonderful figure of a Jew looking out of a casement, which is one of the most characteristic examples of his manner in the Belvedere at Vienna. A view of the Vienna Hofburg, dated 1652, in the same gallery displays his skill as a painter of architecture, whilst in a piece at the Hague representing a Lady Reading a Letter as she crosses a Courtyard, or a Lady Consulting a Doctor, in the Van der Hoop Museum at Amsterdam, he imitates De Hooch. One of his latest works is a portrait of Mathys van den Brouck, dated 1670, in the gallery of Amsterdam. The scarcity of Hoogstraten's pictures is probably due to his versatility. Besides directing a mint, he devoted some time to literary labours, wrote a book on the theory of painting, and composed sonnets and a tragedy. We are indebted to him for some of the familiar sayings of Rembrandt. He was an etcher too, and some of his plates are still preserved. His portrait engraved by himself at the age of fifty still exists.

HOOK, THEODORE EDWARD (1788–1841), novelist, dramatist, and improvisatore, was born in London 22d September 1788. At Harrow he received but a scant education, and although he subsequently matriculated at Oxford he never actually resided at the university. Indeed he seems to have abandoned all thought of serious study about 1802, on the death of his mother, *née* Madden, a lady of singular beauty and ability. The father, James Hook, a composer of some distinction, took great delight in exhibiting the extraordinary musical and metrical gifts of the stripling, and before many months the precocious Theodore had become "the little pet lion of the green room." At the age of sixteen he scored a dramatic success with *The Soldier's Return*, a comic opera, and this he rapidly followed up with a series of over a dozen sparkling ventures, the instant popularity of which was hardly dependent on the inimitable acting of Liston and Mathews. But an overweening love of society withheld Hook from a lucrative career as a dramatic author, and for some ten of the best years of his life he gave himself up to the pleasures of the town, winning a foremost place in the world of fashion by his matchless powers of improvisation and mimicry, and startling the public by the audacity of his practical jokes. His unique gift of impromptu minstrelsy "mystified" Sheridan, astonished Coleridge, and eventually charmed the Prince Regent into a declaration that "something must be done for Hook." The prince was as good as his word, and the victim of social success was appointed accountant-general and treasurer of the Mauritius with a salary of £2000 a year. For five delightful years Hook was the life and soul of the island, but in 1817, a serious deficiency having been discovered in the treasury accounts, he was arrested and brought to England on a criminal charge. It transpired that a sum of about £12,000 had been abstracted by a deputy official, and for this amount Hook was held responsible.

During the tardy scrutiny of the audit board he lived obscurely and maintained himself by writing for magazines and newspapers. In 1820 he launched the *John Bull*, the champion of high Toryism and the virulent detractor of Queen Caroline. Witty, incisive criticism and pitiless invective secured a large circulation for the newspaper, and from this source alone Hook derived, for the first year at least, an income of £2000. In the midst of his labours, however, he was arrested for the second time on account of his debt to the state, which he made no effort to defray. Confined for eight months in a sponging-house, he issued thence the first series of his lively *Sayings and Doings* (3d series, 1828). On his liberation he continued to work with his pen indefatigably, pouring forth in the remaining twenty-three years of his life no fewer than thirty-eight volumes, besides numberless articles, squibs, and sketches. His novels are not works of enduring interest, but they are saved from mediocrity by frequent passages of racy narrative and vivid portraiture. The best are *Maxwell* (1830), *Love and Pride* (1833), the autobiographic *Gilbert Gurney* (1835), *Jack Brag* (1837), *Gurney Married* (1839), and *Peregrine Bunce* (1841). Incessant work had already begun to tell on his health, when Hook returned to his old social habits, and a prolonged attempt to combine industry and dissipation resulted in the sad confession that he was "done up in purse, in mind, and in body too at last." He died 24th August 1841. His writings in great part are of a purely ephemeral character; the less transient, touched though they be with a sparkling fancy, have long since passed out of favour; while the greatest triumphs of the improvisatore may be said to have been writ in wine. Putting aside, however, his claim to literary greatness, Hook will be remembered as one of the most brilliant, genial, and original figures of Georgian times.

See Lockhart's *Biographic Sketch* (1852), and the Rev. R. H. D. Barham's *Life and Remains* (3d ed., 1877).

HOOK, Walter Farquhar (1798–1875), son of the Rev. Dr James Hook, dean of Worcester, and nephew of the witty Theodore, was born in London, 13th March 1798. Educated at Tiverton and Winchester, he graduated at Oxford (Christ Church) in 1821, and after holding an incumbency in Coventry, 1829–37, and in Leeds, 1837–59, was nominated dean of Chichester by Lord Derby. He had received the degree of D.D. in 1837. His friendship towards the Tractarians exposed him to considerable persecution, but his simple manly character and zealous devotion to parochial work gained him the support of widely divergent classes. Throughout life he held steadily by sober high-church principles, and the earnest, elevated tone of his mind is exemplified in such sermons as "Hear the Church!" which was preached before the court in 1837, and subsequently passed through many large editions. The vigorous practical turn of his Christianity is attested by the erection in the parish of Leeds, during his incumbency, of 21 new churches, 32 parsonages, and over 60 schools, in addition to the rebuilding of the parish church at a cost of £28,000. His literary works, which are numerous, attain the limit of their design in advancing some incidental plea or in contributing to the student's resources. The principal are *An Ecclesiastical Biography, containing the Lives of Ancient Fathers and Modern Divines* (8 vols., 1845–52), *A Church Dictionary* (8th ed., 1859), *The Means of Rendering more Effectual the Education of the People* (10th ed., 1851), *The Cross of Christ* (1873), *The Church and its Ordinances* (sermons, 4 vols., 1876), and *Lives of the Archbishops of Canterbury* (12 vols., 1860–76). He died 20th October 1875. A memorial church has been erected in his honour at Leeds; it is a 13th century Gothic structure, designed by Sir G. G. Scott (cost £25,000), and was consecrated 29th January 1880.

See *Life and Letters of Dean Hook* by his son-in-law, W. R. W. Stephens (2 vols., 1878), and *Parish Sermons* (1879).

HOOKE, Robert (1635–1703), an original and ingenious experimental philosopher, was born at Freshwater, in the Isle of Wight, July 18, 1635. His father, who was minister of the parish, destined him for the church; but his constitutional ill-health precluded study, and threw him instead on the resources afforded by his precocious mechanical genius. From the workshop of Sir Peter Lely, where he was placed after his father's death in 1648, he was transferred to the house of Dr Busby, master of Westminster School; and there his education progressed with surprising rapidity both in its classical and mathematical branches. In 1653 he entered Christ Church, Oxford, as servitor; and ten years later he took his M.A. degree by special recommendation of Lord Clarendon, then chancellor of the university. After 1655 he was employed and patronized by the Hon. Robert Boyle, who turned his skill to account in the construction of his celebrated air-pump. Hooke's inventive faculty exercised itself, between 1657 and 1659, in devising thirty different methods of flying, and more profitably in regulating the movement of watches by the application of the balance spring. In 1675 a lively controversy arose between him and Huygens respecting their rival claims to this ingenious invention. The truth seems to be that the original idea belonged to Hooke, but that the coiled form of the spring, on which its practical utility depends, was due to Huygens. On the 12th of November 1662 Hooke was appointed curator of experiments to the Royal Society, and filled the office with extraordinary diligence and skill during the remainder of his life. In 1664 Sir John Cutler instituted for his benefit a mechanical lectureship of £50 a year, and in the following year he was nominated professor of geometry in Gresham College, where he subsequently resided. After the great fire of 1666 he constructed a model for the rebuilding of the city, which was highly approved, although the design of Wren was preferred. During the progress of the works, however, Hooke acted as surveyor, and accumulated in that lucrative employment a sum of several thousand pounds, discovered after his death in an old iron chest, which had evidently lain unopened for above thirty years. He fulfilled the duties of secretary to the Royal Society during five years after the death of Oldenburg in 1677, publishing in 1681–82 the papers read before that body under the title of *Philosophical Collections*. A protracted controversy with Hevelius, in which Hooke urged the advantages of telescopic over plain sights, brought him little but discredit. His reasons were good; but his offensive style of argument rendered them unpalatable and himself unpopular. Many circumstances concurred to embitter the latter years of his life. The death, in 1687, of his niece, Mrs Grace Hooke, who had lived with him for many years, caused him deep affliction; a law suit with Sir John Cutler about his salary (decided, however, in his favour in 1696) occasioned him prolonged anxiety; and the repeated anticipation of his discoveries inspired him with a morbid jealousy. Marks of public respect were not indeed wanting to him. A degree of M.D. was conferred on him at Doctors' Commons, December 7, 1691, and the Royal Society made him, in 1696, a grant to enable him to complete his philosophical inventions. While engaged on this task he died, worn out with disease and toil, March 3, 1703, and was buried in St Helen's Church, Bishopsgate Street.

In personal appearance Hooke made but a sorry show. His figure was crooked, his limbs shrunken; his hair hung in dishevelled locks over his haggard countenance. His temper was irritable, his habits penurious and solitary. He was, however, blameless in morals, and reverent in religion. His scientific performances would probably have been more striking if they had been less varied. He originated much, but perfected little. His optical investigations led him to adopt in an imperfect form the undulatory theory of light, to anticipate the doctrine of interference, and to observe, independently of though subsequently to Grimaldi, the phenomenon of diffraction. He was the first to state clearly that the motions of the heavenly bodies must be regarded as a mechanical problem, and he approached in a remarkable manner the discovery of universal gravitation. He suggested a method of meteorological forecasting and a system of telescopic signalling, anticipated Chladni's experiment of strewing a vibrating bell with flour, investigated the nature of sounds and the function of the air in respiration and combustion, and originated the idea of using the pendulum as a measure of gravity.

His principal writings are *Micrographia*, 1664; *Lectiones Cutlerianæ*, 1674-79; and *Posthumous Works*, containing a sketch of his "Philosophical Algebra," published by Waller in 1705.

HOOKER, JOSEPH (1814-1879), American general, was born in Old Hadley, Massachusetts, November 13, 1814. He was educated at the Military Academy at West Point, 1833-37, and immediately commissioned second lieutenant in the 1st Artillery. In the war with Mexico (1846-48) he served as aide-de-camp and assistant adjutant-general, and was breveted captain, major, and lieutenant-colonel, and commissioned captain, for meritorious services in the engagements at Monterey, National Bridge, and Chapultepec. He was transferred with his regiment to California in 1849. In 1853 he resigned his commission and bought a large farm near Sonoma, which he managed successfully till 1858, when he was made superintendent of military roads in Oregon. Upon the opening of hostilities in the civil war of 1861-65, he sacrificed his fine estate and offered his sword to the Federal Government. He was commissioned brigadier-general of volunteers, May 17, 1861, and major-general May 5, 1862. At Williamsburg, May 5th, he attacked a strong Confederate position, and for nine hours maintained the fight, inflicting and sustaining heavy loss, and winning the title of "Fighting Joe." He was engaged at Fair Oaks, June 1st, and at Malvern Hill, July 1st, and did signal service at Charles City Cross Roads, June 29th, when his division aided in holding a vital position on the flank of the Union Army, in its noted "change of base." In the campaign of Northern Virginia, under General Pope, August 27 to September 1, 1862, he led his division in the actions at Bristoe Station, Manassas, and Chantilly. In the Maryland campaign, September 6-17 (under General M'Clellan), he commanded the first corps, and gallantly carried the north pass of South Mount, opening the way for the advance of the army. He opened the battle of Antietam on the 14th, and on the following morning was pitted against "Stonewall" Jackson, at the noted "cornfield," where he used his artillery with terrible effect, but received a painful wound, and was borne from the field. He was commissioned brigadier-general in the United States army September 20, 1862, and in the disastrous battle of Fredericksburg, under Burnside, he commanded the centre grand division (3d and 5th corps). He commanded the army of the Potomac January 26th to June 28th, 1863, and, having by a fine strategic movement thrown his army across a turbulent stream in face of the foe, fought a severe battle at Chancellorsville, where he was seriously injured; and, his army being thrown into an unfavourable position by the unexpected giving way of his right wing, he decided to retire. He was relieved at his own request, on the 28th of June, with the thanks of Congress "for skill, energy, and endurance" in the beginning of the Gettysburg campaign. He commanded the 20th corps (11th and 12th corps consolidated) in the Atlanta campaign, winning special distinction in the night battle of Wauhatchie, and at Lookout Mountain, "the battle above the clouds." For a hundred days, and until the capture of Atlanta, the noise of battle scarcely ceased, his corps doing signal service at Mill Creek, Resaca, New Hope Church, Pine Mount, Peach Tree Creek, and the siege of Atlanta. He was commissioned brevet-major-general in the United States army, March 13, 1865, and retired from active service at his own request, October 15, 1868. The last years of his life were passed in the neighbourhood of New York. He died at Garden City, Long Island, October 31, 1879.

HOOKER, RICHARD (1553-1600), author of the *Laws of Ecclesiastical Polity*, was born at Heavitree, near the city of Exeter, about the end of 1553 or beginning of 1554. At school, not only his facility in mastering his tasks, but his intellectual inquisitiveness and his fine moral qualities, attracted the special notice of his teacher, who strongly recommended his parents to educate him for the church. Though well connected, they were, however, somewhat straitened in their worldly circumstances, and Hooker was indebted for admission to the university to his uncle, John Hooker, chamberlain of Exeter, and in his day a man of some literary repute, who, besides giving him an annual pension, induced Bishop Jewel to become his patron and to bestow on him a clerk's place in Corpus College, Oxford. To this Hooker was admitted in 1567. Bishop Jewel died in September 1571, but Dr Cole, president of the college, from the strong interest he felt in the young man, on account at once of his character and his abilities, spontaneously offered to take the bishop's place as his patron; and shortly afterwards Hooker, by his own labours as a tutor, became independent of gratuitous aid. Two of his pupils, and these his favourite ones, were Edwin Sandys, afterwards author of *Europæ Speculum*, and George Cranmer, grand-nephew of the archbishop. Hooker's reputation as a tutor soon became very high, for he had employed his five years at the university to such good purpose as not only to have acquired great proficiency in the learned languages, but to have joined to this a wide and varied culture which had delivered him from the bondage of learned pedantry; in addition to which he is said to have possessed a remarkable talent for communicating knowledge in a clear and interesting manner, and to have exercised a special influence over his pupils' intellectual and moral tendencies. In December 1573 he was elected to a foundation in his college; in July 1577 he proceeded M.A., and in September of the same year he was admitted a fellow. In 1579 he was appointed by the chancellor of the university to read the public Hebrew lecture, a duty which he continued to discharge till he left Oxford. Not long after his admission into holy orders, about 1581, he was appointed to preach at St Paul's Cross; and, according to Walton, he was so kindly entertained by Mrs Churchman, who kept the Shunamite's house where the preachers were boarded, that he permitted her to choose him a wife, "promising upon a fair summons to return to London and accept of her choice." The lady selected by her was "her daughter Joan," who, says the same authority, "found him neither beauty nor portion; and for her conditions they were too like that wife's which is by Solomon compared to a dripping house." It is probable that Walton has exaggerated the simplicity and passiveness of Hooker in the matter, but though, as Keble observes with justice, his writings betray uncommon shrewdness and quickness of observation, as well as a vein of keenest humour, it would appear that either gratitude or some other impulse had on this occasion led his judgment astray. After his marriage he was about the end of 1584 presented to the living of Drayton Beauchamp in Buckinghamshire. In the following year he received a visit from his two pupils Edwin Sandys and George Cranmer, who found him with the *Odes* of Horace in his hand, tending the sheep while the servant was at dinner, after which, when they on the return of the servant accompanied him to his house, "Richard was called to rock the cradle." Finding him so engrossed by worldly and domestic cares, "they stayed but till the next morning," and, greatly grieved at his narrow circumstances and unhappy domestic condition, "left him to the company of his wife Joan."

The visit had, however, results of the highest moment, not only in regard to the career of Hooker, but in regard to English literature and English philosophical thought. Sandys prevailed on his father, the archbishop of York, to recommend Hooker for presentation to the mastership of the Temple, and Hooker, though his "wish was rather to gain a better country living," having agreed after some hesitation to become a candidate, the patent conferring upon him the mastership was granted 17th March 1585. The rival candidate was Walter Travers, a Presbyterian and evening lecturer in the same church. Being continued in the lectureship after the appointment of Hooker, Travers was in the habit of attempting a refutation in the evening of what Hooker had spoken in the morning, Hooker again replying on the following Sunday; so it was said "the forenoon sermon spake Canterbury, the afternoon Geneva." On account of the keen feeling displayed by the partisans of both, Archbishop Whitgift deemed it prudent to prohibit the preaching of Travers, whereupon he presented a petition to the council to have the prohibition recalled. Hooker published an *Answer to the Petition of Mr Travers*, and also printed several sermons bearing on special points of the controversy; but, feeling strongly the unsatisfactory nature of such an isolated and fragmentary discussion of separate points, he resolved to compose an elaborate and exhaustive treatise, exhibiting the fundamental principles by which the question in dispute must be decided. It is probable that the work was begun in the latter half of 1586, and he had made considerable progress with it before, with a view to its completion, he petitioned Whitgift to be removed to a country parsonage, in order that, as he said, "I may keep myself in peace and privacy, and behold God's blessing spring out of my mother earth, and eat my own bread without oppositions." His desire was granted in 1591 by a presentation to the rectory of Boscombe near Salisbury. There he completed the volume containing the first four of the proposed *Eight Books of the Laws of Ecclesiastical Polity*. It was entered at Stationers' Hall, 9th March 1592, but was not published till 1593 or 1594. In July 1595 he was promoted by the crown to the rectory of Bishopsbourne near Canterbury, where he lived to see the completion of the fifth book in 1597. In the passage from London to Gravesend some time in 1600 he caught a severe cold from which he never recovered, but, notwithstanding great weakness and constant suffering, he "was solicitous in his study," his one desire being "to live to finish the three remaining books of *Polity*." His death took place about November of the same year. A volume professing to contain the sixth and eighth books of the *Polity* was published at London in 1648, but the bulk of the sixth book, as has been shown by Keble, is an entire deviation from the subject on which Hooker proposed to treat, and doubtless the genuine copy, known to have been completed, has been lost. The seventh book, which was published in a new edition of the work by Gauden in 1662, and the eighth book, may be regarded as in substance the composition of Hooker; but, as, in addition to wanting his final revision, they have been very unskilfully edited, if they have not been manipulated for theological purposes, their statements in regard to doubtful matters must be received with due reserve, and no reliance can be placed on their testimony where their meaning contradicts that of other portions of the *Polity*.

The conception of Hooker in his later years which we form from the various accessible sources is that of a person of low stature and not immediately impressive appearance, much bent by the influence of sedentary and meditative habits, of quiet and retiring manners, and discoloured in complexion and worn and marked in feature from the hard mental toil which he had expended on his great work. There seems, however, exaggeration in Walton's statement as to the meanness of his dress; and Walton certainly misreads his character when he portrays him as a kind of ascetic mystic. Though he was unworldly and simple in his desires, and engrossed in the purpose to which he had devoted his life,—the "completion of the *Polity*,"—his writings indicate that he possessed a cheerful and healthy disposition, and that he was capable of discovering enjoyment in everyday pleasures, and of appreciating human life and character in a wide variety of aspects. He seems to have had a special delight in outward nature—as he expressed it, he loved "to see God's blessing spring out of his mother earth;" and he spent much of his spare time in visiting his parishioners, his deference towards them, if excessive, being yet mingled with a grave dignity which rendered unwarrantable liberties impossible. As a preacher, though singularly devoid of the qualities which win the applause of the multitude, he always excited the interest of the more intelligent, the breadth and finely balanced wisdom of his thoughts and the fascination of his composition greatly modifying the impression produced by his weak voice and ineffective manner. Partly, doubtless, on account of his dimsightedness, he never removed his eye from his manuscript, and, according to Fuller, "he may be said to have made good music with his fiddle and stick alone, having neither pronunciation nor gesture to grace his matter."

To accede without explanation to the claim put forth for the *Ecclesiastical Polity* of Hooker, that it marks an epoch in English prose literature and English thought, would both be to do some injustice to writers previous to him, and, if not to overestimate his influence, to misinterpret its character. By no means can his excursions in English prose be regarded as chiefly those of a pioneer; and not only is his intellectual position inferior to that of Shakespeare, Spenser, and Bacon,[1] who alone can be properly reckoned as the master spirits of the age, but in reality what effect he may have had upon the thought of his contemporaries was soon disregarded and swept out of sight in the hand-to-hand struggle with Puritanism, and his influence, so far from being immediate and confined to one particular era, has since the reaction against Puritanism been slowly and imperceptibly permeating and colouring English thought down to the present time. His work is, however, the earliest in English prose with enough of the preserving salt of excellence to adapt it to the mental palate of modern readers. Attempts more elaborate than those of the old chroniclers had been made two centuries previously to employ English prose both for narrative and for discussion; and, a few years before him, Roger Ascham, Sir Thomas More, Latimer, Sir Philip Sidney, the compilers of the prayer book, and various translators of the Bible had in widely different departments of literature brought to light many samples of the rich wealth of expression that was latent in the language; but Hooker's is the first independent work in English prose of notable power and genius, and the vigour and grasp of its thought are not more remarkable than the felicity of its literary style. Its more usual and obvious excellences are clearness of expression, notwithstanding occasionally complicated methods; great aptness and conciseness in the formation of individual clauses, and such a fine sense of proportion and rhythm in their arrangement as almost conceals the difficulties of syntax by which he was hampered; finished simplicity, notwithstanding a stateliness too uniform and unbroken; a nice discrimination in the choice of words and phrases, so as both to portray the exact shade of his meaning, and to express each of his thoughts with that degree of emphasis appropriate to its place in his composition. In regard to qualities more relating to the matter than the manner we may note the subtle and partly hidden humour; the strong enthusiasm underlying that seemingly calm and passionless exposition of principles

[1] If Bacon was the author of *The Christian Paradoxes*, his philosophical standpoint in reference to religion was not only less advanced than that of Hooker, but in a sense directly opposed to it.

which continually led him away from the minutiæ of temporary disputes, and has earned for him the somewhat misleading epithet of "judicious"; the solidity of learning, not ostentatiously displayed, but indicated in the character and variety of his illustrations and his comprehensive mastery of all that relates to his subject; the breadth of his conceptions, and the sweep and ease of his movements in the highest regions of thought; the fine poetical descriptions occasionally introduced, in which his eloquence attains a grave, rich, and massive harmony that compares not unfavourably with the finest prose of Milton. His manner is, of course, defective in the flexibility and variety characteristic of the best models of English prose literature after the language had been enriched and perfected by long use, and his sentences, constructed too much according to Latin usages, are often tautological and too protracted into long concatenations of clauses; but if, when regarded superficially, his style presents in some respects a stiff and antiquated aspect, it yet possesses an original and innate charm that has retained its freshness after the lapse of nearly three centuries.

The direct interest in the *Ecclesiastical Polity* is now philosophical and political rather than theological, for what theological importance it possessed was rather in regard to the spirit and method in which theology should be discussed than in regard to the decision of strictly theological points. Hooker bases his reasoning on principles which he discovered in Augustine and Thomas Aquinas, but the intellectual atmosphere of his age was different from that which surrounded them; he was acted upon by new and more various impulses enabling him to imbibe more thoroughly the spirit of Greek thought which was the source of their inspiration, and thus to reach a higher and freer region than scholasticism, and in a sense to inaugurate modern philosophy in England. It may be admitted that his principles are only partially and in some degree capriciously wrought out,—that if he is not under the dominion of intellectual tendencies leading to opposite results there are occasional blanks and gaps in his argument where he seems sometimes to be groping after a meaning which he cannot fully grasp; but he is often charged with obscurity simply because readers of various theological schools, beholding in his principles what seem the outline and justification of their own ideas, are disappointed when they find that these outlines instead of acquiring as they narrowly examine them the full and definite form of their anticipations, widen out into a region beyond their notions and sympathies, and therefore from their point of view enveloped in mist and shade. It is the exposition of philosophical principles in the first and second books of the *Polity*, and not the application of these principles in the remaining books that gives the work its standard place in English literature. It was intended to be an answer to the attacks of the Presbyterians on the Episcopalian polity and customs, but no attempt is made directly to oust Presbyterianism from the place it then held in the Church of England. The work must rather be regarded as a remonstrance against the narrow ground chosen by the Presbyterians for their basis of attack, Hooker's exact position being that "a necessity of polity and regiment may be held in all churches without holding any form to be necessary." The general purpose of his reasoning is to vindicate Episcopacy from objections that had been urged against it, but he attains a result which has other and wider consequences than this. The fundamental principle on which he bases his reasoning is the unity and all-embracing character of law—law "whose seat," he beautifully says, "is the bosom of God, whose voice the harmony of the world." Law—as operative in nature, as regulating each man's individual character and actions, as seen in the formations of societies and governments—is equally a manifestation and development of the divine order according to which God Himself acts, is the expression in various forms of the divine reason. He makes a distinction between natural and positive laws, the one being eternal and immutable, the other varying according to external necessity and expediency; and he includes all the forms of government under laws that are positive and therefore alterable according to circumstances. Their application is to be determined by reason, reason enlightened and strengthened by every variety of knowledge, discipline, and experience. The leading feature in his system is the high place assigned to reason, for, though affirming that certain truths necessary to salvation could be made known only by special divine revelation, he yet elevates reason into the criterion by which these truths are to be judged, and the standard to determine what in revelation is temporal and what eternal. "It is not the word of God itself," he says, "which doth or possibly can assure us that we do well to think it His word." At the same time he saves himself from the dangers of abstract and rash theorizing by a deep and absolute regard for facts, the diligent and accurate study of which he makes of the first importance to the proper use of reason. "The general and perpetual voice of men is," he says, "as the sentence of God Himself. For that which all men have at all times learned, nature herself must needs have taught; and, God being the author of nature, her voice is but His instrument." Applying his principles to man individually, the foundation of morality is, according to Hooker, immutable, and rests "on that law which God from the beginning hath set Himself to do all things by;" this law is to be discovered by reason; and the perfection which reason teaches us to strive after is stated, with characteristic breadth of conception and regard to the facts of human nature, to be "a triple perfection: first a sensual, consisting in those things which very life itself requireth, either as necessary supplements, or as beauties or ornaments thereof; then an intellectual, consisting in those things which none underneath man is either capable of or acquainted with; lastly, a spiritual or divine, consisting in those things whereunto we tend by supernatural means here, but cannot here attain unto them." Applying his principles to man as a member of a community, he assigns practically the same origin and sanctions to ecclesiastical as to civil government. His theory of government forms the basis of the *Treatise on Civil Government* by Locke, although Locke developed the theory in a way that Hooker would not have sanctioned. The force and justification of government Hooker derives from public approbation, either given directly by the parties immediately concerned, or indirectly through inheritance from their ancestors. "Sith men," he says, "naturally have no full and perfect power to command whole politic multitudes of men, therefore utterly without our consent we could in such sort be at no man's commandment living. And to be commanded we do consent, when that society whereof we are part hath at any time before consented, without revoking the same after, by the like universal agreement." His theory as he stated it is in various of its aspects and applications liable to objection; but taken as a whole it is the first philosophical statement of the principles which, though disregarded in the succeeding age, have since regulated political progress in England, and gradually modified its constitution into its present form. One of the corollaries of his principles, his theory of the relation of church and state, according to which, with the qualifications implied in his theory of government, he asserts the royal supremacy in matters of religion, and identifies the church and commonwealth as but different aspects of the same government, has not met with such general approval, but practically it is the theory of the ablest defenders of state churches at the present time.

A life of Hooker by Dr Gauden was published in his edition of Hooker's works, London, 1662. To correct the errors in this life Walton wrote another, which was published in the 2d edition of Hooker's works in 1666. The standard modern edition of Hooker's works is that by Keble, which first appeared in 1836, and has since been several times reprinted. The first book of the *Laws of Ecclesiastical Polity* has been edited for the "Clarendon Press Series," by R. W. Church, M.A. (1868). (T. F. H.)

HOOKER, Sir William Jackson (1785-1865), a distinguished English botanist, was born at Norwich, July 6, 1785. His father, Joseph Hooker of Exeter, a member of the same family as the celebrated Richard Hooker, devoted much of his time to the study of German literature and the cultivation of curious plants. The son was educated at the high school of Norwich, on leaving which his independent means enabled him to travel and to take up as a recreation the study of natural history, especially ornithology and entomology. He subsequently confined his attention to botany, on the recommendation of Sir James E. Smith, whom he had consulted respecting a rare moss picked up in a ramble. His first botanical expedition was made in Iceland, in the summer of 1809, at the suggestion of Sir Joseph Banks; but the natural history specimens which he collected, with his notes and drawings, were lost on the homeward voyage through the burning of the ship, and the young botanist himself had a narrow escape with his life. A good memory, however, aided him to publish an account of the island, and of its inhabitants and flora (*Tour in Iceland*, 1809), privately circulated in 1811, and reprinted in 1813. In 1810-11 he made extensive preparations, and sacrifices which proved financially serious, with a view to accompany Sir R. Brownrigg to Ceylon to explore that teeming though then almost unknown island; but the disturbances created by the king of Candy led to the abandonment of the projected expedition. Hooker immediately fixed his attention, however, on the formation of an herbarium which was destined to become the finest in Europe; and in 1814 he spent nine months in botanizing excursions in France, Switzerland, and Northern Italy, during which he became acquainted with many of the leading Continental botanists. The following year he married the eldest daughter of Mr Dawson Turner, F.R.S., a lady who, during forty years, shared in the labours of his study. Settling at Holes-worth, Suffolk, he continued to increase his herbarium, which became the resort and admiration of British and Continental botanists. In 1816 appeared the *British Jungermanniæ*, his first scientific work, which is even now a model of microscopic dissection and of accurate description and figuring. This was succeeded by a new edition of Curtis's *Flora Londinensis*, for which he wrote the descriptions (1817–28); by a description of the *Plantæ Cryptogamicæ* of A. de Humboldt and A. Bonpland; by the *Muscologia Britannica*, a very complete account of the mosses of Great Britain and Ireland, prepared in conjunction with Dr T. Taylor (1818); and by his *Musci Exotici*, 2 vols. (1818–20), devoted to new foreign mosses and other cryptogamic plants. In 1820 he accepted the regius professorship of botany in Glasgow university, and entered upon a new career of activity, in which he soon became popular as a lecturer, his style being both clear and ready. The following year he brought out the *Flora Scotica*, in which the natural method of arrangement of British plants was given with the artificial. During the twenty years he remained at Glasgow he prepared and took part in many works, the more important being the following:—

The *Botanical Illustrations*; *Exotic Flora*, indicating such of the specimens as are deserving cultivation, 3 vols. 1822–27; *Account of Sabine's Arctic Plants*, 1824; *Catalogue of Plants in the Glasgow Botanic Garden*, 1825; the Botany of *Parry's Third Voyage*, 1826; *The Botanical Magazine*, 1827–65, 38 vols.; *Icones Filicum*, in concert with Dr R. K. Greville, 1829–31, 2 vols.; *British Flora*, of which several editions appeared, undertaken with Dr G. A. W. Arnott, 1830, &c.; *British Flora Cryptogamia* (Fungi), 1833; *Characters of Genera from the British Flora*, 1830; *Flora Boreali-Americana*, 1840, 2 vols., being the botany of British North America collected in Sir J. Franklin's voyage; *The Journal of Botany*, 1830–42, 4 vols.; *Companion to the Botanical Magazine*, 1835–36, 2 vols.; *Icones Plantarum*, 1837–54, 10 vols.; the *Botany of Beechey's Voyage to the Pacific and Behring's Straits* (with Dr Arnott, 1841); the *Genera Filicum*, 1842, from the original coloured drawings of F. Bauer, with additions and descriptive letterpress; *The London Journal of Botany*, 1842–48, 7 vols.; *Notes on the Botany of the Antarctic Voyage of the Erebus and Terror*, 1843; *Species Filicum*, 1846–64, 5 vols., the standard work on this subject; *A Century of Orchideæ*, 1846; *Journal of Botany and Kew Garden Miscellany*, 1849–57, 9 vols. In 1849 he edited the *Niger Flora* of Vogel, and the *Rhododendrons of Sikkim*, *Victoria Regia*, 1851; *Museum of Economic Botany at Kew*, 1855; *Filices Exotici*, 1857–59; *The British Ferns*, 1861–62; *A Century of Ferns*, 1854; *A Second Century of Ferns*, 1860–61. The estimation in which he held his patron the duke of Bedford is shown in the *Letter* on his grace's death printed in 1840, calling attention to the services rendered by him to botany and horticulture.

It was mainly by Hooker's exertions that botanists were appointed to the Government expeditions. While his works were in progress his herbarium received large and valuable additions from all parts of the globe, and his position as a botanist was thus vastly improved. He received the honour of knighthood from William IV. in 1836 in consideration of his meritorious researches in scientific botany; and a few years later, in 1841, he was appointed director of the Royal Botanical Gardens of Kew, on the resignation of Mr Aiton. The attainment of this post had long been the object of his life. The gardens flourished under his administration; the Government had confidence in him; and his numerous friends and correspondents took pride in contributing to the scientific needs of his herbarium. From small beginnings the gardens expanded under his direction to 75 acres, with an arboretum of 270 acres; and three museums, enriched with many thousand examples of vegetable products, have been added, forming together, with the magnificent palm-house and conservatories, the most delightful and beautiful resort that the inhabitants of London possess; while his extensive library of reference and admirably arranged herbarium, the greater part of which was presented by Sir William to the country, form a constant attraction to the botanist. He was engaged on the *Synopsis Filicum* with J. G. Baker when an epidemic at Kew brought his valuable life to a close. He died August 12, 1865, in the eighty-first year of his age.

HOOLE, John (1727–1803), translator and dramatist, was born at Moorfields, London, in December 1727. At the age of seventeen he became a clerk in the accountants' department of the East India House. His leisure hours he devoted to the study of Latin and especially Italian, after obtaining a mastery of which he commenced writing translations of the chief works of the Italian poets. He published the *Jerusalem Delivered* of Tasso in 1763, the *Orlando Furioso* of Ariosto in 1773–1783, the *Dramas* of Metastasio in 1767, and *Rinaldo*, an early work of Tasso, in 1792. He also wrote the following dramas—*Cyrus* (1768), *Timanthes* (1770), and *Cleonia* (1775), none of which achieved success. The verses of Hoole have been praised by Johnson, with whom he was on terms of intimacy, but, though correct, smooth, and flowing, they cannot be commended for any other merit; and the noble poetry of Italy, transmuted through the crucible of his translations, becomes spiritless and commonplace. In 1773 he was promoted to be auditor of Indian accounts, which office he resigned in 1783, and in 1786 he retired to Abinger near Dorking, Surrey, where he died 2d April 1803.

See *Anecdotes of the Life of John Hoole*, by the Rev. Samuel Hoole, London, 1803.

HOOPER, John (*c.* 1495–1555), bishop and martyr, was a native of Somersetshire, and was born about 1495. He was educated at Merton College, Oxford, and after taking his degree of bachelor of arts in 1518 joined the order of Cistercian monks at Gloucester. Subsequently, "while living too much of a court life in the palace of the king," his attention was directed to the writings of Zwingli, and the result of his perusing them was that after a diligent study of the Scriptures he became a zealous advocate of the principles of the Reformation. For a short time he was chaplain to Sir Thomas Arundel, but, being warned of the danger to which his opinions exposed him, he in 1539 made his escape to France. Returning to England shortly afterwards, he found that plots were again being laid for his life, and escaped to Ireland disguised as a sailor. From Ireland he again went to France, passing thence to Germany, where he married, probably in 1546. After his marriage he settled in Zurich till March 1549, when he set out for England. Immediately on arriving in London he began to apply himself to the work of instructing the masses, and so successful were his labours that the churches in which he lectured were crowded by eager audiences, and that the king specially requested him to remain in London to further the progress of the Reformation. In 1550 he was presented to the bishopric of Gloucester; but, refusing it on account of objections to the oath and vestments, he was summoned before the council, and ultimately was imprisoned for some time in the Fleet, till he intimated that his scruples had been removed. The duties of his episcopate he discharged with a diligence, zeal, and self-sacrifice that have been rarely equalled. He preached three or four times a day in the towns and villages of his diocese, and so regardless was he of fatigue that his wife wrote Bullinger to "recommend Master Hooper to be more moderate in his labour," lest his "overabundant exertions should cause a premature decay;" he made minute inquiry into the knowledge, doctrine, conduct, and worldly condition of his clergy, whose impoverished livings he petitioned the council to be allowed to augment out of his own income; and he supplied a free dinner in his hall to the poor of the city daily, sitting down and sharing it with them. In 1552 he was created bishop of Worcester *in commendam*. On the accession of Mary in the following year he was immediately arrested and sent to the Fleet, and after suffering eighteen months' imprisonment he was on January 29, 1555, tried for heresy and condemned to death. The sentence was carried out on February 9th, the martyr enduring the agonies of the stake, which on account of the accidental use of green wood were unusually protracted, with great fortitude. Hooper's opinions were more decidedly anti-Romish than those of Cranmer or Ridley, and very nearly identical with those afterwards promulgated by the Puritans. He was the author of various sermons and controversial treatises.

His *Early Writings*, edited for the Parker Society by the Rev. Samuel Carr, appeared in 1843, and his *Later Writings*, edited for the same society by the Rev. Charles Nevinson, M.A., in 1852. A new edition of his works was published at Oxford in 1855.

HOOPING-COUGH, or Whooping-Cough (syn. *Pertussis*, Chin-Cough), an infectious disease of the respiratory mucous membrane, manifesting itself by frequently recurring paroxysms of convulsive coughing accompanied with peculiar sonorous inspirations. It occurs for the most part among children, and only once in a lifetime.

The specific cause of hooping-cough is unknown, but the view which ascribes it to some atmospheric condition appears to derive support from the frequency of this disease as an epidemic; whether, however, that be the presence of a peculiar form of germ, as is held by some, remains as yet undetermined. Although specially a disease of childhood, hooping-cough is by no means limited to that period, but may occur at any time of life, even to old age, should there have been no previous attack. It is most common between the ages of one and four, and is rare after ten. Dr Edward Smith's statistics showed that it was the most fatal of all diseases of children under one year, that 68 per cent. of the deaths from hooping-cough occurred under the age of two, and that only 6 per cent. of the deaths were recorded after five years. It has been occasionally observed in newly-born infants. It is more common in female than in male children. Hooping-cough is highly contagious during any stage of its progress, but apparently more so in its commencement. It is not only communicated by the breath, but may, as has been clearly proved, be conveyed by the medium of clothing and by persons who have been in contact with those affected. It is said to be favoured by cold and damp weather, and to prevail mostly in spring and autumn, doubtless owing to these seasons increasing the predisposition to affections of the respiratory passages. Epidemics of hooping-cough have often been noticed to succeed or even to accompany those of measles or scarlet fever, although no causal connexion between these diseases can be admitted.

With respect to the symptoms of hooping-cough, three stages of the disease are recognized, viz., (1) the catarrhal stage, (2) the spasmodic stage, (3) the stage of decline.

The *first stage* is characterized by the ordinary phenomena of a catarrh, with sneezing, watering of the eyes, irritation of the throat, feverishness and cough, but in general there is nothing in the symptoms to indicate that they are to develop into hooping-cough. The catarrhal stage usually lasts from ten to fourteen days. The *second stage* is marked by the abatement of the catarrhal symptoms, but at the same time by increase in the cough, which now occurs in irregular paroxysms both by day and by night. Each paroxysm consists in a series of violent and rapid expiratory coughs, succeeded by a loud sonorous or crowing inspiration—the "whoop." During the coughing efforts the air is driven with great force out of the lungs, and as none can enter the chest the symptoms of impending asphyxia appear. The patient grows deep-red or livid in the face, the eyes appear as if they would burst from their sockets, and suffocation seems imminent till relief is brought by the "whoop"—the louder and more vigorous the better. Occasionally blood bursts from the nose, mouth, and ears, or is extravasated into the conjunctiva of the eyes. A single fit rarely lasts beyond from half to three-quarters of a minute, but after the "whoop" another recurs, and of these a number may come and go for several minutes. The paroxysm ends by the coughing or vomiting up of a viscid tenacious secretion, and usually after this the patient seems comparatively well, or, it may be, somewhat wearied and fretful. The frequency of the paroxysms varies according to the severity of the case, being in some instances only to the extent of one or two in the whole day, while in others there may be several in the course of a single hour. Slight causes serve to bring on the fits of coughing, such as the acts of swallowing, talking, laughing, crying, &c., or they may occur without any apparent exciting cause. In general children come to recognize an impending attack by a feeling of tickling in the throat, and they cling with dread to their mothers or nurses, or take hold of some object near them for support during the paroxysm; but although exhausted by the severe fit of coughing they soon resume their play, apparently little the worse. The attacks are on the whole most severe at night. This stage of the disease usually continues for thirty to fifty days, but it may be shorter or longer. It is during this time that complications are apt to arise which may become a source of danger greater even than the malady itself. The chief of these are inflammatory affections of the bronchi and lungs, and convulsions, any of which may prove fatal. When, however, the disease progresses favourably, as it usually does, the *third* or *terminal stage* is announced by the less frequent paroxysms of the cough, which generally loses in great measure its "whooping" character. The patient's condition altogether undergoes amendment, and the symptoms disappear in from one to three weeks. It is to be observed, however, that for a long period afterwards in any simple catarrh from which the patient suffers the cough often assumes a spasmodic character, which may suggest the erroneous notion that a relapse of the hooping-cough has occurred.

In severe cases it occasionally happens that the disease leaves behind it such structural changes in the lungs (emphysema, &c.), as entail permanent shortness of breathing or a liability to attacks of asthma. Further, hooping-cough is well known to be one of those diseases of early life which are apt to give rise to a weakened and vulnerable state of the general health, or to call into activity any inherited morbid tendency, such as that towards consumption.

As regards the treatment of hooping-cough in mild cases, little is necessary beyond keeping the patient warm and carefully attending to the general health. The remedies applicable in the case of catarrh or the milder forms of bronchitis are of service here, while gentle counter-irritation to the chest by stimulating liniments may be employed all through the attack. In mild weather the patient may be in the open air. In the more severe forms efforts have to be employed to modify the severity of the paroxysms. Numerous remedies are recommended, the chief of which are the bromides of ammonium or potassium, hydrocyanic acid, chloral, chloric ether, &c. These can only be safely administered under medical advice, and with due regard to the symptoms in individual cases. During convalescence, where the cough still continues to be troublesome, a change of air will often effect its removal. (J. O. A.)

HOOPOE (French *Huppe*, Latin *Upupa*, Greek ἔποψ—all names bestowed apparently from its cry), a bird long celebrated in literature, and conspicuous by its variegated plumage and its large erectile crest,[1] the *Upupa epops* of naturalists, which is the type of the very peculiar Family *Upupidæ*, placed by Prof. Huxley in his group *Coccygomorphæ*,

[1] Hence the secondary meaning of the French word *huppe*—a crest or tuft (*cf.* Littré, *Dict. Française*, i. 2067).

but considered by Dr Murie (*Ibis*, 1873, p. 208) to deserve separate rank as *Epopomorphæ*. This species has an exceedingly wide range in the Old World, being a regular summer-visitant to the whole of Europe, in some parts of which it is abundant, as well as to Siberia, mostly retiring southwards in autumn to winter in equatorial Africa and India, though it would seem to be resident throughout the year in North-Eastern Africa and in China. Its power of wing ordinarily seems to be feeble; but it is capable of very extended flight, as is testified by its wandering habits (for it occasionally makes its appearance in places very far removed from its usual haunts), and also by the fact that when pursued by a Falcon it will rapidly mount to an extreme height and frequently effect its escape from the enemy. About the size of a Thrush, with a long, pointed, and slightly arched bill, its head and neck are of a golden-buff—the former adorned by the crest already mentioned, which begins to rise from the forehead and consists of broad feathers, gradually increasing in length, tipped with black, and having a subterminal bar of yellowish-white. The upper part of the back is of a vinous-grey, and the scapulars

Hoopoe.

and flight-feathers are black, broadly barred with white tinged in the former with buff. The tail is black with a white chevron, marking off about the distal third part of its length. The legs and feet are as well adapted for running or walking as for perching, and the scutellations are continued round the whole of the tarsi. Chiefly on account of this character, which is also possessed by the Larks, Sundevall (*Tentamen*, pp. 53–55) united the *Upupidæ* and *Alaudidæ* in the same "cohors" *Holaspideæ*. Comparative anatomy, however, forbids its being taken to signify any real affinity between these groups, and the resemblance on this point, which is by no means so striking as that displayed by the form of the bill and the coloration in certain Larks (of the genus *Certhilauda*, for instance), must be ascribed to analogy merely, though at present no explanation of the why and the wherefore can be offered.

Pleasing as is the appearance of the Hoopoe as it fearlessly parades its showy plumage, its habits are much the reverse. All observers agree in stating that it delights to find its food among filth of the most abominable description, and this especially in its winter-quarters. But where it breeds, its nest, usually in the hole of a tree or of a wall, is not only partly composed of the foulest material, but its condition becomes worse as incubation proceeds, for the hen scarcely ever leaves her eggs, being assiduously fed by the cock as she sits; and when the young are hatched, their fæces are not removed by their parents,[1] as is the case with most birds, but are discharged in the immediate neighbourhood of the nest, the unsanitary condition of which can readily be imagined. Worms, grubs, and insects generally, form the Hoopoes' food, and upon it they get so fat in autumn that they are esteemed a delicate morsel in some of the countries of Southern Europe, and especially by the Christian population of Constantinople.[2]

Not a year passes but the Hoopoe makes its appearance in some part or other of the British Islands, most often in spring, and if unmolested would doubtless stop to breed in them, and a few instances are known in which it has done so. But its remarkable plumage always attracts attention, and it is generally shot down so soon as it is seen, and before it has time to begin a nest, which there is reason to think would not in a temperate climate become so offensive a nuisance as it is in more southern latitudes. Eight or nine so-called species of the genus have been described, but of them the existence of five only has been recognized by the writers who have most lately investigated them—Messrs Sharpe and Dresser (*Birds of Europe*, pt. vii.). Besides the *Upupa epops* above treated, these are *U. indica*, resident in India and Ceylon; *U. longirostris*, which seems to be the form of the Indo-Chinese countries; *U. marginata*, peculiar to Madagascar; and *U. africana* or *U. minor* of some writers, which inhabits South Africa to the Zambesi on the east and Benguela on the west coast. In habits and appearance they all resemble the best-known and most widely-spread species, and their particular differences cannot, for want of space, be here pointed out.[3] (A. N.)

HOORN, a town of Holland, at the head of an arrondissement in the province of North Holland, 20 miles N.N.E. of Amsterdam and 10 miles S.W. of Enkhuizen, with which it is connected by the road called De Streek, or The Stroke. The Hoornerhop, a bay of the Zuyder Zee, forms a good outer harbour, and the inner harbour is shut in by a sluice which can be opened only when the water within and without has nearly the same level. Of the massive walls by which Hoorn was formerly surrounded few indications are left except in the shape of promenades and gardens; but two of the old gateways, the East Gate and the Cow Gate, and a few towers still remain. The West Gate is gone, with its monument to the filial piety of Lambert Meliszoon, a young man who by heroic exertions managed to bring his aged mother to refuge within the town when the country around was overrun by the Spaniards in 1579. Most of the ordinary houses are old-fashioned, and interesting from the sculptures or carvings with which they are decorated; but the public buildings have little to boast of in the way of architectural excellence or peculiarity. It is enough to mention the town-house (formerly the state college), the weigh-house, the old admiralty-house or princes' court, the house of correction (formerly the admiralty magazine), the old mint, occupied as barracks, the new infirmary, the orphanage, and the old women's hospital. Of the eight churches the principal is the Groote Kerk, occupying the site of the famous 14th century edifice of the same name, which perished by fire in 1838. A communal high school, a Latin school, a medical and chemical society, and a branch of the society *Tot nut van 't Algemeen* are the main

---

[1] This indeed is denied by Naumann, but by him alone; and the statement in the text is confirmed by many eye-witnesses.

[2] Under the name of *Dukipath*, in the authorized version of the Bible translated "Lapwing" (Lev. xi. 19, Deut. xiv. 18), the Hoopoe was accounted unclean by the "Jewish law." Arabs have a great reverence for the bird, imparting to it marvellous medicinal and other qualities, and making use of its head in all their charms (*cf.* Tristram, *Nat. Hist. of the Bible*, pp. 208, 209).

[3] The genera *Rhinopomastus* and *Irrisor* are generally placed in the Family *Upupidæ*, but Dr Murie (*l.c.*), after an exhaustive examination of their osteology, regards them as forming a group of equal value.

educational institutions. The extensive foreign commerce which Hoorn enjoyed in the 16th and 17th centuries has almost entirely vanished; but there is still a good trade with other parts of the Netherlands, especially in cheese and cattle. The annual export of cheese is about 23,000 tons. Saw-mills and boat-building yards are the chief industrial establishments. The population was 8780 in 1870, and 9763 in 1876. Of the 9391 inhabitants in the commune in 1870, 5112 belonged to the Dutch Reformed Church, 2954 were Roman Catholics, and 386 were Jews.

Hoorn, Latinized as Horna or Hornum, has existed at least from the first part of the 14th century, as it is mentioned in a document of the year 1311, five years earlier than the date usually assigned for its foundation. It was at Hoorn in 1416 that the first great net was made for the herring fishery, an industry which long proved an abundant source of wealth to the town. During the 15th century Hoorn shared in the troubles occasioned by the different factions; in 1518 it was molested by Groote Pier, and in 1566 and 1567 by Henry of Brederode. The Spanish forces entered the town in 1569; but in 1572 it cast in its lot with the States of the Netherlands, and four years later it assisted in defeating the duke of Alva's admiral, Count de Bossu, who remained for some time a prisoner within its walls. The riot against the burgomaster Langewagen in 1672 was a matter of purely local interest. A company of commerce and navigation was formed at Hoorn in 1720; but on the other hand, in 1795, the admiralty offices and storehouses were removed to Medemblik. The English under Abercromby took possession of the town in 1799, and in 1811 it suffered severely from the French. Among the celebrities of Hoorn are William Schouten, who discovered in 1616 the passage round Cape Horn or Hoorn, as he called it in honour of his birthplace; Abel Janszoon Tasman, whose fame is associated with Tasmania; and Jan Pieters Koen, the founder of Batavia.

HOP (German, *Hopfen*; French, *houblon*), *Humulus Lupulus*, L., the sole representative of its genus, an herbaceous twining plant, belonging to the natural order *Cannabinaceæ*, which is by some botanists included in the larger group called *Urticaceæ* by Endlicher. It is of common occurrence in hedges and thickets in the southern counties of England, but is believed not to be native in Scotland. On the Continent it is distributed from Greece to Scandinavia, and extends through the Caucasus and Central Asia to the Altai Mountains. It is common, but doubtfully indigenous, in the northern and western States of North America, and has been introduced into Brazil, Australia, and the Himalayas.

It is a diœcious perennial plant, producing annually several long twining roughish striated stems, which twist from left to right, are often 15 to 20 feet long, and climb freely over hedges and bushes. The leaves are stalked, opposite, 3–5 lobed, and coarsely serrate, and bear a general resemblance to those of the vine, but are, as well as the whole plant, rough to the touch; the upper leaves are sometimes scarcely divided, or quite entire. The stipules are interpetiolar, each consisting of two lateral ones united, or rarely with the tips free. The male inflorescence (fig. 1, A) forms a panicle; the flowers consist of a small greenish five-parted perianth (*a*) enclosing five stamens, whose anthers (*b*) open by terminal slits. The female inflorescence (fig. 1, B) is less conspicuous in the young state. The catkin or strobile consists of a number of small acute bracts, with two sessile ovaries at their base, each subtended by a rounded bractlet (*c*). Both the bracts and bractlets enlarge greatly during the development of the ovary, and form, when fully grown, the membranous scales of the strobile (fig. 2, *a*). The bracts can then only be distinguished from the bractlets by being rather more acute and more strongly veined. The perianth (fig. 1, *d*) is short, cup-shaped, undivided, and closely applied to the ovary, which it ultimately encloses. In the young strobile the two purple hairy styles (*e*) of each ovary project beyond the bracts. The ovary contains a single exalbuminous seed, containing a spirally-coiled embryo (fig. 2, *b*).

The ovary and the base of the bracts are covered with a yellowish powder, consisting of minute sessile grains (see vol. iv. p. 91, fig. 48) called lupulin or lupulinic glands (see vol. i. p. 381). These glands (fig. 2, *c*) are stated by Stoddart to be from $\frac{1}{200}$ to $\frac{1}{140}$ inch in diameter, like flattened subovate little saucers in shape, and attached to a short pedicel; by the expansion of the central portion during growth their apex ultimately becomes convex instead of concave. The upper or hemispherical portion consists of a delicate continuous membrane, and the lower part of tabular polyhedric cells. The stalk is not perceptible in the gland as found in commerce. When fresh the gland

Fig. 1.—Male (A) and Female (B) Inflorescence of the Hop.

is seen to be filled with a yellowish or dark brown liquid; this on drying contracts in bulk and forms a central mass. The contents of these glands, according to Lermer, are chiefly wax (myricylic palmitate) and resins, one of which is crystalline and unites with bases; with these the bitter acid of hops is present in small proportion. It is to these lupulinic glands that the medicinal properties of the hop are chiefly due. By careful sifting, about 1 oz. may be obtained from 1 lb of hops, but the East Kent variety is said to yield more than the Sussex hops.

In hop gardens a few male plants, usually three or four to an acre, are sometimes planted, that number being deemed sufficient to fertilize the female flowers. It is stated, however, that the female plant produces sufficient male flowers for self-fertilization (Royle). The blossoms are produced in August, and the strobiles are fit for gathering from the beginning of September to the middle of October, according to the weather.

The cultivation of hops for use in the manufacture of beer dates from an early period. In the 8th and 9th centuries hop gardens, called "humularia" or "humuleta," existed in France and Germany. In the herbarium of Apuleius (1050 A.D.), the hop ("hymele") is said to have been put in the usual drinks of England on account of its good qualities. Until the 16th century, however, hops appear to have been grown in a very fitful manner, and to a limited extent, generally only for private consumption; but after the commencement of the 17th century the cultivation increased rapidly. At the present time England produces a larger quantity than any other country in Europe. Formerly several plants were used as well as hops to season ale, hence the name "alehoof" for *Nepeta Glechoma*, and "alecost" for *Balsamita vulgaris*. The sweet gale, *Myrica Gale*, and the sage, *Salvia officinalis*, were also similarly employed. Various hop substitutes, in the form of powder, have been offered in commerce of late years, most of which appear to have quassia as a chief ingredient.

The young tender tops of the hop are in Belgium cut off in spring and eaten like asparagus, and are forced from December to February. They are not only considered a delicacy, but valuable as a diet for anæmic, scrofulous, and rachitic persons.

Fig. 2.—Fruit of Hop.

Hops are extensively cultivated in parts of New England, New York, and Michigan, and most of the hops consumed in the United States are supplied by those districts. Although the hop was introduced into America nearly 250 years ago, and its cultivation encouraged by legislative enactments in 1657, it is only about seventy-five years since its culture was commenced on an extensive scale; but from that time the progress has been rapid, and hops have been grown in nearly every State in the Union. The amount produced in the United States was estimated in 1840 at 6196 bales, in 1850 at 17,485, in 1860 at 54,960, and in 1870 at 127,283. As in England, the hop is subject to disease and blight, and in consequence the crop is variable; thus, in 1869, 69,463 bales were exported from New York and none imported, and in 1873 only 315 bales were exported and 20,885 imported. The English cluster and grape hops seem to be most generally cultivated in New York and Wisconsin. Hops are also grown largely in Belgium, Prussia, France, Würtemberg, and central Germany. In 1879 only 7153 cwts. of hops were exported from England chiefly to Australia and other British possessions, while 262,765 cwts. were imported, of which 108,306 cwts. were derived from the United States, 63,485 cwts. from Belgium, 50,567 from Germany, 26,796 from Holland, and smaller quantities from France and British North America. The first packages of hops collected in England often fetch an extravagant price, and are sometimes disposed of with remarkable celerity. The first pocket of hops gathered in 1879 is said to have been picked, dried, sent to London, sold by auction, subjected to hydraulic pressure, packed and banded with iron, covered with three coats of paint, and despatched to an Indian mail steamer—all within twenty-four hours. The better qualities are usually packed in fine and the inferior in coarse sacking. In Germany two varieties of the hop are distinguished, the August and the autumn hop, the former being preferred.

The stem of the hop abounds in fibre similar to that of hemp and flax, and has been used in Sweden in the production of a strong durable white cloth. Hitherto it has been usual to steep the stem in water during the whole winter in order to separate the fibre easily. A much quicker process has, however, been patented, by which the fibre can be speedily extracted. This process consists in boiling the stems first for three quarters of an hour in alkaline lye, and then, after rinsing in water, for the same time in acetic acid; the fibre is thus obtained in a state fit for bleaching. The leaves, stem, and root possess also an astringent property, and their use for tanning purposes was hence at one time patented in England. The leaves have also been recommended as fodder in the fresh state, mixed with other materials, and are said to increase the quantity and improve the quality of milk yielded by cows. The stems or "bine" are usually burned in the hop garden. The spent hops from breweries form excellent manure for light soils, and together with the leaves should be returned to the hop-gardens, the materials absorbed from the ground by the hop plant being thus in some measure restored to it.

By distillation with water, hops yield 0·9 per cent. of a volatile oil, of a greenish colour if from fresh, but reddish-brown if from old hops. Exposed to the air it resinifies. This oil, according to Personne, contains *valerol*, $C_6H_{10}O$, which soon passes into valerianic acid, 0·1 to 0·17 of this acid having been found by Méhu in the lupulinic glands. The unpleasant odour of old hops is due to this change, which may be prevented or retarded by exposure to the action of sulphurous acid gas. For medicinal use fresh hops which have neither undergone this change nor been treated with sulphurous acid should be used. For brewing purposes, according to Liebig, the use of sulphured hops is not objectionable. The bitter acid principle, $C_{32}H_{50}O_7$, to which hops probably owe their tonic properties, although noticed by Payen, was first obtained in the pure state by Lermer in 1863. It crystallizes in large rhombic prisms, and is soluble in ether. It has been variously called lupulin, lupuline, lupulite, and humulin. Griessmayer (1874) has shown that hops contain also in small proportion a liquid volatile alkaloid, not yet analysed, which has the odour of conia; to this alkaloid its narcotic property is perhaps due. The same chemist found trimethylamine in hops. Etti (1876–78) has found in the scales of the hop strobiles an astringent principle, *humulotannic acid*, $C_{50}H_{48}O_{26}$, which is incapable of precipitating gelatin, but which, when boiled in alcohol or water or heated to 130° C., changes to a red substance, *phlobaphen*, $C_{50}H_{46}O_{25}$, whose solution in alcohol possesses that property. Etti likewise obtained a crystalline white and an amorphous brown resin,[1] also malate,

[1] Issleib (*Archiv der Pharmacie*, May 1880) has further elucidated the chemical relationship of the constituents of the resin, essential oil, and bitter principle.

citrate, nitrate, phosphate, and sulphate of potassium, and pectic acid.

The use of hops in medicine dates from a very early period. Coles, in his *History of Plants* (1657), says—"They are good to cleanse the kidneys of gravel and provoke urine; they likewise open obstructions of the liver and spleen, and cleanse the blood and loosen the belly; and as they cleanse the blood, so consequently they help to cure eruptions of the skin." Brooke's *Dispensatory* (1753) recommends them also as an alterative, and as a remedy for hypochondriasis. Hops are, however, but little used in medicine at the present day, although official in the British and United States Pharmacopœias. According to Bartholow hops increase the action of the heart, excite the cutaneous circulation, and cause diaphoresis. A slight cerebral excitement is first produced, soon followed by a disposition to sleep. Hops also possess some anaphrodisiac properties. The preparations used are the tincture, infusion, and extract, the oleoresin, and the lupulinic glands. The drug is generally employed either as a stomachic in dyspepsia, or to allay nervous irritability or cerebral excitement in delirium tremens, where the use of opium is inadmissible. A combination of the tinctures of lupulin and capsicum is said to be one of the best substitutes for alcoholic stimulants when their habitual use is to be discontinued. A pillow stuffed with hops forms a well-known domestic remedy for sleeplessness, and a bag of hops dipped in hot water is often used as an external application to relieve pain or inflammation, especially of the abdominal organs.

(E. M. H.)

HOPE, THOMAS (*c.* 1770–1831), the author of *Anastasius*, born at London about 1770, was descended from a branch of an old Scotch family who for several generations were extensive merchants in London and Amsterdam. About the age of eighteen he started on a tour through various parts of Europe, Asia, and Africa, where he interested himself especially in architecture and sculpture, making a large collection of the principal objects which attracted his attention. On his return to London he purchased a house in Duchess Street, which he fitted up in a very ornamental and elaborate style, from drawings made by himself. In 1805 he published sketches of his furniture, accompanied by letterpress, in a folio volume, entitled *Household Furniture and Decoration*, which had considerable influence in effecting a change in the upholstery and interior decoration of houses. In 1809 he published the *Costumes of the Ancients*, and in 1812 *Designs of Modern Costumes*, works which display a large amount of special antiquarian research. He was also a munificent patron of the highest forms of art, and both at his London house and his country seat at Deepdene near Dorking he formed large collections of paintings, sculpture, and antiques. Thorwaldsen, the Danish sculptor, was indebted to him for the early recognition of his talents, and he also gave frequent employment to Chantrey and Flaxman. In 1819 he published anonymously his novel *Anastasius, or Memoirs of a Modern Greek, written at the close of the 18th century*, a work which, chiefly on account of the novel character of its subject, caused a great sensation. It was generally attributed to Lord Byron, but, though remarkable for the acquaintance it displays with Eastern life, and distinguished by considerable imaginative vigour and much graphic and picturesque description, its paradoxes are not so striking as those in which Lord Byron indulged; and, notwithstanding some eloquent and forcible passages, the only reason which warranted its ascription to him was the general type of character to which its hero belonged. Hope died February 3, 1831. He was the author of two works published posthumously,—the *Origin and Prospects of Man*, 1831, in which he indulged in speculations diverging widely from the usual orthodox opinions, and an *Historical Essay on Architecture*, 1835, an elaborate description of the architecture of the Middle Ages, illustrated by drawings made by himself in Italy and Germany.

HÔPITAL. See L'HÔPITAL.

HOPKINS, EZEKIEL (1633–1690), bishop of Londonderry, and a Calvinistic divine of some repute, was born at Stanford, Devon (where his father was curate), in 1633, was educated at Magdalen College, Oxford, where he identified himself with the Presbyterian party, and about 1660 became assistant to Dr W. Spurstow of Hackney, the W.S. [UU.S.] of "Smectymnuus." He was subsequently presented to the living of St Mary Woolnoth, London, which at the outbreak of the plague he exchanged for that of St Mary's, Exeter. Having married a daughter of Lord Robartes, who in 1669 became lord-lieutenant of Ireland, he was soon afterwards promoted to the deanery of Raphoe, and in 1671 he was raised to the bishopric of that diocese. Translated to the see of Londonderry in 1681, he continued to discharge his episcopal functions until the period of the famous siege, when, after having vainly sought to inculcate the doctrine of passive resistance, he withdrew to London, where in 1689 he accepted the living of St Mary Aldermanbury. He died in June 1690.

His works, consisting chiefly of discourses, but including *A practical Exposition of the Lord's Prayer* and *An Exposition of the Ten Commandments*, were first published in a complete and uniform edition in 1701; they were reprinted in 4 vols. in 1809, with a *Life* prefixed, by Pratt, and again, in 2 vols., in 1841-44. Though marked by "strength of thought, originality of illustration, and felicity of style," they are now but seldom read.

HOPKINS, SAMUEL (1721–1803), the theologian from whom the Hopkinsians or Hopkinsian Calvinists take their name, was born at Waterbury, Connecticut, on September 17, 1721. About his fifteenth year he entered Yale College, where he graduated in 1741; he afterwards studied divinity at Northampton with Jonathan Edwards; and in 1743 he was ordained pastor of the church at Housatonnuc (now Great Barrington), Massachusetts. There in the midst of a small settlement of only thirty families he laboured for six and twenty years, preaching, studying, and writing, until in 1769 he was dismissed from his office on the alleged ground of want of funds for his support. He next began to preach in Newport, Rhode Island, where, in 1770, he was settled as pastor of a small congregation, and where, with an interval from 1776 to 1780, caused by the occupation of the British, he continued to labour until about the close of the century. In 1799 he had an attack of paralysis, from which he never wholly recovered; but he continued to preach occasionally, and with unimpaired mental vigour, almost until his death, which occurred on December 20, 1803.

While in vigour of intellect and in strength and purity of moral tone hardly inferior to Jonathan Edwards, Hopkins considerably excelled his master in force and energy of character. To him belongs the honour of having been one of the first to stir up and organize political action against slavery; and to his persistent though bitterly opposed efforts are chiefly to be attributed the law of 1774, which forbade the importation of negroes into New England, as also that of 1784, which declared that all children of slaves born after the following March should be free. He was the author of numerous pamphlets, addresses, and sermons; and he also published lives of Jonathan Edwards, Susannah Anthony, and Mrs Osborn. But his distinctive theological tenets are chiefly to be sought in his important work, the *System of Theology*, which, published in 1791, has had an influence hardly inferior to that exercised by the writings of Edwards himself. They may be summed up as follows:—(1) God is the efficient cause of all the volitions of the human heart, whether these be good or evil; (2) the guilt of Adam's first sin lies upon Adam alone; moral corruption consists exclusively in the opposition offered by the human heart to the doing of that which it is really and fully capable of doing; (3) all virtue or true holiness consists in disinterested benevolence; (4) all sin consists in selfishness; (5) reconciliation and redemption are fundamentally distinct; the former opens the gate of mercy, the latter applies to individuals Christ's saving benefits; (6) effectual calling consists in a willingness to allow himself to be saved, produced in the heart of the sinner by God; (7) although the righteousness of Christ is the sole ground of the sinner's justification, yet is that righteousness not imputed; (8) repentance is prior in point of time to the exercise of faith in Christ.

The works of Hopkins, first published in two volumes at Boston in 1791, appeared in a 2d edition in 1811. The latest and best edition is that of 1852, in three volumes, also published at Boston; to it there is prefixed a biographical sketch by Professor Park of Andover.

HOPKINSON, Francis (1737–1791), an American author, and one of the signers of the Declaration of Independence, was born at Philadelphia in 1737. He studied at the college of Philadelphia, and after graduating in 1763, resolved to prepare himself for the legal profession. After being admitted to the bar in 1765, he spent two years in England, and on his return in 1768 he obtained a lucrative public appointment in New Jersey. In 1776–77 he represented that State in Congress. In 1779 he was appointed judge of admiralty for Pennsylvania, and in 1790 district judge for the same state. He died at Philadelphia 9th May 1791. Hopkinson was the author of several songs to which he wrote popular airs, and of various political poems, pamphlets, and *jeux d'esprit*, which from their humorous satire had a wide circulation, and powerfully assisted in arousing and fostering the spirit of political independence that issued in the American Revolution.

His principal writings are *The Pretty Story*, 1774; *The Prophecy*, 1776; *The Political Catechism*, 1777. Among his songs may be mentioned *The Treaty*, *The Battle of the Kegs*, and *The New Roof, a Song for Federal Mechanics*; and the best known of his satirical pieces are *Typographical Method of conducting a Quarrel*, *Essay on White Washing*, and *Modern Learning*. His *Miscellaneous Essays and Occasional Writings* were published at Philadelphia in 3 vols., 1792.

HOPPNER, John (1758–1810), English portrait-painter, was born, it is said, on April 4, 1758, at Whitechapel. His father was of German extraction, and his mother was one of the German attendants at the royal palace. Hoppner was consequently brought early under the notice and received the patronage of George III., whose regard for him gave rise to unfounded scandal. As a boy he was a chorister at the royal chapel, but showing strong inclination for art, he in 1775 entered as a student at the Royal Academy. In 1778 he took a silver medal for drawing from the life, and in 1782 the Academy's highest award, the gold medal for historical painting, his subject being King Lear. He first exhibited at the Royal Academy in 1780. His earliest love was for landscape, but necessity obliged him to turn to the more lucrative business of portrait-painting. At once successful, he had, throughout life, the most fashionable and wealthy sitters, and was the greatest rival of the growing attraction of Lawrence. Ideal subjects were very rarely attempted by Hoppner, though a Sleeping Venus, Belisarius, Jupiter and Io, a Bacchante, and Cupid and Psyche are mentioned among his works. The prince of Wales especially patronized him, and many of his finest portraits are in the state apartments at St James's Palace, the best perhaps being those of the prince, of the duke and duchess of York, of Lord Rodney, and of Lord Nelson. Among his other sitters we may mention Sir Walter Scott, Wellington, Frere, and Sir George Beaumont. Competent judges have deemed his most successful works to be his portraits of women and children. A *Series of Portraits of Ladies* was published by him in 1803, and a volume of translations of Eastern tales into English verse in 1805. The verse is of but mediocre quality. In his later years Hoppner suffered from a chronic disease of the liver; he died January 23, 1810. He was confessedly an imitator of Reynolds. When first painted, his works were much admired for the brilliancy and harmony of their colouring, but they have been much injured by lapse of time. His drawing is faulty, but his touch has qualities of breadth and freedom that give to his paintings a faint reflexion of the charm of Reynolds. Hoppner was a man of great social power, and had the knowledge and accomplishments of a man of the world.

HOR, Mount (הֹר הָהָר, Ὢρ τὸ ὄρος), a lofty and conspicuous double-topped mountain in Arabia Petræa, forming part of the great Jurassic chain of Shera or Seir. It stands on the eastern edge of the great valley of the Arabah, which extends from the head of the Gulf of Akabah to the valley of the Jordan, and it is referred to in Scripture as "on the border" or "at the edge" of the land of Edom (Numb. xx. 23, xxxiii. 37). According to the most recent measurements, its height is 4800 feet above the level of the sea. Mount Hor was the first halting-place of the Israelites after they had turned from Kadesh on their way southwards towards Zalmonah and the Red Sea, in order to encompass the land of Edom; and it was while the host was encamped at Kadesh that Aaron ascended this mountain to die. This last event is commemorated in the modern name of the mountain, Djebel Nebi Harûn, "the hill of the prophet Aaron," whose "tomb," a small square Saracenic structure, now occupies one of the summits. Another Mount Hor (τὸ ὄρος τὸ ὄρος, LXX.) is mentioned in Scripture in the passage which (Numb. xxxiv. 7, 8) defines the northern boundary of the prospective conquests of the Israelites. It is probably to be identified with Lebanon.

HORACE (65–8 b.c.). No ancient writer has been at once so familiarly known and so generally appreciated in modern times as Quintus Horatius Flaccus. We seem to know his tastes and habits, and almost to catch the tones of his conversation, from his own works, as we know the character and manner of Dr Johnson from the pages of Boswell. His twofold function of a satiric moralist and a lyric poet give a peculiar value both to his self-portraiture and to the impressions which he has left of his age. From his *Satires*, which deal chiefly with the manners and outward lives of men, we know him in his relations to society and his ordinary moods; from his *Epistles*, which deal more with the inner life, we best understand his deepest convictions and the practical side of his philosophy; while his *Odes* have perpetuated the finest pleasure which he derived from art, nature, and the intercourse of life, have idealized some of the graver as well as the lighter aspects of his reflexion, and given an elevated expression to his sympathy with the national ideas and movement of his time.

His own writings afford much the fullest and most trustworthy materials for his biography and for the estimate of his character. But a few facts, in addition to those recorded by the poet himself, are known from the short life originally contained in the work of Suetonius, *De Viris Illustribus*.

Horace was born on the 8th of December 65 b.c., in the consulship of L. Manlius Torquatus and L. Aurelius Cotta (*Ode* iii. 21, 1; *Epode* 13, 6). His birthplace was the town of Venusia on the borders of Lucania and Apulia, whence he describes himself as "Lucanus an Apulus anceps" (*Sat.* ii. 1, 34). In his "Journey to Brundusium" (*Sat.* i. 5) he marks his recognition of the familiar shapes of the Apulian hills—

> "Incipit ex illo montes Apulia notos
> Ostentare mihi;"

and in one of his finest odes he speaks of Mount Vulturnus as the scene of an adventure of his childhood, which marked him out as a special object of divine protection and as appointed to a poetic destiny. The descriptive touches in that passage, such as "celsæ nidum Acherontiæ," show that the scenery by which he was surrounded in his early years had imprinted itself vividly on his mind. As he connects his native mountains with the dawn of his poetic inspiration, so he associates the name of the "far-sounding Aufidus," the river familiar to his early recollection, in more than one passage of his *Odes* (iii. 30, 10; iv. 9, 2) with his hopes of poetic immortality. He dwells fondly on the virtues of the people belonging to his native district, as in that picture of family happiness and innocence which he paints in the second *Epode*—

> "Quod si pudica mulier in partem juvet
> Domum atque dulces liberos,
> Sabina qualis, aut perusta solibus
> Perniciis uxor Apuli;"

and elsewhere he recalls with pride the old martial glory of the race amongst whom his first years were passed (*Ode* i. 22, 14; iii. 5, 9). Like Virgil he regards the Sabellian stock as that branch of the Italian people which had contributed most to the virtue of Rome as well as to her greatness in war. In the Ofella of the *Satires* we meet with a still surviving type of that primitive virtue. The Servius Oppidius, whose dying directions to his sons are recorded in *Sat.* ii. 3, 168, &c., seems to have been another representative of "the wisdom unborrowed from the schools," who must have been known to Horace through the tie of neighbourhood. We note also, as a trace of the influence of early impressions on his later tastes, that the name of the "Bandusian fountain," which he has made as immortal as the names of Castalia or Aganippe, seems to have been transferred by him from a spring in his native district to one on his Sabine farm, which charmed and inspired him in the meridian of his poetical power. We may thus trace some of the germs of his poetical inspiration, as well as of his moral sympathies, to the early years which he spent on the farm near Venusia. But the most important moral influence of his youth was the training and example of his father, of whose worth, affectionate solicitude, and homely wisdom Horace has given a most pleasing and life-like picture (*Sat.* i. 6, 70, &c.). He was a freedman by position; and it is supposed that he had been originally a slave of the town of Venusia, and on his emancipation had received the gentile name of Horatius from the Horatian tribe in which the inhabitants of Venusia were enrolled. After his emancipation he acquired by the occupation of "coactor" (a collector of the payments made at public auctions, or, according to another interpretation, a collector of taxes) sufficient means to enable him to buy a small farm ("macro pauper agello," *Sat.* i. 6, 71), to make sufficient provision for the future of his son (*Sat.* i. 4, 108), and to take him to Rome to give him the advantage of the best education there. To his care Horace attributes, not only the intellectual training which enabled him in later life to take his place among the best men of Rome, but also his immunity from the baser forms of moral evil (*Sat.* i. 6, 68, &c.). To his practical teaching he attributes also his tendency to moralize and to observe character (*Sat.* i. 4, 105, &c.)—the tendency which enabled him to become the most truthful painter of social life and manners which the ancient world produced. If Horace drew some of his poetical sensibility from the influences of his native district, we may believe that he derived his moral health and practical sagacity from a father who combined with the intelligence and prudence which raised him above his original position the serious spirit and respect for the morality handed down from their forefathers—

> ("mi satis est si
> Traditum ab antiquis morem servare," &c.)—

which formed the basis of the old Italian character.[1]

In one of his latest writings (*Epist.* ii. 2, 42, &c.) Horace gives a further account of his education; but we hear no more of his father, nor is there any allusion in his writings to the existence of any other member of his family or any other relative. After the ordinary grammatical and literary training at Rome, he went to Athens, the most famous school of philosophy, as Rhodes was of oratory; and he describes himself while there as "searching after truth among the groves of the Academy" as well as advancing in literary accomplishment. His pleasant residence there was interrupted by the breaking out of the civil war. Following the example of his young associates, he attached himself to the cause of Brutus, whom he seems to have accompanied to Asia, probably as a member of his staff; and he served at the battle of Philippi in the post of military tribune. He shared in the rout which followed the battle, and in an ode addressed to his old comrade Pompeius Grosphus he alludes, in imitation of a similar confession of Alcæus, to the inglorious casting away of his shield. In interpreting such passages in the works of Horace, we have always to bear in mind the irony habitual to him, and the reserve imposed on him by his subsequent relations to the chiefs of the victorious party. The enthusiasm which he had felt for the republican cause, though necessarily repressed, still betrays itself in some expressions of that ode, and in that addressed to Asinius Pollio (ii. 1, 21, &c.); and though he describes himself as

> "Imbellis et firmus parum,"

and as more fitted to treat of the light warfare of love than of the themes of actual war, yet both the martial and the patriotic feeling expressed in many of his later *Odes* enables us to understand the motives which induced him to quit the placid haunts of art and literature for the harsher experience of the campaign and battlefield.

He returned to Rome shortly after the battle, stripped of his property, which formed part of the land confiscated for the benefit of the soldiers of Octavianus and Antony. It may have been at this time that he encountered the danger of shipwreck, which he mentions among the perils from which his life had been protected by supernatural aid (*Ode* iii. 4, 28). He procured in some way the post of a clerkship in the quæstor's office, and about three years after the battle of Philippi, he was introduced by Virgil and Varius to Mæcenas. This was the turning-point of his fortunes. He owed his friendship with the greatest of literary patrons to his personal merits rather than to his poetic fame; for, though some of his shorter and less important pieces may have been known to a small circle of friends before the date of this introduction, his first published work (book i. of the *Satires*) shows that the relations of intimacy and mutual confidence which were never afterwards disturbed had been established between the statesman and poet some time before this book was given to the world. He tells us in one of his *Satires* (i. 10, 31) that his earliest ambition was to write Greek verses. In giving this direction to his ambition, he was probably influenced by his admiration of the old iambic and lyrical poets whom he has made the models of his own *Epodes* and *Odes*. A parallel to this may be found in the early Latin verse of Milton and Gray, in whom, as in Horace, the gift of expression has been brought to the highest perfection. His common sense as well as his national feeling fortunately saved him from becoming a second-rate Greek versifier in an age when poetic inspiration had passed from Greece to Italy, and the

[1] *Cf.* the line of Ennius, which Cicero compares to the voice of an oracle—

> "Moribus antiquis stat res Romana virisque."

living language of Rome was a more fitting vehicle for the new feelings and interests of men than the echoes of the old Ionian or Æolian melodies. His earliest Latin compositions were, as he tells us, written under the instigation of poverty; and they alone betray any trace of the bitterness of spirit which the defeat of his hopes and the hardships which he had to encounter on his first return to Rome may have temporarily produced on him. Some of the *Epodes*, of the nature of personal and licentious lampoons, and the second *Satire* of book i., in which there is some trace of an angry republican feeling, belong to these early compositions. But by the time the first book of *Satires* was completed and published (35 B.C.) his temper had recovered its natural serenity, and, though he had not yet attained to the height of his fortunes, his personal position was one of comfort and security, and his intimate relation with the leading men in literature and social rank was firmly established.

About a year after the publication of this first book of *Satires* Mæcenas presented him with a farm among the Sabine hills, in the valley crowned by Mount Lucretilis and watered by the stream Digentia, which joins the main valley of the Anio near the modern Vico Varo (the "Varia" mentioned in the *Epistles*), and about 8 miles above the modern Tivoli. No kind of gift could have added more to the poet's happiness or exercised a more salutary influence on his genius. It made him independent in point of fortune; it satisfied the love of nature which had been implanted in him during the early years spent on the Venusian farm; and it afforded him a welcome escape from the distractions of city life and the dangers of a Roman autumn. The lines (*Epist.* i. 16, 15, &c.)—

> "Hæ latebræ dulces, etiam, si credis, amœnæ,
> Incolumem tibi me præstant Septembribus horis"—

express with simple and sincere feeling the charm of peace and outward beauty as well as the restorative influence which this retreat in the Sabine highlands afforded him. Many passages in the *Satires*, *Odes*, and *Epistles*, which recur to the memory of every reader of his poems, express the happiness and pride with which the thought of his own valley filled him, and the interest which he took in the simple and homely ways of his country neighbours. The inspiration of the *Satires* came from the heart of Rome; the feeling of many of the *Odes* comes direct from the Sabine hills; and even the meditative spirit of the later *Epistles* tells of the leisure and peace of quiet days spent among books, or in the open air, at a distance from "the smoke, wealth, and tumult" of the great metropolis.

The second book of *Satires* was published in 29 B.C.; the *Epodes* apparently about a year earlier, though many of them are, as regards the date of their composition, to be ranked among the earliest extant writings of Horace. Horace speaks of them under the name of "iambi." In one of his *Epistles* (i. 19, 25) he rests his first claim to originality on his having introduced into Latium the metres and spirit of Archilochus—

> "Parios ego primus iambos
> Ostendi Latio, numeros animosque secutus
> Archilochi."

Yet, whatever technical claim he may have to have naturalized some special combination of metre employed by the poet of Paros, Catullus, Calvus, and Bibaculus had in the preceding generation employed the iambic metre in the spirit of Archilochus more effectively than Horace. His personal lampoons are the least successful of his works; and those of the *Epodes* which treat of other subjects in a poetical spirit are inferior in metrical effect, and in truth and freshness of feeling, both to the lighter lyrics of Catullus and to his own later and more carefully meditated *Odes*. The *Epodes* are chiefly interesting as a record of the personal feelings of Horace during the years which immediately followed his return to Rome, and as a prelude to the higher art and inspiration of the first three books of the *Odes*, which were published together about the end of 24 or the beginning of 23 B.C.[1] The composition of these *Odes* extended over several years, but all the most important among them belong to the years between the battle of Actium and 24 B.C., at which time the poet was between the age of thirty-five and forty. His lyrical poetry is thus, not, like that of Catullus, the ardent utterance of his youth, but the mature and finished workmanship of his manhood. The state of public affairs was more favourable than it had been since the outbreak of the civil war between Cæsar and Pompey for the appearance of lyrical poetry. Peace, order, and national unity had been secured by the triumph of Augustus, and the enthusiasm in favour of the new government had not yet been chilled by experience of its repressing influence. The poet's circumstances were, at the same time, most favourable for the exercise of his lyrical gift during these years. He lived partly at Rome, partly at his Sabine farm, varying his residence occasionally by visits to Tibur, Præneste, or Baiæ. His intimacy with Mæcenas was strengthened. He was no longer one among a favoured band of poets, but he had become the familiar friend of the great minister. He was treated with distinction by Augustus, and by the foremost men in Roman society. He complains occasionally that the pleasures of his youth are passing from him, but he does so in the spirit of a temperate Epicurean, who found new enjoyments in life as the zest for the old enjoyments decayed, and who considered the wisdom and meditative spirit,—"the philosophic mind that years had brought,"—an ample compensation for the extinct fires of his youth. The sobering influence of time is acknowledged by him in such lines as

> "Lenit albescens animos capillus;"

or in the still finer expression of the *Epistles* (ii. 2, 211),

> "Lenior et melior fis accedente senecta?"

About four years after the publication of the three books of *Odes*, the first book of the *Epistles* appeared, introduced, as his *Epodes*, *Satires*, and *Odes* had been, by a special address to Mæcenas. From these *Epistles*, as compared with the *Satires*, we gather that he had gradually adopted a more retired and meditative life, and had become fonder of the country and of study, and that, while owing allegiance to no school or sect of philosophy, he was framing for himself a scheme of life, was endeavouring to conform to it, and was bent on inculcating it on others. He maintained his old friendships, and continued to form new intimacies, especially with younger men engaged in public affairs or animated by literary ambition. After the death of Virgil he was recognized as pre-eminently the greatest living poet, and was accordingly called upon by Augustus to compose the sacred hymn for the celebration of the secular games in 17 B.C. About four years later he published the fourth book of *Odes*, having been called upon to do so by the emperor, in order that the victories of his stepsons Drusus and Tiberius over the Rhæti and Vindelici might be worthily celebrated. He lived about five years longer, and during these years published the second book of *Epistles*, and the *Epistle to the Pisos*, more generally known as the "*Ars Poetica*." These later *Epistles* are mainly devoted to literary criticism, with the especial object of vindicating the poetic claims of his own age over those of the age of Ennius and the other early poets of Rome. He might have been expected, as a great critic and lawgiver on literature, to have exercised a beneficial influence on the future poetry

[1] The date is determined by the poem on the death of Quintilius Varus (who died 24 B.C.), and by the reference in *Ode* i. 12 to the young Marcellus (died in autumn 23 B.C.) as still alive. *Cf.* Wickham's Introduction to the *Odes*.

of his country, and to have applied as much wisdom to the theory of his own art as to that of a right life. But his critical *Epistles* are chiefly devoted to a controversial attack on the older writers and to the exposition of the laws of dramatic poetry, on which his own powers had never been exercised, and for which either the genius or circumstances of the Romans were unsuited. The same subordination of imagination and enthusiasm to good sense and sober judgment characterizes his opinions on poetry as on morals.

He died somewhat suddenly in the November of the year 8 B.C., within a few weeks of the death of Mæcenas, thus strangely confirming the declaration made by him in one of his *Odes* (ii. 17). Though not an old man, he had reached the full maturity of his faculties, and fully accomplished the work he was fitted to do in the world. He lived longer than any of the illustrious poets immediately contemporary with him or belonging to the preceding generation; and his works show a mature character and a mellow wisdom in striking contrast to the tone of the only other great lyrical poet of Rome, "the young Catullus."

Horace is one of the few writers, ancient or modern, who have written a great deal about themselves without laying themselves open to the charge of weakness or egotism. His chief claim to literary originality is not that on which he himself rested his hopes of immortality,—that of being the first to adapt certain lyrical metres to the Latin tongue,—but rather that of being the first of those whose works have reached us who establishes a personal relation with his reader, speaks to him as a familiar friend, gives him good advice, tells him the story of his life, and shares with him his private tastes and pleasures,—and all this without any loss of self-respect, any want of modesty or breach of good manners, and in a style so lively and natural that each new generation of readers might fancy that he was addressing them personally and speaking to them on subjects of everyday modern interest. In his self-portraiture, so far from wishing to make himself out better or greater than he was, he seems to write under the influence of an ironical restraint which checks him in the utterance of his highest moral teaching and of his poetical enthusiasm. He affords us some indications of his personal appearance, as where he speaks of the "nigros angusta fronte capillos" of his youth, and describes himself after he had completed his forty-fourth December as of small stature, prematurely grey, and fond of basking in the sun (*Epist.* i. 20, 24).

In his later years his health became weaker or more uncertain, and this caused a considerable change in his habits, tastes, and places of residence. It inclined him more to a life of retirement and simplicity, and also it stimulated his tendency to self-introspection and self-culture. In his more vigorous years, when he lived much in Roman society, he claims to have acted in all his relations to others in accordance with the standard recognized among men of honour in every age, to have been charitably indulgent to the weakness of his friends, and to have been exempt from petty jealousies and the spirit of detraction. If ever he deviates from his ordinary vein of irony and quiet sense into earnest indignation, it is in denouning conduct involving treachery or malice in the relations of friends—as in the lines (*Sat.* i. 4, 81, &c.)—

> "Absentem qui rodit amicum,
> Qui non defendit alio culpante, solutos
> Qui captat risus hominum famamque dicacis,
> Fingere qui non visa potest, commissa tacere
> Qui nequit, hic niger est, hunc tu, Romane, caveto."[1]

[1] "He who maligns an absent friend's fair fame,
Who says no word for him when others blame,
Who courts a reckless laugh by random hits,
Just for the sake of ranking among wits,
Who feigns what he ne'er saw, a secret blabs,
Beware him, Roman! that man steals or stabs."
—*Conington.*

He claims to be and evidently aims at being independent of fortune, superior to luxury, exempt both from the sordid cares of avarice and the coarser forms of profligacy. At the same time he makes a frank confession of indolence and of occasional failure in the pursuit of his ideal self-mastery. He admits his irascibility, his love of pleasure, his sensitiveness to opinion, and some touch of vanity or at least of gratified ambition arising out of the favour which through all his life he had enjoyed from those much above him in social station, "Me primis urbis belli placuisse domique" (*Epist.* i. 20, 23). Yet there appears no trace of any unworthy deference in Horace's feelings to the great. Even towards Augustus he maintained his attitude of independence, by declining the office of private secretary which the emperor wished to force upon him; and he did so with such tact as neither to give offence nor to forfeit the regard of his superior. His feeling towards Mæcenas is more like that which Pope entertained to Bolingbroke than that which a client in ancient or modern times entertains towards his patron. He felt pride in his protection and in the intellectual sympathy which united him with one whose personal qualities had enabled him to play so prominent and beneficent a part in public affairs. Their friendship was slowly formed, but when once established continued unshaken through their lives. Many passages in the *Odes* and the *Epistles* show how perfect the confidence was between them, how completely Horace remained his own master, how certainly the bond that united them was one of mutual affection and esteem, not of vanity and interest.

There is indeed nothing more remarkable in Horace than the independence, or rather the self-dependence, of his character. This saved him from the danger to which his genial qualities exposed him of becoming, like Moore or Burns, the slave of society or the slave of passion. The enjoyment which he drew from his Sabine farm consisted partly in the refreshment to his spirit from the familiar beauty of the place, partly in the "otia liberrima" from the claims of business and society which it afforded him. His love poems, when compared with those of Catullus, Tibullus, and Propertius, show that he never, in his mature years at least, allowed his peace of mind to be at the mercy of any one. They are the expressions of a fine and subtle and often a humorous observation rather than of ardent feeling. There is perhaps a touch of pathos in his reference in the *Odes* to the early death of Cinara, but the epithet he applies to her in the *Epistles*,

> "Quem scis immunem Cinaræ placuisse rapaci,"

shows that the pain of thinking of her could not have been very heart-felt. Even when the *Odes* addressed to real or imaginary beauties are most genuine in feeling, they are more the artistic rekindling of extinct fires than the utterance of recent passion. In his friendships he had not the self-forgetful devotion which is the most attractive side of the character of Catullus; but he studied how to gain and keep the regard of those whose society he valued, and he repaid this regard by a fine courtesy and by a delicate appreciation of their higher gifts and qualities, whether proved in literature, or war, or affairs of state, or the ordinary dealings of men. He made life more pleasant to himself and others by restraining the propensities which give pain to others, as well as by active good offices and the expression of kindly feelings. He enjoyed the great world, and it treated him well; but he resolutely maintained his personal independence and the equipoise of his feelings and judgment. The mention of Virgil and Mæcenas elicits from him warmer expressions of affection and appreciation than that of any of the other famous men of the time; but there is no strain of exaggeration in the language which he applies even to them. If it is thought that in attributing a divine function to Augustus he has gone beyond the bounds of a sincere and temperate admiration, a comparison of the *Odes* in which this occurs with the first *Epistle* of the second book shows that he certainly recognized in the emperor a great and successful administrator on whom depended the peace, order, and prosperity of the world, and that the language which at first sight offends our modern sensibilities is to be regarded rather as the artistic expression of the prevailing national sentiment than as the tribute of an insincere adulation.

The aim of Horace's philosophy was to "be master of oneself"—

"Ille potens sui
Lætusque deget," &c.;

to retain the "mens æqua" in all circumstances—

"Quod petis hic est,
Est Ulubris, animus si te non deficit æquus;"

to use the gifts of fortune while they remained, and to be prepared to part with them with equanimity; to make the most of life, and to contemplate its inevitable end without anxiety. Self-reliance and resignation are the lessons which he constantly inculcates. His philosophy is thus a mode of practical Epicureanism combined with other elements which have more affinity with Stoicism. In his early life he professed his adherence to the former system, and several expressions in his first published work show the influences of the study of Lucretius. At the time when the first book of the *Epistles* was published he professes to assume the position of an eclectic rather than that of an adherent of either school (*Epist.* i. 1, 13–19). We note in the passage here referred to, as in other passages, that he mentions Aristippus, the chief of the Cyrenaic school which anticipated the doctrines of Epicurus, rather than Epicurus himself, as the master under whose influence he from time to time insensibly lapsed. Yet the dominant tone of his teaching is that of a refined Epicureanism, not so elevated or purely contemplative as that preached by Lucretius, but yet more within the reach of a society which, though luxurious and pleasure-loving, had not yet become thoroughly frivolous and enervated. His advice is to make the most of the present which alone is within our power—

"Quod adest memento
Componere æquus;"

to enjoy the pleasures of youth in their season, but to choose some more serious object as life goes on—

"Nec lusisse pudet, sed non incidere ludum;"

to subdue all violent emotion of fear or desire; to estimate all things calmly—"nil admirari;" to choose the mean between a high and low estate; and to find one's happiness in plain living rather than in luxurious indulgence. His social and friendly qualities, his enjoyment of refined and simple pleasures, the attitude which he assumed of a critical spectator rather than of an active participator in the various modes of human activity, were all in harmony with the practice and the teaching of Epicurus. Still there was in Horace a robuster fibre, inherited from the old Italian race, which moved him to value the dignity and nobleness of life more highly than its ease and enjoyment. This is perhaps the secret cause of that weariness and dissatisfaction with the comfortable routine of existence which occasionally betrays itself in some of his later writings. But in some of the stronger utterances of his *Odes*, where he expresses sympathy with the manlier qualities of character, whether manifested in the persons of the ancient national heroes or in the civic dress of his own day, we recognize the resistent attitude of Stoicism rather than the passive acquiescence of Epicureanism. The concluding stanzas of the address to Lollius (*Ode* iv. 9) exhibit the Epicurean and Stoical view of life so combined as to be more worthy of human dignity than the genial worldly wisdom of the former school, more in harmony with human experience than the formal precepts of the latter:—

"Non possidentem multa vocaveris
Recte beatum; rectius occupat
Nomen beati, qui deorum
Muneribus sapienter uti
Duramque callet pauperiem pati,
Pejusque leto flagitium timet;
Non ille pro caris amicis
Aut patria timidus perire."

It is interesting to trace the growth of Horace in elevation of sentiment and serious conviction from his first ridicule of the paradoxes of Stoicism in the two books of the *Satires* to the appeal which he makes in some of the *Odes* of the third book to the strongest Roman instincts of fortitude and self-sacrifice. A similar modification of his religious and political attitude may be noticed between his early declaration of Epicurean unbelief—

"Namque deos didici securum agere ævum"—

and the sympathy which he shows with the religious reaction fostered by Augustus; and again between the Epicurean indifference to national affairs expressed in the words

"Quid Tiridatem terreat unice
Securus"

and the strong support which he gives to the national policy of the emperor in the first six *Odes* of the third book, and in the fifth and fifteenth of the fourth book. In his whole religious attitude he seems to stand midway between the consistent denial of Lucretius and Virgil's pious endeavour to reconcile ancient faith with the conclusions of philosophy. His introduction into some of his *Odes* of the gods of mythology must be regarded as merely artistic or symbolical. Yet in such lines as

"Di me tuentur, dis pietas mea
Et musa cordi est,"
"Dis te minorem quod geris, imperas,"
"Immunis aram si tetigit manus," &c.,

we recognize the expression of a natural piety, thankful for the blessing bestowed on purity and simplicity of life, and acknowledging a higher and more majestic law, governing nations through their voluntary obedience. On the other hand, his allusions to a future life, as in the "domus exilis Plutonia," and the "furvæ regna Proserpinæ," are shadowy and artificial. The image of death is constantly obtruded in his poems to enhance the sense of present enjoyment. In the true spirit of paganism he associates all thoughts of love and wine, of the meeting of friends, or of the changes of the seasons with the recollection of the transitoriness of our pleasures—

"Nos, ubi decidimus
Quo pius Æneas, quo dives Tullus et Ancus,
Pulvis et umbra sumus."

Horace is so much of a moralist in all his writings that, in order to enter into the spirit both of his familiar and of his lyrical poetry, it is essential that we should realize to ourselves what were his views of life and the influences under which they were formed. He is, though in a different sense from Lucretius, eminently a philosophical and reflective poet. He is also, like all the other poets of the Augustan age, a poet in whose composition culture and criticism were as conspicuous elements as spontaneous inspiration. In the judgment he passes on the older poetry of Rome and on that of his contemporaries, he seems to attach more importance to the critical and artistic than to the creative and inventive functions of genius. It is on the labour and judgment with which he has cultivated his gift—

"Spiritum Graiæ tenuem Camenæ"—

that he rests his hopes of fame. The whole poetry of the Augustan age was based on the works of older poets, Roman as well as Greek. Its aim was to perfect the more immature workmanship of the former, and to adapt the forms, manners, and metres of the latter to subjects of immediate and national interest. As Virgil performed for his generation the same kind of office which Ennius performed for an older generation, so Horace in his *Satires*, and to a more limited extent in his *Epistles*, brought to perfection for the amusement and instruction of his contemporaries the rude but vigorous designs of Lucilius. Notwithstanding great differences in their intellectual tastes and culture, and the great differences between a time of republican freedom and one of imperial restraint, in which their respective lots were cast, there was a real affinity of temper and disposition between the first and the second in the line of the great Roman satirists. Horace seems to have made Lucilius to some extent his model, in his manner of life as well as in the form and substance of his satire. We find in the fragments of Lucilius expressions of a love of freedom and independence, of indifference to wealth or public employment, of joy at escaping from the storms of life into a quiet haven, of contentment with his own lot, of the superiority of plain living to luxury, identical in spirit and often similar in manner to those that are almost the common-places of Horace.

It was the example of Lucilius which induced Horace to commit all his private thoughts, feelings, and experience "to his books as to trusty companions," and also to comment freely on the characters and lives of other men. Many of the subjects of particular satires of Horace were immediately suggested by those treated by Lucilius. Thus the "Journey to Brundusium" reproduced the outlines of Lucilius's "Journey to the Sicilian Straits." The discourse of Ofella on luxury was founded on a similar discourse of Lælius on gluttony, and the "Banquet of Nasidienus" may have been suggested by the description by the older poet of a rustic entertainment. The same kinds of excess are satirized by both, especially the restless passion of money-making and the sordid anxieties of money-saving, and the opposite extreme of profuse and ostentatious expenditure. There was more of moral censure and personal aggressiveness in the satire of the older poet. The ironical temper of Horace induced him to treat the follies of society in the spirit of a humorist and man of the world, rather than to assail vice with the severity of a censor; and the greater urbanity of his age or of his disposition restrained in him the direct personality of satire. The names introduced by him to mark types of character, such as Nomentanus, Mænius, Pantolabus, &c., are reproduced from the writings of the older poet. Horace also followed Lucilius in the variety of forms which his satire assumes, and especially in the frequent adoption of the form of dialogue, derived from the "dramatic medley" which was the original character of the Roman *Satura*. This form suited the spirit in which Horace regarded the world, and also the dramatic quality of his genius, just as the direct denunciation and elaborate painting of character suited the "sæva indignatio" and the oratorical genius of Juvenal.

Horace's satire is accordingly to a great extent a reproduction in form, manner, substance, and tone of the satire of Lucilius; or rather it is a casting in the mould of Lucilius of his own observation and experience. There is little trace of the influence of his Greek studies either in the matter or the manner of this thoroughly Roman work; though he mentions in one passage that, as aids to composition, he had carried with him to the country the works of Archilochus, and of the comic poets Eupolis, Plato, and Menander. But a comparison of the fragments of Lucilius with the finished compositions of Horace brings out in the strongest light the artistic originality and skill of the latter poet in his management of metre and style. Nothing can be rougher and harsher than the hexameters of Lucilius, or cruder than his expression. In his management of the more natural trochaic metre, he has shown much greater ease and simplicity. It is one great triumph of Horace's genius that he was the first and indeed the only Latin writer who could bend the stately hexameter to the uses of natural and easy, and, at the same time, terse and happy conversational style. Catullus, in his hendecasyllabics, had shown the vivacity with which that light and graceful metre could be employed in telling some short story or describing some trivial situation dramatically. But no one before Horace had succeeded in applying the metre of heroic verse to the uses of common life. But he had one great native model in the mastery of a terse, refined, ironical, and natural conversational style, Terence; and the *Satires* show, not only in allusions to incidents and personages, but in many happy turns of expression very frequent traces of Horace's familiarity with the works of the Roman Menander.

The *Epistles* are more original in form, more philosophic in spirit, more finished in style than the *Satires*. The form of composition may have been suggested by that of some of the satires of Lucilius, which were composed as letters to his personal friends. But letter-writing in prose, and occasionally also in verse, had been common among the Romans from the time of the siege of Corinth; and a practice originating in the wants and convenience of friends temporarily separated from one another by the public service was ultimately cultivated as a literary accomplishment. It was a happy idea of Horace to adopt this form for his didactic writings on life and literature. It suited him as an eclectic and not a systematic thinker, and as a friendly counsellor rather than a formal teacher of his age. It suited his circumstances in the latter years of his life, when his tastes inclined him more to retirement and study, while he yet wished to retain his hold on society and to extend his relations with younger men who were rising into eminence. It suited the class who cared for literature,—a limited circle of educated men, intimate with one another, and sharing the same tastes and pursuits. While giving expression to lessons applicable to all men, he in this way seems to address each reader individually, "admissus circum præcordia ludit," with a subtle power of sympathy and of inspiring sympathy, which respects both himself and his reader. In spirit the *Epistles* are more ethical and meditative than the *Satires*. Like the *Odes* they exhibit the twofold aspects of his philosophy, that of temperate Epicureanism and that of more serious and elevated conviction. In the actual maxims which he lays down, in his apparent belief in the efficacy of addressing philosophical texts to the mind, he exemplifies the triteness and limitation of all Roman thought. But the spirit and sentiment of his practical philosophy is quite genuine and original. The individuality of the great Roman moralists, such as Lucretius and Horace, appears not in any difference in the results at which they have arrived, but in the difference of spirit with which they regard the spectacle of human life. In reading Lucretius we are impressed by his earnestness, his pathos, his elevation of feeling; in Horace we are charmed by the serenity of his temper and the flavour of a delicate and subtle wisdom. We note also in the *Epistles* the presence of a more philosophic spirit, not only in the expression of his personal convictions and aims, but also in his comments on society. In the *Satires* he paints the outward effects of the passions of the age. He shows us prominent types of character—the miser, the parasite, the legacy-hunter, the parvenu, &c., but he does not try to trace these different manifestations of life to their source. In the *Epistles* he finds the secret spring of the social vices of the age in the desire, as marked in other times as in those of Horace, to become rich too fast, and in the tendency to value men according to their wealth, and to sacrifice the ends of life to a superfluous care for the means of living. In the *Satires* he dwells on the discontent of men with their actual condition as he noticed the outward manifestation of this spirit in the various callings of life; in his *Epistles* he lays his finger on the real evil from which society was suffering. The cause of all this aimless restlessness and unreasonable desire is summed up in the words "Strenua nos exercet inertia." In point of style the *Epistles* occupy a middle position between the "sermo pedestris" of the *Satires*, and the studied grace or the grave majesty of the *Odes*. It is the perfection of that kind of style which conceals much thought, insight, and character under a quiet and unpretending exterior. It combines two great excellences of manner both in writing and in conduct, self-restraint with sincerity and simplicity.

In his *Satires* and *Epistles* Horace shows himself a genuine moralist, a subtle observer and true painter of life, and an admirable writer. But for both of these works he himself disclaims the title of poetry. He rests his claims as a poet on his *Odes*. They reveal an entirely different aspect of his genius, his spirit, and his culture. He is one among the few great writers of the world who have attained high excellence in two widely separated provinces of literature. If this division of his powers has been unfavourable to the intensity and spontaneity of his lyrical poetry, it has made him more interesting as a man, and more complete as a representative of his age. Through all his life he was probably conscious of the "ingeni benigna vena," which in his youth made him the sympathetic student and imitator of the older lyrical poetry of Greece, and directed his latest efforts to poetic criticism. But it was in the years that intervened between the publication of his *Satires* and *Epistles* that his lyrical genius asserted itself as his predominant faculty. At that time he had outlived the coarser pleasures and risen above the harassing cares of his earlier career; a fresh source of happiness and inspiration had been opened up to him in his beautiful Sabine retreat; he had become not only reconciled to the rule of Augustus, but a thoroughly convinced and, so far as his temperament admitted of enthusiasm, an enthusiastic believer in its beneficence. But it was only after much labour that his original vein of genius obtained a free and abundant outlet. He lays no claim to the "profuse strains of unpremeditated art," with which other great lyrical poets of ancient and modern times have charmed the world. He recognizes with modest and truthful self-appreciation the source of his power in the lines in which he contrasts his genius with that of Pindar:—

> "Ego, apis Matinæ
> More modoque,
> Grata carpentis thyma per laborem
> Plurimum, circa nemus uvidique
> Tiburis ripas, operosa parvus
> Carmina fingo."

His first efforts were apparently imitative, and were directed to the attainment of perfect mastery over form, metre, and rhythm. The first nine *Odes* of the first book are experiments in different kinds of metre. They and all the other metres employed by him are based on those employed by the older poets of Greece,—Alcæus, Sappho, Archilochus, Alcman, &c. He has built the structure of his lighter *Odes* also on their model, while in some of those in which the matter is more weighty, as in that in which he calls on Calliope "to dictate a long continuous strain," he has endeavoured to reproduce something of the intricate movement, the abrupt transitions, the interpenetration of narrative and reflexion, which characterize the art of Pindar. He frequently reproduces the language and some of the thoughts of his masters, but he gives to them new application, or stamps them with the impress of his own experience. He brought the metres which he has employed to such perfection that the art perished with him. A great proof of his mastery over rhythm is the skill with which he has varied his metres according to the sentiment which he wishes to express. He has impressed the stamp of his own individuality or of his race upon all of them. Thus his great metre, the Alcaic, has a character of stateliness and majesty in addition to the energy and impetus originally imparted to it by Alcæus. The Sapphic metre he employs with a peculiar lightness and vivacity which harmonize admirably with his gayer moods. In his combinations of the Asclepiadean we note the grave and thoughtful temperance of tone which pervades those in which the three Asclepiadean line are combined with one Glyconic as in the "Quis desiderio, &c.," "Inclusam Danaen," &c., the "Divis orte bonis," &c., and the peculiar simplicity and grace, of a graver character than that of the Sapphic, in those *Odes* in which two Asclepiadean lines are combined with one Pherecratean and one Glyconic, as in the

> "Quis multa gracilis te puer in rosa,"

or the

> "O fons Bandusiæ, splendidior vitro."

Again in regard to his diction, if Horace has learned his subtlety and moderation from his Greek masters, he has tempered those qualities with the masculine characteristics of his race. No writer is more Roman in the stateliness and dignity, the terseness, occasionally even in the sobriety and bare literalness, of his diction. The individuality of the man is equally marked in his vivid and graphic condensation of phrase, whether employed in description of outward scenery or in moral portraiture, in the latent fervour or ironical reserve employed in the indication of personal feeling, and in the generalizing maxims which transmute the experience of some special occasion into a universal experience.

While it is mainly owing to the extreme care which Horace gave to form, rhythm, and diction that his own prophecy

> "Usque ego postera
> Crescam laude recens"

has been so amply fulfilled, yet no greater injustice could be done to him than to rank him either as poet or critic with those who consider form everything in literature. Had he been a writer of that stamp he would probably have attached himself to the school of Alexandrian imitators; and such excellence as he might have obtained would have been appreciated only by limited coteries, whose opinion and tastes do not long influence either the educated or uneducated world. With Horace the mastery over the vehicle of expression was merely an essential preliminary to making a worthy and serious use of that vehicle. He may have erred, in theory at least, rather in the other extreme of exaggerating the didactic office of poetry. If an explanation is to be sought for his disparaging reference to the lyrical art of his predecessor, Catullus, it is not necessary to find that explanation in jealousy, nor in any insensibility to a power of expression of which he has shown the sincerest admiration by attempting to imitate it. It is more likely that he was repelled by the purely personal and, as he may have thought, trivial subjects, whether of love or hate, to which the art of his predecessor was almost exclusively limited. The poet, from Horace's point of view, was intended not merely to give refined pleasure to a few, but, above all things, to be "utilis urbi." Yet he is saved, in his practice, from the abuse of this theory by his admirable sense, his ironical humour, his intolerance of pretension and pedantry. Opinions will differ as to whether he or Catullus is to be regarded as the greater lyrical poet. Those who assign the palm to Horace will do so, certainly not because they recognize in him richer or equally rich gifts of feeling, conception, and expression, but because the subjects to which his art has been devoted have a fuller, more varied, more mature, and permanent interest for the world.

For the most complete and exact account of the MSS. and the various editions of Horace, readers are referred to the Introduction to the admirable edition of Mr E. C. Wickham, of which only the first volume, containing the *Odes* and *Epodes*, has appeared. For English readers the translation of the *Odes* and *Satires* by Sir Theodore Martin, and of the *Odes*, *Satires*, and *Epistles* by the late Professor Conington, and the *Life of Horace* by the late Dean Milman, may be especially recommended. (W. Y. S.)

HORATII, three brothers born at one birth, who were the champions of Rome in the war against Alba Longa. Three Alban brothers, named the Curiatii, likewise born at one birth, were opposed to them. The mothers were also twin sisters, who had been married at the same time, and had given birth to their sons on one day. When the Alban army under their king Cluilius lay encamped some miles from Rome, Tullus Hostilius the Roman king agreed with them that the issue should depend on the combat between the two families. Two of the Horatii were soon slain; the third brother feigned flight, and when the Curiatii who were all wounded pursued him without concert he turned and slew them one by one. Now the sister of the Horatii was engaged to one of the Curiatii, and had made for him a beautiful mantle. When the victor, adorned with this trophy, was entering Rome in triumph, his sister came to greet him by the Porta Capena; but when the fatal mantle, which he wore as a trophy, showed her that her lover had fallen by her brother's hand, she invoked a curse on him. Enraged at her reproaches, he slew her on the spot; and the body of her that preferred her lover to her country lay unburied till passers by covered it with stones. Horatius was condemned by *duumviri*, specially appointed as his judges, to be scourged to death; but his father justified his action, and on appeal the people spared his life, condemning him in penalty to walk with veiled head below the *sororium tigillum.* Horatius was afterwards sent to destroy Alba Longa and transport all the inhabitants to Rome. Monuments of the tragic tale were shown by the Romans in the time of Livy:—the *pila Horatia* in the forum, where the victor hung his spoils; the beam under which the brother passed, and which stood across a narrow street near the site of the later Flavian Amphitheatre; the sister's grave outside the gate; the grave of the two Horatii, and those of the three Curiatii where each had fallen; the *fossa Cluilia* dug by the Albans to defend their camp.

The mythical character of many of these details is evident; and indeed it was even doubtful which of the two sets of brothers belonged to Rome and which to Alba. Under the tale lie historical facts known on other evidence —the close relationship and the final internecine strife between the two cities. Alba, the ancient city on the Alban mount, was the mother of all the Latin cities, and of Rome itself; but the ancient city on the Alban hill had gradually given way to the younger cities in the plain, and was finally destroyed by them, while the inhabitants were transported to Rome and various other Latin cities. With the tale that formed round this fact were connected various monuments on the road that led from the Roman forum to Alba Longa. According to Schwegler, the *fossa Cluilia* (*clueo*, to purify) was probably an attempt to drain the country; and the *sororium tigillum* was perhaps the memorial of the substitution of judicial trial for the older patriarchal jurisdiction in case of murder. Dyer, *Kings of Rome*, maintains the historical character of the tale.

HORDE, a manufacturing town of Westphalia, Prussia, circle of Dortmund, government district of Arnsberg, is situated on the railway from Dortmund to Soest, 2 miles south-east from Dortmund. It has one Roman Catholic and two Evangelical churches. Its industry is almost wholly connected with iron, and it possesses a large smelting-work, foundries, puddling-works, rolling mills, and manufactures of iron and plated wares. In the neighbourhood there are large iron and coal-pits. The population in 1875 was 12,837.

HOREB. See SINAI.

HOREHOUND (Ang.-Sax., *harhune*; Germ., *Andorn*; Fr., *Marrube*), *Marrubium*, L., a genus of perennial, usually cottony or woolly herbs, of the natural order *Labiatæ*, and tribe *Stachydeæ.* Common or white horehound, *M. vulgare*, L., has a short and stout rootstock, and thick stems, about a foot in height, which, as well as their numerous branches, are coated with a white or hoary felt—whence the popular name of the plant. The leaves have long petioles, and are roundish, or rhombic-ovate, crenate-serrate, much wrinkled, white and woolly below, and pale green and downy above; the flowers are sessile, in dense whorls or clusters, small, and dull-white, with calyx 10-toothed, and the upper lobe of the corolla long and bifid. The plant occurs in Europe, North Africa, and North Asia to North-West India, and has been naturalized in parts of America. In Britain, where it is found generally on sandy or dry chalky ground, it is far from common. White horehound contains a volatile oil, resin, a crystallizable bitter principle termed *marrubiin*, and other substances, and has a not unpleasant aromatic odour, and a persistent bitter taste. It possesses expectorant, tonic, and carminative properties, and in large doses is diuretic and laxative. Formerly it was official in British pharmacopœias; and the infusion, syrup, or confection of horehound has long been in repute for the treatment of coughs and asthma, and has been recommended also in phthisis, chronic rheumatism, hepatic and uterine disorders, hysteria, and chlorosis. For medicinal purposes the plant should be gathered when in flower, and is preferable in the fresh condition. Black horehound, *Ballota nigra*, L., is a hairy perennial labiate plant, of fœtid odour; is 2 to 3 feet in height; has petiolate, roundish-ovate, serrate leaves, and numerous flowers, in dense axillary clusters, with a green or purplish calyx, and a pale red-purple corolla; and occurs in Europe, North Africa, and Russian Asia, and in Britain, except in northern Scotland, and has been introduced into North America. Water horehound is the *Lycopus europæus* of Linnæus.

Horehound.

HORGEN, a village in the Swiss canton of Zurich, capital of the district of Horgen, is situated on the left bank of the Zurich Lake, 1500 feet above sea-level, and 9 miles south of Zurich. It is surrounded by meadows and vineyards, and possesses many handsome houses, and a beautiful church with frescos by Barzaghi. The town is one of the centres of the Zurich silk industry and vine culture, and the meeting-place of the boats which ply on the north and south banks of the lake. The population in 1870 was 5199, of whom 4744 were Protestants.

HORITZ (Bohemian *Hořice*), a town of Bohemia, Austria, government district of Königgrätz, is situated on the right bank of the Bistritz, 10 miles N.E. from Bidschow. Among the principal buildings are the district court of justice, the castle, the synagogue, the town-house, the poor-house, and the infirmary. It possesses woollen and linen manufactories, a brewery, flour-mills, and saw-mills. Flax and fruit are grown in the vicinity. The population in 1869 was 5659.

HORMAYR, JOSEPH, BARON VON, German statesman and historian, was born at Innsbruck, January 20th 1781, and died at Munich, November 5th, 1848. After studying law for several years (1794–1797) in his native town, and attaining the rank of major in the Tyrol landwehr, the young man, who had the advantage of being the grandson of Joseph von Hormayr (1705–1781), chancellor of Tyrol, obtained a post in the foreign office at Vienna (1801), from which he rose in 1803 to be court secretary and director of the secret archives of the kingdom and court. During the insurrection by which in 1809 the Tyrolese sought to throw off the Bavarian supremacy confirmed by the treaty of Pressburg, Hormayr was the mainstay of the Austrian party, and assumed the administration of everything save the military arrangements; but, returning home without the prestige and protection of success, he fell into disfavour both with the emperor Francis I. and the prime minister Metternich, and at length in 1813 he was arrested and imprisoned. In 1816 some amends were made to him by his appointment as historiographer royal; but so little was he satisfied with the general policy and conduct of the Austrian court that in 1828 he accepted an invitation to the Bavarian capital, where he became ministerial councillor in the department of foreign affairs. In 1832 he was appointed Bavarian minister at Hanover, and from 1839 to 1846 he held the same position at Bremen. The last two years of his life were spent at Munich as superintendent of the national archives. Hormayr's literary activity was closely conditioned by the circumstances of his political career: while the access which he enjoyed to original documents gave value to his treatment of the past, his record or criticism of contemporary events received authority and interest from the character of his personal experience. In his later writings he is a keen opponent of the policy of the court of Vienna.

The following are among Hormayr's more important works:—*Kritisch-diplomatische Beiträge zur Geschichte Tirols im Mittelalter*, Innsb., 1802-3; *Gesch. der gefürst. Grafschaft Tirol*, Tüb., 1806-8; *Österreichischer Plutarch*, 20 vols., Vienna, 1807-20; *Archiv für Gesch. Stat. Lit. und Kunst*, 20 vols., 1809-28; *Wien, seine Gesch. und Denkwürdigkeiten*, Vienna, 1823-25; *Lebensbilder aus dem Befreiungskriege*, Jena, 1841-44; *Die goldene Chronik von Hohenschwangau*, Munich, 1842; *Anemonen aus dem Tagebuch eines alten Pilgermanns*, Jena, 1845-47. Along with Mednyanski (1784-1844) he founded *Taschenbuch für die Vaterländ. Gesch.*, Vienna, 1811-48.

HORMISDAS, pope from 514-523, in succession to Symmachus, was a native of Campania. Although on his election overtures were at once made by Anastasius I., emperor of the East, for the reunion of the Eastern and Western Churches, which had been separated since the excommunication of Acacius in 484, the zeal or intolerance of the pope delayed it till he was able to procure it on his own terms, in 519, from the orthodox emperor Justin. Hormisdas paid much attention to the instruction of his clergy in psalmody. He was succeeded in 523 by John I. Eighty of his letters are preserved in Labbe's *Sacrosancta Concilia*, vol. v. (1728), and are also to be found in vol. lxiii. of Migne's *Patrologiæ Cursus Completus* (Latin series).

HORN. The weapons which project from the heads of various species of animals, constituting what are known as horns, embrace substances which are, in their anatomical structure and chemical composition, quite distinct from each other; and although in commerce also they are known indiscriminately as horn, their uses are altogether dissimilar. These differences in structure and properties are thus indicated by Professor Owen:—"The weapons to which the term horn is properly or technically applied consist of very different substances, and belong to two organic systems, as distinct from each other as both are from the teeth. Thus the horns of deer consist of bone, and are processes of the frontal bone; those of the giraffe are independent bones or 'epiphyses' covered by hairy skin; those of oxen, sheep, and antelopes are 'apophyses' of the frontal bone, covered by the corium and by a sheath of true horny material; those of the prong-horned antelope consist at their basis of bony processes covered by hairy skin, and are covered by horny sheaths in the rest of their extent. They thus combine the character of those of the giraffe and ordinary antelope, together with the expanded and branched form of the antlers of deers. Only the horns of the rhinoceros are composed wholly of horny matter, and this is disposed in longitudinal fibres, so that the horns seem rather to consist of coarse bristles compactly matted together in the form of a more or less elongated sub-compressed cone." True horny matter is really a modified form of epidermic tissue, and consists of an albuminoid principle termed "keratin." It forms, not only the horns of the ox tribe, but also the hoofs, claws, or nails of animals generally, the carapace of the tortoises and the armadilloes, the scales of the pangolin, porcupine quills, and birds' feathers, &c. The principal application of horns is for the manufacture of combs, and under the heading COMB, vol. vi. pp. 177–78, that industry is described. The other uses to which horn is now devoted, among which may be noted the pressing of buttons, the making of handles for walking-sticks, umbrellas, and knives, the manufacture of drinking-cups, spoons of various kinds, and snuff-boxes, do not here require extended notice. The parings and refuse of horn are valuable for the manufacture of prussiate of potash and as manure; and the ash of the cores of horn makes excellent cupels for the assay of precious metals. In former times horn was applied to several uses for which it is no longer required, although such applications have left their traces in our language. Thus the musical instruments and fog signals known as horns indicate their descent from earlier and simpler forms of apparatus made from horn. In the same way powder-horns were spoken of long after they ceased to be made of that substance; to a small extent lanterns still continue to be "glazed" with thin transparent plates of horn, a practice which a century ago was universal. Horn-books consisted of spelling-books with their leaves protected by thin plates of horn, and it was in former times customary to protect the titles of valuable MSS. in the same way. Deer-horn is almost exclusively used for handles by cutlers and walking-stick and umbrella makers. The largest supply is obtained from the East Indies, and consists principally of the antlers of the axis, *Axis maculata*, and the Rusa deer, *Rusa Aristotelis*.

HORN, or FRENCH HORN, a wind instrument made at various times of various materials such as wood, ivory, and several metals, but belonging in its modern significance to the class of brass instruments. In how far the instruments of similar type or character used by the Jews and other Eastern nations, by the Romans, and by mediæval knights may have been related to the modern horn it is needless to investigate here. The instrument as we know it dates at least from the 16th century, for a picture of the circular horn is found in Virdung's *Musica* (1511). But ruder representations of similarly-shaped instruments occur in armorial bearings of a much remoter period. The horn in its earlier form served exclusively the various purposes of the hunt, whence its name in the different languages: Italian, corno di caccia; French, cor de chasse; German, Waldhorn. Originally there seems to have been only a single ring, but a second semicircle occurs at an early date. The capabilities of the primitive instrument were as limited as its purpose, the latter being chiefly that of announcing by signals the various stages and incidents of the hunt, such as the *Reveille*, the *Hallali*, and the *Mort*. Simple tunes, however, were within its range, for Mersenne mentions a "concert à quatre" for horns as early as 1637. The demands on the horn were naturally much enlarged when it was introduced into the orchestra as an exponent of artistic and complicated music. As to the date of this event opinions differ considerably. It has been asserted that Gossec was the first to make use of the horn in an important orchestral part in 1759. But this is true, if true at all, of France only. In Germany and England the instrument was in common use at a much earlier period. From 1712–1740 two hornists were members of the imperial chapel in Vienna at the not inconsiderable salary of 360 florins. Moreover, both Handel (in his *Water Music*, 1715, and elsewhere) and Bach assign important parts to the horn. The notes natural to the horn and produced by the action of the lips alone are the so-called harmonics or partial tones of the bottom note between the extreme limits of the C below the staff in the bass clef to the E in alt. Some of these notes are, however, not used in practice. In order to supply the notes not in the scale of natural harmonics various methods have been used. The simplest is the insertion of the hand in the bell of the instrument, accidentally discovered by a German hornplayer towards the end of the last century. The effect is to lower the note by a semitone or a whole tone, according to the extent that the orifice is closed. The drawback attaching to this system is that the "closed" or "stopped" (*étouffé*) notes differ in character from the open ones, and are in part dull. It is true that a good composer may produce certain effects by this means. In the modern horn a mechanical contrivance generally takes the place of the hand. This is the valve or ventil, an apparatus for lowering the note by means of the pressure of the fingers. There are three valves attached to the ventil-horn, lowering the note by one, two, and three semitones respectively. Most modern composers write for the ventil-horn exclusively; others use it in combination with natural or hand horns. Another important appliance of the horn is the crook, which may best be described as a transposing machine. The crooks can be removed at will, their effect (by altering the length of the tube) being to transpose the notes produced by the lips into anything that is required. The player therefore plays as it were in one and the same key, and the difficulty of transposing his part mentally is saved to him. In consequence the horn part in a score is always written in the key of C, which may be changed into E flat or F or E by merely inserting the crook intended for that key. In this way not only the diatonic scale, but all kinds of chromatic progressions can be produced on the horn. Of these opportunities modern composers have largely availed themselves, frequently tasking the capabilities of the players to the utmost degree. The passage for three horns in the great scena of Fidelio in Beethoven's opera of that name is celebrated for its effectiveness as well as for its difficulty. With Wagner also the horns are favourite instruments. In the economy of the orchestra the horns form the transition from the wood winds to the trumpets, trombones, and other loud brass instruments; they share the softness of the former with the power of the latter, and may be used with equal effect both in filling up the harmony and in emphasizing the melody. In works of a romantic character, such as Mendelssohn's overture to *A Midsummer Night's Dream*, or Weber's *Der Freischütz*, they are invaluable for the purpose of local colouring. There are also many solo pieces written for the horn, amongst which Mozart's three concerti for horn and orchestra, Schumann's concerto for 4 horns and orchestra (op. 86), Beethoven's horn sonata (op. 17), and Brahms's trio for pianoforte, violin, and horn (op. 40) may be cited.

HORNBEAM, *Carpinus*, Tournef., a small genus of trees of the natural order *Cupuliferæ* and sub-order *Corylcæ*. The Latin name *Carpinus* has been thought to be derived from the Celtic *car*, wood, and *pin* or *pen*, head, the wood of hornbeams having been used for yokes of cattle (see Loudon, *Ency. of Pl.*, p. 792, new ed., 1855, and Littré, *Dict.*, ii. 556). The common hornbeam, or yoke-elm, *Carpinus Betulus*, L. (Gr., probably ζυγία; Germ., *Hornbaum* and *Hornbuche*; Fr., *charme*), is indigenous in the temperate parts of western Asia and of Asia Minor, and in Europe, where it ranges as high as 55° and 56° N. lat. It is common in woods and hedges in parts of Wales and of the south of England. The trunk is usually flattened, and twisted as though composed of several stems united; the bark is smooth, and light grey; and the leaves are sub-distichous, 2 to 3 inches long, elliptic-ovate, doubly serrate, pointed, numerously ribbed, hairy below, and opaque, and not glossy as in the beech, have large stipules and short petioles, and when young are plaited. The flowers appear with the leaves in April and May. The male catkins are about 1½ inches long, and have pale yellow anthers, bearing tufts of hairs at the apex; the female attain a length of 2 to 4 inches, with bracts 1 to 1½ inches long. The green and angular fruit or "nut" ripens in October; it is about ¼ inch in length, is in shape like a small chestnut, and is enclosed in leafy, 3-lobed bracts. The hornbeam thrives well on stiff, clayey, moist soils, into which its roots penetrate deeply; on chalk or gravel it does not flourish. Raised from seed it may become a tree 40 to as much as 70 feet in height, greatly resembling the beech, except in its rounder and closer head. It is, however, rarely grown as a timber-tree, its chief employment being for hedges. "In the single row," says Evelyn (*Sylva*, p. 29, 1664), "it makes the noblest and the stateliest *hedges* for long Walks in *Gardens* or *Parks*, of any Tree whatsoever whose leaves are *deciduous*." As it bears clipping well, it was formerly much used in geometric gardening. The branches should not be lopped in spring, on account of their tendency to bleed at that season.

The wood of the hornbeam is white and close-grained, and polishes ill, is of considerable tenacity and little flexibility, and is extremely tough and hard to work—whence, according to Gerard, the name of the tree. It has been found to lose about 8 per cent. of its weight by drying. As a fuel it is excellent; and its charcoal is much esteemed for making gunpowder. The bark of the hornbeam has tonic properties, and the inner part is stated by Linnæus to afford a yellow dye. In France the leaves serve as fodder. The tree is a favourite with hares and rabbits, and the seedlings are apt to be destroyed by mice. Pliny (*Nat. Hist.*, xxvi. 26), who describes its wood as red and easily split, classes the hornbeam with maples. The American hornbeam, blue or water beech, or iron-wood, is *Carpinus americana*, Mich.; the common hop-hornbeam, a native of the south of Europe, is *Ostrya vulgaris*, Willd., and the American, *O. virginica*, Willd.

Bot.*, viii. 176, 1868; J. D. Hooker, *Student's Flora*, p. 365, 2d ed., 1878; and ARBORICULTURE, vol. ii. p. 317.

HORNBILL, the English name for a long while generally given to all the birds of the Family *Bucerotidæ* of modern ornithologists, from the extraordinary horn-like excrescence (*epithema*) developed on the bill of most of the species, though to which of them it was first applied seems doubtful. Among classical authors Pliny had heard of such animals, and mentions them (*Hist. Nat.*, lib. x. cap. lxx.) under the name of *Tragopan*; but he deemed their existence fabulous, comparing them with *Pegasi* and *Gryphones*—in the words of Holland, his translator (vol. i. p. 296)—"I thinke the same of the Tragopanades, which many men affirme to bee greater than the Ægle; having crooked hornes like a Ram on either side of the head, of the colour of yron, and the head onely red." Yet this is but an exaggerated description of some of the species with which doubtless his informants had an imperfect acquaintance. Mediæval writers found Pliny's bird to be no fable, for specimens of the beak of one species or another seem occasionally to have been brought to Europe, where they were preserved in the cabinets of the curious, and thus Aldrovandus was able to describe pretty fairly and to figure (*Ornithologia*, lib. xii. cap. xx. tab. x. fig. 7) one of them under the name of "*Rhinoceros Avis*," though the rest of the bird was wholly unknown to him. When the exploration of the East Indies had extended further, more examples reached Europe, and the "*Corvus Indicus cornutus*" of Bontius became fully recognized by Willughby and Ray, under the title of the "Horned Indian Raven or *Topau* called the Rhinocerot Bird." Since the time of those excellent ornithologists our knowledge of the Hornbills has been steadily increasing, but it must be confessed that in regard to many points there is still great lack of precise information, and accordingly the completion of Mr Elliot's "*Monograph of the Bucerotidæ*" (now in course of publication) is most earnestly to be desired, for therein it is to be hoped that all questions respecting their history and classification may be fully treated. At present great diversity of opinion prevails as to how many real genera the Family comprises, or how many species. The group, though no doubt ought to be entertained as to its limits,[1] has not attracted sufficient notice from ornithologists, and therefore, apart from the merest superficial characters, the difference of the several sections which it includes has never been properly explained, nor have their distinctions been placed on a firm basis. Some authors appear to have despaired of dividing it satisfactorily, and have left all the described species in the Linnæan genus *Buceros*, as for example, Professor Schlegel (*Cat. du Mus. des Pays Bas*, Buceros); others have split that genus into more than a score—a number which seems to be quite unnecessary. Sundevall (*Tentamen*, pp. 96, 97), with his usual caution, has restrained himself to the recognition of three genera, but it is unquestionable that more should reasonably be admitted, though the present writer is not prepared to state how many are required.

The first genus admitted by Sundevall is *Rhinoplax*, which seems properly to contain but one species, the *Buceros vigil*, *B. scutatus*, or *B. galeatus* of authors, commonly known as the Helmet-Hornbill, a native of Sumatra and Borneo. This is easily distinguished by having the front of its nearly vertical and slightly convex *epithema* composed of a solid mass of horn[2] instead of a thin coating of the light and cellular structure found in the others. So dense and hard is this portion of the "helmet" that Chinese and Malay artists carve figures on its surface, or cut it transversely into plates, which from their agreeable colouring, bright yellow with a scarlet rim, are worn as brooches or other ornaments. This bird, which is larger than a Raven, is also remarkable for its long graduated tail, having the two middle feathers nearly twice the length of the rest. Nothing is known of its habits. Its head was figured by Edwards more than a century ago, but little else had been seen of it until 1801, when Latham described the plumage from a specimen in the British Museum, and the first figure of the whole bird from an example in the Museum at Calcutta was published by Hardwicke in 1823 (*Trans. Linn. Society*, xiv. pl. 23). Yet more than twenty years elapsed before French naturalists became acquainted with it. Under *Rhinoplax* Sundevall places the *Buceros cornutus* of Raffles; but this would seem to be a wrong position for that species, the type of Bonaparte's genus *Berenicornis*, since it does not appear to possess a frontlet of solid horn.

Sundevall divides the genus *Buceros* into three sections, of which one, *Buceros* proper, contains the species having the *epithema* developed to its greatest extent, such as *B. rhinoceros*, *B. hydrocorax*, *B. bicornis*, and others, while the remaining sections have little or no *epithema*, and one of them has the throat feathered. This last includes the African forms which seem to belong to the genus *Toccus* of Lesson, while the other comprises the Oriental species exemplified by Mr Hodgson's genus *Aceros*; but the arrangement cannot be deemed wholly satisfactory, and must be regarded only as an approach to a better. The presence or absence of the *epithema* may indeed be considered in distinguishing genera; but among those that possess it, seeing that its development is to a great degree dependent upon age and perhaps sex (this last being uncertain), its size and shape hardly afford good generic characters, and, though the group assigned by Sundevall to *Buceros* proper doubtless requires further separation, some less superficial distinctions must be pointed out than those which have been taken as sufficient to establish many of the "genera" of this family suggested by several ornithologists. Again, in the grouping of those forms which possess little or no *epithema* sound characters are equally wanting for the divisions as yet set forth, and until further investigations have been made the limits of even the genera *Aceros* and *Toccus* cannot be laid down. Tickell in his manuscript *Birds of India* (in the library of the Zoological Society of London) divides the Hornbills of that country into two genera only, *Buceros* and *Aceros*, remarking that the birds of the former fly by alternately flapping their wings and sailing, while those of the latter fly by regular flapping only.[3] Several differences of structure are presented by the sternal apparatus of the various *Bucerotidæ*, and it is quite possible that these differences may be correlated with Tickell's observations so as to furnish, when more is known about these birds, a better mode of classing them, and the same may be said of those of the African group containing the genus *Toccus* and its allies.

Lastly, we have the genus *Bucorvus*, or *Bucorax* as some call it, confined to Africa, and containing at least two and perhaps more species, distinguishable by their longer legs and shorter toes, the Ground-Hornbills of English writers, in contrast to all the preceding, which are chiefly arboreal in their habits, and when not flying move by short leaps or hops, while the members of this group walk and run with facility. From the days of Bruce at least there are few African travellers who have not met with and in their narratives more or less fully described one or other of these birds, whose large size and fearless habits render them conspicuous objects.

As a whole the Hornbills, of which more than 50 species have been described, form a very natural and in some respects an isolated group, placed by Professor Huxley among his *Coccygomorphæ*. It has been suggested that they have some affinity with the Hoopoes (*Upupidæ*), but even if that view be good the affinity cannot be very near. Their supposed alliance to the Toucans (*Rhamphastidæ*) rests only on the apparent similarity presented by the enormous beak, and is contradicted by important structural characters. In many of their habits, so far as these are known, all Hornbills seem to be much alike, and though the modification in the form of the beak, and the presence or absence of the extraordinary excrescence,[4] whence their name is

[1] Such genera as *Euryceros*, *Scythrops*, and some others, together with the whole Family *Momotidæ*, which had been at various times and by various systematists placed among the *Bucerotidæ*, have evidently no real affinity to them.

[2] Apparently correlated with this structure is the curious thickening of the "prosencephalic median septum" of the cranium as also of that which divides the "prosencephalic" from the "mesencephalic chamber," noticed by Professor Owen (*Cat. Osteol. Ser. Mus. Roy. Coll. Surg. England*, i. p. 287); while the solid horny mass is further strengthened by a backing of bony props, directed forwards and meeting its base at right angles. This last singular arrangement, which is not perceptible in the skull of any other species examined by the present writer, does not seem to have been described.

[3] The noise made by the wings of some of the large species in their flight is compared by Mr Wallace, in an admirable article on the Family (*Intellectual Observer*, 1863, pp. 310 *et seqq.*), to the puffing of a locomotive steam-engine when starting with a train, and can be heard a mile off.

[4] Buffon, as was his manner, enlarges on the cruel injustice done to these birds by Nature in encumbering them with this deformity, which

derived, causes great diversity of aspect among them, the possession of prominent eyelashes (not a common feature in Birds) produces a uniformity of expression which makes it impossible to mistake any member of the family. Hornbills are social birds, keeping in companies, not to say flocks, and living chiefly on fruits and seeds; but the bigger species also capture and devour a large number of snakes, while the smaller are great destroyers of insects. The older writers say that they eat carrion, but further evidence to that effect is required before the statement can be believed. Almost every morsel of food that is picked up is tossed into the air, and then caught in the bill before it is swallowed. They breed in holes of trees, laying large white

Great Indian Hornbill (*B. bicornis*). After Tickell's drawing in the Zoological Society's library.

eggs, and when the hen begins to sit the cock plasters up the entrance with mud or clay, leaving only a small window through which she receives the food he brings her during her incarceration.

This remarkable habit, almost simultaneously noticed by Dr Mason in Burma, Tickell in India, and Livingstone in Africa, and since confirmed by other observers, especially Mr Wallace[1] in the Malay Archipelago, has been connected by Mr Bartlett (*Proc. Zool. Society*, 1869, p. 142) with a peculiarity as remarkable, which he was the first to notice. This is the fact that Hornbills at intervals of time, whether periodical or irregular is not yet known, cast the epithelial layer of their gizzard, that layer being formed by a secretion derived from the glands of the proventriculus or some other upper part of the alimentary canal. The epithelium is ejected in the form of a sack or bag, the mouth of which is closely folded, and is filled with the fruit that the bird has been eating. The announcement of a circumstance so extraordinary naturally caused some hesitation in its acceptance, but the essential truth of Mr Bartlett's observations has been abundantly confirmed by Professor Flower (*tom. cit.*, p. 150), and especially by Dr Murie (*op. cit.*, 1874, p. 420), and what seems now to be most wanted is to know whether these castings are really intended to form the hen bird's food during her confinement. (A. N.)

he declares must hinder them from getting their food with ease. The only corroboration his perverted view receives is afforded by the observed fact that Hornbills, in captivity at any rate, never have any fat about them. The part played by the wonderful *epithema* in the birds' economy is altogether unknown.

[1] In his interesting work (i. p. 213), this gentleman describes a nestling Hornbill (*B. bicornis*) which he obtained as "a most curious object, as large as a pigeon, but without a particle of plumage on any part of it. It was exceedingly plump and soft, and with a semi-transparent skin, so that it looked more like a bag of jelly, with head and feet stuck on, than like a real bird."

HORN-BOOK, a name sometimes given to an elementary treatise on any subject. It was originally applied to a sheet containing the letters of the alphabet, which formed a primer for the use of children. It was mounted on wood and protected with transparent horn. Sometimes the leaf was simply pasted against the slice of horn. The wooden frame had a handle, and it was usually hung at the child's girdle. The sheet, which in ancient times was of vellum and latterly of paper, contained first a large cross—the criss-crosse—from which the horn-book was called the Christ Cross Row, or criss-cross-row. The alphabet in large and small letters followed. The vowels then formed a line, and their combinations with the consonants were given in a tabular form. The usual exorcism—"in the name of the Father and of the Sonne and of the Holy Ghost, Amen"—followed, then the Lord's Prayer, the whole concluding with the Roman numerals. The horn-book is mentioned in Shakespeare's *Love's Labour's Lost*, v. 1, where the *ba*, the *a*, *e*, *i*, *o*, *u*, and the horn, are alluded to by Moth. It is also described by Ben Jonson—

> "The letters may be read, *through the horn*,
> That make the story perfect."

Horn-books are now of great rarity. A representation of a good specimen will be found prefixed to Halliwell's *Notices of Fugitive Tracts*, in the twenty-ninth volume of the works printed for the Percy Society.

HORNCASTLE, a market-town giving its name to a soke in Lincolnshire, England, is situated at the foot of a line of low hills called the Wolds, on an angle formed by the confluence of the Bain and Waring, and at the terminus of a branch line of the Great Northern Railway, 21 miles east of Lincoln. The principal buildings are the parish church of St Mary's (supposed to have been originally erected in the time of Henry VII., possessing a square embattled tower, many fine old monuments, and an old brass), Queen Elizabeth's grammar school founded in 1562, the dispensary opened in 1789, the corn exchange opened in 1856, with a room for public meetings, and accommodation for the mechanics' institute, a library, and a news-room. There are also national and Wesleyan schools, and an infant school for poor children. Among the charities is one for apprenticing orphan boys belonging to the parish. A few fragments still remain of the ancient fortification from which the town takes its name, and many Roman urns and coins have been discovered in the vicinity. Near the confluence of the rivers there at one time existed an ancient labyrinth called the Julian bower. To the south-east of the town there is a spot called Hangman's Corner, where criminals were formerly executed. The prosperity of the town is chiefly dependent on agriculture and its horse fairs,—that held in August being the largest of its class in England. Brewing, malting, and currying are carried on, and there is some trade in coal and iron. The population of the parish in 1871 was 4947, and of the soke 10,469.

Horncastle is believed to be the Roman *Banovallum*. The fort is said to have been originally constructed by the Romans, refortified and strengthened by Horsa, the brother of Hengest, but shortly afterwards demolished by Vortimer, king of the Britons. The manor at the time of the Norman survey belonged to the king, and after being for an unknown period in private hands, was sold in the reign of Henry III. to the bishop of Carlisle, who received from Henry a charter authorizing him to try felons and hold a court leet, and granting free warren and an annual fair.

HORNE, George (1730–1792), bishop of Norwich, was born on November 1, 1730, at Otham near Maidstone, where his father was a clergyman, and received his early education at the Maidstone school, whence he proceeded to University College, Oxford. In 1749 he became a fellow of Magdalen College, of which in 1768 he was appointed president. As a preacher he early attained great popularity; and his reputation was further helped by several clever if somewhat wrong headed publications, including a satirical pamphlet entitled *The Theology and Philosophy of Cicero's Somnium Scipionis* (1751), a defence of the Hutchinsonians in *A Fair, Candid, and Impartial State of the Case between Sir Isaac Newton and Mr Hutchinson* (1753), and critiques upon Dr Shuckford (1754) and Dr Kennicott (1760). In 1776 he published his well-known *Commentary on the Book of Psalms*, and in the same year he was chosen vice-chancellor of his university; in 1781 he was made dean of Canterbury, and in 1790 he was raised to the see of Norwich, which, however, he held for less than two years. He died at Bath January 17, 1792.

His collected *Works* were first published, with a Memoir by one of his chaplains (Jones), in 1795. There have been several subsequent editions, the latest being that of 1830. The most popular and also the best of his writings, the *Commentary on the Psalms*, has been still more frequently reprinted, occasionally along with an essay by James Montgomery, or with a much more remarkable discourse by Edward Irving.

HORNE, Thomas Hartwell (1780–1862), a well-known writer on Biblical introduction, was born in London on October 20, 1780, and from 1789–95 was educated at Christ's Hospital, where Coleridge was an elder contemporary. On leaving school, his circumstances not permitting him to proceed to the university, he became clerk to a barrister, but early manifested an unconquerable passion for literary pursuits. When barely twenty years of age he published (1800) *A Brief View of the Necessity and Truth of the Christian Revelation*, which reached a second edition in 1802. In the years immediately following he became the author of several minor works, and in 1814, having been appointed librarian of the Surrey Institution, he issued his *Introduction to the Study of Bibliography*. This was followed in 1818 by the work to which he had devoted the best part of many years, the *Introduction to the Critical Study of the Holy Scriptures*, which rapidly attained a rare popularity, and secured for its author a high and secure place among contemporary scholars. In 1819 he received ordination from the bishop of London, although unpossessed of the customary university degree, and some time afterwards he was appointed to the cure of the united parishes of St Edmund the King and St Nicolas Acons in London. On the breaking up of the Surrey Institution in 1823, he was appointed (1824) to superintend the classification and publication of the British Museum Catalogue. After the project of making a classed catalogue had been abandoned, he continued to take part in the preparation of the alphabetical catalogue, and his connexion with the museum continued to subsist until 1861, when his infirmities caused him to resign. He died in London on January 26, 1862.

Besides the works already mentioned Horne wrote numerous others of secondary importance, which, as catalogued in Allibone's *Dictionary* by himself, exceed forty in number. The *Introduction*, edited by Ayre and Tregelles, reached a 12th edition in 1869 (4 vols. 8vo); but, owing to the recent rapid advances of critical science, it is now somewhat out of date.

HORNELLSVILLE, a township and post village of Steuben county, New York, is situated on the Canisteo river and on the Erie Railway, 90 miles south-east of Buffalo. It is well supplied with schools and churches, and possesses planing-mills, tanneries, and factories for sashes and blinds, furniture, cars, mowing-machines, and boots and shoes. The population was 5639 in 1870, and 9852 in 1880.

HORNER, Francis (1778–1817), political economist, was born at Edinburgh, August 12th, 1778. After passing through the usual courses at the high school and university of his native city, he devoted five years, the first two in England, to comprehensive but desultory study, and in 1800 was called to the Scotch bar. Desirous, however, of a wider sphere, Horner removed to London in 1802, and occupied the interval that elapsed before his admission to the English bar in 1807 with researches in law, philosophy, and political economy, and latterly with parliamentary duties. In February 1806 he became one of the commissioners for adjusting the claims against the nawab of Arcot, and in November entered parliament as member for St Ives. Next year he sat for Wendover, and in 1812 for St Mawes, in the patronage of the marquis of Buckingham. In 1811, when Lord Grenville was organizing a prospective ministry, Horner had the offer, which he refused, of a treasury secretaryship. He had resolved not to accept office till he could afford to live out of office; and his professional income, on which he depended, was at no time proportionate to his abilities. His labours at last began to tell upon a constitution never robust, and in October 1816 his physicians ordered him to Italy, where, however, he sank under his malady. He died at Pisa, February 8, 1817. He was buried at Leghorn, and a marble statue by Chantrey was erected to his memory in Westminster Abbey.

Without the advantages of rank, or wealth, or even of genius, Francis Horner rose to a high position of public influence and private esteem. The speeches in the House of Commons on the occasion of moving for a new writ for St Mawes combine with the letters of private friends in testifying to the respect and honour commanded by his integrity and wide and cultured intellect, and to the affection won by his sweet and noble disposition, as well as to the general regret for the untimely death of one who gave promise of such abilities as a statesman. The early friend of Brougham and Jeffrey in Edinburgh, and welcomed in London by Romilly, Mackintosh, Abercromby, and Lord Holland, Horner was by sincere conviction a Whig. His special field was political economy. Master of that subject, and exercising a sort of moral as well as intellectual influence over the House of Commons, he, by his nervous and earnest rather than eloquent style of speaking, could fix its attention for hours on such dry topics as finance, and coinage, and currency. As chairman of the parliamentary committee for investigating the depreciation of bank notes, for which he moved in 1810, he extended and confirmed his fame as a political economist by his share in the famous *Bullion Report*. It was chiefly through his efforts that the paper-issue of the English banks was checked, and gold and silver reinstated in their true position as circulating media; and his views on free trade and commerce have been generally accepted at their really high value. Horner was one of the promoters of the *Edinburgh Review* in 1802. His articles in the early numbers of that publication, chiefly on political economy, form his only literary legacy.

Memoirs and Correspondence of Francis Horner, M.P., was published by his brother in 1843. See also the *Edinburgh* and *Quarterly Reviews* for the same year; and *Blackwood's Magazine*, vol. i.

HORNET. See Wasp.

HORNPIPE was originally the name of an instrument no longer in existence, and is now used for an English national dance. The sailor's hornpipe, although the most common, is by no means the only form of the dance, for there is a pretty tune known as the "College Hornpipe," and other specimens of a similar kind might be cited. The composition of hornpipes flourished chiefly in the last century, and even Handel did not disdain to use the characteristic rhythm. The hornpipe may be written in $\frac{3}{2}$ or in common time, and is always of a lively nature.

HORROCKS, JEREMIAH (1619–1641), an astronomer of extraordinary promise blighted by a premature death, was born in 1619 at Toxteth Park, near Liverpool. Of the circumstances of his family little is known, further than that they were poor; but the register of Emmanuel College, Cambridge, testifies to his entry as sizar, May 18, 1632. Isolated in his scientific tastes, and painfully straitened in means, he pursued amid innumerable difficulties his purpose of self-education. His university career lasted three years, and on his return to Lancashire he devoted to astronomical observations the brief intervals of leisure snatched from the harassing occupations of a laborious life. In 1636 he met with a congenial spirit in William Crabtree, a draper of Broughton, near Manchester; and encouraged by his advice he exchanged the guidance of Lansberg, a pretentious but inaccurate Belgian astronomer, for that of Kepler. He now set himself to the revision of the Rudolphine Tables (published by Kepler in 1627), and in the progress of his task became convinced that a transit of Venus overlooked by Kepler would nevertheless occur on the 24th of November (O.S.) 1639. He was at this time curate of Hoole, near Preston, having recently taken orders in the Church of England, although, according to the received accounts, he had not attained the canonical age. The 24th of November falling on a Sunday, his clerical duties threatened fatally to clash with his astronomical observations; he was, however, released just in time to witness the punctual verification of his forecast, and carefully noted the progress of the phenomenon during half an hour before sunset (3.15 to 3.45). This transit of Venus is remarkable as the first ever observed, that of 1631 predicted by Kepler having been invisible in Europe. Notwithstanding the rude character of the apparatus at his disposal, Horrocks was enabled by his observation of it to introduce some important corrections into the elements of the planet's orbit, and to reduce to its exact value the received estimate of its apparent diameter.

After a year spent at Hoole, he returned to Toxteth, and there, on the eve of a long-promised visit to his friend Crabtree, unexpectedly expired, January 3, 1641, in the twenty-second year of his age. It is difficult to overestimate the services which, had his life been prolonged, this singularly gifted youth might have rendered to astronomical science. To the inventive activity of the discoverer he already united the patient skill of the observer and the practical sagacity of the experimentalist. Before he was twenty he had afforded a specimen of his powers by an important contribution to the lunar theory. He first brought the revolutions of our satellite within the domain of Kepler's laws, pointing out that her apparent irregularities could be completely accounted for by supposing her to move in an ellipse with a variable eccentricity and directly rotatory major axis, of which the earth occupied one focus. These precise conditions were afterwards demonstrated by Newton to follow necessarily from the law of gravitation.

In his speculations as to the physical cause of the celestial motions, his mind, though not as yet wholly emancipated from the tyranny of gratuitous assumptions, was working steadily towards the light. He clearly perceived the significant analogy between terrestrial gravity and the force exerted in the solar system, and used an ingenious experiment to illustrate the composite character of the planetary movements. He also reduced the solar parallax to 14″ (less than a quarter of Kepler's estimate), corrected the sun's semi-diameter to 15′ 45″, recommended decimal notation, and was the first to make tidal observations.

Only a remnant of the papers left by Horrocks was preserved by the care of William Crabtree. After his death (which occurred soon after that of his friend), these were purchased by Dr Worthington, of Cambridge; and from his hands the treatise *Venus in sole visa* passed into those of Hevelius, and was published by him in 1662 with his own observations on a transit of Mercury. The remaining fragments were, under the directions of the Royal Society, reduced by Dr Wallis to a compact form, with the heading *Astronomia Kepleriana defensa et promota*, and published with numerous extracts from the letters of Horrocks to Crabtree, in a volume entitled *Jeremiæ Horroccii Opera Posthuma*, London, 1672. A memoir of his life by the Rev. Arundell Blount Whatton, prefixed to a translation of the *Venus in sole visa*, appeared at London in 1859.

HORSE

PART I.—ZOOLOGY AND ANATOMY.

Zoology.

THE horse and its near allies, the several species of asses and zebras, constitute the genus *Equus* of Linnæus, a small group of animals of the class *Mammalia*, so distinct in their organization from all other existing members of the class that in many of the older zoological systems they were placed in an order apart, under the name of *Solidungula* or *Monodactyla*.

Investigations in comparative anatomy have, however, demonstrated that their structure, at first sight so singular and exceptional, is really but a modification of the same general plan upon which the tapirs and rhinoceroses are formed, and the discovery and restoration of the characters of extinct species, inaugurated by Cuvier during his fruitful researches into the fauna of the Paris basin, continued in various European localities by Kaup, Rütimeyer, Gervais, Gaudry, Huxley, and others, and recently conducted on a more ample scale in the prolific fossiliferous strata of North America by Leidy, Marsh, and Cope, have revealed numerous intermediate stages through which the existing horses appear to have passed in their modification from a very different ancestral form.

We shall best understand what a horse really is if we first consider its origin and lineage; and this we are in a better position to do than with almost any other animal, as it is one of the few whose history (if the evidence afforded by palæontology can be relied upon) can be traced back through an almost unbroken chain of links as far as the earliest Tertiary age.

We have as yet no cognizance of the history of any mammals of the group to which the horse belongs before the dawn of the Eocene period. Of where they lived and what they were like, from what earlier forms and by what stages of modifications descended, our actual knowledge is an absolute blank. Conjecture helps us but little, and why none of their remains have not ere this been discovered is a palæontological mystery. We have, however, certain knowledge that when the land which formed the bottom of the great cretaceous ocean which flowed over a considerable part of the present continents of Europe and North America was lifted above the level of the water and became fitted for the habitation of terrestrial animals, it was very soon the abode of vast numbers of herbivorous mammals belonging to the group now called *Ungulata* or "hoofed animals." Wherever they came from, they had existed sufficiently long to have become already completely differentiated into two principal forms, separated from each other by many distinct points in their organization, among which one of the most externally conspicuous was the structure of their feet. From this character the one form has received the name of *Artiodactyla* or "even-toed," the other *Perissodactyla* or "odd-toed." It is only of the latter that we shall have to speak in this article.

Perhaps the best notion of a perissodactyle ungulate of the Eocene age can be derived from the tapir of the present day, an animal which has changed less from the primitive and generalized type of the group of that time than any other existing member of the order. These early forms had all the complete number of teeth found in so many of the mammals of that period of various orders, arranged according to the well-known formula—*incisors* $\frac{3}{3}$, *canines* $\frac{1}{1}$, *premolars* $\frac{4}{4}$, *molars* $\frac{3}{3} = \frac{11}{11}$ on each side, or 44 in all. The molar teeth had very short square crowns, with transverse or oblique ridges on the grinding surface. In the fore limbs the radius and ulna, and in the hind limbs the tibia and fibula, were distinct and well-developed bones. Whatever the number of toes on each foot, the one corresponding to the middle or third digit of the generalized pentadactyle limb was the longest; its ungual phalanx was symmetrical in itself, and it formed the centre of the foot, on each side of which the other toes were arranged in complete or partial symmetry according to the stage of development. In the hind foot in all known cases the symmetry was complete, only one toe on each side of the middle digit being present (fig. 3, *c*); but in the fore foot the primitive symmetry, formed by the presence of two toes on each side of the middle toe, had been lost in nearly all, by the disappearance of one of the outer toes (the first), the condition still retained by the tapirs (fig. 3, *a*); or it had been replaced by the second stage of symmetry, in which both outer toes are absent, and only three remain, as in the modern rhinoceros (fig. 3, *c*). By no animal of this period had the third, or most highly specialized stage of symmetry, that which, as we shall see, characterizes the modern horses (fig. 3, *e*), been attained.

By various and gradually progressing deviations from the common original type, these animals began at a very early period to break up into several groups, some of which (as *Macrauchenia*), after undergoing a considerable degree of specialization, have become extinct without leaving successors; but three of these modified types, already distinct at the close of the Eocene period, have continued up to the present day, gradually, as time advanced, becoming more and more divergent from each other. These are now represented by the three families of the rhinoceroses, the tapirs, and the horses. Great as may be the differences between these animals as we see them now, we can trace their history step by step, as revealed by the fragments preserved from former ages, further and further back in time, their differences continually becoming less marked, and ultimately blending together, if not into one common ancestor, at all events into forms so closely alike in all essentials that no reasonable doubt can be held as to their common origin.

Leaving out of further consideration the two collateral branches, it will be our purpose now to follow the history of the special subject of this article.

The remains of the earliest known animals to which it is possible to trace back the modern horse by a series of successive modifications are found in the lowest strata of the great lacustrine formations assigned to the Eocene period, spread over considerable portions of the present territories of New Mexico, Wyoming, and Utah in North America. That similar animals may have existed in other parts of the world is extremely probable. Negative evidence in such cases is of little value, as may be judged by the fact that it is only within a very few years that the existence of these deposits teeming with fossil remains of previously unsuspected forms has been brought to light, and their systematic exploration has scarcely yet commenced. A little animal, not larger than a fox, *Eohippus* of Marsh, presented the most generalized form of the perissodactyle type as yet discovered, as besides the four well-developed toes of the fore foot, found in so many others, it had at least a rudiment of a fifth. All analogy leads to the supposition that this must in its turn have been represented at a still earlier period by another form with all five toes complete, but direct evidence of this is at present wanting.

The transition from this horse-like animal of the early period to the horses of modern times has been accompanied by a gradual increase in size. The diminutive Eocene *Eohippus* and *Orohippus* were succeeded in the Miocene period by other forms to which the names of *Anchitherium* and *Miohippus* have been given, of the size of sheep; these again in Pliocene times by *Hipparion* and *Pliohippus*, as large as the modern donkeys; and it is only in the Pleistocene period that *Equidæ* appeared which approached in size the existing horse. Important structural modifications have also taken place, with corresponding changes in the mode of life of the animal. The neck has become elongated, the skull altered in form, the teeth greatly modified, and the limbs have undergone remarkable changes. The last two require to be described more in detail.

The teeth in the Eocene forms had, as mentioned above, the characteristic number of forty-four. This number has been retained throughout the series, at least theoretically; but one tooth on each side of each jaw, the anterior premolar, which in all the Eocene and Miocene species was a well-developed tooth, persisting through the life time of the animal, is in all modern horses rudimentary, functionless, and generally lost at an early period of life, evidently passing through a stage which must soon lead to its complete disappearance. The canines have also greatly diminished in size, and are rarely present in the female sex, so that practically a very large number of adult horses of the present day have eight teeth less than the number possessed by their predecessors. The diastema or interval between the incisor and premolar teeth, of essential importance in the domesticated horse to his master, as without it there could be no room for inserting the special instrument of subjugation to his commands, the bit, already existed in the earliest known forms, but has gradually increased in length. The incisors have undergone in comparatively recent times that curious change producing the structure which will be more fully described hereafter, and which distinguishes the horse's incisors from those of all other known animals. Lastly, the molars have undergone a remarkable series of modifications, much resembling in principle those that have taken place in several other groups of herbivorous animals. Distinctions in form which existed between the premolars, at least the anterior members of the series, and the true molars have gradually disappeared, the teeth becoming all very uniform in the shape and structure of their grinding surface. The crowns of all these teeth in the early forms were very short (see fig. 2, *a*); there was a distinct constriction, the neck, between the crown and roots; and when the tooth was developing, as soon as the neck once rose fairly above the alveolar margin, the tooth remained permanently in this position. The term "brachyodont" expresses this condition of teeth, the mode of growth of which may be illustrated by those of man. The free surface had two nearly transverse curved ridges, with valleys between (fig. 2, *a*); but the valleys were shallow and had no deposit of cementum filling them, the whole exposed surface of the unworn tooth being formed of enamel. When the ridges became worn down the dentine of the interior was exposed, forming islands surrounded by enamel. With the progress of time the crowns of the teeth gradually become longer, the valleys deeper, and the ridges not only more elevated but more curved and complex in arrangement. To give support to these high ridges and save them from breaking in use, the valleys or cavities between them became filled up to the top with cementum, and as the crown wore down an admirable grinding surface consisting of patches and islands of the two

FIG. 1.—*a*, Grinding surface of unworn molar tooth of *Anchitherium*; *b*, corresponding surface of unworn molar of young horse; *c*, the same tooth after it has been some time in use. The uncoloured portions are the dentine or ivory, the shaded parts the cementum filling the cavities and surrounding the exterior. The black line separating these two structures is the enamel or hardest constituent of the tooth

softer substances, dentine and cement, separated by variously reduplicated and contorted lines of intensely hard enamel, resulted (fig. 2, *c*). The crown continued lengthening until in the modern horses it has assumed the form called "hypsidont" (fig. 2, *b*). Instead of contracting into a neck, and forming roots, its sides continue parallel for a considerable depth in the socket, and as the surface wears away, the whole tooth slowly pushes up, and maintains the grinding edge constantly at the same level above the alveolus, much as in the perpetually growing rodent's teeth. But in existing horses there is still a limit to the growth of the molar. After a length is attained which in normal conditions supplies sufficient grinding surface for the lifetime of the animal, a neck and roots are formed, and the tooth is reduced to the condition of that of the brachyodont ancestor. It is perfectly clear that this lengthening of the crown adds greatly to the power of the teeth as organs of mastication, and enables the animals in which it has taken place to find their sustenance among the comparatively dry and harsh herbage of the open plains, instead of being limited to the more succulent vegetable productions of the marshes and forests in which their predecessors mainly dwelt.

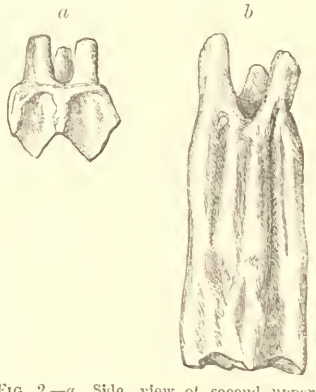

FIG. 2.—*a*, Side view of second upper molar tooth of *Anchitherium* (brachyodont form); *b*, corresponding tooth of horse (hypsidont form).

The modifications of the limbs which took place *pari passu* with those of the teeth must have been associated with increased speed, especially over firm and unyielding ground. Short, stout legs, and broad feet, with numerous toes, spreading apart from each other when the weight of the creature is borne on them, are sufficiently well adapted for plodding deliberately over marshy and yielding surfaces, and the tapirs and the rhinoceroses, which in the structure of the limbs have altered but little from the primitive Eocene forms, still haunt the borders of streams and lakes and the shady depths of the forests, as was probably the habit of their ancient representatives, while the horses are all inhabitants of the open plains, for life upon which their whole organization is in the most eminent degree adapted. The length and mobility of the neck, position of the eye and ear, and great development of the organ of smell, give them ample means of becoming aware of the approach of enemies, while the length of their limbs, the angles the different segments form with each other, and especially the combination of firmness, stability, and lightness in the reduction of all the toes to a single one, upon which the whole weight of the body and all the muscular power are concentrated, give them speed and endurance surpassing that of almost any other animal. When surprised, however, they are by no means helpless, both fore and hind feet becoming at need powerful weapons of defence.

If we were not so habituated to the sight of the horse as hardly ever to consider its structure, we should greatly marvel at being told of a mammal so strangely constructed that it had but a single toe on each extremity, on the end of the nail of which it walked or galloped. Such a formation is without a parallel in the vertebrate series, and is one of the most remarkable instances of specialization, or deviation from the usual type, in accordance with special conditions of life. It can be demonstrated, both by the structure of the foot itself, and also by an examination of the intermediate forms, that this toe corresponds to the middle or third of the complete typical or pentadactyle foot, the "ring finger" of man; and there is very strong evidence to show that by a gradual concentration of all the power of the limb upon this toe, and the concurrent dwindling away and final disappearance of all the others, the present condition of the horse's foot has been produced.

The small horse-like animals of the Eocene period with four, or rudiments at least of five, toes on the fore foot have been already mentioned. In the early Miocene period the animal most like an existing horse was the *Anchitherium*, the remains of which are found in a fossil state both in Europe and in America. In this genus there were three well-developed toes reaching the ground on each foot, and

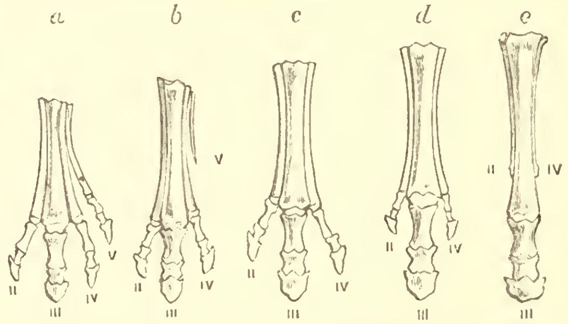

FIG. 3.—Successive stages of modification of the feet of extinct forms of horse-like animals (chiefly from Marsh), showing gradual reduction of the outer and enlargement of the middle toe (III). *a*, *Orohippus* (Eocene); *b*, *Mesohippus* (Early Miocene); *c*, *Miohippus* and *Anchitherium* (Late Miocene); *d* *Hipparion* and *Pliohippus* (Pliocene); *e*, *Equus* (Pleistocene).

the radius and ulna, and the tibia and fibula of the hind leg, were complete and distinct. This was succeeded on the European and Asiatic continent by *Hipparion* and in America by *Pliohippus*, perhaps more directly in the line of descent, as *Hipparion* has some special characters of its own in the teeth and skull, which make it probable that it is a collateral branch which became extinct without leaving descendants. In these and other forms which flourished at this period, the lateral toes, though containing the full number of bones, were much reduced in size, and did not reach the ground, but were suspended to the outside of and rather behind the large middle one, like the rudimentary outer toes of the deer, or the short first digit ("dew-claw") of the dog. Horses, or rather horse-like creatures, with this structure of feet were no longer met with in the Pleistocene period, but then for the first time appeared the true horse in its development exactly or very nearly as we know it now. The outer toes were reduced to rudiments of the metacarpals or metatarsals only, the so-called "splint bones" entirely concealed beneath the skin (fig. 3, *e*, II. and IV.), the middle toe (III.) greatly elongated, and with its ungual phalanx and hoof expanded, and the stability of the forearm and leg increased by the complete subordination of the ulna and fibula to the larger bones, the radius and tibia, which alone are concerned in the formation of the wrist and ankle joint.

Fossil remains of true horses, differing but very slightly from the smaller and inferior breeds of those now existing, are found abundantly in deposits of the most recent geological age, in almost every part of America, from Escholz Bay in the north to Patagonia in the south. In that continent, however, they became quite extinct, and no horses, either wild or domesticated, existed there at the time of the Spanish conquest, which is the more remarkable as, when introduced from Europe, the horses that ran wild proved by their rapid multiplication in the plains of South America and Texas that the climate, food, and other circumstances were highly favourable for their existence. The former great abundance of *Equidæ* in America, their complete extinction, and their perfect acclimatization when reintroduced by man, form curious but as yet unsolved problems in geographical distribution.

The existing species of the genus *Equus* are the following:—

(1.) The Horse, *Equus caballus*, Linn., is distinguished from the others by the long hairs of the tail being more abundant and growing quite from the base as well as the end and sides, and also by possessing a small bare callosity on the inner side of the hind leg, just below the "hock" or heel joint, in addition to the one on the inner side of the forearm above the carpus, common to all the genus. The mane is also longer and more flowing, and the ears shorter, the limbs longer, and the head smaller.

Though the existing horses are usually not marked in any definite manner, or only irregularly dappled, or spotted with light surrounded by a darker ring, many examples are met with showing a dark median dorsal streak like that found in all the other members of the genus, and even with dark stripes on the shoulders and legs indicating "the probability of the descent of all the existing races from a single dun-coloured, more or less striped, primitive stock, to which our horses still occasionally revert." [1]

In Europe wild horses were extremely abundant in the Neolithic or polished-stone period. Judging from the quantity of their remains found associated with those of the men of that time, the chase of these animals must have been among his chief occupations, and they must have furnished him with one of his most important food supplies. The characters of the bones preserved, and certain rude but graphic representations carved on bones or reindeers' antlers, enable us to know that they were rather small in size, and heavy in build, with large heads and rough shaggy manes and tails, much like, in fact, the present wild horses of the steppes of the south of Russia. These horses were domesticated by the inhabitants of Europe before the dawn of history, but it is doubtful whether the majority of the animals now existing on the Continent are derived directly from them, as it is more probable that they are descendants from horses imported though Greece and Italy from Asia, derived from a still earlier domestication, followed by gradual improvement through long-continued attention bestowed on their breeding and training. Horses are now diffused by the agency of man throughout almost the whole of the inhabited parts of the globe, and the great modifications they have undergone in consequence of domestication and selective breeding are well exemplified by comparing such extreme forms as the Shetland pony, dwarfed by uncongenial climate, the thoroughbred racer, and the London dray-horse. In Australia, as in America, horses imported by the European settlers have escaped into the unreclaimed lands, and multiplied to a prodigious extent, roaming in vast herds over the plains where no hoofed animal ever trod before.

(2.) *Equus asinus*, Linn.—The Domestic Ass is nearly as widely diffused and useful to man as the horse. It was known in Egypt long before the horse, and is probably of African origin, indeed its close resemblance to the existing wild ass of Abyssinia, *E. tæniopus*, Heuglin, leaves little doubt as to its identity with that species.

(3.) The Asiatic Wild Asses, which roam in small herds in the open plains of Syria, of many parts of Persia, of the north-west of India, and the highlands of Tartary and Tibet from the shores of the Caspian to the frontiers of China, differ from the last in being of a more rufous or isabelline colour, instead of pure grey, in wanting the dark streak across the shoulder, and having smaller ears. They have all a dark-coloured median dorsal stripe. Though it is considered probable by many zoologists that they form but a single species (*E. hemionus*, Pallas), they present such marked variations in size and form that they have commonly been divided into three—the Syrian Wild Ass (*E. hemippus*, Geoff.), the Onager (*E. onager*, Pall.) from Persia, the Punjab, Scinde and the desert of Cutch, and the Kiang or Dzeggetai (*E. hemionus*, Pallas) of the high table-lands of Tibet, where it is usually met with at an elevation of 15,000 feet and upwards above the sea-level. The last is considerably larger than either of the others, and differs from them in external appearance, having more the aspect of the horse. They are all remarkably swift, having been known to outstrip the fleetest horse in speed.

Lastly, there are three striped species, all inhabitants of South Africa. These constitute the genus *Hippotigris* of Hamilton Smith, but they are not separable except by their coloration from the true asses, and one of them (4), the Quagga (*E. quagga*, Gmel.), may be considered as intermediate. This animal has the dark stripes limited to the head, neck, and shoulders, upon a brown ground. In (5) the Dauw or Burchell's Zebra (*E. burchellii*, Gray), the ground colour is white, and the stripes cover the body and upper part of the limbs. This is the commonest species in the great plains of South Africa, where it roams in large herds, often in company with the quagga and numerous species of antelope. It ranges from the Orange River to the confines of Abyssinia. In (6) the Mountain Zebra (*E. zebra*, Linn.) the contrast between the clear white of the ground and the black of the stripes is most marked, and the latter extend quite down to the hoofs. This is, consequently, the most beautiful species of the group as regards colour, if the horse may bear the palm in elegance of form. It frequents mountainous districts rather than the open plains which are the dwelling-places of the other two species, and as it appears to be limited to the southern portion of the continent, within the confines of the Cape Colony, its numbers are rapidly diminishing under the encroachments of European civilization.

There are thus at least six modifications of the horse type at present existing, sufficiently distinct to be reckoned as species by all zoologists, and easily recognized by their external characters. They are, however, all so closely allied that each will, at least in a state of domestication or captivity, breed with perfect freedom with any of the others. Cases of fertile union are recorded between the horse and the quagga, the horse and the dauw or Burchell's zebra, the horse and the hemionus or Asiatic wild ass, the common ass and the zebra, the common ass and the dauw, the common ass and the hemionus, the hemionus and the zebra, and the hemionus and the dauw. The two species which are perhaps the farthest removed in general structure, the horse and the ass, produce, as is well known, hybrids or

[1] Darwin, *Variation of Animals and Plants under Domestication*, 1868, vol. i., chap. ii.

mules, which in some qualities useful to man excel both their progenitors, and in some countries and for certain kinds of work are in greater requisition than either. Although occasional instances have been recorded of female mules breeding with the males of one or other of the pure species, it is doubtful if any case has occurred of their breeding *inter se*, although the opportunities of doing so must have been great, as mules have been reared in immense numbers for at least several thousands of years. We may therefore consider it settled that the different species of the group are now in that degree of physiological differentiation which enables them to produce offspring with each other, but does not permit of the progeny continuing the race, at all events unless reinforced by the aid of one of the pure forms.

The several members of the group show mental differences quite as striking as those exhibited by their external form, and more than perhaps might be expected from the similarity of their cerebral organization. The patience of the ass, the high spirit of the horse, the obstinacy of the mule, have long been proverbial. It is very remarkable that, out of so many species, two only should have shown any aptitude for domestication, and that these two should have been from time immemorial the universal and most useful companions and servants of man, while all the others remain in their native freedom to this day. It is, however, still a question whether this really arises from a different mental constitution causing a natural capacity for entering into relations with man, or whether it may not be owing to their having been brought gradually into this condition by long continued and persevering efforts when the need of their services was keenly felt. It is quite possible that one reason why most of the attempts to add new species to the list of our domestic animals in modern times have ended in failure is that it does not answer to do so in cases in which existing species supply all the principal purposes to which the new ones might be put. It can hardly be expected that zebras and quaggas fresh from their native mountains and plains can be brought into competition as beasts of burden and draught with horses and asses, whose naturally useful qualities have been augmented by the training of thousands of generations of progenitors.

Not unfrequently instances occur of domestic horses being produced with a small additional toe with complete hoof, usually on the inside of the principal toe, and, though far more rarely, three or more toes may be present. These malformations are often cited as instances of reversion to the condition of some of the earlier forms of equine animals previously mentioned. Such explanations, however plausible they appear at first sight, are nevertheless very doubtful. All the feet of polydactyle horses which we have examined bear little resemblance to those of the extinct *Hipparion* or *Anchitherium*, but look rather as if due to that tendency to reduplication of parts which occurs so frequently as a teratological condition, especially among domestic animals, and which, whatever its origin, certainly cannot in many instances, as the cases of entire limbs superadded, or of six digits in man, be attributed to reversion.

ANATOMY.

The anatomical structure of the horse has been described in great detail in several works devoted to the subject, which will be mentioned in the bibliography, though these have generally been written from the point of view of the veterinarian rather than of the comparative anatomist. The limits of the present article will only admit of the most salient points being indicated, particularly those in which the horse differs from the other *Ungulata*. Unless otherwise specified, it must be understood that all that is stated here, although mostly derived from observation upon the horse, applies equally well to the other existing members of the group.

Skeleton.—The skull as a whole is greatly elongated, chiefly in consequence of the immense size of the face as compared with the hinder or true cranial portion. The basal line of the cranium from the lower border of the foramen magnum to the incisor border of the palate is very nearly straight. The orbit, of nearly circular form, though small in proportion to the size of the whole skull, is distinctly marked, being completely surrounded by a strong ring of bone with prominent edges. Behind it, and freely communicating with it beneath the osseous bridge (the post-orbital process of the frontal) forming the boundary between them, is the small temporal fossa occupying the whole of the side of the cranium proper, and in front is the great flattened expanse of the "cheek," formed chiefly by the superior maxilla, giving support to the long row of molar teeth, and having a prominent ridge running forward from below the orbit for the attachment of the masseter muscle. The lacrymal occupies a considerable space on the flat surface of the cheek in front of the orbit, and below it the malar does the same. The latter sends a horizontal or slightly ascending process backwards below the orbit to join the

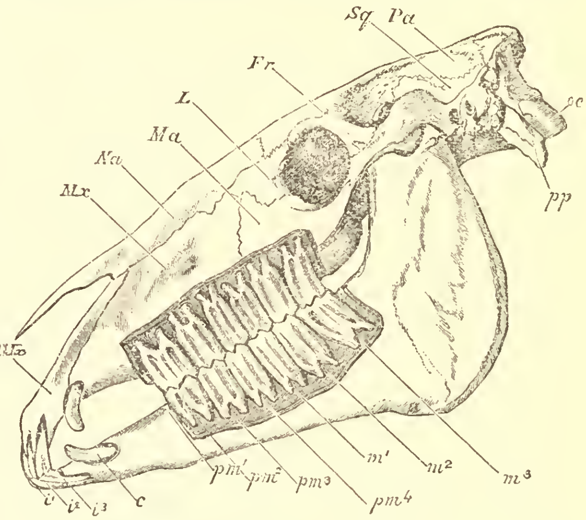

FIG. 4.—Side view of skull of horse, with the bone removed so as to expose the whole of the teeth. *PMx*, premaxilla; *Mx*, maxilla, *Na*, nasal bone; *Ma*, malar bone; *L*, lacrymal bone; *Fr*, frontal bone; *Sq*, squamosal bone; *Pa*, parietal bone; *oc*, occipital condyle; *pp*, paroccipital process; i^1, i^2, and i^3, the three incisor teeth; *c*, the canine tooth; pm^1, the situation of the rudimentary first premolar, which has been lost in the lower, but is present in the upper jaw; pm^2, pm^3, and pm^4, the three fully-developed premolar teeth; m^1, m^2, and m^3, the three true molar teeth.

under surface of the zygomatic process of the squamosal, which is remarkably large, and instead of ending as usual behind the orbit, runs forwards to join the greatly developed post-orbital process of the frontal, and even forms part of the posterior and inferior boundary of the orbit, an arrangement not met with in other mammals. The closure of the orbit behind distinguishes the skull of the horse from that of its allies the rhinoceros and tapir, and also from all of the perissodactyles of the Eocene period. In front of the cerebral cavity, the great tubular nasal cavities are provided with well-developed turbinal bones, and are roofed over by very large nasals, broad behind, and ending in front by a narrow decurved point. The opening of the anterior nares is prolonged backwards on each side of the face between the nasals and the elongated slender premaxillæ. The latter expand in front, and are curved downwards to form the semicircular alveolar border which supports the large incisor teeth. The palate is narrow in the interval between the incisor and molar teeth, in which are situated the large anterior palatine foramina. Between the molar teeth it is broader, and it ends posteriorly in a rounded excavated border opposite the hinder border of the penultimate molar tooth. It is mainly formed by the maxillæ, as the palatines are very narrow. The pterygoids are delicate slender slips of bone attached to the hinder border of the palatines, and supported externally by, and generally ankylosed to, the rough pterygoid plates of the alisphenoid, with no pterygoid fossa between. They slope very obliquely forwards, and end in curved, compressed, hamular processes. There is a distinct alisphenoid canal for the passage of the internal maxillary artery. The base of the cranium is long and narrow; the alisphenoid is very obliquely perforated by the foramen rotundum, but the foramen ovale is confluent with the large foramen lacerum medium behind. The glenoid surface for the articulation of the mandible is greatly extended transversely, concave from side to side, convex from before backwards in front, and hollow behind, and is bounded posteriorly at its inner part by a prominent post-glenoid process. The squamosal enters considerably into the formation of the temporal fossa, and, besides sending the zygomatic process forwards, it sends down behind the meatus auditorius a post-tympanic process which aids to hold in place the otherwise loose tympano-periotic bone. Behind this the exoccipital gives off a very long paroccipital process. The periotic and tympanic are ankylosed together, but not with the squamosal. The former has a wide but shallow floccular fossa on its inner side, and sends backwards a considerable "pars mastoidea," which appears on the outer surface of the skull between the post-tympanic process of the squamosal and the exoccipital. The tympanic forms a tubular meatus auditorius externus directed outwards and slightly backwards. It is not dilated into a distinct bulla, but ends in front in a pointed styliform process. It completely embraces the truncated cylindrical tympanohyal, which is of great size, corresponding with the large development of the whole anterior arch of the hyoid. This consists mainly of a long and compressed stylohyal, expanded at the upper end, where it sends off a triangular posterior process. The basi-hyal is remarkable for the long, median, pointed, compressed "glossohyal" process, which it sends forward from its anterior border into the base of the tongue. A similar but less developed process is found in the rhinoceros and tapir. The mandible is largely developed, especially the region of the angle, which is expanded and flattened, giving great surface for the attachment of the masseter muscle. The condyle is greatly elevated above the alveolar border; its articular surface is very wide transversely, and narrow and convex from before backwards. The coronoid process is slender, straight, and inclined backwards. The horizontal ramus, long, straight, and compressed, gradually narrows towards the symphysis, where it expands laterally to form with the ankylosed opposite ramus the wide, semicircular, shallow alveolar border for the incisor teeth.

The vertebral column consists of seven cervical, eighteen dorsal, six lumbar, five sacral, and fifteen to eighteen caudal vertebræ. There may be nineteen rib-bearing vertebræ, in which case five only will be reckoned as belonging to the lumbar series. The odontoid process of the atlas is wide, flat, and hollowed above, as in the ruminants. The bodies of the cervical vertebræ are elongated, strongly keeled, and markedly opisthocœlous, or concave behind and convex in front. The neural laminæ are very broad, the spines almost obsolete, except in the seventh, and the transverse processes not largely developed. In the trunk vertebræ the opisthocœlous character of the centrum gradually diminishes. The spinous processes of the anterior thoracic region are high and compressed. To these is attached the powerful elastic ligament, *ligamentum nuchæ*, or "paxwax," which passing forwards in the middle line of the neck above the neural arches of the cervical vertebræ, to which it is also connected, is attached to the occiput and supports the weight of the head. The transverse processes of the lumbar vertebræ are long, flattened, and project horizontally outwards or slightly forward from the arch. The metapophyses are moderately developed, and there are no anapophyses. The caudal vertebræ, except those quite at the base, are slender and cylindrical, without processes and without chevron bones beneath. The ribs are eighteen or nineteen in number on each side, flattened, and united to the sternum by short, stout, tolerably well ossified sternal ribs. The sternum consists of six pieces; the anterior or præsternum is extremely compressed, and projects forwards like the prow of a boat. The segments which follow gradually widen, and the hinder part of the sternum is broad and flat.

As in all other ungulates, there are no clavicles. The scapula is long and slender; the supra-scapular border is rounded, and slowly and imperfectly ossified. The spine is very slightly developed; rather above the middle its edge is thickened and somewhat turned backwards, but it gradually subsides at the lower extremity without forming any acromial process. The coracoid is a prominent rounded nodule. The humerus is stout and rather short. The ulna is quite rudimentary, being only represented by little more than the olecranon. The shaft gradually tapers below and is firmly ankylosed to the radius. The latter bone is of nearly equal width throughout. The three bones of the first row of the carpus (the scaphoid, lunar, and cuneiform) are subequal in size. The second row consists of a very broad and flat magnum, supporting the great third metacarpal, having to its radial side the trapezoid, and to its ulnar side the unciform, which are both small, and articulate distally with the rudimentary second and fourth metacarpals. The pisiform is large and prominent, flattened, and curved; it articulates partly with the cuneiform and partly with the lower end of the radius. The large metacarpal is called in veterinary anatomy "cannon bone"; the small lateral metacarpals, which gradually taper towards their lower extremities, and lie in close contact with the large one, are called "splint bones." The single digit consists of a moderate-sized proximal (*os suffraginis*, or large pastern), a very short middle (*os coronæ*, or small pastern), and a wide, semi-lunar, ungual phalanx (*os pedis*, or coffin bone). There is a pair of large nodular sesamoids behind the metacarpo-phalangeal articulation, and a single large transversely-extended sesamoid behind the joint between the second and third phalanx, called the "navicular bone."

The carpal joint, corresponding to the wrist of man, is commonly called the "knee" of the horse, the joint between the metacarpal and the first phalanx the "fetlock," that between the first and second phalanges the "pastern," and that between the second and third phalanges the "coffin joint."

In the hinder limb the femur is marked, as in all other known perissodactyles, by the presence of a "third trochanter," a flattened process, curving forwards, arising from the outer side of the bone, about one-third of the distance from the upper end. The fibula is reduced to a mere styliform rudiment of the upper end. The lower part is absent or completely fused with the tibia. The os calcis has a long and compressed calcaneal process. The astragalus has a large flat articular surface in front for the navicular, and a very small one for the cuboid. The navicular and the external cuneiform bones are very broad and flat. The cuboid is small, and the internal and middle cuneiform bones are small and united together. The metapodals and phalanges resemble very closely those of the fore limb, but the principal metatarsal is more laterally compressed at its upper end than is the corresponding metacarpal.

The joint between the femur and tibia, corresponding to the knee of man, is called the "stifle joint"; that between the tibia and tarsus, corresponding to the ankle of man, is called the "hock." The bones and joints of the foot have the same names as in the fore limb. The horse is eminently "digitigrade," standing on the extremity of the single digit of each foot, which is kept habitually in a position approaching to vertical.

The muscles of the limbs are modified from those of the ordinary mammalian type in accordance with the reduced condition of the bones and the simple requirements of flexion and extension of the joints, no such actions as pronation and supination, or opposition of digits, being possible or needed. The muscles therefore which perform these functions in other quadrupeds are absent or rudimentary.

Below the carpal and tarsal joints, the fore and hind limbs correspond almost exactly in structure as well as function. On the anterior or extensor surface of the limb a powerful tendon (7 in fig. 5), that of the anterior extensor

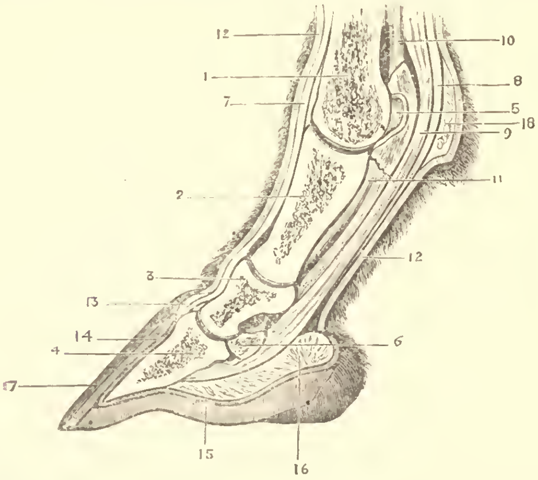

FIG. 5.—Section of foot of horse. 1, metacarpal bone; 2, first phalanx (*os suffraginis*); 3, second phalanx (*os coronæ*); 4, third or ungual phalanx (*os pedis*, or coffin bone); 5, one of the upper sesamoid bones; 6, lower sesamoid or navicular bone; 7, tendon of anterior extensor of the phalanges; 8, tendon of superficial flexor (*fl. perforatus*); 9, tendon of deep flexor (*fl. perforans*); 10, suspensory ligament of fetlock; 11, inferior or short sesamoid ligament; 12, derma or skin of the foot, covered with hair, and continued into 13, the coronary cushion, 14, the podophyllous or laminar membrane, and 15, the keratogenous membrane of the sole; 16, plantar cushion; 17, hoof; 18, fatty cushion of fetlock.

of the phalanges (corresponding to the *extensor communis digitorum* of the arm and *extensor longus digitorum* of the foot of man) passes down over the metacarpal bone and phalanges, to be inserted mainly into the upper edge of the anterior surface of the last phalanx or pedal bone. There is also a much smaller second extensor on the outer side of this in each limb, the lateral extensor of the phalanges. In the fore leg the tendon of this muscle (which corresponds with the *extensor minimi digiti* of man) receives a slip from that of the principal extensor, and is inserted into the first phalanx. In the hind leg (where it is the homologue apparently of the *peroneus brevis* of man) the tendon becomes blended with that of the large extensor.

A very strong ligamentous band behind the metapodium, arising from near the upper extremity of its posterior surface, divides into two at its lower end, and each division, being first connected with one of the paired upper sesamoid bones, passes by the side of the first phalanx to join the extensor tendon of the phalanges. This is called in veterinary anatomy the "suspensory ligament of the sesamoids," or of the "fetlock" (10 in fig. 5); but its attachments and relations, as well as the occasional presence of muscular fibres in its substance, show that it is the homologue of the interosseous muscles of other mammals, curiously modified both in structure and function, to suit the requirements of the horse's foot. Behind or superficial to this are placed the two strong tendons of the flexor muscles, the most superficial, or *flexor perforatus* (8), dividing to allow the other to pass through, and then inserted into the middle phalanx. The *flexor perforans* (9) is as usual inserted into the terminal phalanx. In the fore leg these muscles correspond with those similarly named in man. In the hind leg, the perforated tendon is a continuation of that of the plantaris, passing pulley-wise over the tuberosity of the os calcis. The perforating tendon is derived from the muscle corresponding with the long flexor of man, and the smaller tendon of the oblique flexor (*tibialis porticus* of man) is united with it.

The hoof of the horse corresponds to the nail or claw of other mammals, but is so constructed as to form a complete and very solid case to the expanded termination of the toe, giving a firm basis of support formed of a non-sensitive substance, which is continually renewed by the addition of material from within, as its surface wears away by friction against the ground. The terminal phalanx of the toe is greatly enlarged and modified in form to support this hoof, and the size of the internal framework of the foot is further increased by a pair of lateral fibro-cartilaginous masses attached on each side to the hinder edges of the bone, and by a fibro-cellular and adipose plantar cushion in the median part. These structures are all enclosed in the keratogenous membrane or "subcorneous integument," a continuation of the ordinary derma of the limb, but extremely vascular, and having its superficial extent greatly increased by being developed into papillæ or laminæ. From this the horny material which constitutes the hoof is exuded. A thickened ring encircling the upper part, called coronary cushion (13), and the sole (15), are covered with numerous thickly-set papillæ or villi, and take the greatest share in the formation of the hoof; the intermediate part constituting the front and side of the foot (14), corresponding with the wall of the hoof, is covered with parallel, fine longitudinal laminæ, which fit into corresponding depressions in the inner side of the horny hoof.

The horny hoof is divided into a wall or crust consisting of the front and sides, the flattened or concave sole, and the frog, a triangular median prominence, notched posteriorly, with the apex turned forwards, situated in the hinder part of the sole. It is formed of pavement epithelial cells, which are mainly grouped in a concentric manner around the vascular papillæ of the keratogenous membrane, so that a section near the base of the hoof, cut transversely to the long axis of these papillæ, shows a number of small circular or oval orifices, with cells arranged concentrically round them. The nearer the surface of the hoof, or further removed from the seat of growth, the more indistinct the structure becomes.

Small round or oval plates of horny epithelium called "chestnuts," growing like the hoof from enlarged papillæ of the skin, are found on the inner face of the fore arm, above the carpal joint in all species of *Equidæ*, and in the horse (*E. caballus*) similar formations occur near the upper extremity of the inner face of the metatarsus. Their use is unknown.

Dentition.—The dentition of the horse, when all the teeth are in place, is, as stated before, expressed by the formula $i.\ \frac{3}{3},\ c.\ \frac{1}{1},\ p.\ \frac{4}{4},\ m.\ \frac{3}{3} = 44$. The incisors of each jaw are placed in close contact, forming a semicircle. The crowns are broad, somewhat awl-shaped, and of nearly equal size. They have all the great peculiarity, not found in the teeth of any other mammal, and only in the *Equidæ* of comparatively recent geological periods, of an involution of the external surface of the tooth (see fig. 6), by which what should properly be the apex is carried deeply into the interior of the crown, forming a fossa or pit, the bottom of which becomes partially filled up with crusta petrosa or cementum. As the tooth wears, the surface, besides the external enamel layer as in an ordinary simple tooth, shows in addition a second inner ring of the same hard substance surrounding the pit, which of course adds greatly to the efficiency of the tooth as an organ for biting tough, fibrous substances. This pit, generally filled in the living animal with particles of food, is conspicuous from its dark colour, and constitutes the "mark" by which the age of the horse is judged, as in consequence of its only extending to a certain depth in the crown it becomes obliterated as the crown wears away, and then the tooth assumes the character of that of an ordinary incisor, consisting only of a core of dentine, surrounded by the external enamel layer. It is not quite so deep in the lower as in the upper teeth.

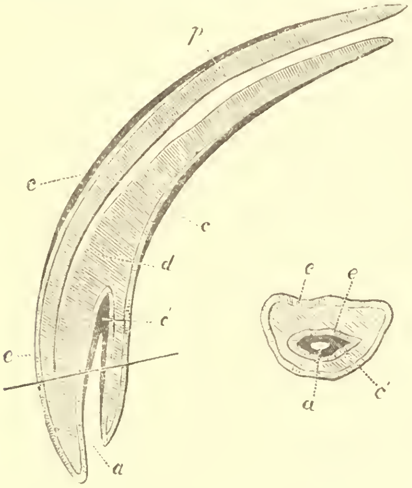

Fig. 6.—Longitudinal and transverse section of upper incisor of horse. *p*, pulp cavity; *d*, dentine or ivory; *e*, enamel; *c*, outer layer of cementum or crusta petrosa; *c′*, inner layer of cementum, lining *a*, the pit or cavity of the crown of the tooth.

The canines are either quite rudimentary or entirely absent in the female. In the male they are compressed, pointed, and smaller than the incisors, from which they are separated by a slight interval. The teeth of the molar series are all in contact with each other, but separated from the canines by a considerable toothless space. The anterior premolars are quite rudimentary, sometimes not developed at all, and generally fall by the time the animal attains maturity, so that there are but six functional grinding teeth,—three that have predecessors in the milk dentition, and hence are considered as premolars, and three true molars, but otherwise, except the first and last of the series, not distinguishable in form or structure. These teeth in both upper and lower jaws are extremely long-crowned or hypsidont, successive portions being pushed out as the surface wears away, a process which continues until the animal becomes advanced in age. The enamelled surface is infolded in a complex manner (a modification of that found in other perissodactyles), the folds extending quite to the base of the crown, and the interstices being filled and the surface covered with a considerable mass of cement, which binds together and strengthens the whole tooth. As the teeth wear, the folded enamel, being harder than the other constituents, the dentine and cement, forms projecting ridges on the surface arranged in a definite pattern, which give it great efficiency as a grinding instrument (see fig. 1, *b* and *c*). The free surfaces of the upper teeth are quadrate, except the first and last, which are nearly triangular. The lower teeth are much narrower than the upper.

The milk dentition consists of $i.\ \frac{3}{3}$, $c.\ \frac{0}{0}$, $m.\ \frac{3}{3} = 24$,—the canines and first or rudimentary premolars having apparently no predecessors. In form and structure they much resemble the permanent teeth, having the same characteristic enamel foldings. Their eruption commences a few days after birth, and is complete before the end of the first year, the upper teeth usually appearing somewhat earlier than those of the lower jaw. The first teeth which appear are the first and second milk molars (about five days), then the central incisor (from seven to ten days); this is followed by the second incisor (at one month), then the third molar, and finally the third incisor. Of the permanent teeth the first true molar appears a little after the end of the first year, followed by the second molar before the end of the second year. At about two and a half years the first premolar replaces its predecessor. Between two and a half and three years the first incisor appears. At three years the second and third premolars, and the third true molar have appeared, at from three and a half to four years the second incisor, at four to four and a half years the canine, and, finally, at five years, the third incisor, completing the permanent dentition. Up to this period the age of the horse is clearly shown by the condition of dentition, and for some time longer indications can be obtained from the wear of the incisor teeth, though this depends to a certain extent upon the hardness of the food or other accidental circumstances. As a general rule, the depression caused by the infolding of the surface of the incisor (the "mark") is obliterated in the first or central incisor at six years, in the second at seven years, and in the third at eight years. In the upper teeth, as the depressions are deeper, this obliteration does not take place until about two years later. After this period no certain indications can be obtained of the age of the horse from the teeth.

Digestive Organs.—The lips are flexible and prehensile. The membrane that lines them and the cheeks is quite smooth. The palate is long and narrow; its mucous surface has seventeen pairs of not very sharply defined oblique ridges, extending as far back as the last molar tooth, beyond which the velum palati extends for about 3 inches, having a soft corrugated surface, and ending posteriorly in an arched border without uvula. This embraces the base of the epiglottis, and, except while swallowing food, shuts off all communication between the cavity of the mouth and the pharynx, respiration being, under ordinary circumstances, exclusively through the nostrils. Between the mucous membrane and the bone of the hard palate is a dense vascular and nervous plexus. The membrane lining the fauces is soft and corrugated. An elongated raised glandular mass, 3 inches long and 1 inch from above downwards, extending backwards from the root of the tongue along the side of the fauces, with openings on the surface leading into crypts with glandular walls, represents the tonsil. The tongue, corresponding to the general form of the mouth, is long and narrow. It consists of a compressed intermolar portion with a flat upper surface, broad behind and becoming narrower in front, and of a depressed anterior part rather shorter than the former, and which is narrow behind and widens towards the evenly rounded apex. The dorsal surface generally is very soft and smooth. There are two large circumvallate papillæ near the base, rather irregular in form, about a quarter of an inch in diameter and half an inch apart. The conical papillæ are very small and close set, though longer and more filamentous on the intermolar portion. There are no fungiform papillæ on the dorsum, but a few not very conspicuous ones scattered along the sides of the organ.

Of the salivary glands the parotid is by far the largest, and elongated in the vertical direction, and narrower in the middle than at either upper or lower extremity. Its upper extremity embraces the lower surface of the cartilaginous ear-conch; its lower end reaches the level of the inferior margin of the mandible, along the posterior margin of which it is placed. Its duct leaves the inferior anterior angle, at first descends a little, and runs forward under cover of the rounded inferior border of the mandibular ramus, then curves up along the anterior margin of the masseter muscle, becoming superficial, pierces the buccinator, and enters the mouth by a simple aperture opposite the middle of the crown of the third premolar tooth. It is not quite so thick as a goosequill when distended, and nearly a foot in length.

The submaxillary gland is of very similar texture to the last, but much smaller; it is placed deeper, and lies with its main axis horizontal. It is elongated and slender, and flattened from within outwards. Its posterior end rests against the anterior surface of the transverse process of the atlas, from which it extends forwards and downwards, slightly curved, to beneath the ramus of the jaw. The duct which runs along its upper and internal border passes forwards in the usual course, lying in the inner side of the sublingual gland, to open on the outer surface of a distinct papillæ, situated on the floor of the mouth, half an inch from the middle line, and midway between the lower incisor teeth and the attachment of the frænum linguæ. The sublingual is represented by a mass of glands lying just beneath the mucous membrane of the floor of the mouth on the side of the tongue, causing a distinct ridge, extending from the frænum backwards, the numerous ducts opening separately along the summit of the ridge. The buccal glands are arranged in two rows parallel with the molar teeth. The upper ones are the largest, and are continuous anteriorly with the labial glands, the ducts of which open on the mucous membrane of the upper lip.

The stomach of the horse is simple in its external form, with a largely developed right *cul de sac*, and is a good deal curved on itself, so that the cardiac and pyloric orifices are brought near together. The antrum pyloricum is small and not very distinctly marked off. The interior is divided by the character of the lining membrane into two very distinct portions, right and left. Over the latter the dense white smooth epithelial lining of the œsophagus is continued, terminating abruptly by a raised crenellated border. Over the right part (rather the larger portion) the mucous membrane has a greyish-red colour and a velvety appearance, and contains very numerous peptic glands, which are wanting in the cardiac portion. The œsophageal orifice is very small, and is guarded by a strong crescentic or rather horseshoe-like band of muscular fibres, which is supposed to be the cause of the difficulty of vomiting in the horse. The small intestine is of great length (80 to 90 feet), its mucous membrane being covered with numerous fine villi. The cæcum is of conical form, about 2 feet long and nearly a foot in diameter; its walls are sacculated, especially near the base, having four longitudinal muscular bands; and its capacity is about twice that of the stomach. It lies with its base near the lower part of the abdomen, and its apex directed towards the thorax. The colon is about one-third the length of the small intestine, and very capacious in the greater part of its course. As usual it may be divided into an ascending, transverse, and descending portion; but the middle or transverse portion is folded into a great loop, which descends as low as the pubis; so that the colon forms altogether four folds, generally parallel to the long axis of the body. The descending colon is much narrower than the rest, and not sacculated, and, being considerably longer than the distance it has to traverse, is thrown into numerous folds.

The liver is tolerably symmetrical in its general arrangement, being divided nearly equally into segments by a well-marked umbilical fissure. Each segment is again divided by lateral fissures, which do not extend quite to the posterior border of the organ; of the central lobes thus cut off, the right is rather the larger, and has two fissures in its free border subdividing it into lobules. The extent of these varies, however, in different individuals. The two lateral lobes are subtriangular in form. The Spigelian lobe is represented by a flat surface between the postal fissure and the posterior border, not distinctly marked off from the left lateral by a fissure of the ductus venosus, as this vessel is buried deep in the hepatic substance, but the caudate lobe is distinct and tongue-shaped, its free apex reaching nearly to the border of the right lateral lobe. In most works on the anatomy of the horse this has been confounded with the Spigelian lobe of man. There is no gall-bladder, and the biliary duct enters the duodenum about 6 inches from the pylorus. The pancreas has two lobes or branches, a long one passing to the left and reaching the spleen, and a shorter right lobe. The principal duct enters the duodenum with the bile-duct, and there is often a second small duct which opens separately near to this.

Circulatory and Respiratory Organs.—The heart has the form of a rather elongated and pointed cone. There is one anterior vena cava, formed by the union of the two jugular and two axillary veins. The aorta gives off a large branch (the anterior aorta) very near its origin, from which arise—first, the left axillary, and afterwards the right axillary and the two carotid arteries.

Under ordinary circumstances the horse breathes entirely by the nasal passages, the communication between the larynx and the mouth being closed by the velum palati. The nostrils are placed laterally, near the termination of the muzzle, and are large and very dilatable, being bordered by cartilages upon which several muscles act. Immediately within the opening of the nostril, the respiratory canal sends off on its upper and outer side a diverticulum or blind pouch (called "false nostril") of a conical form, and curved, 2 to 3 inches in depth, lying in the notch formed between the nasal and premaxillary bones. It is lined by mucous membrane continuous with that of the nasal passage, and its use is not apparent. It is longer in the ass than in the horse. Here may be mentioned the guttural pouches, large air sacs, diverticula from the Eustachian tubes, and lying behind the upper part of the pharynx, the function of which is also not clearly understood. The larynx has the lateral sacculi well developed, though entirely concealed within the alæ of the thyroid cartilage. The trachea divides into two bronchi, one for each lung.

Nervous System.—The brain differs little, except in details of arrangement of convolutions, from that of other ungulates. The cerebral hemispheres are rather elongated and subcylindrical, the olfactory lobes are large and project freely in front of the hemispheres, and the greater part of the cerebellum is uncovered. The eye is provided with a nictitating membrane or third eyelid, at the base of which the ducts of the Harderian gland open.

Reproductive System.—The testes are situated in a distinct sessile or slightly pedunculated scrotum, into which they descend from the sixth to the tenth month after birth. The accessory generative glands are the two vesiculæ seminales, with the median third vesicle, or *uterus masculinus*, lying between them, the single bilobed prostate, and a pair of globular Cowper's glands. The penis is very large, cylindrical, with a truncated, expanded, flattened termination. When in a state of repose it is retracted, by a muscle arising from the sacrum, within the prepuce, a cutaneous fold attached below the symphysis pubis.

The uterus is bicornuate. The vagina is often partially divided by a membraneous septum or hymen. The mammæ are two, inguinally placed. The surface of the chorion is covered evenly with minute villi, constituting a diffuse non-deciduate placenta. The period of gestation is eleven months.

PART II.—HISTORY, MANAGEMENT, AND BREEDING.

From the evidence of philology it is plain that the horse was already known to the Aryans before the period of their dispersion.[1]

The first mention of the British horse occurs in the well-known passages in Cæsar (*B. G.*, iv. 24, 33; v. 15, 16; *cf.* Pomp. Mela, iii. 6), in which he mentions the native "essedarii" and the skill with which they handled their war chariots. We are left quite in the dark as to the character of the animal thus employed; but there would appear to be much probability in the surmise of Youatt, who conjectures the horse to have been, "then as ever, the creature of the country in which he lived. With short fare, and exposed to the rigour of the seasons, he was probably the little hardy thing we yet see him; but in the marshes of the Nen and the Witham, and on the borders of the Tees and the Clyde, there would be as much proportionate development of frame and strength as we find at the present day." After the occupation of the country by the Romans, it appears that the horses of their cavalry were crossed with the native mares, and thus there was infused into the breed new blood, consisting probably of strains from every quarter from which Roman remounts were procured. As to the effect of this cross we are not, however, in a position to judge. We are also quite uncertain as to the extent to which the Jutes and Saxons may in their turn have again introduced a new breed of horses into England; and even to the close of the Anglo-Saxon period of English history allusions to the horse are still very unfrequent. The *horsthegn* we know, however, was from an early period a high court official; and from such a law as that of Athelstan prohibiting the exportation of horses except as presents, it may be inferred that the English breed was not only much valued at home but also in great request abroad.[2]

The period of the Norman Conquest marks an important stage in the history of the British horse. William the Conqueror's own horse was of the Spanish breed, and others of the same kind were introduced by the barons on their estates. But the Norman horses included many varieties, and there is no doubt that to the Conquest the inhabitants of Britain were indebted for a decided improvement in the native horse, as well as for the introduction of several varieties previously unknown. According to Giraldus Cambrensis, Roger de Bellesme, a follower of William I., afterwards created earl of Shrewsbury, imported some stallions from Spain into England; their produce was celebrated by Drayton the poet. It is curious to notice that agriculture seems to be the last use to which the horse has been put. The earliest suggestion that horses were used in agriculture is derived from a piece of the Bayeux tapestry, where a horse is represented as drawing a harrow. This, however, must have been an exceptional case, for we know that oxen were used until a comparatively late time, and that in Wales a law existed forbidding horses to be used for ploughing.

In 1121 two Eastern horses are said to have been imported,—one of them remaining in England, and the other being sent as a present by King Alexander I. to the church of St Andrews, in Scotland. It has been alleged that these horses were Barbs from Morocco, but a still more likely theory is that they existed only in name, and never reached either England or Scotland. The crusades were probably the means of introducing fresh strains of blood into England, and of giving opportunity for fresh crossings. The Spanish jennet was brought over about 1182. King John gave great encouragement to horse-breeding: one of his earliest efforts was to import a hundred Flemish stallions, and, having thus paved the way for improving the breed of agricultural horses, he set about acquiring a valuable stud for his own use.

Edward III. was likewise an admirer of the horse; he procured fifty Spanish horses, probably jennets. At this time there was evidently a tendency to breed a somewhat lighter and speedier horse; but, while the introduction of a more active animal would soon have led to the displacement of the ponderous but powerful cavalry horse then in use, the substituted variety would have been unable to carry the weight of armour with which horse and rider were alike protected; and so in the end the old breed was kept up for a time. With the object of preserving to England whatever advantages might accrue from her care and skill in breeding an improved stamp of horses, Edward III. forbade their exportation; they consequently improved so rapidly in value that Richard II. compelled dealers to limit their prices to a fixed maximum. In the ninth year of his reign, Edward received from the king of Navarre a present of two running horses, supposed to have been valuable. The wars of 1346 checked the improvement of horses, and undid much of what had been previously accomplished, for we read that the cavalry taken into France by Edward III. were but

[1] Compare Sanscr., *açva*; Zendish and Old Persian, *açpa*; Lithuanian, *aszra* (mare); Prussian, *asvinan* (mare's milk); Old High German, *ehu*; Anglo-Saxon, *eoh*; Icel., *iör*; Gothic, *aihos*, *aihous* (?); Old Irish, *ech*; Old Cambrian and Gaelic, *ep* (as in *Epona*, the horse goddess); Lat., *equus*; Gr., ἵππος or ἴκκος. The word seems, however, to have disappeared from the Slavonic languages. The root is probably *ak*, with the idea of sharpness or swiftness (ἄκρος, ὠκύς, *acus*, *ocior*). See Pott, *Etym. Forsch.*, ii. 256, and Hehn, *Kulturpflanzen u. Hausthiere in ihrem Uebergang aus Asien nach Griechenland u. Italien sowie in das übrige Europa* (3d ed., 1877), p. 38. The last-named author, who points out the absence of the horse from the Egyptian monuments prior to the beginning of the 18th century B.C., and the fact that the earliest references to this animal in Hebrew literature (Judg. v. 22, 28; *cf.* Josh. xi. 4) do not carry us any further back, is of opinion that the Semitic peoples as a whole were indebted for the horse to the lands of Iran. He also shows that literature affords no trace of the horse as indigenous to Arabia prior to about the beginning of the 5th century A.D., although references abound in the pre-Islamitic poetry. Horses were not numerous even in Mahomet's time (Sprenger, *Leb. Moh.*, iii. 139, 140). Compare Ignazio Guidi's paper "Della sede primitiva dei popoli Semitici" in the *Transactions* of the Accademia dei Lincei (1878–79).

[2] Some fragments of legislation relating to the horse about this period may be gleaned from *Ancient Laws and Institutes of England* (fol., London, 1840), and *Ancient Laws and Institutes of Wales* (fol., London, 1841).

indifferently mounted, and that in consequence he had to purchase large numbers of foreign horses from Hainault and elsewhere for remounts. The reign of Richard III. does not seem to have been remarkable for the furtherance of horse-breeding; but it was then that post-horses and stages were introduced.

Our information on the whole subject is but scanty down to the reign of Henry VII., who continued the enactment against the exportation of stallions, but relaxed it in the case of mares above two years old. His object was to retain the best horses in the country, and to keep the price of them down by limiting the demand and encouraging the supply. In his reign gelding is believed to have had its origin, on account of numerous herds of horses belonging to different proprietors grazing together, especially in time of harvest. Henry VIII. was particularly careful that horse-breeding should be conducted on right principles, and his enactments, if somewhat arbitrary, were singularly to the point. In the thirty-second year of this reign, the "bill for the breed of horses" was passed, the preamble of which runs thus:—"Forasmuch as the generation and breed of good and strong horses within this realm extendeth not only to a great help and defence of the same, but also is a great commodity and profit to the inhabitants thereof, which is now much decayed and diminished, by reason that, in forests, chases, moors, and waste grounds within this realm, little stoned horses, and nags of small stature and of little value, be not only suffered to pasture thereupon, but also to cover mares feeding there, whereof cometh in manner no profit or commodity." Section 2 of the Act provides that no entire horse being above the age of two years, and not being of the height of 15 "handfulls," shall be put to graze on any common or waste land in certain counties; any one was to be at liberty to seize a horse of unlawful height, and those whose duty it was to measure horses, but who refused to do so, were to be fined 40s. By section 6 all forests, chases, commons, &c., were to be "driven" within fifteen days of Michaelmas day, and all horses, mares, and colts not giving promise of growing into serviceable animals, or of producing them, were to be killed. The aim of the Act was to prevent breeding from animals not calculated to produce the class of horse suited to the needs of the country. By another Act (27 Henry VIII. chapter 6), after stating that the "breed of good strong horses" was likely to diminish, it was ordered that the owners of all parks and enclosed grounds of the extent of one mile should keep two mares 13 hands high for breeding purposes, or, if the extent of the ground was four miles, four mares. The statute was not to extend to the counties of Westmoreland, Cumberland, Northumberland, or the bishopric of Durham. Henry took great pains to improve the royal stud: according to Sir Thomas Chaloner—a writer in the reign of Elizabeth—he imported horses from Turkey, Naples, and Spain.

Queen Elizabeth is reputed to have been an accomplished horsewoman, and to have indulged in riding late in life. In the first year of her reign she revived an Act passed by Henry VIII. making it felony "to sell, exchange, or deliver within Scotland, or to the use of any Scottishman, any horse;" this, however, was very naturally repealed by James I. Carriages were soon after introduced, and the use of them speedily became so fashionable that a bill was brought in "to restrain the excessive and superfluous use of coaches." Prior to the introduction of carriages, horseback was the means of locomotion, and Queen Elizabeth rode in state to St Paul's on a pillion; but even after carriages were used, horseback was held to be more dignified, for James I. and his judges rode on horseback to Westminster Hall. One advantage of the introduction of carriages was that it created a demand for a lighter and quicker sort of horse, instead of the ponderous animal which, despite all attempts to banish him, was still the horse of England—the age of chivalry having been the first epoch of the British horse.

Gunpowder, too, was invented; and now that the weight of the cavalry soldier was diminished by the substitution of lighter armour, a quicker and better bred horse was thought desirable for military service. The introduction of carriages and the invention of gunpowder thus opened out a new industry in breeding; and a decided change was gradually creeping on by the time that James I. came to the throne (1603), which commences the second epoch. James was a thorough sportsman, and his taste for racing, in which he freely indulged, caused him to think but little of the speed of even the best English horses. With the laudable motive therefore of effecting improvement in horses, he gave the then large sum of 500 guineas for an Arab stallion which had been procured from Constantinople by a Mr Markham, since known as the "Markham Arabian." This is the first authentic account we have of the importation of Arab blood, and the *Stud-Book* says he was the first of that breed ever seen in England. The people having to do with horses at that time were as conservative in their notions as most of the grooms are now, and the "Markham Arabian" was not at all approved of. The duke of Newcastle, in his treatise on horsemanship, said that he had seen the above Arabian, and described him as a small bay horse and not of very excellent shape. In this instance, however, prejudice (and it is difficult to believe that it was anything else) was right, for King James's first venture does not appear to have been a success either as a race-horse or as a sire, and thus Arabian blood was brought into disrepute. The king, however, resolved to give Eastern blood another trial, and bought a horse known as Place's White Turk from a Mr Place, who subsequently held some office in connexion with the stable under Cromwell. Charles I. followed in the footsteps of James, and lent such patronage to the breeding of a better kind of horse that a memorial was presented to him, asking that some measures might be taken to prevent the old stamp of horse "fit for the defence of the country" from dying out.

We now come to a very important period in the history of the British horse, for Charles II. warmly espoused the introduction of Eastern blood into England. He sent his master of the horse abroad to purchase a number of foreign horses and mares for breeding, and the mares brought over by him (as also many of their produce) were called "royal mares"; they form a conspicuous feature in the annals of breeding. The *Stud-Book* shows of what breed the royal mares really were: one of them, the dam of Dodsworth (who, though foaled in England, was a natural Barb), was a Barb mare; she was sold by the stud-master, after Charles II.'s death, for forty guineas, at twenty years old, when in foal by the Helmsley Turk.

James II. was a good horseman, and had circumstances been more propitious he might have left his mark in the sporting annals of the country. In his reign, according to the *Stud-Book*, the Stradling or Lister Turk was brought into England by the duke of Berwick from the siege of Buda.

The reign of William III. is noteworthy as the era in which, among other importations, there appeared the first of three Eastern horses to which the modern thoroughbred race-horse traces back as the founders of his lineage. This was the Byerly Turk, of whom nothing more is known than that—to use the words of the first volume of the *Stud-Book*—he was Captain Byerly's charger in Ireland in King William's wars. The second of the three horses above alluded to was the Darley Arabian, who was a genuine Arab, and was imported from Aleppo by a brother of Mr Darley of Aldby Park, Yorkshire, about the end of the reign of William III. or the beginning of that of Anne. The third horse of the famous trio, the Godolphin Arabian or Barb, brought to England about five and twenty years after the Darley Arabian, will be more particularly referred to further on. All the horses now on the turf or at the stud trace their ancestry in the direct male line to one or other of these three,—the Byerly Turk, the Darley Arabian, and the Godolphin Arabian or Barb. In the female line their pedigrees can be traced to other sources, but for all practical purposes it suffices to regard one or other of these three animals as the *ultima Thule* of racing pedigree. Of course there is a large interfusion of the blood of each of the trio through the dams of horses of the present day; indeed, it is impossible to find an English race-horse which does not combine the blood of all three.

Thorace-horse. *The Thoroughbred.*—The third and last epoch of the British horse, viz., that of the thoroughbred racer, may be taken to date from the beginning of the 18th century. By thoroughbred is meant a horse or mare whose pedigree is registered in the *Stud-Book* kept by Messrs Weatherby, the official agents of the Jockey Club—originally termed the keepers of the match-book—as well as publishers of the *Racing Calendar*. The first attempt to evolve order out of the chaos which had long reigned supreme was made in 1791, for we find in the preface of the first volume of the *Stud-Book*, published in 1808, that "with a view to correct the then increasing evil of false and inaccurate pedigrees, the author was in the year 1791 prevailed upon to publish an *Introduction to a General Stud-Book*, consisting of a small collection of pedigrees which he had extracted from racing calendars and sale papers and arranged on a new plan." It will be seen that the compiler of the volume on which so much depends had to go back fully a century, with little else to guide him but odds and ends in the way of publications and tradition. Mistakes under such circumstances are pardonable. The *Stud-Book* then (vol. i.), which is the oldest authority we have, contains the names and in most cases the pedigrees, obscure though they may be, of a very large number of horses and mares of note from the earliest accounts, but with two exceptions no dates prior to the 18th century are specified in it. These exceptions are the Byerly Turk, who was "Captain Byerly's charger in Ireland in King William's Wars (1689, &c.)," and a horse called Counsellor, bred by Mr Egerton in 1694, by Lord D'Arcy's Counsellor by Lord Lonsdale's Counsellor by the Shaftesbury Turk out of sister to Spanker—all the dams in Counsellor's pedigree tracing back to Eastern mares. There is not the least doubt that many of the animals named in the *Stud-Book* were foaled much earlier than the above dates, but we have no particulars as to time; and after all it is not of much consequence.

The *Stud-Book* goes on to say of the Byerly Turk that he did not cover many bred mares, but was the sire of the Duke of Devonshire's Basto, Halloway's Jigg, and others. Jigg, or Jig, is a very important factor, as will be seen hereafter. The *Stud-Book*, although silent as to the date of his birth, says he was a common country stallion in Lincolnshire until Partner was six years old—and we know from the same authority that Partner was foaled in 1718; we may therefore conclude that Jigg was a later foal than Basto, who, according to Whyte's *History of the Turf*, was a brown horse foaled in 1703.

The reign of Queen Anne, however (1702 to 1714), is that which will ever be inseparably connected with the thoroughbred race-horse on account of the fame during that period of the Darley Arabian, a bay stallion, from whom our very best horses are descended. According to the *Stud-Book*, "Darley's Arabian was brought over by a brother of Mr Darley of Yorkshire, who, being an agent in merchandise abroad, became member of a hunting club, by which means he acquired interest to procure this horse." The *Stud-Book* is silent, and other authorities differ, as to the date of the importation of this celebrated Arab, some saying he came over in the year 1700, others that he arrived somewhat later; but we know from the *Stud-Book* that Manica (foaled in 1707), Aleppo (1711), Almanzor (1713), and Flying Childers (1715) were got by him, as also was Bartlett's Childers, a younger brother of Flying Childers. It is generally believed that he was imported in Anne's reign, but the exact date is immaterial, for, assuming that he was brought over as early as 1700 from Aleppo, he could scarcely have had a foal living before 1701, the first year of the 18th century. The Darley Arabian did much to remove the prejudice against Eastern blood which had been instilled into the public mind by the duke of Newcastle's denunciation of the Markham Arabian. Prince George of Denmark, consort of Queen Anne, was himself a large horse-owner; and it was in a great measure owing to his intervention that so many valuable stallions were imported during her reign.

At this period we find, among a mass of horses and mares in the *Stud-Book* without any dates against their names, many animals of note with the earliest chronology extant, from Grey Ramsden (1704) and Bay Bolton (1705) down to a mare who exercised a most important influence on the English blood-horse. This was Roxana (1718) by the Bald Galloway, her dam sister to Chanter by the Akaster Turk, from a daughter of Leedes's Arabian and a mare by Spanker. Roxana threw in 1732 the bay colt Lath by the Godolphin Arabian, the sorrel colt Roundhead by Childers in 1733, and the bay colt Cade by the Godolphin Arabian in 1734, in which year she died within a fortnight after foaling, the produce—Cade—being reared on cow's milk. The Godolphin Barb or Arabian, as he was commonly called, was a brown bay about 15 hands in stature, with an unnaturally high crest, and with some white on his off hind heel. He is said to have been imported into England from France by Mr Coke, where, as the editor of the *Stud-Book* was informed by a French gentleman, he was so little thought of that he had actually drawn a cart in the streets of Paris. Mr Coke gave him to a Mr Williams, who in his turn presented him to the earl of Godolphin. Although called an Arabian, there is little doubt he was a Barb pure and simple. In 1731, being then the property of Mr Coke, he was teazer to Hobgoblin, and on the latter refusing his services to Roxana, the mare was put to the Godolphin, and the produce was Lath (1732), the first of his get, and the most celebrated race-horse of his day after Flying Childers. He was also the sire of Cade, own brother to Lath, and of Regulus the maternal grandsire of Eclipse. He died at Gogmagog in Cambridgeshire, in the possession of Lord Godolphin, in 1753, being then, as is supposed, in his twenty-ninth year. He is believed to have been foaled in Barbary about 1724, and to have been imported during the reign of George II.

In regard to the mares generally, we have a record of the royal mares already alluded to, and likewise of three Turk mares brought over from the siege of Vienna in 1684, as well as of other importations; but it is unquestionable that there was a very large number of native mares in England, improved probably from time to time by racing, however much they may have been crossed at various periods with foreign horses, and that from this original stock were to some extent derived the size and stride which characterized the English race-horse, while his powers of endurance and elegant shape were no doubt inherited from the Eastern horses, most of which were of a low stature, 14 hands or thereabouts. It is only necessary to trace carefully back the pedigree of most of the famous horses of early times to discover faults on the side of the dam—that is to say, the expression "dam's pedigree unknown," which evidently means of original or native blood. Whatever therefore may be owing to Eastern blood, of which from the middle of the 17th to the beginning of the 18th century a complete wave swept over the British Isles, some credit is unquestionably due to the native mares (which Blaine says were mostly Cleveland bays) upon which the Arabian, Barb, or Turk blood was grafted, and which laid the foundation of the modern thoroughbred. Other nations may have furnished the blood, but England has made the race-horse.

Without prosecuting this subject further, it may be enough here to follow out the lines of the Darley Arabian, the Byerly Turk, and the Godolphin Arabian or Barb, the main ancestors of the British thoroughbred of the 18th and 19th centuries, through several famous race-horses, each and all brilliant winners,—Flying Childers, Eclipse, Herod, and Matchem,—to whom it is considered sufficient to look as the great progenitors of the race-horse of to-day.

1. The Darley Arabian's line is represented in a twofold degree—first, through his son Flying Childers, his grandsons Blaze and Snip, and his great-grandson Snap, and, secondly, through his other son Bartlett's Childers and his great-great-grandson Eclipse. Flying or Devonshire Childers, so called to distinguish him from other horses of the same name, was a bay horse of entirely Eastern blood, with a blaze in his face and four white feet, foaled in 1715. He was bred by Mr Leonard Childers of Carr House near Doncaster, and was purchased when young by the duke of Devonshire. He was got by the Darley Arabian from Betty Leedes, by Careless from sister to Leedes, by Leedes's Arabian from a mare by Spanker out of a Barb mare, who was Spanker's own mother. Spanker himself was by D'Arcy's Yellow Turk from a daughter of the Morocco Barb and Old Bald Peg, by an Arab horse from a Barb mare. Careless was by Spanker from a Barb mare, so that Childers's dam was closely in-bred to Spanker. Flying Childers—the wonder of his time—was never beaten, and died in the duke of Devonshire's stud in 1741, aged twenty-six years. He was the sire of, among other horses, Blaze (1733) and Snip (1736). Snip too had a celebrated son called Snap (1750), and it is chiefly in the female line through the mares by these horses, of which there are fully thirty in the *Stud-Book*, that the blood of Flying Childers is handed down to us.

The other representative line of the Darley Arabian is through Bartlett's Childers, also bred by Mr Leonard Childers, and sold to Mr Bartlett of Masham, in Yorkshire. He was for several years called Young Childers,—it being generally supposed that he was a younger brother of his Flying namesake, but his date of birth is not on record,—and subsequently Bartlett's Childers. This horse, who was never trained, was the sire of Squirt (1732), whose son Marske (1750) begat Eclipse and Young Marske (1762), sire of Shuttle (1793). This at least is the generally accepted theory, although Eclipse's dam is said to have been covered by Shakespeare as well as by Marske. Shakespeare was the son of Hobgoblin by Aleppo, and consequently the male line of the Darley Arabian would come through these horses instead of through Bartlett's Childers, Squirt, and Marske; the *Stud-Book*, however, says that Marske was the sire of Eclipse. This last-named celebrated horse—perhaps the most celebrated in the annals of the turf—was foaled on the 1st of April 1764, the day on which a remarkable eclipse of the sun occurred, and he was named after it. He was bred by the duke of Cumberland, after whose decease he was purchased by a Mr Wildman, and subsequently sold to Mr D. O'Kelly, with whom he will ever be identified. His dam Spiletta was by Regulus, son of the Godolphin Barb, from Mother Western, by a son of Snake from a mare by Old Montague out of a mare by Hautboy, from a daughter of Brimmer and a mare whose pedigree was unknown. In Eclipse's pedigree there are upwards of a dozen mares whose pedigrees are not known, but who are supposed to be of native blood. Eclipse was a chestnut horse with a white blaze down his face; his off hind leg was white from the hock downwards, and he had black spots upon his rump—this peculiarity coming down to the present day in direct male descent. His racing career commenced at five years of age, viz., on the 3d May 1769, at Epsom, and terminated on the 4th October 1770, at Newmarket. He ran or walked over for eighteen races, and was never beaten. It was in his first race that Mr O'Kelly took the odds to a large amount before the start for the second heat, that he would place the horses. When called upon to declare, he uttered the exclamation, which the event justified, "Eclipse first, and the rest nowhere."

Eclipse commenced his stud career in 1771, and had an enormous number of foals, of which four only in the direct male line have come down to us, viz., Potoooooooo, or, as he is commonly called, Pot-8-os (1773), his most celebrated son, King Fergus (1775), Joe Andrews (1778), and Mercury (1778), though several others are represented in the female line. Pot-8-os was the sire of Waxy, (1790) out of Maria (1777) by Herod out of Lisette (1772) by Snap. Waxy, who has been not inaptly termed the ace of trumps in the *Stud-Book*, begat Whalebone (1807), Web (1808), Woful (1809), Wire (1811), Whisker (1812), and Waxy Pope (1806), all but the last being out of Penelope (1798) by Trumpator (1782) from Prunella (1788) by Highflyer out of Promise by Snap, while Waxy Pope was out of Prunella, dam of Parasol (1800) by Pot-8-os. Trumpator was a son of Conductor, who was by Matchem out of a mare by Snap.

Whalebone's best sons were Camel (1822) and Sir Hercules (1826). Camel was the sire of Defence (1824) and Touchstone (1831), while Sir Hercules was the sire of Birdcatcher (1833) and Faugh-a-Ballagh (1841), own brothers, and of Gemma di Vergy (1854). Touchstone was the sire of Newminster (1848), who begat Lord Clifden, Adventurer, and the Hermit, as well as of Orlando (1841) sire of Teddington (1848). Whalebone's blood also descends through Waverley (1817) and his son the Saddler (1828), while Whisker is represented by the Colonel (1825) and by Economist (1825) and his son Harkaway (1834), sire of King Tom (1851). Birdcatcher begat, besides Saunterer (1854), the Baron (1842), sire of Stockwell (1849) and of Rataplan (1850). Stockwell, who was a chestnut with black spots, was the sire of Blair Athol (1861), a chestnut, and also of Doncaster (1870), another chestnut, but with the characteristic black spots of his grandsire; and Doncaster was the sire of the chestnut Bend Or (1877).

To turn to Eclipse's other sons. King Fergus (1775) was the sire of Beningbrough (1791), whose son was Orville (1799), whence comes some of the stoutest blood on the turf, including Emilius (1820) and his son Priam (1827), Plenipotentiary (1831), Muley (1810), Chesterfield (1834), and the Hero (1843). Joe Andrews (1778) was the sire of Dick Andrews (1797), and from him descend Tramp (1810), Lottery (1820), Liverpool (1828), Sheet Anchor (1832), Lanercost (1835), Weatherbit (1842), Beadsman (1855), and Blue Gown (1865). Mercury was sire of Gohanna (1790), who was foaled in the same year as Waxy, and the two, who were both grandsons of Eclipse and both out of Herod mares, had several contests, Waxy generally getting the better of his cousin. Gohanna's descendants come down through Golumpus (1802), Catton (1809), Mulatto (1823), Royal Oak (1823), and Slane (1833).

2. The Byerly Turk's line is represented by Herod, the Turk being the sire of Jigg, who was the sire of Partner (1718), whose son Tartar (1743) begat King Herod, or Herod as he was commonly called, foaled in 1758. Herod's dam was Cypron (1750) by Blaze (1733), son of Flying Childers. Cypron's dam was Selima by Bethel's Arabian from a mare by Graham's Champion from a daughter of the Darley Arabian and a mare who claims Merlin for her sire, but whose mother's pedigree is unknown. In Herod's pedigree there are fully a dozen dams whose pedigree is unknown. Herod was a bay horse about 15 hands 3 inches high, possessed both of substance and length,—those grand requisites in a race-horse,—combined with uncommon power and stamina or lasting qualities. He was bred by William, duke of Cumberland, uncle of King George III. He commenced his racing career in October 1763, when he was five years old, and ended it on the 16th of May 1767. He ran ten times, winning six and losing four races. He died in 1780, and among other progeny left two famous sons, Woodpecker (1773), whose dam was Miss Ramsden (1760) by Cade, son of the Godolphin Barb, but descended also on the dam's side from the Darley Arabian and the Byerly Turk, and Highflyer (1774), whose dam was Rachel (1763) by Blank, son of the Godolphin Barb from a daughter of Regulus, also son of the Godolphin. These two horses have transmitted Herod's qualities down to the present day in the direct male line, although in the female line he is represented through some of his other sons and his daughters as well. Woodpecker was the sire of Buzzard (1787), who in his turn became the father of three celebrated sons, Castrel (1801), Selim (1802), and Rubens (1803), all three chestnuts, and all out of an Alexander mare (1790), who thereby became famous. This mare was by Eclipse's son Alexander (1782) out of a mare by Highflyer (son of Herod) out of a daughter of Alfred, by Matchem out of a daughter of Snap. Bustard (1813), whose dam was a daughter of Shuttle, and his son Heron (1833), Sultan (1816) and his sons Glencoe (1831) and Bay Middleton (1833) and Middleton's sons Cowl (1842) and the Flying Dutchman (1846), Pantaloon (1824) and his son Windhound (1847), Langar (1817) and his son Epirus (1834) and grandson Pyrrhus the First (1843), are representatives of Castrel and Selim.

Highflyer is represented through his greatly esteemed son Sir Peter Teazle, commonly called Sir Peter (1784), whose dam was Papillon by Snap. Sir Peter had five sons at the stud, Walton (1790), Stamford (1794), and Sir Paul (1802) being the chief.

Paulowitz (1813), Cain (1822), Ion (1835), Wild Dayrell (1852), and his son Buccaneer (1857) bring down Sir Paul's blood; whilst Walton is represented through Phantom (1806), Partisan (1811) and his sons Glaucus (1829) and Venison (1833) and Gladiator (1833), Venison's sons Alarm (1842) and Kingston (1849), Gladiator's son Sweetmeat (1842), Sweetmeat's sons Macaroni (1860) and Parmesan (1857), and Parmesan's sons Favonius (1868) and Cremorne (1869). It may be added that in the first volume of the *Stud-Book* there are nearly a hundred Herod and Highflyer mares registered.

3. The Godolphin Barb is represented by Matchem, as the former was the sire of Cade (1734), and Cade begat Matchem, who was foaled in 1748. He was thus ten years the senior of Herod, representing the Byerly Turk, and sixteen years before Eclipse, though long subsequent to Flying Childers, who represent the Darley Arabian. Matchem was a brown bay horse with some white on his off hind heel, about 15 hands high, bred by Sir John Holme of Carlisle, and sold to Mr W. Fenwick of Bywell, Northumberland. His dam was sister to Miss Partner (1735) by Partner out of Brown Farewell by Makeless (son of the Oglethorpe Arabian) from a daughter of Brimmer out of Trumpet's dam, by Place's White Turk from a daughter of the Barb Dodsworth and a Layton Barb mare; while Brimmer was by D'Arcy's Yellow Turk from a royal mare. Matchem commenced his racing career on the 2d of August 1753, and terminated it on 1st September 1758. Out of thirteen engagements he won eleven and lost two. He died in 1781, aged thirty-three years. His best son was Conductor (1767) out of a mare by Snap; Conductor was the sire of Trumpator (1782), whose two sons, Sorcerer (1790) and Paynator (1791), transmit the blood of the Godolphin down to modern times. Sorcerer was the sire of Soothsayer (1808), Comus (1809), and Smolensko (1810). Comus was the sire of Humphrey Clinker (1822), whose son was Melbourne (1834), sire of West Australian (1850) and of many valuable mares, including Canezou (1845) and Blink Bonny (1854), dam of Blair Athol. Paynator was the sire of Dr Syntax (1811), who had a celebrated daughter called Beeswing (1833), dam of Newminster by Touchstone.

The gems of the three lines may be briefly enumerated thus:—(1) of the Darley Arab's line—Snap, Shuttle, Waxy, and Orville—the stoutest blood on the turf; (2) of the Byerly Turk's line—Buzzard and Sir Peter—speedy blood, the latter the stouter of the two; (3) of the Godolphin Barb's line—Sorcerer—often producing large-sized animals, but showing a tendency to die out, and becoming rare.

On the principle that as a rule like begets like, it has been the practice to select as sires the best public performers on the turf, and of two horses of like blood it is sound sense to choose the better as against the inferior public performer. But there can be little doubt that the mating of mares with horses has been often pursued on a haphazard plan, or on no system at all; to this the *Stud-Book* testifies too plainly. Recently more attention seems to be paid to the successful blending of certain strains of blood, though it cannot be said that more than two or three really first class horses are produced each year. The following is a list of the principal sires whose progeny find a place among the winners of the three great races, the Derby (D), Oaks (O), and St Leger (L):—

Eclipse: Young Eclipse (D), Saltram (D), Sergeant (D), Annette (O).
Herod: Bridget (O), Faith (O), Maid of the Oaks (O), Phenomenon (L).
Matchem: Teetotum (O), Hollandaise (L).
Florizel (son of Herod): Diomed (D), Eager (D), Tartar (L), Ninety-three (L).
Highflyer: Noble (D), Sir Peter Teazle (D), Skyscraper (D), Violante (O), Omphale (L), Cowslip (L), Spadille (L), Young Flora (L).
Pot-8-os: Waxy (D), Champion (D, L), Tyrant (D), Nightshade (O).
Sir Peter (D): Sir Harry (D), Archduke (D), Ditto (D), Paris (D), Hermione (O), Parasite (O), Ambrosio (L), Fyldener (L), Paulina (L), Petronius (L).
Waxy (D): Pope (D), Whalebone (D), Blucher (D), Whisker (D), Music (O), Minuet (O), Corinne (O).
Whalebone (D): Moses (D), Lapdog (D), Spaniel (D), Caroline (O).
Woful: Augusta (O), Zinc (O), Theodore (L).
Whisker (D): Memnon (L), The Colonel (L).
Phantom: Cedric (D), Middleton (D), Cobweb (O).
Orville (L): Octavius (D), Emilius (D), Ebor (L).
Tramp: St Giles (D), Dangerous (D), Barefoot (L).
Emilius (D): Priam (D), Plenipotentiary (D), Oxygen (O), Mango (L).
Priam (D): Miss Seltz (O), Industry (O), Crucifix (O).
Sir Hercules: Coronation (D), Faugh-a-Ballagh (L), Birdcatcher (L).
Touchstone (L): Cotherstone (D), Orlando (D), Surplice (D, L), Mendicant (O), Blue Bonnet (L), Newminster (L).
Birdcatcher (L): Daniel O'Rourke (D), Songstress (O), Knight of St George (L), Warlock (L), The Baron (L).
The Baron (L): Stockwell (L).
Melbourne: West Australian (D, L), Blink Bonny (D, O), Sir Tatton Sykes (L).
Newminster (L): Musjid (D), Hermit (D), Lord Clifden (L).
Sweetmeat: Macaroni (D), Mincemeat (O), Mincepie (O).
Stockwell (L): Blair Athol (D, L), Lord Lyon (D, L), Doncaster (D), Regalia (O), St Albans (L), Caller Ou (L), The Marquis (L), Achievement (L).
King Tom: Kingcraft (D), Tormentor (O), Hippia (O), Hannah (O, L).
Rataplan (son of the Baron): Kettledrum (D).
Monarque: Gladiateur (D, L).
Parmesan (son of Sweetmeat): Favonius (D), Cremorne (D).
Buccaneer: Kisber (D), Formosa (O, L), Brigantine (O).
Lord Clifden (L): Jannette (O, L), Hawthornden (L), Wenlock (L), Petrarch (L).
Adventurer: Pretender (D), Apology (O, L), Wheel of Fortune (O).
Blair Athol (D, L): Silvio (D, L), Craig Millar (L).

The successes of the St Leger winners, the Baron and his son Stockwell and his grandson Blair Athol, as well as of Touchstone and his son Newminster and his grandsons Lord Clifden and Adventurer, as stud horses, are more marked than perhaps those of any others in the annals of the turf, except Waxy and his descendants, of whom Whalebone is perhaps the best. Indeed the most successful cross of modern times is the double cross of Whalebone, the "ready money" cross as it is called, which is arrived at by intermixing the descendants of Whalebone through Sir Hercules, Birdcatcher, the Baron, Stockwell, Rataplan, Camel, Touchstone, Newminster, and Adventurer. Isonomy, by Sterling, son of Oxford by Birdcatcher, is a case in point; he is one of the best and best bred horses of the century. He has no less than five strains of Whalebone and seven of Waxy in his pedigree, as well as one of Shuttle, the scarcest blood of all.

In regard to mares it has very frequently turned out that animals which were brilliant public performers have been far less successful as dams than others which were comparatively valueless as runners. Beeswing, a brilliant public performer, gave birth to a good horse in Newminster; the same may be said of Alice Hawthorn, dam of Thormanby, of Canezou, dam of Fazzoletto, of Crucifix, dam of Surplice, and of Blink Bonny, dam of Blair Athol; but many of the greatest winners have dropped nothing worth training. On the other hand, there are mares of little or no value as racers who have become the mothers of some of the most celebrated horses on the turf; among them we may cite Queen Mary, Pocahontas, and Paradigm. Queen Mary, who was by Gladiator out of a daughter of Plenipotentiary and Myrrha by Whalebone, when mated with Melbourne produced Blink Bonny (winner of the Derby and Oaks); when mated with Mango and Lanercost she produced Haricot, dam of Caller Ou (winner of the St Leger). Pocahontas, perhaps the most remarkable mare in the *Stud-Book*, never won a race on the turf, but threw Stockwell and Rataplan to the Baron, son of Birdcatcher, King Tom to Harkaway, Knight of St Patrick to Knight of St George, and Knight of Kars to Nutwith—all these horses being 16 hands high and upwards, while Pocahontas was a long, low mare of about 15 hands or a trifle more. She also gave birth to Ayacanora by Birdcatcher, and to Araucaria by Ambrose, both very valuable brood mares, Araucaria being the dam of Chamant by Mortemer, and of Rayon d'Or by Flageolet, son of Plutus by Touchstone. Paradigm again produced, among several winners of more or less celebrity, Lord Lyon (winner of the Two Thousand Guineas, Derby, and St Leger) and Achievement (winner of the St Leger), both being by Stockwell. Another mare that has become famous was Manganese (1853) by Birdcatcher from Moonbeam by Tomboy from Lunatic by the Prime Minister from Maniac by Shuttle. Manganese when mated with Rataplan threw Mandragora, dam of Apology, winner of the Oaks and St Leger, whose sire was Adventurer, son of Newminster. She also threw Mineral, who, when mated with Lord Clifden, produced Wenlock, winner of the St Leger, and after being sold to go to Hungary, was there mated with Buccaneer, the produce being Kisber, winner of the Derby. It is usual to select sound, roomy mares, giving preference to those that are comparatively speaking low and long, and whose temper and disposition are good, of course paying strict attention to their blood, more especially if breeding from such large horses as the sons of Pocahontas.

We append the pedigree of Blair Athol, winner of the Derby and St Leger in 1864, who, when subsequently sold by auction, fetched the unprecedented sum of 12,000 guineas, as it contains, not only Stockwell (the emperor of stallions, as he has been termed), but Blink Bonny and Eleanor—in which latter animal are combined the blood of Eclipse, Herod, Matchem, and Snap,—the only two mares that have ever won the Derby, in 1801 and 1857 respectively, as well as those queens of the stud, Eleanor's great-granddaughter Pocahontas and Blink Bonny's dam Queen Mary. Both Eleanor and Blink Bonny won the Oaks as well as the Derby, and it may be observed that they are the only winners of the former race that appear in the pedigree.

* Winner of the Derby. † Winner of the Oaks. ‡ Winner of the St Leger.

oints of e race- rse.

The shape of a race horse is of considerable importance, although it is said with some degree of truth that they win in all shapes. There are the neat and elegant animals, like the descendants of Saunterer and Sweetmeat; the large-framed, plain-looking, and heavy-headed Melbournes, often with lop ears; the descendants of Birdcatcher, full of quality, and of more than average stature, though sometimes disfigured with curby hocks; and the medium-sized but withal speedy descendants of Touchstone, though in some cases characterized by somewhat loaded shoulders. In height it will be found that the most successful racers average from 15 to 16½ hands, the former being considered somewhat small, while the latter is unquestionably very large; the mean may be taken as between 15½ and 16 hands (the hand = 4 inches). The head should be light and lean, and well set on; the ears small and pricked, but not too short; the eyes full; the forehead broad and flat; the nostrils large and dilating; the muzzle fine; the neck moderate in length, wide, muscular, and yet light; the throat clean; the windpipe spacious and loosely attached to the neck; the crest thin, not coarse and arched. The withers may be moderately high and thin; the chest well developed, but not too wide or deep; the shoulder should lie well on the chest, and be oblique and well covered with muscle, so as to reduce concussion in galloping; the upper and lower arms should be long and muscular; the knees broad and strong; legs short, flat, and broad; fetlock joints large; pasterns strong and of moderate length; the feet should be moderately large, with the heels open and frogs sound

—with no signs of contraction. The body or barrel should be moderately deep, long, and straight, the length being really in the shoulders and in the quarters; the back should be strong and muscular, with the shoulders and loins running well in at each end; the loins themselves should have great breadth and substance, this being a vital necessity for weight-carrying and propelling power uphill. The hips should be long and wide, with the stifle and thigh strong, long, and proportionately developed, and the hind quarters well let down. The hock should have plenty of bone, and be strongly affixed to the leg, and show no signs of curb; the bones below the hock should be flat, and free from adhesions; the ligaments and tendons well developed, and standing out from the bone; the joints well formed and wide, yet without undue enlargement; the pasterns and feet similar to those of the forehand. The tail should be high set on, the croup being continued in a straight line to the tail, and not falling away and drooping to a low set tail. Fine action is the best criterion of everything fitting properly, and all a horse's points ought to harmonize or be in proportion to one another, no one point being more prominent than another, such as good shoulders, fine loins, or excellent quarters. If the observer is struck with the remarkable prominence of any one feature, it is probable that the remaining parts are deficient. A well-made horse wants dissecting in detail, and then if a good judge can discover no fault with any part, but finds each of good proportions, and the whole to harmonize without defect, deformity, or deficiency, he has before him a well-shaped horse; and of two equally well-made and equitably proportioned horses the best bred one will be the best. As regards hue, the favourite colour of the ancients, according to Xenophon, was bay, and for a long time it was the fashionable colour in England; but for some time chestnut thoroughbreds have been the most conspicuous figure on English race-courses, so far as the more important events are concerned. Eclipse was a chestnut; Castrel, Selim, and Rubens were chestnuts; so also were Glencoe and Pantaloon, of whom the latter had black spots on his hind quarters like Eclipse, and more recently Stockwell and Doncaster. Birdcatcher was a chestnut, so also were Stockwell and his brother Rataplan, Manganese, Mandragora, Thormanby, Kettledrum, St Albans, Blair Athol, Regalia, Formosa, Hermit, Marie Stuart, Doncaster, George Frederick, Apology, Craig Millar, Prince Charlie, Rayon d'Or, and Bend Or. The dark browns or black browns, such as the Sweetmeat tribe, are not so common as the bays, and black or grey horses are almost as unusual as roans. The skin and hair of the thoroughbred are finer, and the veins which underlie the skin are larger and more prominent than in other horses. The mane and tail should be silky and devoid of curl, which is a sign of impurity.

Whether the race-horse of to-day is as good as the stock to which he traces back has often been disputed, chiefly no doubt because he is brought to more early maturity, commencing to win races at two years instead of at five years of age, as in the days of Childers and Eclipse; but the highest authorities, and none more emphatically than the late Admiral Rous, aver that he can not only stay quite as long as his ancestors, but also go a good deal faster. In size and shape the modern race-horse is unquestionably superior, being on an average fully a hand higher than the Eastern horses from which he is descended; and in elegance of shape and beauty of outline he has certainly never been surpassed. That experiments, founded on the study of his nature and properties, which have from time to time been made to improve the breed, and bring the different varieties to the perfection in which we now find them, have succeeded, is best confirmed by the high estimation in which the horses of Great Britain are held in all parts of the civilized world; and it is not too much to assert that, although the cold, humid, and variable nature of their climate is by no means favourable to the production of these animals in their very best form, Englishmen have by great care, and by sedulous attention to breeding, high feeding, and good grooming, with consequent development of muscle, brought them to the highest state of perfection of which their nature is capable. See the section on Horse-Racing, p. 199.

The hunter.

The Hunter.—A good specimen of an English hunter may be described as a horse for universal use. He may be a coach-horse, for in many of the animals running in the coaches called into existence during the summer months by the coaching revival may be recognized a hunter of known character; he may be a good roadster, for, so far as conformation is concerned, there is nothing in a hunter to unfit him from being a first-class hack; nor is hunting incompatible with military duties, for, by the regulations of the service, officers are permitted to hunt their second chargers. For harness work he is perfectly adapted, provided only the vehicle to be drawn is in proportion to his size; while most people will recall instances of hunters having for some reason or other to be so far humbled as to have to take a turn at the plough or harrow, or, in their older days, even in a chaff-cutter.

Thorough-bred hunters.

A hunter may be either thoroughbred or halfbred. In the grass countries, such as Leicestershire or Northamptonshire, riders to hounds endeavour to get their hunters as nearly clean bred as possible; but, in spite of this ambition, it may be doubted whether one in twenty, even in the most fashionable countries, is thoroughbred, thereby proving that a thoroughbred hunter, although undoubtedly a luxury, is not a virtual necessity. When it can be acquired, a thoroughbred hunter that knows his business is a most desirable possession, save perhaps in a rough country, where his fine skin shrinks from contact with the objects therein encountered. The comparative scarceness of these animals is, however, easily accounted for. From 12 to 14 stone is by no means an uncommon weight for a man to ride hunting, saddle included, but few thoroughbreds are up to it; one that is commands a large price, from £250 upwards, according to "manners." It is often said that thoroughbreds do not make pleasant hunters, but the complaint, if there is any ground for it at all, is really against the result of the treatment to which nineteen out of twenty thoroughbreds have to submit, and not against pure blood itself. A large proportion of thoroughbred stock come to the starting-post at two years old; and this means that they have been in the trainer's hands since they were yearlings at least. Now a training stable is just the place for colts to pick up sundry undesirable tricks, which may at some future time cause the unprofessional rider a little trouble; they get to lean on the hand, often turn out fidgety and fractious, and are not unfrequently inveterate pullers. When fit to go, the young one will have been tried, and if he fails to gallop half a mile at best pace he is probably turned out of training, although perhaps it was not till the last dozen yards were reached that there was any sign of failing power. Now, although the colt may be unable to stand the test applied to him by the trainer, there is no reason at all why he should not be able to go all day at hunting pace, because the powers of speed are not taxed to the same degree. The young thoroughbred is then perhaps educated for hunting; and hence it is that nearly all hunters—thoroughbred ones, that is to say—begin life in a training stable. Instances are comparatively rare of persons breeding thoroughbred stock and then keeping them for hunting purposes. The ranks of hurdle-racers and steeple-chasers too are filled by thoroughbred horses, which but for these interventions come under the care of the hunting groom.

alf- ed nters. The halfbred hunter, as he is technically called, may be, and is, a very good substitute for the thoroughbred; he may have nineteen-twentieths of pure blood in his veins, and still be only "halfbred." Perhaps seven-eighths of pure blood is about the average for high-class horses; but, taking English hunters all round, the majority are halfbred in a more literal sense, being for the most part by a horse nearly, if not quite, thoroughbred, out of a common mare. It is much to be regretted that the breeding of halfbred hunters is too often neglected altogether, or at least conducted on haphazard principles. Many men take it into their heads to breed a colt simply because they have a mare which, owing to age or accident, is no longer fitted for active work; and then, be the mare good, bad, or indifferent, there is little or no judgment exercised in the choice of a sire. Nearly all country places are periodically visited by travelling stallions, many of which are utterly worthless, but nevertheless the services of one of them are probably secured by the intending breeder simply because of the saving of trouble. He forgets that there is but little difference between the charge for a good and that for a bad horse, and finds, when the offspring is ready for sale, that the result of his happy-go-lucky system remains on his hands for lack of a buyer, and costs as much to keep as a valuable animal. Very often, too, a man who has expected to breed a hunter will find himself the owner of a fairly promising colt for a brougham, but having hoped for a hunter he is unwilling to believe it anything else.

eed- g. Compare this method of setting to work with that adopted by breeders of thoroughbred stock, and indeed by all judicious breeders. To begin with, the choice of a dam is a matter of moment; and it is difficult to see why anything should be thought good enough for a hunter, even by the inexperienced. The first requisite for a brood-mare is that she should be free from all constitutional infirmities, such as roaring, bad sight, &c.; and the breeder should be on his guard when breeding from mares whose legs have given way. True, it may be the result of an accident, but care should be taken to ascertain that it arose from that cause, and that a predisposition to inflammation had nothing to do with it. For the same reason persons should be chary of breeding from mares that have splints, spavins, &c., and should certainly reject one whose dam or sire had them as well. Mares that have done much hard work are not the best dams that can be selected, as they are apt to slip their foals, or to throw undersized ones. The selection of a stallion is the more important the more defects there are in the mare. Should she be the least delicate, the stallion should be remarkable for a hardy constitution, for considering that a hunter has to be out of his stable for as much as twelve hours sometimes, and rarely less than seven or eight, and has to carry a heavy weight and gallop and jump, it is plain that a horse with no stamina would be nearly worthless as a hunter, no matter what other good qualities he might possess. So, too, as to shape: should the mare be too long on the leg or in the back, or too low in front, the stallion should be singularly free from the defect in question.

While the mare is in foal she should be kept on the best food, for the nourishment given to her is given indirectly to the foal. The keep of the foal in its early days is not less important than the choice of dam and sire. Thoroughbred colts eat corn from the time they are a month or five weeks old; and the same generous diet should be allowed to halfbred horses, as it is only by this, accompanied of course by proper exercise, that the frames of young horses expand to their full extent, or that a foundation is laid for a good constitution. This system is, of course, more expensive than keeping a colt on hay and grass during the first three years of his life, but it will repay itself in the long run, for very often under its influence a colt will develop into a weight-carrying hunter or valuable carriage horse, where, under more parsimonious treatment, he would never have grown into anything strong enough to carry over 11 or 12 stone.

The breaking and training of hunters is all-important, because, in spite of the care that may have been expended upon the choice of sire and dam and the keep of the colt, many young ones are ruined beyond all hope of recovery during this process. The colt should be handled from the day of its birth, so that it may grow thoroughly accustomed to man, without ever having experienced the feeling of fear. The person selected to attend on mares and foals, as well as he that undertakes the training part, should be naturally fond of animals; he should be cool, and of an almost imperturbable temper, or he will be unfitted to deal with the waywardness of some of his pupils, which during their early career may at times expose him to personal danger, especially if they be well bred; he should therefore be well endowed with courage and firmness, for an irresolute man is sure to spoil every horse he has to do with. Breaking and training.

When about six months old the colt should receive his first lesson in jumping. Where practicable, there is no better plan than to feed him in one spot, the approach to which is guarded by a stout rail, which should in the first instance lie on the ground, and over which he must step in order to reach his corn. In the course of about a month the rail may be raised 6 inches, and so on from time to time, but the process should be gradual in the extreme; 2 or 3 inches a month is sufficient until it is a couple of feet high, where it should remain for a time, but at three years the colt should jump it at 3 feet. Before he reaches this age the saddle should have been put on and left there for half an hour at a time, the groom letting the girths and stirrups flap about. At three years the pupil should be backed by a light weight; if the rider be the usual attendant, so much the better, for then it is improbable that much resistance will be shown. The riding exercise should be varied by the young horse being led by a rather long rein over roughish ground, such as a common or a ploughed field, when it is not too hard, and over little ditches and very low fences, but they must be small, as it is very undesirable to have a horse refuse at first, or to have him fall down in attempting a jump. He should be subsequently ridden over small places, but should always have a lead given to him by an old horse; and the two should stand in adjoining boxes, so that the colt may be accustomed to his pilot. At four years old he may be ridden to the meet, and suffered to see a fox found, but should on no account be ridden up to the hounds, nor should he be used as a regular hunter till he is six,—if not till seven it will be all the better for him.

In the hunting field there are three kinds of jumps at which many refusals and falls take place. The first is timber, the second water or wide open ditches, and the third a hedge with a ditch on the taking off side. As to timber jumping, the course we have just recommended is the best possible preparation; in jumping the rail, the colt begins early to exercise, and therefore to strengthen, the very muscles he will want by and by in jumping a gate,—if his owner ever rides him at one. A further course of instruction in this most useful art may be given in a "circus," that is, a double row of posts and rails in a circle about the size of a circus ring. Between the two sets a couple of strong timber jumps should be put up, one of about 3 feet and the other of about 3 feet 6 inches in height; the horse is then put into the space between the two rails, one person standing in the centre holding a lunge rein, while an assistant is present with a whip, which should, however, be used but sparingly. Really good water jumpers are so scarce that it would well repay the owner of a promising young one to teach him, or have him taught, this most important part of a hunter's business. If a small water-course can be found handy, it will do for a commencement; the colt should, in his early days, be led over this; and, if possible, the place should be widened gradually, and the water dammed up, the colt being always lunged over it before being ridden, and when ridden led over by an old horse. The same course should be pursued in the case of dry ditches, and hedges with a ditch on the taking off side, both of which must be jumped boldly, if the rider wish to keep his place with hounds. This gradual teaching, and the trouble it undoubtedly entails, may sound too theoretical to some who are desirous of turning out a finished hunter in the space of six weeks; but it is to this hurrying, and the substitution of coercive measures for time and gentleness, that we are to attribute the number of indifferent hunters we find. Every hunting man knows the enormous prices realized by really clever hunters; and these animals are simply ordinary horses on whose education much trouble has been expended.

Qualifications for a hunter.

Qualifications for a Hunter.—Of horses equally good jumpers, and equally fast, that will be most valuable which can gallop and jump with the greatest weight on his back. Very good horses for 10 or 11 stone can be obtained at any time, and at a moderate price, but a horse up to weight will always fetch a large sum. Whatever weight has to be carried, mere size must not be confounded with power; a horse 16½ hands high is not necessarily a weight carrier. A compact well-knit frame is of primary importance; and although it is a task of great difficulty to explain the points of a horse on paper, the intending buyer may with advantage have his attention drawn to some of the more important requisites. To cross a country well, the hunter must have long and oblique shoulders; and, in the case of a weight carrier, they should be rather thick. Should the reader have any difficulty in deciding what oblique shoulders are, he may get some assistance from putting a saddle on a horse, setting it of course in the right place, and then looking at the horse from a side view. Should the horse have good shoulders, the stirrup leather will hang down at some distance behind the forelegs; but if, on the other hand, the shoulders be upright, the stirrups will be comparatively close to the forelegs, and, on mounting, the rider will find himself sitting over the legs instead of behind them. Care should be taken, however, that the shoulder is well clothed with muscle. The chest should be broad; narrow horses are supposed to be faster, but under weight they knock their legs about. The arm must be long, and of course muscular, the knee wide, the "cannon bone" (*i.e.*, the bone between the knee and the fetlock) short, and the legs flat, with strong back sinews. The foot should be moderately wide, and have good strong heels, or they will not stand the battering about that falls to the lot of even the most carefully ridden hunter.

The chest must be deep (otherwise the horse will in all likelihood be a short-winded one), and as a consequence the girth will be great; a weight carrier should measure 6 feet 3 inches in condition round the barrel, just where the girth comes. A horse with a well-developed frame, and of large girth, is generally a short-legged horse, as it is called, not that the legs are really shorter—very short legs are a deformity—but the body is not too small in proportion to the height of the leg.

It is commonly said that the back of a weight carrier must be short; but this does not mean that the horse should be short from the chest to the tail, for he should have much of his length in his shoulders and quarters. For very heavy men, the back proper should not be long; but, as a matter of fact, few horses are found the length of whose back would be adjudged perfection. A moderate length of back is essential to pace, and on this question the late Major Whyte Melville writes as follows:—"It may not be out of place here to observe, as an illustration of the well-known maxim 'Horses can go in all shapes,' that of the three heaviest men I can call to mind who rode perfectly straight to hounds, the best hunter owned by each was too long in the back." The loins should be strong, and the hips wide; if ragged they will be none the worse.

The hind legs are most important, not only because the seat of the propelling power is there, but also because they affect the carriage of the animal, and the way in which he yields to his rider's hand. The thigh should be long and muscular, the hock well bent, and not bending inwards, when the horse is called "cow-hocked," nor outwards, like a bandy-legged man. The shank bone should be well guarded by strong sinews, and the pasterns moderately long, and by no means straight. Horses with straight, short pasterns are rough to ride, and ill adapted to stand hard work.

So far, then, as the body is concerned, strong legs, wide hips, depth of girth, and a short back, or, more properly, a back not too long, are all important; but it must be remembered that, beyond a certain point, the development of any extraordinary strength is accompanied by a loss of speed, therefore very heavy men must be content to be carried by an animal not unlike an active cart-horse, for a well-bred horse capable of galloping and jumping under 18 stone is rarely seen, and the few that do exist cannot be acquired except at an enormous outlay.

When a man gets on a horse to try him, the formation and the carriage of the head and neck have a great deal to do with the subsequent purchase or rejection of him. If appearance be a *sine qua non*, the head should be small, but, except for the look of the thing, the size is immaterial, provided it be well set on to a properly shaped neck, the characteristics of which will be presently explained. The jaws should be wide, as also should the head between the ears. The nostrils, through which alone a horse breathes, should be moderately large, otherwise free respiration will be interfered with. The eye should be bright and full, but not unduly prominent; small pig-like eyes are nearly certain indications of bad temper. The neck should rise out of the shoulders in an easy curve, and be neither very long nor very short; muscular it must be, and the principal muscle is the one running along the top of the neck; a muscular development here is usually accompanied by muscular proportions generally. The strength of the neck is important, because upon this the position of the head depends, and if the head be wrongly placed, the horse will never go pleasantly to the hand; indeed, of such moment is the position of the head that a horse is often unmanageable when his head is in an improper position, although he is easy of control when it is in the right place. A short-necked horse is sure to make the rider carry its head, because, from the lower part being thick, as it must be where it springs from the shoulder, the head cannot be set on at a proper angle. It has been said that a long neck is productive of the same inconvenience, but the better opinions are hostile to this theory, and experience does not tend to convince one that a long-necked horse is necessarily heavy in the hand.

A hunter should have a good mouth, and should not pull,—both which matters depend a good deal upon the rider,—and should not be given to shying. He should, however, be naturally bold, or he may refuse any fence of an uninviting appearance. Good temper is an absolute necessity. A strong and resolute rider may put up with a puller, in consideration of many good points, but a bad-tempered horse is of no use in the field, as he is sure to lose his rider his place in a run; moreover, a horse that will be wanted all day cannot afford to lose his temper and take what is equal to half an hour's work out of himself at every turn or check, or at every gate-post that may be encountered during the day.

Whatever number of good points a hunter may possess, they will all be utterly valueless unless he be sound into the bargain. There are two kinds of soundness, practical and legal. A horse is not legally sound, that is to say, he is legally unsound, if there is any structural alteration, however slight, in any part of his body, though it may not unfit him in any degree for the immediate performance of his duties. To be legally sound, a horse must be in the same perfect state as when foaled; and each reader must determine for himself how often this can be found in a field of say one hundred horses. To be practically sound, a horse must have nothing the matter with him that is likely to interfere with his duties as a hunter, and he can be in this condition without being legally sound. For instance, suppose a man, after buying a horse warranted sound, take off the shoes and find the smallest possible corn, which would never be felt, nor diminish the value by one penny, that horse is not legally sound, because the corn, small as it is, is held to be a structural alteration; so, too, a pimple on the body where the saddle would cover it is an unsoundness in a hunter while it lasts, if it prevents the saddle from being put on. A temporary cough is also an unsoundness; so is lameness caused by being pricked during shoeing; yet for some of these no man in the world would reject a good hunter. It need hardly be added that any enlarged joints, or other tokens of work, prevent a horse from being legally sound. On the other hand a horse, if not actually lame, is legally sound although its legs are so badly formed that the merest tyro could predict lameness as the inevitable result of half an hour's journey.

As to the wind and eyes, however, a hunter should be legally and absolutely sound. The usual method of testing the wind by punching the horse or pinching the windpipe is not quite satisfactory; the horse should be galloped. The amateur will do well to get the best veterinary surgeon within reach to examine the eyes of any horse he contemplates buying. Cataract, in its incipient stage, is so difficult to discover that it escapes the notice of any but the most practised person. With regard to the feet and legs, the buyer will have to rest satisfied with an assurance that his horse is practically sound; for of really sound horses there are not two in a hundred.

The Purchase of a Hunter.—The nature of the country in which the horse is to be used should be the intending purchaser's first consideration, because upon it will depend the stamp of animal required, and it is advisable, if possible, to get a horse that has been used to the prevalent style of fences. Where the fields are large and strongly enclosed with what are called flying fences, nothing is better than a horse which is nearly or quite thoroughbred; but if the enclosures are small, and separated from each other by banks, with or without hedges on the top, and with a ditch on one or both sides, a rather more compact horse will not only be more suitable, but cheaper into the bargain. A horse intended for Leicestershire, or any other grass country, *must* be nearly thoroughbred, and not under 15 3, or he would be blown before he had crossed half a dozen of the big fields there; while a little horse would take too much out of himself at each fence. But for Devonshire, Surrey, Essex, or Sussex, where the fields are small and the fencing for the most part what is called cramped, a horse with less blood and of smaller stature will answer every purpose, and, what is a great consideration, can be bought for about one-third of the price of a Leicestershire horse. So too a horse unaccustomed to water would be useless in Lord Fitzhardinge's country, nor would a bad timber jumper show to advantage with the Blackmoor Vale hounds. Whatever stamp of horse is used, however, the points we have insisted on must exist: good shoulders, back, loins, legs, hocks, and feet are needed in every hunting country in the United Kingdom.

The horse may be purchased either at auction, from a private person, or from a dealer. The first method is not to be recommended unless the buyer or his agent be a good judge of a horse, or unless one or the other happen to know something of the antecedents of any lot intended to be purchased. Few real bargains are picked up at the hammer. Horses of known character, especially if comprised in a stud, always fetch their full value; and to buy a horse of which nothing is known is simply to take part in a lottery. Buying from a private person is not always a satisfactory proceeding, even when the performances of the horse are known. People entertain different ideas as to what constitutes unsoundness: and in many cases the groom is the only person who knows that there is a screw loose somewhere, and what that screw is. Purchasing from a dealer requires some little knowledge. Some men trade only in the highest class of horses, and must perforce ask long prices to afford a fair margin of profit to cover the original outlay, coupled with the expense of schooling and keep. Others again make a specialty of "useful" animals at a moderate price. The buyer's success in either case will, to a great extent, depend upon how he goes to work. The best course is to select a dealer who has a name to lose, and to tell him at once the kind of horse that is wanted, and about the price the purchaser is willing to pay. The dealer will then offer whatever horses he can sell at the price, and the buyer can take or reject them as he pleases.

Formerly a warranty of soundness by the seller was a necessary factor in every horse sale; but now warranties are going out of fashion, many of the leading dealers refusing altogether to give one. Nor is this surprising when the effect of a warranty is looked at; no lapse of time puts an end to a warranty. The seller of a yearling may have an action brought against him in four years' time, and, if the jury can be got to believe that the unsoundness complained of existed at the time of sale, the buyer will win. In giving a warranty, the seller of a horse insures, as it were, the care and skill of the buyer, and may have to suffer for selling a sound horse which ignorance and carelessness reduced to the level of a screw in six months.

There is also a limited warranty; that is, the dealer may be willing to warrant the horse for one month, or fourteen days, or for any other fixed period. In this case, the dealer only warrants against such defects as may be discovered within the stipulated time. This kind of warranty should be looked at with some amount of suspicion. It is very often given with a horse that might not pass the veterinary surgeon, and that has some defect of which the dealer knows, which renders it problematical whether he will keep sound for any lengthened period. With a limited warranty the horse often escapes the veterinary surgeon's inspection; he lasts sound for a short time, and then goes lame, the time of the limited warranty having meanwhile expired.

The most satisfactory and at present perhaps the most usual course of business is for a horse to be sold subject to a veterinary examination and a trial. A skilful man should discover all symptoms of what may be called external unsoundness, while as to disease of the liver, or any internal complaint, if the veterinary surgeon cannot discover it there is no reason why the dealer should have been able to find it out. The trial the buyer will probably make himself, and, if with hounds, it will be well to ascertain what condition the horse is in. An animal just out of a dealer's show stable would have neither his muscles nor his wind in a state that would enable him to live with hounds ten minutes, even at a moderate pace. Early symptoms of distress therefore, under such circumstances, should not of themselves prompt the rejection of a horse, if he is satisfactory at starting, and if his physical structure is that of a hunter. The age of the horse is determined by the appearance of the teeth till he is seven years old, but the legs are as good a test as anything. Many a horse at five years old is often worth less as a hunter than one of ten or twelve years old, owing either to a natural want of stamina or to premature overwork. If the legs show much signs of work, and if the joints are round and big, the money paid should as a rule differ materially from a "sound price." Not that perfectly fresh legs can be expected in aged horses, particularly if good performers; but there is a point below which "honourable scars" should be looked upon as an objection, unless the buyer intend to have a "screw."

The Hack.—Under the term "hack" may be ranked cover hack, park hack, cob, pony, and, in short, saddle horses of all kinds save hunters and racers. The hack.

The park hack, as its name implies, is for use in fashion-frequented places, and must therefore be worth looking at. Fashion has prescribed that the genuine thing shall be about 14 3, with a small and well set-on head, good sloping shoulders, and well formed hind legs; he must also be very well bred. So much for his points. A wonderfully good temper is absolutely essential. Street vehicles give but little place to the equestrian, and a series of hurried retreats out of harm's way might ruffle a horse of uncertain temper and not hard worked into the bargain. Tricks of all sorts must be unknown; a whole week's idleness should not produce any uncalled-for gambols. The park hack's breeding and shape will probably have endowed him with a fair turn of speed; this is not a necessity, providing his walk and trot be perfection. He should be able to walk 5 miles in an hour, or he will be perpetually breaking into an uncomfortable jog when required to keep pace with a quick walking companion. In trotting he should have good but not extravagant action, and, if he is equally easy whether going $5\frac{1}{2}$ or 9 miles per hour, he is one of twenty. He should be bitted to a nicety, and should have been thoroughly well trained. Especial care should be exercised in the selection of the lady's horse; and the perfection which is so often theoretical in the case of a gentleman's hack should approach a reality when a horse is intended to carry a lady. With regard to the size, it had better not be under 15 1 at the least, and should have very good shoulders and by no means a short neck, or else the rider will experience that uncomfortable sensation of having nothing in front of the saddle. Park hack.

The cob is a nondescript animal, but withal a very valuable one when good. An underbred thickset animal, termed a "stocky" horse in some parts of England, is not the fashionable cob, which should have a good deal of breeding and the strength of a dray horse. Although a cob should not exceed 14·1, he should be master of 15 stone, being generally ridden by elderly heavy persons. To be worth a large sum he must unite to a symmetrical shape an even temper, perfect manners, and easiness in his paces. "If any one," says a writer in the *Field*, "possesses a cob up to 16 stone, who can walk 4 miles an hour and trot 12, with a good mouth and amiable disposition, who fears nothing, and never stumbles, let him, if a rich man, keep him, he will not get another such in a hurry; if a poor one, let him, in offering him for sale, fear not to 'open his mouth' boldly, and demand for him a price which shall make a difference in his (the owner's) year's income; for people must, and usually are ready to, pay for their fancies, and a good cob, as already remarked, is, of all the equine race, essentially a fancy article, and one too for which the demand is always brisk." Cob.

A Galloway, although strictly speaking a distinct breed, is commonly understood to be a horse not over 14 hands. Prior to the introduction of railways, or even before the fast coaches were put upon the road, Galloways were a Galloway.

favourite means of locomotion by persons of moderate weight and stature.

ny. A pony must be less than 52 inches (13 hands) from the ground to the top of the withers; else he is a Galloway. Ponies, as a rule, will do far more work than a full-sized horse; they improve wonderfully in a well organized stable; they are, it is said, never lame in the feet, and seldom become roarers; but, as a set off against these good points, they are often very tricky, and sometimes troublesome in the stable. In proof of the powers of endurance possessed by ponies, it is related that a well known one, 12 hands high, called Sir Teddy, raced the mail from London to Exeter, beating it by 59 minutes, and doing the 172 miles in 23 hours and 28 minutes. The extraordinary little animal was led between two other horses all the way, and carried no weight.

ver cks. The chief use of the cover hack is to take the rider to the meet, usually at the unnecessarily hasty pace of 10 to 12 miles an hour, at which rate the hack should be able to go with tolerable ease to himself and great ease to his rider. He should be from 14 to 15 hands in size, and should, in fact, be a somewhat undersized light-weight hunter. Although the cover hack will generally be asked to canter or gallop, he may be required to trot, and this must be done at 9 or 10 miles per hour. To accomplish this he must have good hind action, but in front he should waste no time by picking up his feet after the showy manner of his park brother; in fact, appearance is not of much importance so long as the necessary working qualifications exist. A good temper is desirable, and, although the cover hack need not have such a perfect mouth as the London horse, he should be by no means a puller.

eed- g of cks. The breeding of hacks, like breeding for any particular stamp of horse, is all chance work, especially in the case of halfbreds. A rather small thoroughbred horse and a hackney mare may produce a thing like a pony, or a bigger animal that is quite useless for saddle work. Even in breeding for hunters, two or perhaps three out of five colts will grow up more fitted for the shafts than for a bridle. Perhaps the generality of hacks are either thoroughbreds which have been turned out of training, or horses that have grown up too small for hunting purposes.

arger l op- rse. *The Charger and Troop-Horse.*—These are bracketed together because their training and duty are nearly identical (the charger of a field officer of an infantry regiment need only be a decent saddle horse that will stand fire), the chief difference between the two being that the latter being paid for by the country is ordinarily a cheaper article than the former, which the officer buys for himself.

A charger, fit for the mounted arm of the service, is a difficult article to meet with, at least a perfect one is, because so many good qualities must be found combined. A hunter is capital raw material out of which to make a charger; but appearance, which is not a *sine qua non* in a hunter, is indispensable in a charger, which must also have high action, though the paces must be easy in consequence of much riding having to be done without stirrups. The best size for a charger or a trooper is about 15·2 or 15·3; moderate-sized horses can be made more handy than larger ones, and experience seems to show that they are more hardy and better doers than horses of greater stature. When a horse has been found that for shape and size will do for a charger, he must be of the right colour for the regiment, if it be *de rigueur* to have any particular colour, and he must be passed as sound by the regimental veterinary surgeon.

The troop-horse must be as much like the charger as possible, but, as the trooper's price is limited to about £40, a difference, and that a very striking one, must always exist. The bulk of the troop-horses are bought when rising four years, having of course been passed by the veterinary surgeon; and, being nourished on the best food, these often develop into well-grown animals by the time they take their place in the ranks. Before that time comes, however, there is a good deal to be done in the way of training, for no matter how quiet the four year old may be to ride, or how well he may have been broken from a civilian's point of view, he is no more fitted for cavalry purposes, until he has passed through the rough rider's hands, than if he had never been handled at all.

The young horse's presence at barracks shows that both the colonel and the regimental veterinary surgeon are satisfied with him. Lunging constitutes the first part of his education, after which he is ridden. Now comes the formation of the paces, instruction in passaging, *i.e.*, walking sideways on a pressure by the rider's leg on the side opposite to that towards which the horse is required to move, and in reining back. All these things are done with the snaffle only; and, when something like familiarity with these exercises has been acquired, the bit is used. The troop-horse goes more on his haunches than a civilian's horse, and, while he is taught to walk at a fairly quick pace, the canter is practised as slowly as possible. Then comes jumping practice over the bar; and finally sword, carbine, or lance exercise is performed by his rider, and he is ridden first at drill practice, then at ordinary drills, and last of all on a field day.

As the cavalry soldier has to use his weapons with one hand, he has only one for the reins; and this renders it important first that the horse should be so broken that the rider can effect with his leg or heel what civilians do with the second hand, and next that the horse should be well under the control of a single hand. As before remarked, the position of the head makes a great difference in the ease with which the horse can be governed, and as troopers have all to do the same things in the saddle, it follows that they should as far as possible all ride the same sort of horses; accordingly all troop-horses are trained to carry their heads as nearly as possible in one position, that being chosen in which the angle formed by the head and neck gives most power to the rider.

Harness Horses.—Just as a hunter is metamorphosed Harness into a hack by using a sharper bit and riding him on the horses. road, so the mere fact of driving a horse in harness makes him a harness horse, whether he really be hack, hunter, or charger. Carriages are now made of endless patterns and of all sizes, so that there is not a saddle horse to be found that could not be accommodated with something adapted to his appearance and powers. Perhaps the only class of harness horses except cart horses that are not fitted for saddle work are the regular heavy carriage horses—great upstanding animals 16½ or 17 hands high. These are generally bay, and are bred in Yorkshire or abroad. They are purchased at three years old by the few dealers who trade in them, and are brought to town, where they are carefully driven about by an experienced breaksman until they are well used to the sights and sounds of London, and have action and strength enough to go to regular work. One well-known firm of dealers never sells these horses, but jobs them, the charge for a year varying from £80 to £120 for a pair, according to the value, the hirer of course keeping them, but having the right to call upon the dealers to send a fresh horse to replace one that may fall sick or become lame or fail to give satisfaction to the hirer. During the London season many of these pairs may be seen in the carriages of the titled and the wealthy. They are imposing-looking animals owing to their great size and to the massiveness of the harness, but when closely examined they exhibit many faults. Their heads are often large, shoulders straight, and hind legs defective in power. They are not a very profitable stamp of horse to have much to do with; they must have a certain amount of action, and this on the London stones soon knocks to pieces legs that are not particularly calculated to withstand wear and tear in the first instance; and it very often happens that during breaking a horse's legs show signs of failing, and he has to be thrown up for a while. Carriage horses are of course not always bay; but greys, chestnuts, and browns are not of any distinct breed.

A really well-matched pair, with good action, are worth a long price; and it is most unreasonable for persons, after selecting their horses no less with an eye to their natural good appearance than for other qualities, to persist in making them carry themselves in a highly unnatural position, by the grossly unnatural use of the bearing rein, which is buckled up cruelly short. If a carriage horse carried his head naturally in the position into which it is forced by the abuse of this contrivance, he would be rejected at once; tight reining up is the cause of many horses becoming roarers.

With regard to harness horses of a smaller size, their ranks may be recruited from the class that supplies hunters and hacks; but straight and loaded shoulders and straight hind legs, unpardonable defects in a saddle horse, are not quite so objectionable behind the collar. Phaeton horses should have moderately high action, and be compactly built, and should not exceed 15·1, unless the vehicle be very high on the wheel. Stage coaching, as a trade, no longer exists in England, but, during the summer months, many well-appointed coaches are put on different roads to places within a day's journey, not only from London, but elsewhere. For this work the leaders are generally about 15·2, and the wheelers an inch higher; they should all have good sound legs and feet, and free but not high action; the wheelers should have plenty of strength for the exertion required of them in going down hill.

art-orse. *The Cart-Horse.*—At the present time it is difficult to classify cart-horses, and to point to any distinct breeds. The true Cleveland horse is practically extinct, and the animal now called a Cleveland bay bears but a slight resemblance to his ancestors. The old Cleveland horses were noted for their strength; they are said to have *carried* a weight of 760 lb, or more than 54 stone, a distance of 60 miles in 24 hours. The old Suffolk Punch, originally descended from Norman stallions and Suffolk cart mares, is also extinct, the modern representative of that breed being the result of different crossings; he is found of two different kinds, light and heavy. The Clydesdale horse is well adapted for use in a hilly country. It derives its name from a district on the Clyde in Scotland, whither it was introduced by one of the dukes of Hamilton, who crossed the Lanark mares with imported Flemish stallions.

The native English cart-horse is a huge animal, usually of a black colour, and stands about 17 hands high and more. These horses are bred chiefly but not solely in Lincolnshire. At two years old they are generally sold by the breeder, who thus is enabled to secure a fair profit at an early period. They are at once put to gentle work by the first purchaser, and so earn something towards their keep. During this period they are well fed, and when they have attained their fourth year they are made up for the market, by being fed with oilcake, grains, and other fattening food, besides oats. When their preparation is finished, they find purchasers at a sum sometimes exceeding £100.

The use of these very heavy horses is now chiefly confined to brewers' drays, to contractors' trollies for conveying blocks of stone, and for drawing carts containing building materials, and heavy iron work, such as boilers, parts of bridges, &c. From their great size they require a large amount of food; and, although occasionally useful for drawing heavy weights, they are being gradually displaced by a lighter and more active horse.

Stable Management.

In treating of this part of the subject, it is assumed that the stable is in a healthy situation, for in an unhealthy one trouble or expense will be simply thrown away. Horses dislike bad smells; the drainage of the stable should therefore be well looked to, and the traps should be as far from the stable as circumstances will permit. The pit for the reception of the manure and foul litter, which should be constantly removed, should also be some distance from the stable.

Stalls. Stalls should not be less than 6 feet wide; if 3 inches more can be had so much the better. The partitions should be long enough to prevent horses kicking each other, and high enough, towards the head, to prevent them biting one another. Some authorities recommend that the partitions be so arranged that horses cannot see each other; it makes them restless they say. The soundness of this advice is open to question: it may perhaps hold good with regard to race-horses; but the horse is fond of company, and certainly horses that are driven together, or ridden in company, seem to like the society of their fellows in the stable, while, as already stated, a stable companion is useful to lead young horses over fences in their early attempts at leaping.

In dealers' stables the floor of the stalls often slopes considerably from front to back. This makes a horse look bigger than he really is, but it throws all the strain of supporting the body on to the back tendons, and should not be permitted in private stables. A fall of $2\frac{1}{2}$ inches is more than enough for the purposes of draining.

Lighting. As regards the internal arrangements, especial care should be paid to light, ventilation, and temperature. A sufficient amount of light is indispensable for the health of the horse. Horses, like men, are greatly influenced by surroundings, and, considering the number of hours in the week spent indoors, a horse can no more thrive in a dark stable than a man in a dark room. Moreover, a horse brought out of a dark stable is much more likely to shy than one whose eyes had not been dazzled by the sudden change from dark to light. Dark stables were once thought to be conducive to good feeding, and to making a horse lie down, but the idea is now exploded. The horse owner may here be warned against seeking to make up for a deficiency of natural light by having the whole of the interior of the stable whitewashed. To the height of 7 feet from the ground the walls should be coloured with some neutral tint, that the horse's eyes may not be injured by the glare inseparable from whited walls. Dark stables encourage carelessness in the groom, the result being an accumulation of dirt; and, even if the stableman be an honest worker, he cannot see to clean the floors and corners properly unless light be freely admitted to the building.

Ventilation. In the ventilation of stables many theories have been propounded, and many appliances suggested, but most of the latter have failed from letting in cold currents to a greater extent than they let out the foul air. In nineteen cases out of twenty, the ventilation of private stables consists of holes in the brickwork. In using these it will be found advisable to have thin pieces of zinc, with felt edging to prevent noise, and with easy working hinges, nailed outside the wall, to act as valves; then should the wind set from the quarter in which the ventilators are situated, the zinc coverings will be blown against the apertures, and the entrance of cold currents to any great extent thereby hindered. When the stable is empty, doors and windows should be thrown open if the weather allow it to be done without reducing the temperature too much. These remarks on ventilation apply chiefly to smaller stables built in the vicinity of a dwelling house; in the case of stables built in open spaces, for the reception of a large stud, recourse will generally be had to the advice of a civil engineer on the question of ventilation, but even then experience has shown that the difficulty will not be wholly overcome. The apertures in the walls for the escape of foul air, which, being lighter than fresh, ascends, should in no case be less than 7 feet from the ground. If the ventilators are lower than this there will be a current of cold air blowing on the horse's body, which would be injurious at all times, but especially when the horse comes in warm from work.

emper-ure. Temperature is of course an important matter, but chiefly so during the colder portions of the year. In summer it is all but impossible to keep stables cool when the thermometer is standing at 80° Fahr. in the shade; still if the situation is favourable to coolness, and the temperature can be kept below 70°, so much the better. During the hunting season, stables may be too warm by accident or from design: they may be overheated owing to insufficient ventilation, or because the groom connects a glossy coat with a stable bordering on tropical heat. About 55° Fahr. is a good mean temperature, but this cannot of course be maintained when the outside air is some 10 or 15 degrees higher; the most that can be done is to keep the temperature up to that point in cold weather A moderate temperature and moderate clothing are better than too low a temperature with excessive covering, or too high a temperature with but little clothing.

oth-g. Having mentioned clothing incidentally, it may here be said that the best shape is the ordinary sheet, cut out at the neck, and buckled across the chest; the sheet should be long enough to reach the root of the tail, and should be large enough to buckle easily round the chest; if it be tight the hair will be rubbed. Some people prefer a straight rug that does not buckle, the front being formed of a separate breast cloth. Hoods are only needed when at exercise in bad weather, or when the horse is travelling by railway. Particular care should be taken that the roller does not touch the back bone; the pads should be so placed that there is a clear space of 4 inches between them, so as to leave a clear channel over the back bone. The neglect of this precaution will inevitably produce a sore back, and, while first of all making the horse shy of being touched, may subsequently make him vicious in the stable.

neral nage-nt. Regularity is absolutely indispensable to successful stable management; without it, the horse may be subjected to a dozen different kinds of treatment in as many days, a course obviously detrimental to his health.

The engagement of a good groom is the first step. Where there is a stud of ten or more horses, a stud groom will probably be kept, and, as he will not do much work himself, —indeed it is better that he should not,—he should know how things ought to be done, and see that they are done. In small establishments, however, there will be but one or two men; but the head one should be a thorough stableman. The more ignorant he is of the veterinary art the better; indeed, every horse owner should, in the strictest terms, forbid his servants to administer any drug or medicine whatever without permission; and the owner himself may be advised never to sanction the giving of any physic, but always to seek good professional advice if any signs of sickness are visible.

Stable work should commence early, as soon after 6 A.M. as possible. The first duty is to examine each animal carefully, to discover whether any injury has been received during the night from kicking, getting cast, or any other cause. Horses are then fed and watered, the litter is turned up, that which has been in use during the night not being allowed to remain in the stable during the day, and the stable is put in order; exercise succeeds, after which the animals are thoroughly dressed, but the dressing should never be performed out of doors. Feeding takes place again at 12 noon, 4 P.M., and 8 P.M., when the horses are done up for the night.

Of the feeding of race-horses nothing need be said here, as their care is a business of itself, with which the private person has nothing to do. Feeding

Oats and hay form the diet upon which horses are kept, to which beans are added for hunters and horses in hard work; while bran, linseed, and carrots are used for special purposes, in addition to, or sometimes in substitution for, the regular food. Hacks and horses in light work will do well on a daily allowance of 8 to 10 ℔ of oats and 10 or 12 ℔ of hay. Beans, which contain about 30 per cent. of nutriment, are heating, and should be given only now and then in small quantities. The oats are best divided into four feeds, and beans when used should be given at the midday and last feeds A handful or two of chaff is useful with each feed, as it compels a horse to masticate, but in many stables there is a prejudice against it, and the hay is put into the rack four times a day, not more than 3 ℔ being given at one time. Oats should be bruised; but, as they soon turn sour, it will be best to bruise every morning only as much as will suffice for the day's consumption.

Bran is indigestible, but it is a laxative, and, so far as hunters are concerned, it is only given in the form of a mash after a day's hunting, and on Saturday nights. To make a bran mash, put half a pint of linseed in a pan, pour a quart of boiling water upon it, and let it soak for four hours, then take about 2½℔ of bran and mix with it enough hot water to saturate it; stir the linseed composition into this, and it is fit for use. Should the mash be put in the manger, the latter should be scoured out with hot water afterwards, or the sourness of the remains of the mash will make many horses refuse their corn.

A few carrots, which must be carefully washed and scraped, given every now and then, are useful as tending to keep the blood in good order, and checking any symptoms of fever induced by the dry food upon which horses live.

Maize or Indian corn contains so small a proportion of nutritious matter that it is not fit for hunters or for horses from which fast work is required. The London General Omnibus Company feed their large stud almost entirely on this diet, and it is found to answer (see Mr Church's evidence before Lord Rosebery's Horse Committee, 1873). It is given in the same quantity as oats.

Of late years corn merchants have introduced the system of foraging gentlemen's horses at the fixed price of one shilling per hand per week. Thus a horse of 15·2 would be foraged for 16s., and one between 14 and 15 hands for 15s.

A correct system of watering horses is no less important than proper feeding with dry food. Many grooms, in their horror at giving too much, fall into the opposite extreme, and stint the horses under their care to an extent that is positively cruel. The result of such a system is fever in various shapes, and a general loss of condition. There has of late years been a growing tendency to favour the plan of letting horses have access to water at all hours of the day and night, and experience has shown that the effect is beneficial. A separate tank in the stall or loose box is fed by a tap, and a constant supply should be kept up. If a horse watered on this plan be watched, it will be seen that Watering.

he never takes more than a very few small mouthfuls at a time, nothing like the quantity allowed by the most stingy groom; and, if the amount consumed be measured, it will be found that, after the first day or two, the horse actually drinks less than when watered at stated intervals. Where the *ad libitum* plan is not adopted, horses should be watered four times a day. Nothing can be more unwise than the undue stinting hunters of their water on hunting days; no one could expect a satisfactory day's work from an animal suffering from excessive thirst. Where horses can have water when they like, it will scarcely be necessary to do more than to put the cover on the water tank at about 9·30 on hunting mornings, assuming the meet to be at 11. It need hardly be said that the quality of water supplied to stables should be carefully attended to. Horses are easily made sick by impurities, and are very dainty in their choice of water. When on a journey, horses should never be allowed to drink at public troughs, as disease is very likely to be contracted by such a proceeding.

Exercise. Exercise is a great preservative of health, but, like food and medicine, it should be given at proper times and in proper quantities. Exercise must not be confounded with work; the severe work horses are sometimes called upon to perform takes much out of them, and exercise is one of the means adopted to counteract any ill effects of hard work. In order that the muscles of a horse may not become prematurely tired, it is not sufficient that they should be violently taxed some three days a fortnight as with hunters; they must be used every day, and the exercise by which this is effected causes all the tissues of the body to receive their support by reason of the tone given to the circulation of the blood. Hacks, harness horses, and particularly ladies' horses, should be sufficiently well exercised to guard against an excessive exuberance of spirits; for nothing is more annoying than to have an animal, quiet enough in an ordinary way, perpetually jumping about at the approach of vehicles or other horses, merely because he is too fresh. Hunters should have two hours walking exercise daily; sometimes a slow trot of 3 or 4 miles may be indulged in, but, when the hunting season fairly sets in, and horses are hunted regularly, cantering should be forbidden at exercise unless either master or man happens to be a very good judge of what kind of exercise a horse requires.

Treatment of hunters. Hacks and harness horses are but rarely called upon to perform duties so exhausting as those of the hunter. In the case of the former animals, a suitable stable, good food and water, ventilation, and exercise, coupled of course with careful supervision, should, save under exceptional circumstances, suffice to keep them in good health. All the previous remarks apply in the case of hunters, but with them something more is needed. First there is the getting the animal into condition, and then comes the proper mode of treatment after work, when the system is exhausted, and the horse suffering perhaps from the effects of a blow or a fall. The art of getting hunters into condition has made great strides during the last fifty years. Nowadays one seldom hears of horses dying in the field through sheer exhaustion; and it cannot be said that their work is lighter now than it was then.

To begin at the beginning, a hunter should be fit for use by the end of October, and the question then arises, How long before this time should he have been in what may be called training?—using the word, of course, in a different sense from what is understood by training in a racing stable. The answer to this question depends very much upon how, at the termination of the last hunting season, the owner solved the difficulty of "what to do with the horses." Assuming horses are to be kept through the summer, it will probably be nearly a month after the last hunting day before the summering treatment is adopted. A dose of physic will have been administered, and, if wise, the owner will have called in a veterinary surgeon to see what damages have been sustained; but he should be one used to hunters and their peculiar infirmities.

Many persons with the best intentions, and following very ancient traditions, turn their horses out to grass, saying that a "summer's run" will put new life into them, but not explaining why a horse that up to Monday night is kept clothed in a warm stable and fed on hard food, should be greatly benefited by being turned into a field on Tuesday without his clothing, and left to subsist entirely on grass. This sudden change of living, which used to be so universal in the case of horses, is condemned in the human subject; and that is not the least powerful argument that can be urged against it. Moreover, most veterinary surgeons agree that more hunters have been made roarers or contracted disease of some kind from being turned out to grass than from almost any other cause. In the days when summering in the fields was the usual method pursued, a hunter was never really fit until the season was far advanced, and the turning out to grass in May was simply undoing all that had been done since the previous August. Although here and there a few individuals adopted a more common sense way of summering their hunters, the full evils of the grazing system were not impressed upon the public until "Nimrod," in letters to the *Old Sporting Magazine*, advocated the adoption of a more enlightened system, and showed the weak points in the old one. The advantages claimed for the plan of turning out to grass were that the horse's system and his feet benefited, and that it was cheaper. But violent changes in the manner of living cannot be beneficial, and, as regards the feet, Mr Goodwin, veterinary surgeon to George IV., said: "I have invariably observed, where horses are turned out to grass during the dry and hot summer months, that, on bringing them up to be put into stable condition, their feet are in a much worse state than when they went out, dried up, and so hard and brittle that, on the application of a tool to bring them into a form to receive a shoe, the horn breaks like a piece of glass, and all the naturally tough and elastic property is lost, so that it requires some months to remove its bad effects. . . . . . . Horses at grass are much inclined to thrush." As to the expense, the objection is too trifling to be taken as a set off against any real advantages the system advocated by "Nimrod," and now generally adopted, may be found to possess.

But in whatever way a horse is summered, it is clear that there must be a great change from a state of hard work to one of absolute rest and quiet, and this change should not be the work of a moment. Unless an owner be particularly lucky, some one or more of his hunters will generally show signs of wear and tear before the end of the season has arrived, and these should be the first thrown up. They should be exercised daily, but their corn should be diminished, and their dressing in the stable need not be of the same thorough kind as when they were in full work. After about a fortnight of this treatment summering may begin in its full sense. The state of the horse's legs, and the judgment of the owner, will determine whether the horse shall be exercised during the summer, or left to exercise himself. In the former case he must remain shod, and have his feet stopped two nights a week with damp tow, or, if there be much tendency to fever, with tow dipped in the best Stockholm tar. Exercise should take place in the cool of the day, in the morning for choice, on soft ground, for about an hour and a half. Where the horse is left to exercise himself, he should be housed in a good-sized shed or box opening into a straw-yard or small paddock, which should be shaded by trees or buildings, so that the maximum of air can be breathed with the minimum of exposure to the sun. A horse thus kept should have his shoes removed, and, as his feet cannot then be stopped, he should stand once or twice a week, for an hour at a time, on wet clay.

The constitution of each particular horse should be taken into account in deciding how he shall be fed during the summer months. The aim to be kept in view is to maintain the strength, but not to engender fever,—to let the system down as it were, but not to undo all that has been done during the hunting season to a greater extent than may be found necessary. As a general rule, three feeds of oats a day (the feeds being rather smaller than those given during work) will be sufficient; beans should be eschewed, but 8 or 9 lb of hay may be given. Green food should be given with caution, say twice or thrice a week, to assist in maintaining a healthy action of the bowels.

The getting the horse into condition again for the ensuing season should be accomplished gradually, and all violent exertion should be avoided. About the beginning of August the shoes should be put on the unshod horse, and he should have an hour's walking exercise daily for about a week, when the time may be extended by degrees. The horse that has been exercised all the summer will need no special attention until the beginning of September, about which time all the horses should have slow trotting exercise twice a week on soft, but not deep, ground. During October cantering may be indulged in twice a week, but plenty of walking exercise should form part of every day's work. The quantity of oats given should of course be increased as the work gets stronger, until, before the commencement of the hunting season, the full quantity is reverted to.

It is of course the groom's duty to get a hunter into condition, and to apply the proper treatment on his return to the stable, when tired by the day's work; but during the day the horse will be under the care of the rider, and carelessness or want of judgment on his part may occasion injuries not to be overcome by any known system of stable management. As soon as the hounds leave off, the rider, if more than a mile or two from home, or if the day has been at all severe, should get his horse some gruel at the nearest inn or cottage, or, failing gruel, a little tepid water, with or without a handful or two of flour stirred into it. A horse's stomach is small in proportion to the size of his body; he should not therefore be kept without sustenance of some sort longer than is necessary. Should the animal show signs of great distress, he should be got into the first stable that is reached, or if there is not one handy into a shed, and the more airy it is the better. The head and legs should be well rubbed; clothing should be put on the body, and a cordial of some sort administered as quickly as possible,—sherry, spirits, or beer will do; and a veterinary surgeon should be sent for at once.

When the hunter returns to his own stable, he should first have his pail of warm gruel and linseed made according to the receipt given above; and after he is dressed, it will only be necessary to see whether he feeds as usual. If he does not, water with the chill off may be given to him. Should he be merely fatigued, a night's rest in an airy box will soon restore him; and here it may be observed that all stables should include at least one loose box for the reception of a horse returning from hunting; rest cannot be so satisfactorily taken in a stall.

reat- ent of rses' gs. The treatment of horses' legs is a most important part of stable management, and one which is but too often imperfectly understood by men who, though nothing but strappers, call themselves grooms. In many stables it is the custom to wash the feet and legs of horses returning from work, but the practice is calculated to produce cracked heels, a state of things which often results also from a too frequent use of wet linen bandages. The better plan is to forbid the use of water above the hoof; and, as soon as the hunter comes in, some rough serge bandages (kept for the purpose) should be put loosely on his legs. These may be removed after the rest of his body has been dressed, when the legs will be found quite dry, and the mud will crumble off like sand, while half the labour that would have been needed to dry the washed legs will suffice to brush every particle of grit from the hair and skin. The legs should then be well hand-rubbed, and the ordinary bandages may be put on for about four hours; on their removal more hand-rubbing should take place. A constant use of bandages is to be deprecated, unless it is ordered for some particular purpose by the veterinary surgeon.

nor sual- s. The reader has been already warned against being his own veterinary surgeon; but there are certain minor casualties to which every horse is liable, and which an average groom should know how to treat. A very common cause of a hunter being laid up is a blow on the leg, which may be either on the skin or on the sinew. If on the skin, the leg should be bathed with hot vinegar and water, in equal proportions, three or four times a day. A blow on the bone often causes a bony enlargement, but beyond constituting a blemish is of no importance. A blow on the sinew is generally the cause of a long period of lameness, and firing may be needed. If the blow be only a slight one, bathing in cold water is the best thing that can be done.

Cutting. Cutting is sometimes the result of malformation of the legs, and sometimes the result of fatigue, for some horses will now and then brush themselves after a long and tiring day, who never do so in going to cover. A boot and change of shoeing must be resorted to.

Corns. Corns are to be laid at the door of the shoeing smith. They arise from the shoe being too tight, or from its being nailed too near the heel. A careful groom should superintend the shoeing, and should instruct the smith to pare the sole at the seat of the corn, and to take care that the new shoes do not press upon the sole. The sole must be kept well pared and dressed with tar. Should the corns be so bad as to suppurate, hot linseed meal poultices should be applied, and work dispensed with.

Thrush. Thrush is a diseased state of the frog, caused, in most instances, by the feet being neglected in the stable. The diseased parts should be cut away, and the openings in the hoof stopped with tow dipped in tar.

Cracked heels. Cracked heels generally owe their existence to the legs having been left wet after washing. In the early stages cut the hair from the sore part, wash with warm water, dry, and apply glycerin lotion. If riding or driving a horse with cracked heels, never allow the sores to be rubbed with grease before starting, as the dust or dirt will cling to this, and by getting into the sore make it worse than ever.

Over-reach. An over-reach is a not uncommon occurrence in the hunting field. An old piece of linen, folded three or four times, should be soaked in water and fastened on the place, and a piece of oiled silk should be kept on over the linen to prevent evaporation.

Sore back. Sore backs are very troublesome to get rid of, and would not happen so often as they do were more attention paid to the fitting of the saddle and the way it is stuffed. Most saddlers put too little stuffing in a saddle, and so after it is used a few times the inside becomes hard. When the skin is found to be rubbed, use the wet linen and oiled silk as for an over-reach, and afterwards chloride of zinc lotion.

Fever in feet. Fever in the feet is generally the result of too much knocking about on hard roads. Directly lameness appears, take off the shoe and place the foot in cold water, putting on a poultice at night.

PART III.—HORSEMANSHIP.

Horses being ridden for several distinct purposes, viz., in the cavalry service, for hunting, racing, steeple-chasing, on the road, and in the school, there are separate styles of horsemanship adapted to each purpose, and a rider excelling in one is not of necessity a proficient in the others; in fact few persons, if any, are equally good, for instance, at military or *manége* riding and at steeple-chasing.

ount- . The first step in horsemanship is to mount a horse; but for the performance of this apparently simple feat no fixed rule can be laid down for the guidance of the civilian. Having taken up the reins, the rider should stand at his horse's near shoulder facing towards the tail, and in that position hold the stirrup with his right hand for the reception of his left foot. By standing at the shoulder the rider is out of harm's way in the event of the horse kicking while he mounts. It is perfectly easy to carry out these directions when the man and horse are both of middle height; but it is simply impossible for a short man to mount a horse of 16 hands high in such a manner, he must risk the kick and stand where he can reach the stirrup—behind it. Having gained the saddle, the necessity arises for seat and hands. The fact that the seat of a civilian rider must vary to some extent according to the size and shape of the animal upon which he finds himself, does not preclude certain principles from applying in the formation of it, and it is towards the proper understanding of these principles, and the adoption of the right position of the legs and body, that good instruction is desirable at the outset.

The great desideratum in a seat on horseback is that it should be firm, and this for two reasons. In the first place, a rider with an insecure seat is apt to be thrown by any unexpected movement the horse may make, such as a slight stumble, or shying; and secondly, without a firm seat, the acquirement of good hands is well nigh hopeless, because, when the balance is once disturbed, the rider will have to depend on something else for the maintenance of his seat, and this other means of support will generally take the shape of "riding the bridle," a practice as much opposed to good horsemanship as it is injurious to the horse's mouth.

Having gained the saddle, the rider should seat himself in the middle of it, and should never allow any part of his person to overlap the cantle, as is but too often seen. Many rules are given for adjusting the stirrups to the proper length before mounting, but in practice they are not to be depended upon,—first, because all men are not made in quite the same proportions; secondly, where two men are of equal height, the man with the thicker and rounder legs will require a shorter stirrup than the one with lean and flat legs; and thirdly, men of any build will need a shorter stirrup on a wide horse than on a narrow one, besides which, if a horse pulls at all, another hole or two will give the rider additional power over his animal. The proper length of stirrup, then, cannot be satisfactorily ascertained till the rider is mounted. Sitting well in the middle of the saddle, the thighs being turned in, and the heels drawn somewhat back, the stirrup leathers may be let out or taken up until the tread of the stirrup is on a level with the inner ankle bone, and at this length, when the rider stands up, his fork will clear the pommel of the saddle by about 3 inches. For maintaining his seat the horseman should depend upon his thighs and knees, and not upon the knee and calf only; at times, of course, when on a restive horse, every available muscle may have to be brought into play, but the proper rule is as stated. Some people say they ride by balance only, and others that they ride by grip; a proper seat should be an admixture of the two: a man riding by balance only is sure to be kicked off, while to grip with all one's might during an hour's ride is to undertake as much exertion as should last for a whole day. The position of the foot exercises some influence on the security of the seat; at one time it was thought proper to turn the toes in and depress the heel, a posture that tended to diminish the grip of the thighs, but now the toe should be turned a little outward, and but very little upward. A good seat on a horse should not be strong merely; it should be as graceful as the make and shape of horse and rider allow; but it should not be a stiff, stuck-up seat, which is never graceful, because it is not natural. Above the loins the body should be loose, so as readily to adapt itself to every motion of the horse; but it should be upright, for if the rider lean forward in his saddle, a false step on the part of the horse is very apt to send him flying over its head. The position of the hands has a great deal to do with the seat, but the hands and the reins will be treated of presently.

Beginners are often advised to learn to ride without stirrups; if they do, they should have no saddle either, for riding in a saddle without stirrups is likely to produce rupture. The soundness of this advice, however, may be questioned, because, although riding without stirrups will undoubtedly tend to a firm seat, it will not be one of the same sort as when stirrups are used; there must therefore be a process of learning and unlearning. The better plan is to practice both ways concurrently. Thus let the pupil be properly placed in a saddle with stirrups, and when he has ridden half an hour let a cloth be substituted for the saddle for about ten minutes, care being taken to observe the rules already laid down for the position of the legs; in this way the proper seat will be strengthened, instead of a new one being formed.

The hands and the reins.

The proper adjustment of the reins is the next thing to be attended to, and as the management of these depends so much upon the seat being firm and independent of the bridle, the acquisition of a firm seat is certainly half way towards the acquirement of good hands. Assuming a single rein snaffle to be the bridle used, the second, third, and fourth fingers of the left hand should be inserted between the reins, which should be drawn up gently with the right hand until the rider feels that he has got an equal hold of his horse's mouth on both sides, and with just so much pressure that the slightest movement of the left or right rein would cause him to turn to the left or right respectively; the fore and middle fingers of the right hand should then take hold of the right rein, which may be drawn out from the left hand so as to enable the hands to be held about 4 or 5 inches apart. The arms from the shoulder to the elbow should hang naturally close to the sides, and the arms from elbow to wrist should be about parallel to the ground, the wrist being kept loose, so as to yield gently with every motion of the horse. The rider sitting in the position described, square to the front, with his shoulders well back, will be riding with fairly long reins, one of the secrets of good hands; if he stoop forward and carry his bridle hand at some distance in front of his body, so as to take a short hold of his horse's head, seat and hands will both be bad.

When a double reined bridle is used, the third finger of the left hand should be first inserted between the snaffle reins, and then the little, third, and second fingers should be between the curb reins, the two outside reins will then be the curb, and the two inside ones the snaffle. In this manner of holding the reins the snaffle is not so likely to slip, while the curb can be easily slackened or drawn tighter. As military riders invariably use the curb only, the position of snaffle and curb as just explained is reversed in the cavalry service.

When the horse is in motion, the hands should not be kept in one spot, so as to act like the peg on the pad of a harness horse to which the bearing rein is fastened, as the mouth would thereby become dead, and the horse would lean unpleasantly on the bit; but the rider should give and take, so that while the pressure is not stronger at one moment than at another (unless there be a reason for it), yet, on the other hand, the hold should never be entirely relaxed.

Walking.

In order to encourage the horse to walk, the head must not be confined, but the light feeling on the horse's mouth must be kept up. Should the horse break into that uncomfortable pace, a jog trot, which, by the way, a well-broken hack should not do, never snatch at his mouth, but restrain him gently. To trot press the legs to the saddle, raise the bridle hand a little, and urge him if necessary with the voice. The rising to the trot should be performed easily; the legs must not swing backwards and forwards, nor should the hands be jerked up and down, while the action of the rider should be in perfect time with the motion of the horse, or a passer by may remark that the horseman is riding faster than his horse. To start in the canter take up the curb rein a little and turn the horse's head slightly to the right, at the same time pressing the left leg behind the saddle, the horse will then lead with the off fore leg, which is generally preferred under ordinary circumstances; but a well-broken hack should be taught to lead with either, and if he be cantered in a circle to the left he must lead with the near leg, as otherwise an ugly fall is likely to result from the leg being crossed. Galloping is a pace not generally indulged in by hack riders; when it is, the hands should be kept low, the body thrown back, and an extra grip taken, as nearly all horses pull more or less when extended.

Hitherto, only road or park riding has been considered, and, with wise people, hacking (except hacking to cover, or in the performance of a journey against time) means progressing at a strictly moderate pace—for the sake of their horse, if for no other reason.

Beginners of all ages are strongly advised to undergo proper instruction when commencing to learn to ride. The few directions already given may serve to remind a person what to avoid, but an hour's teaching is worth volumes of theory. The instructor should, however, be a practical and well-taught horseman himself; to be this it matters not whether he be a professional riding-master or not. When once the proper place for the legs and hands is pointed out, and the proper way of handling a horse and sitting in the walk, trot, and canter,—when, in short, a person has been put in the way of becoming a fair road rider, he has made some progress towards being a hunting man. But if, on the other hand, first principles are disregarded, and a rider believes in the system of "it doesn't matter how you ride so long as you only stick on," it will be a long while before he reaches his own standard, except with the comparatively few men who seem to have been intended by nature for horsemen. Few self-taught riders attain to anything like excellence; they may ride quiet horses with fair success, and even in hunting, if possessed of plenty of courage, and mounted on a bold and not too tender-mouthed horse, they may keep a good place, but horsemen in the proper sense of the word they never will be.

Now, assuming the beginner to have acquired some proficiency in riding, and to have had a little practice over the leaping bar, he may be desirous of making his first appearance with hounds, and the question then arises how is the hacking-seat to be exchanged for the hunting one, of which he will probably have heard a great deal, and have seen some very extraordinary specimens.

he
nting
at.

For practical purposes the chief difference between a park seat and a hunting one consists in the substitution of boots and breeches for trousers, and the shortening of the stirrups some two or three holes. Next to that of a jockey, the seat of the hunting man is the most important of any connected with amusement; he must sit firm, so as not to be thrown off when his horse leaps, or makes a slight mistake, technically called "pecking," on landing after jumping a fence, and so as to be able to handle his horse delicately under all circumstances, and to make as much of him as possible. As with road riding, so with hunting, the actual length of the stirrups will depend a good deal upon the form and action of the horse, but the nature of the animal and the peculiarities of the country ridden over will also have something to do with their adjustment. A puller will compel the rider to pull up his leathers one or perhaps two extra holes—a course that may also be rendered necessary in a hilly country, for, in going down hill, the stirrups, if kept at the ordinary length, will generally feel a great deal too long. The rider's body must be kept close to the saddle in leaping, for if he were jerked up, the weight of say only a 10-stone man coming down on the horse a couple of seconds after he has negotiated a large fence is sufficient to throw him down. Nothing but actual practice with hounds can teach a man the kind of horsemanship required for hunting where land of all kinds has to be ridden over, and obstacles of various sorts, natural and artificial, have to be encountered.

Considerable progress may, as already stated, be made in seat and hands within the four walls of a good riding school, but as the art of warfare must be learned on active service, and not on the parade ground, so nothing but actual practice in the hunting field will teach a man that kind of horsemanship adapted to the ever-varying conditions and different situations to be met with in a single day's hunting. For example, the ground gone over is not always the level springy turf of the race-course; it is up hill and down dale, across ridge and furrow, over ground studded with ant-hills (which, unlike mole-hills, are often very hard), over ploughed lands, and in boggy countries. Now each of these varieties requires a different method of riding over, and nearly every horse will require different handling under similar circumstances; some can go well through the dirt, while others can only go on the top of the ground; some will require rousing at their fences, while others will want quieting.

od
nds.

It will therefore be seen that much depends on the rider having good hands. This qualification, though generally understood, is very difficult to define. A rider with good hands never depends upon his reins for retaining his seat; nor does he pull at the horse's mouth so as to make him afraid to go up to his bit; nor again does he ever use any more force than is necessary for the accomplishment of what he desires to perform. But besides all this, there is an unaccountable something about the man with good hands that cannot be described. Pullers appear to renounce pulling, refusers take to jumping, and clumsy horses appear nearly as handy as a trick horse in a circus. Though "hands" can to a great extent be acquired by care and practice, yet in the highest form it is a gift like the "hand for crust" which is denied to many cooks and cannot be learned.

ces.

There are different kinds of "fences," as all obstacles are generically called. First, there is timber, such as gates, stiles, and rails; the first two are, nine times out of ten, awkward jumps, as the take off is either poached by cattle, or else is on the ascent or descent. Hedges vary according to the custom of the country in which they are found: they either grow in the soil of the field, and are protected by a ditch on one side, or are planted on a bank with a ditch on one side or sometimes on both. The rider may here be reminded that if a bank is high and the ditch before it but small, there is pretty certain to be another ditch on the far side, for the bank is made by throwing up the earth taken from the ditches. Then again there are the large banks found in Wales, Devon, and Cornwall. Lastly come water jumps, which are met with in two forms: the water is either within an inch or two of the top of the bank, so as to be about on a level with the field through which it flows, or there may be a space of some 6 or 7 feet from the bank to the water. For the successful negotiation of brooks a bold horse is required, ridden by a bold man. No fence that is ever encountered stops such a large proportion of the field as water; even a clear 6 feet of it will prove a hindrance to some, while anything over 10 or 12 feet will in general be crossed only by a very few. Some horses, good performers over any other description of fence, will not jump water under any circumstances; while the chance of a ducking deters many from riding at it; and, however bold the horse may be, he will soon refuse water if his rider be perpetually in two minds when approaching a brook.

The pace at which a hunter should be ridden at his fences depends upon the nature of the fence itself, and the peculiarities of each individual horse. With some very good jumpers—they can hardly be called good hunters—to steady them is to bid for a fall, while with some very clever hunters to hurry them is to bring them to grief. With ordinary horses, however, it is a good general rule to ride at fences of all descriptions as slowly as the nature of the obstacle admits. In grass countries, where "flying fences" are found, the rate of speed must of necessity be quicker than when about to take a Devonshire bank of some 7 feet high, but even at a flying fence the rider should steady his horse so as to contract the length of his stride, in order that he may measure the distance for taking off with greater accuracy. Flying fences consist of a hedge with or without a post and rail, and with or without a ditch on one or both sides; consequently a horse has to jump both high and wide to clear them. But in jumping a gate, or a flight of rails, as ordinarily situated, there is no width to be covered, and to make a horse go through the exertion of jumping both high and wide when he need only do one is to waste his power, added to which to ride fast at timber, unless very low with a ditch on the landing side, is highly dangerous.

All hedges on banks, banks, and doubles must be ridden at slowly; they are usually of such a size as to make flying them impossible, or at least undesirable. Horses jump them on and off, and in taking them at a moderate pace there is a chance of stopping on the top and choosing a better place to jump from, or, if needs be, of returning and taking the fence at another place. Cramped places will have to be jumped from a walk or even at a stand; for instance, a tree may be in a line with and close to the only practicable place in a fence; it then becomes necessary to go round the tree before a run at the place can be managed. So, too, with places that have to be crawled over between trees, or with dykes to be crawled down.

In jumping an ordinary hedge or ditch at moderate speed, there is of course a moment of time during which the horse is on his hind legs, and in theory the rider should then lean forward, but, in practice, this position is so momentary, and the lash out of the hind legs in the spring is so powerful, that it is best not to lean forward at all, because of the difficulty, if not impossibility, of getting back in time for the reverse movement, when the rider should be preparing to render the horse some assistance with the bridle as his feet touch the ground.

Water, as was said before, stops a field more than any other kind of fence, because, so far as the rider is concerned, a strain to the horse's back or a bad over-reach is likely to result, and the contemplation of a ducking is not pleasant on a cold day. Then as to the horse, if he ever got into a brook when young, and found any difficulty in getting out again, it is ten to one against his ever taking kindly to water afterwards. When a line of willows indicates the whereabouts of a brook, the horse should be well collected, a clear place selected, so far as circumstances allow, and the pace increased, though in short strides, up to the very brink. If the hounds jump at the brook, even though they fail to clear it, the rider may take it for granted that at that place the leap is within the capacity of any ordinary hunter in his stride; hence if, when going at three parts speed, a horse's feet come just right to take off, the mere momentum of his body would take him over a place 15 feet wide.

Riding to hounds. Now jumping a fence is one thing, and riding to hounds is another; a man may be a very good horseman, and yet be a very bad man to hounds. The leading hounds should be watched, and when they turn right or left the rider should turn too. Then the choice of ground is important; ridge and furrow should be taken diagonally, or, if the field be entered towards either end, time will ultimately be saved in going round by the firmer ground at the sides. Ploughed land requires the rider's special attention; an injudicious hurry over a couple of deep fields has settled many a good hunter for the remainder of the run. In jumping into a ploughed field the fence should be taken slowly, and the rider should lean well back in the saddle, because, lacking the elasticity of turf, a ploughed field, especially after rain or a frost, will let a horse's legs sink in deep on landing, and if he has been ridden at the fence quickly, the sudden resistance offered by the soft ground will inevitably cause a fall. When the ground is deep, therefore, the rider's judgment will be shown in avoiding, where possible, large flying fences into a ploughed field, and in choosing places that can be jumped quietly.

Pace. Pace is a relative term; when the thoroughbred is but cantering, the underbred will be doing his utmost; the horseman must therefore always have an eye to his horse, and must be careful not to press him beyond a certain pace, unless of course he means to be satisfied with a short life and a merry one.

Gate opening. The experience of a single day's hunting will teach the novice that gates are far oftener opened than jumped; it is therefore necessary that a hunter should be handy at opening them. Many accidents have arisen from horses rushing through a gateway directly the latch is released, or from their jumping a gate at which they have been pulled up to enable the rider to open it. The horse should be taught to obey the leg as well as the hand, and, by a slight pressure of the leg, should throw his haunches round to the left or right as occasion may require.

Falls. Most writers on hunting aver that there is an art in falling, and the young sportsman is duly told to get clear of his horse as soon as possible. It is not to be denied that the number of accidents in the hunting field are but few considering the number of falls that take place during the hunting season, but the rarity of accidents can hardly be ascribed in all seriousness to a proficiency in the art of falling. In the first place, ditches cause many falls, by the horse dropping his hind legs into them; that is to say, his progress is arrested while the rider continues in the course his horse would have taken had the ditch not been there. When the hind legs are dropped the rider clutches instinctively with his hands and legs, and the violence of his fall is thereby broken, while in ninety-nine cases out of every hundred the ditch prevents the horse from rolling over the recumbent sportsman. Then again as to falls at flying fences taken at a somewhat quick rate, it is lucky for hunting men that under such circumstances the rider is in the majority of instances thrown clear of his horse independently of any skill or effort of his own. It is only in what may be termed "slow falls" that the rider can save himself by presence of mind and activity. When a horse slips into a ditch, or drops quietly on to his knees preparatory to rolling on his side, a practised rider has time to get clear; but in falls over timber, or over fences ridden at quickly, the freedom from accident must in sober truth be ascribed to luck rather than to good judgment.

Saddles and bridles. Saddles and bridles form no unimportant feature in the equestrian art, as well as in the establishment of a sportsman. A well-made saddle and bridle make a horse look worth an extra £20, while nothing contributes more to the safety and comfort of a rider than a well-made roomy saddle. The hunting man will be well advised if he patronizes only such establishments as make hunting saddles their peculiar study. Each horse should have its own saddle, and the closer it fits, provided it does not press upon the withers or touch the spine, the better; but, as even the best saddlers are addicted to putting too little stuffing into them, the purchaser should, when ordering, stipulate for a liberal quantity. The stirrup irons should be moderately heavy, and, if they are for full grown men, of the largest size made, for the foot will be all the less likely to be caught in the event of a fall.

The selection of a bridle will depend upon the horse's mouth and upon the rider's hands. For hacking purposes a double bridle is almost invariably used, the curb enabling the rider to make the horse appear to the best advantage; and, as a general rule, a double bridle with an easy curb bit (the curb chain being protected by a leather strap) is best for hunting purposes, as with it the horse can be collected at his fences, and held together in deep ground better than with the snaffle only. Some persons use nothing but snaffles on principle, and will submit to a vast amount of discomfort rather than call in the aid of a curb; but there are not five perfect snaffle-bridle hunters out of a hundred, and riding a horse in a snaffle is quite another thing from riding a snaffle-bridle horse. The curb, however, should be of no greater severity than is absolutely necessary; pulling is far more often caused by the pain of a sharp bit than by anything else. Whatever bit be used, it is useless to keep up one continued drag at the horse's mouth, as it thereby becomes callous and ceases to be sensitive to any gentle indications. With a puller the bit should be kept moving in the mouth, and a change of bits is often beneficial, each pattern acting in a different way, and taking a horse, so to speak, by surprise.

The less whips and spurs are used the better; unfinished riders will do well to leave the latter at home, for although they are very useful on the heels of a skilful person, an unintentional application of them is often attended with disastrous consequences.

Training of jockeys. The qualities possessed by a good jockey, either on the flat or over a country, fully bear out what has been said before concerning the value of early instruction in riding, and the impossibility of the existence of any regular system of civilian horsemanship. After having been some time in a training stable, a lad is put on a quiet horse at exercise; his stirrups are adjusted, and the reins knotted for him at a proper length. He subsequently rides other horses, each with some peculiarity perhaps, and, to keep his place in the string, a slug must be kept going, and an impetuous one restrained; they cannot both be ridden alike, but they must both be ridden as a jockey should ride them. In this way the lad learns the principle of holding a puller, getting pace out of a lazy one, and leaving well alone with a nice free but temperate mover; he learns to do everything in a horsemanlike manner, and when he has raised himself to the pitch of a "fashionable" jockey, he will frequently be called upon to ride three or four horses a day at race meetings. A jockey must therefore, more than any other civilian rider, have a hand for all sorts of horses, and in the case of two and three year olds a very good hand it must be. The same ability to adapt himself to circumstances must be possessed by the steeple-chase jockey, who should possess fine hands to enable him to handle his horse while going at his fences at three-quarter speed. In most details the nearer a hunting man approaches to a steeple-chase jockey the better; but in the matter of the seat it must be remembered that a jockey's exertions last but a few minutes, while none can tell when the hunting man may finish his day's work; the jockey can therefore ride with more absolute grip during his race than the rider to hounds.

PART IV.—HORSE-RACING.

Probably the earliest instance of horse-racing recorded in literature occurs in *Il.* xxiii. 212–650, where the various incidents of the chariot race at the funeral games held in honour of Patroclus are detailed with much vividness. How far such competitions, which bear in Homer a semi-religious character, may have arisen out of the not unnatural practice an instance of which occurs earlier in the same connexion (*Il.* xxiii. 13, 14) can only be conjectured; it is certain, however, that they very soon came to be of national importance. According to the ancient authorities the four-horse chariot race was introduced into the Olympic games as early as the 23d Olympiad; to this the race with mounted horses was added in the 33d; while other variations (such as two-horse chariot races, mule races, loose-horse races, special races for under-aged horses) were admitted at a still later period. Of the training and management of the Olympic race-horse we are left in ignorance; but it is known that the equestrian candidates were required to enter their names and send their horses to Elis at least thirty days before the celebration of the games commenced, and that the charioteers and riders, whether owners or proxies, went through a prescribed course of exercise during the intervening month. At all the other national games of Greece (Pythian, Isthmian, Nemean), as well as at many of the local festivals (the Athenian Olympia and Panathenæa), similar contests had a prominent place. Some indication of the extent to which the passion for horse-racing was indulged in at Athens, for example, about the time of Aristophanes may be obtained from the scene with which *The Clouds* opens; while it is a significant fact that the Bœotians termed one of the months of their year, corresponding to the Athenian Hecatombæon, Hippodromius ("Horse-race month"; see Plutarch, *Cam.* 15). Details as to the chariot-races and horse-races of the Greeks, and also of their imitators the Romans, will be found under the headings CIRCUS and GAMES.

There is no direct historical evidence to show that the ancient Britons addicted themselves to any form of this amusement; but there are indications that among some at least of the Germanic tribes, from a very early period, horse-racing was an accompaniment of their religious cultus. There can be no doubt that the Romans encouraged the pursuit in Britain, if they did not introduce it; traces of race-courses belonging to the period of their occupation have been frequently discovered. The influence of the Christian Church was everywhere at first strongly against the practice. The opinion of Augustine and other fathers of the church with regard to attendance at the spectacles, whether of theatre or of circus, is well known; those who performed in them were rigidly excluded from church fellowship, and sometimes even those who merely frequented them. Thus the first council of Arles, in its fourth canon, declared that those members of the church who drove chariots at the public games should, so long as they continued in that employment, be denied communion. (Compare the rule in the *Ap. Const.*, viii. 32; *ap.* Bingham, *Ant. Chr. Church*, xvi. 4, 10.) In many cases, however, the weight of ecclesiastical authority proved insufficient to cope with the force of old custom, or with the fascination of a sport the unchristian character of which was not very easily demonstrable; and ultimately in Germany and elsewhere the old local races appear to have been admitted to a recognized place among the ceremonies peculiar to certain Christian festivals.

The first distinct indication which contemporary history affords of horse-racing as a sport occurs in the "Description of the City of London" of William Fitzstephen (*c.* 1174). He says that in a certain "plane field without one of the gates (quidam planus campus re et nomine—*Smithfield*, quasi Smoothfield) every Friday, unless it be one of the more solemn festivals, is a noted show of well-bred (*nobilium*) horses exposed for sale. The earls, barons, and knights who are resident in the city, as well as a multitude of citizens, flock thither either to look on or buy." After describing the different varieties of horses brought into the market, especially the more valuable chargers (*dextrarios preciosos*), he says: "When a race is to be run by such horses as these, and perhaps by others which, in like manner, according to their breed are strong for carriage and vigorous for the course, the people raise a shout and order the common horses to be withdrawn to another part of the field. The jockeys, who are boys expert in the management of horses, which they regulate by means of curb bridles, sometimes by threes and sometimes by twos, as the match is made, prepare themselves for the contest. Their chief aim is to prevent a competitor from getting before them. The horses too, after their manner, are eager for the race; their limbs tremble, and impatient of delay they cannot stand still; upon the signal being given they stretch out their limbs, hurry on the course, and are borne along with unremitting speed. The riders, inspired with the love of praise and the hope of victory, clap spurs to their flying horses, lashing them with whips, and inciting them by their shouts" (see Stow's Translation).

In the reign of Richard I. knights rode at Whitsuntide on steeds and palfreys over a three-mile course for "forty pounds of ready gold," according to the old romance of Sir Bevys of Hampton. The feats of the tilt-yard, however, seem to have surpassed horse-racing in popular estimation at the period of the crusades. That the sport was to some extent indulged in by King John is quite possible, as running horses are frequently mentioned in the register of royal expenditure; and we know that Edward III. had a number of running horses, but it is probable they were chiefly used for field sports.

An evidence of the growing favour in which horse-racing was held as a popular amusement is furnished by the fact that public races were established at Chester in 1512. Randle Holme of that city tells us that towards the latter part of Henry VIII's reign, on Shrove Tuesday, the company of saddlers of Chester presented to "the drapers a wooden ball embellished with flowers, and placed upon the point of a lance. This ceremony was performed in the presence of the mayor at the cross of the Roody or Roodee, an open place near the city; but this year (1540) the ball was changed into a silver bell, valued at three shillings and sixpence or more, to be given to him who shall run best and furthest on horseback before them on the same day, Shrove Tuesday; these bells were denominated St George's bells." In the reign of Elizabeth there is evidence from the poems of Bishop Hall (1597) that racing was in vogue, though apparently not patronized by the queen, or it would no doubt have formed part of the pastimes at Kenilworth; indeed, it seems then to have gone much out of fashion.

The accession of the Stuarts opened up an era of prosperity for the sport, for James I., who, according to Youatt, had encouraged if not established horse-racing in Scotland, greatly patronized it in England when he came to the throne. Not only did he run races at Croydon and Enfield, but he endeavoured to improve the breed of horses by the purchase for a high figure of Markham's Arabian, which little horse, however, was beaten in every race he ran.

In 1607, according to Camden's *Britannia*, races were run near York, the prize being a little golden bell. Camden also mentions as the prize for running horses in Gatherley Forest a little golden ball, which was apparently anterior to the bell. In 1609 Mr Robert Ambrye, sometime sheriff of the city of Chester, caused three silver bells to be made of good value, which bells he appointed to be run for with horses on St George's day upon the Roodee, the first horse to have the best bell and the money put in by the horses that ran—in other words, a sweepstake—the bells to be returned that day twelvemonth as challenge cups are now; towards the expenses he had an allowance from the city. In 1613 subscription purses are first mentioned. Nicholls, in his *Progress of James I.*, makes mention of racing in the years 1617 and 1619. Challenge bells appear to have continued to be the prizes at Chester, according to Randle Holme the younger, and Ormerod's *History of Chester*, until 1623 or 1624, when Mr John Brereton, mayor of Chester, altered the course and caused the horses to run five times round the Roodee, the bell to be of good value, £8 or £10, and to be a free bell to be held for ever,—in other words, a presentation and not a challenge prize.

During James's reign public race meetings were established at Gatherley or Garterley, near Richmond in Yorkshire, at Croydon in Surrey, and at Enfield Chase, the last two being patronized by the king, who not only had races at Epsom during his residence at Nonsuch, but also built a house at Newmarket for the purpose of enjoying hunting, and no doubt racing too, as we find a note of there having been horse-races at this place as early as 1605. Races are also recorded as having taken place at Linton near Cambridge, but they were probably merely casual meetings. The prizes were for the most part silver or gold bells, whence the phrase "bearing away the bell." The turf indeed appears to have attracted a great deal of notice, and the systematic preparation of running horses was studied, attention being paid to their feeding and training, to the instruction of jockeys,—although private matches between gentlemen who rode their own horses were very common,—and to the adjustment of weights, which were usually about 10 stone. The sport also seems to have taken firm hold of the people, and to have become very popular.

The reign of Charles I., which commenced in 1625, saw still more marked strides made, for the king not only patronized the racing at Newmarket, which we know was current in 1640, but thoroughly established it there, and built a stand house in 1667, since which year the races have been annual. Mention is likewise made in the comedy of the *Merry Beggars*, played in 1641, of races, both horse and foot, in Hyde Park, which were patronized by Charles I., who gave a silver cup, value 100 guineas, to be run for instead of bells. Butcher, in his survey of the town of Stamford (1646), also says that a race was annually run in that town for a silver and gilt cup and cover, of the value of £7 or £8, provided by the care of the aldermen for the time being out of the interest of a stock formerly made by the nobility and gentry of the neighbourhood.

In 1648 Clarendon tells us that a meeting of Royalists was held at Banstead Downs, as Epsom Downs were then called, "under the pretence of a horse-race," so that horse-racing at Epsom was not unknown early in the 17th century; Pepys, too, in his *Diary* of 1663, mentions his having intended to go to Banstead Downs to see a famous horse-race. Cromwell is said to have kept running horses in the year 1653, but in 1654 he appears to have gone so far as to forbid racing for six and eight months respectively. After the Restoration in 1660, a new impetus was given to horse-racing, which had languished during the civil wars, and the races at Newmarket, which had been suspended, were restored and attended by the king; and as an additional spur to emulation, according to Youatt, royal plates were given at each of the principal courses, and royal mares, as they were called, were imported from abroad. Charles II. rebuilt the house originally erected at Newmarket by James I., which had fallen into decay. The Round course was made in 1666, and racing at the headquarters of the turf was regulated in the most systematic way, as to the course, weights, and other conditions. Charles II. was the first monarch who entered and ran horses in his own name; and, besides being a frequent visitor at the races on Newmarket Heath, and on Burford Downs, near Stockbridge, where the Bibury Club meeting was held, he established races at Datchet. In the reign of James II. nothing specially noteworthy occurred, but William III. continued former crown donations and even added to them.

Anne was much devoted to horse-racing, and not only gave royal plates to be competed for, but ran horses for them in her own name. In 1703 Doncaster races were established, when 4 guineas a year were voted by the corporation towards a plate, and in 1716 the Town Plate was established by the same authority, to be run on Doncaster Moor. Nearly a century, however, elapsed before the St Leger was instituted. Matches at Newmarket had become common, for we find that Basto, one of the earliest race-horses of whom we have any authentic account, won several matches there in 1708 and 1709. In the latter year, according to Camden, York races were established, the course at first being on Clifton Ings, but it was subsequently removed to Knavesmire, on which the races are now run. In 1710 the first gold cup said to have been given by the Queen, of 60 guineas value, was run for by six year old horses carrying 12 stone each, the best of three 4-mile heats, and was won by Bay Bolton. In 1711 it was increased to 100 guineas. In 1712 Queen Anne's gelding Pepper ran for the Royal Cup of £100 at York, and her Mustard, a nutmeg grey horse, ran for the same prize in 1713. Again in 1714 her Majesty's bay horse Star won a sweepstake of 10 guineas added to a plate of £40 at the same place, in four heats, carrying 11 stone. In 1716 the Ladies' Plate at York for five year olds was won by Aleppo, son of the Darley Arabian. Racing and match making continued to be a regular sport at Newmarket, and at York and Hambleton, and we also find a record of a race at Lincoln in August 1717 for a silver tea-board, won by Brocklesby Betty, as was the Queen's Plate at Black Hambleton in the year before.

Between 1714 and 1720 there were races at Pontefract in Yorkshire for plates or money. The best of two out of three heats was to be the winner, provided the said horse was not distanced in the third heat—the distance post being 1 furlong from the winning post; and this appears to have been a usual condition. In or about the year 1721 Flying Childers is said to have run a trial against Almanzor and Brown Betty over the Round course at Newmarket (3 m. 4 f. 93 y.) in 6 m. 40 s., and another trial over the Beacon course (4 m. 1 f. 138 y.) in 7 m. 30 s.—which is fast even for a six year old; but it is just possible that in those days the art of time-taking was anything but perfect. In 1721 George I. gave 100 guineas in specie in lieu of the gold cup at York presented by Anne, and the king's or queen's plates have been given in cash ever since. In 1725 a ladies' plate was run for on September 14 by female riders on Ripon Heath in Yorkshire. In 1727 Mr John Cheney established the *Racing Calendar*—an historical list of all the horse matches run, and of all plates and prizes run for in England and Wales of the value of £10 or upwards in 1727, &c. No systematic records had till then been preserved of the running of the race-horses of the day, and it is only through the performances of certain celebrated horses and mares that we have any information of what actually took place, and even that is more or less of a fragmentary kind. At this time racing was thoroughly established as a national and popular sport, for there were upwards of a hundred meetings in England and Wales; but the plates or sweepstakes run for were for the most part of small value, as £10, £20, £30, £40, and sometimes £50. In 1727, according to Whyte, there were only a dozen royal plates run for in England:—one at Newmarket in April for six year old horses at 12 stone each, in heats over the Round course—first called the King's Plate course; one for five year old mares at 10 stone each, in one heat, and another in October for six year old horses at 12 stone, in heats over the same course; one at York (which commenced in 1711) for six year old horses, 12 stone each, 4-mile heats; one at Black Hambleton, Yorkshire (of which no regular account was kept until 1715), for five year old mares, 10 stone, 4 miles; one at each of the following places, Nottingham, Lincoln, Guildford, Winchester, Salisbury, and Lewes, for six year old horses, 12 stone each, 4-mile heats; and one at Ipswich for five year old horses, 10 stone each. A royal plate was also run for at Edinburgh in 1728 or 1729, and one at the Curragh of Kildare in 1741.

In 1739 an Act was passed to prevent racing by ponies and weak horses, 13 Geo. II. cap. 10, which also prohibited prizes or plates of less value than £50. At this period the best horses seldom ran more than five or six times, and some not so often, there being scarcely any plates of note except royal ones, and very few sweepstakes or matches of value except at Newmarket until after 1750; moreover, as the races were run in heats, best three out of four, over a course of several miles in length, the task set the horses before winning a plate was very severe, and by no means commensurate with the value of the prize. In 1751 the great subscription races commenced at York, the city also giving £50 added money to each day's racing. At Newmarket there were only two meetings, one in April and the other in October, but in 1753 a second spring meeting was established, and in that year the Jockey Club, which was founded in 1750, purchased the present racing ground. In 1762 a second October meeting was added, in 1765 the July meeting, in 1770 the Houghton meeting, and in 1771 the Craven meeting. In 1766 Tattersall's was established at Hyde Park Corner by Richard Tattersall for the sale of horses; it remained the great emporium of horses, and the rendezvous for betting on horse races, until 1865, when, the lease of the premises at the Corner having run out, it was removed to its present site at Knightsbridge.

We now come to a very important period—that at which the great three year old races were instituted.

The St Leger.

The St Leger was established in 1776 by Colonel St Leger, who resided at Parkhill, near Doncaster. On the 24th September, during the Doncaster races, which took place annually in the autumn, at his suggestion a sweepstake of 25 guineas each for three year old colts and fillies was run over a 2-mile course; there were six competitors, the property of as many subscribers,—a very small beginning, it must be owned. The race was won by a filly by Sampson, belonging to Lord Rockingham, which was afterwards named Allabaculia. In the following year the same stake had twelve subscribers and ten starters, and was won by Mr Sotheron's Bourbon. It was not, however, until the succeeding year, 1778, that it was named the St Leger, in complement to the founder, at the suggestion of the marquis of Rockingham, on which occasion it was won by Mr T. Gascoigne's Hollandaise, another filly; thus at the beginning, as well as a century later, the fillies, from Allabaculia and Hollandaise to Apology and Jannette, owing to the cool season of the year at which it is run, were found capable of taking their own part against the colts in the race. The stakes were increased in 1832 to 50 sovs. each, and the weights have been raised from time to time to keep pace with modern requirements. The Doncaster Cup, a weight for age race for three year olds and upwards, was established in 1801. The course is nearly flat, of an oval or kite shape, about $1\frac{3}{4}$ miles round the town-moor. It has been run in 3 m. 14 s. by three year old horses, carrying 8 st. 10 ℔, and fillies 8 st. 5 ℔.

The Derby and Oaks.

The Derby and Oaks were established in 1779 and 1780, the Oaks in the former and the Derby in the latter year. It is true that in 1730 Epsom races became annual, but the prizes were nothing more than the usual plates run for in heats, the money required being raised by voluntary subscriptions, as well by the owners of booths on the downs as by the parties more immediately interested, whence arose the custom of charges being made by the lord of the manor for permission to erect booths, &c., during the race meetings. On the 14th May 1779 the twelfth earl of Derby originated the Oaks stakes (named after his seat or hunting box "The Oaks" at Woodmansterne), a sweepstake for three year old fillies run on a course $1\frac{1}{2}$ miles long. The race on its inception was won by Lord Derby's bay filly Bridget, bred by himself—her sire being Herod and her dam Jemima. In the following year the earl established a sweepstake of 50 sovs. each, half forfeit, for three year old colts. The distance was then one mile, but it has since been altered to a mile and a half, and is now run on a new course starting on a higher level than before, and joining the old course on the top of the hill. Being a very hilly or up and down course, Epsom is excessively trying to horses not perfectly sound. On the first occasion of the Derby being run it was won by Sir C. Bunbury's chestnut colt Diomed by Florizel, son of Herod, who beat eight opponents, including the duke of Bolton's Bay Bolton and Lord Grosvenor's Diadem. These two races have since been run for regularly every year, the Derby, which before 1839 was run on the Thursday, now taking place on the Wednesday, and the Oaks on the Friday in the same week at the end of May. Two fillies only have won both races, viz., Sir C. Bunbury's Eleanor in 1801 and Mr W. I'Anson's Blink Bonny in 1857, but Deception ran second for the Derby in 1839, and subsequently won the Oaks. The course has been run in 2 m. 43 s. by colts and in 2 m. 44 s. by fillies.

Ascot races. Ascot races, which are held on Ascot Heath, on the confines of Windsor Park, close to the kennels of the royal buckhounds, were established by the duke of Cumberland, uncle of George III., and are patronized by royalty in state or semi-state. They are mentioned in the first *Racing Calendar*, published in 1727, but the races were for the most part plates and other prizes of small importance, though a royal plate for hunters appears to have been given in 1785. The Gold Cup was first given in 1807, and has been regularly competed for ever since, though from 1845 to 1853 inclusive it went by the designation of the Emperor's Plate, the prize being offered by the emperor of Russia. In 1854, during the Crimean war, the cup was again called the Ascot Gold Cup, and was given from the race fund. The Queen's Vase was first given in 1838, and the Royal Hunt Cup in 1843, while in 1865 a new long-distance race for four year olds and upwards was established, and named the Alexandra Plate, after the Princess of Wales.

Goodwood. Goodwood races were established by the duke of Richmond on the downs at the northern edge of Goodwood Park in 1802, upon the earl of Egremont discontinuing races in his park at Petworth. The course is situated in most lovely scenery, about 5 miles from Chichester, with downs and woodlands to the north, and the sea and the Isle of Wight to the south. The races take place at the end of July, on the close of the London season. The Goodwood Cup, the chief prize of the meeting, was first given in 1812; but from 1815 to 1824 inclusive there was no race for it, with the single exception of 1816. Since 1824 it has been competed for annually.

During the latter half of the 18th century horse-racing declined very much in England, and numbers of meetings were discontinued, the wars which took place necessarily causing the change. From the beginning of the 19th century, and especially after the conclusion of the French war in 1815, racing rapidly revived, and many new meetings were either founded or renewed after a period of suspension, and new races were from time to time established. Two Thousand, &c. Among others the Two Thousand Guineas at Newmarket for three year old colts and fillies, and the One Thousand Guineas for fillies, were established in 1809 and 1814 respectively, the Goodwood Stakes in 1823, the Chester Cup and Brighton Stakes in 1824, the Liverpool Summer Cup in 1828, the Northumberland Plate in 1833, the Manchester Cup in 1834, the Ascot Stakes and the Cesarewitch and Cambridgeshire Handicaps at Newmarket in 1839, the Stewards' and Chesterfield Cups at Goodwood in 1840, the Great Ebor Handicap at York in 1843, and, to omit others, the City and Suburban Handicap at Epsom in 1851, and the Lincoln Handicap in 1853. With the exception of the Two Thousand and One Thousand Guineas run for in the spring at Newmarket, which are as it were junior Derby and Oaks, or at any rate public trials for Handicaps. those events, all these races are handicaps, which came into fashion for the following reasons:—

In the early days of racing the plates or stakes were given for competition by horses of not less than five and generally of six years of age, all carrying the same weights, so that if a four year old, as sometimes happened, entered, it took no allowance from its older and more mature opponents, but had to compete with them on even terms, or at a material disadvantage considering the difference in age. We then find that weight for age races were introduced, a specified difference in weight for each year, where all were not of the same age, being conceded by the older horses. As time went on, however, it was found that when well-known winners entered for a race, other competitors withdrew, and sport was spoiled. A remedy was devised in handicapping, that is, in apportioning a table of weights to the competitors, placing the heaviest impost on the best public performers, and lighter weights in a descending scale upon those of lower calibre, in proportion to their known or assumed demerits. The object of course was in theory to place all, both good and bad, on an equal footing,—in other words, so to burden them that on paper they should all be equal and run a dead heat. In practice it is often far otherwise, for the real merits of a horse are frequently kept secret, and he is sent to run in public half trained, with the view of deceiving the handicapper, who then puts on him a lighter weight than he is capable of carrying, and the race and a large stake of money in bets are frequently so won. It is unnecessary to say that handicaps are thus responsible for much of the malpractice which prevails on the turf, and for keeping in training inferior horses otherwise valueless.

No horses of less than three years of age are allowed to run in handicaps, and at present the lowest weight is 5 st. 7 lb, although some years back it was as low as 4 stone, a weight carried to victory in the Chester Cup by Red Deer in 1844. It would be a step in the right direction to raise the minimum to 7 stone, which would not only tend to the improvement of the horses running, but permit abler and stronger jockeys than the present feather-weights to ride.

Two year old racing was established very shortly after the great three year old races, and on a similar footing, that is to say, the competitors carried the same weights, with the exception of a slight allowance for sex,—the July Stakes at the Newmarket midsummer meeting having been founded as early as 1786. The Woodcote Stakes at Epsom succeeded in 1807, the Champagne Stakes at Doncaster in 1823, the Criterion Stakes at the Houghton meeting in 1829, the Chesterfield Stakes at the Newmarket July meeting in 1834, the New Stakes at Ascot in 1843, the Middle Park Plate (or two year old Derby, as it is sometimes called) at the Newmarket second October meeting in 1866, the Dewhurst plate at the Houghton meeting in 1875, and the Richmond Stakes at Goodwood in 1877.

No race is now run over a shorter course than 5 furlongs.

Statistics of racing in Great Britain. The number of races in Great Britain in the year 1879, according to the *Racing Calendar*, was 1626, of which fifty-nine only were of 2 miles and upwards, ten of 3 miles and above, and two of 4 miles. The number of horses competing was 844 two year olds, 633 three year olds, 314 four year olds, and 322 of five years and upwards—in all 2113; and the value of the stakes run for amounted to £380,699. During the same period there were foaled 955 thoroughbred colts and 900 fillies, while 716 mares were barren, 98 slipped their foals, 152 were covered by halfbred horses or not covered at all, and 174 either died or were sent abroad before foaling—the total number of mares on the register being nearly 3000. The horses at the stud who sired the above foals amounted in round numbers to 350.

The following table will show the value of the principal two and three year old races for the last six years:—

	1874.	1875.	1876.	1877.	1878.	1879.
	£	£	£	£	£	£
Two Thousand Guineas	4200	4550	4100	5200	4650	6250
One Thousand Guineas	3050	2350	3100	4750	4500	4200
Derby	5350	4950	5575	6050	5825	7050
Oaks	4375	2925	4300	4150	5000	4425
St Leger	4625	4150	4825	5025	5750	6550
Middle Park Plate	3340	3430	3860	3610	3790	3470

Few handicaps ever reach £2000 in value; but to the Manchester Cup of 1880 the sum of £2000 added money was advertised, being the largest amount ever given to a single race, of course irrespective of the stakes of the individual entries.

In regard to the sums won by individual horses we may instance £18,681 won by Gladiateur as a three year old, and £18,025 by Lord Lyon, both of whom won Guineas, Derby, and St Leger; £17,850 by Formosa, who divided the Two Thousand Guineas, and won the One Thousand, Oaks, and St Leger; £11,755 by Achievement, who took the One Thousand and St Leger, after having won £10,387 as a two year old; and £12,074 by Wheel of Fortune, including the One Thousand and the Oaks, after having taken £7665 as a two year old.

Training. The treatment or training of racers is essentially a trade of itself, for horses intended to run for stakes are either sent, if few in number, to a public training stable, such as those at Newmarket and other places, or else, when numerous, are prepared for their engagements by a private trainer, the treatment in both cases being the same. The usual charge per horse in a public stable is from 2 to 2½ guineas a week, which includes feeding and grooming.

Foreign racing. Racing has made considerable progress in other countries besides Great Britain, notably in France, Germany, and Austria-Hungary, whither some of the very best bred English horses and mares have from time to time been exported to increase the numbers of thoroughbreds reared on the Continent. Thence have been sent to compete in England such horses as Jouvence, Baroncino, Monarque, Dollar, and Flageolet, winners of the Goodwood Cup in 1853, 1855, 1857, 1864, and 1873 respectively; Gladiateur, winner of the Two Thousand Guineas, Derby, and St Leger in 1865; Fille de l'Air, Reine, and Enguerrande, winners of the Oaks in 1864, 1872, and 1876; Mortemer, Henry, Boiard, and Verneuil, winners of the Ascot Cup in 1871, 1872, 1874, and 1878; Chamant, winner of the Two Thousand Guineas in 1877; Sornette and Dutch Skater, winners of the Doncaster Cup in 1870 and 1872; and Rayon d'Or, winner of the St Leger in 1879. From Austria-Hungary have come Kisber, winner of the Derby in 1876, and the unbeaten filly Kincsem, winner of the Goodwood Cup in 1878. In France especially, enormous strides have been made in racing, and, when the superiority of its climate over that of England is considered, it is not surprising that French horses have achieved a fair measure of success in the leading races of the English turf.

American horses have sometimes been sent over to compete in England, but on the whole they have not been very successful, as they have found the English horses too good for them. Their chief successes have been those of Prioress in the Cesarewitch in 1857, of Starke in the Goodwood Cup of 1861, and of Parole in the Newmarket Handicap and the City and Surburban and Metropolitan Stakes at Epsom in 1879.

Steeple-chasing and hurdle-racing. Steeple-chasing and hurdle-racing take place during the winter months, partly in amalgamated meetings of flat and cross-country races, and partly in meetings purely across country and over fences. The chief event is the Liverpool Grand National, run at Aintree towards the close of the hunting season. It dates from 1839, and, though formerly won by well-bred hunters, now commonly falls to thoroughbreds cast off from racing stables as too slow for the flat, as do nearly all the steeple-chases and hurdle-races. Its value averages from £1500 to £1700. There are many meetings in the provinces and in the London district at which steeple-chases and hurdle races are run, but the more important of them are at Croydon, Sandown Park near Esher, Lincoln, Rugby, Warwick, Bristol, &c. The prizes are nearly always won by thoroughbreds. (E. D. B.)

Horse-Racing and Trotting in the United States.

American racing. Horse-racing was indulged in to a limited extent in Maryland and Virginia as early as the middle of the 17th century, particularly in the latter colony. Most of the inhabitants of both were either from the British Isles or were descended from parents who had immigrated from them, and they inherited a taste for the sport. The animals used for this purpose, however, were not highly prized at the time, and the pedigree of not even one of them has been preserved. A horse called Bully Rock by the Darley Arabian out of a mare by the Byerly Turk, granddam by the Lister Turk, great-granddam a royal mare, foaled 1718, is the first recorded importation of a thoroughbred horse into America. He was imported into Virginia in 1730. In 1723 the duke of Bolton bred a mare named Bonny Lass by his celebrated horse Bay Bolton out of a daughter of the Darley Arabian. She became celebrated in England as a brood mare, and was the first thoroughbred mare, according to the records, that was carried to America. This is supposed to have been in or after 1740, as the *Stud-Book* shows she produced in England after 1739 a filly by Lord Lonsdale's Arabian, and subsequently became familiar to the public as the granddam of Zamora. The importations increased very rapidly from this period, and many valuable shipments were made before the war which resulted in a separation of the colonies from the mother country. This acquisition of thoroughbred stock increased the number and value of racing prizes, and extended the area of operations into the Carolinas in the South, and New Jersey and New York in the North. The first race run in South Carolina was in February 1734, for £20. It took place over "the Green," on Charleston Neck. This shows that the earlier races in America were actually on the turf, as they have always been in England. The next year a Jockey Club was organized at Charleston (1735), and a course was prepared, such as those which have since come into general use throughout the States, from which the turf is removed and the ground is made as nearly level as may be. They are generally oval in shape, and a mile in length, with posts a furlong apart. A race of greater distance than one mile is accomplished by traversing the track the necessary number of times to complete the distance prescribed by the conditions of the race.

After the establishment of the government of the United States (1776), the importation of thoroughbred horses from England became quite common, and selections were made from the best stocks in the United Kingdom. This continued and even increased as the country became developed, down to 1840. The following Derby winners, were among those carried into the States:—Diomed, who won the first Derby in 1780; Saltram, winner in 1783; John Bull, winner in 1792; Spread Eagle, winner in 1795; Sir Harry, winner in 1798; Archduke, winner in 1799; and Priam, who won in 1830. The most important and valuable importations, however, proved to be Jolly Roger, Fearnought, Medley, Traveller, and Diomed in the last century, and Glencoe, Leviathan, Tranby, Lexington, Margrave, Yorkshire Buzzard, Albion, and Leamington of the present century. The best results have been obtained from Diomed and Glencoe. Diomed sired one horse, Sir Archy, who founded a family to which nearly all the blood horses of America trace back. He was foaled in 1805, in Virginia, and became celebrated as a sire. The superiority of his progeny was so generally conceded, that they were greatly sought after. From this period, too, the number and value of races increased; still they were comparatively few in number, and could not compare in value with those of Great Britain. Up to 1860 the value of racing prizes was quite inadequate to develop large breeding establishments, or to sustain extensive training stables. During that year the number of races run was about 250, of the estimated value of $100,000 (£20,000). The institution, however, was in a healthy condition, and gained rapidly in public favour, when the civil war between the North and the South broke out, which raged for four years. Breeding establishments were broken up during that time; the horses were taken by the armies for cavalry purposes, for which service they were highly prized; and racing was completely paralysed for that period. It took some time to regain its strength; but an era of prosperity set in, about 1870, and it has since continued to grow and extend the area of its operations, until it has become the chief sport and amusement of the more populous cities of the States.

In 1874 there were 958 races run of the value of $496,772; in 1875, 866 races, of the value of $490,649; in 1876, 782 races, valued at $485,509; in 1877, 907 races, valued at $441,652; in 1878, 1058 races, valued at $461,395; and in 1879, 1221 races were run, of the value of $545,624. In 1877 as many as 1093 horses started; in 1878 there were 1382, and last year 1524. This increase in the value of racing events, and the consequent demand for horses of this class, have stimulated the breeding interests of the country. There are only four prominent breeding establishments which breed and sell the foals produced as yearlings to the public annually. There are, however, a large number of private breeding establishments, some of them nearly or quite as extensive as the public studs. The number of brood mares in the country is about 2100; the stallions number over 300, and the annual number of foals is estimated at about 1400. There are no official records of the produce.

One of the peculiar features of racing in America is that all events are officially timed, and the time is recorded by the clerks of the jockey clubs upon the books of the club. By it the value of different performances by the same or different horses is generally estimated. Of course other elements are considered, such as the weight carried, the age of the horses, the weather, the condition of the track, &c. If a horse of the same age and weight, and over courses of similar conditions, can run a mile a second quicker than another horse, he is regarded as faster at the distance than his rival. The artificial tracks of the country make time a reasonably accurate test when weighed in connexion with other circumstances. Each club has its official timer, who gives the time taken to the clerk as soon as the race is over. The following is the fastest time made at all distances in the United States, down to July 1, 1880:—

Half mile.—Two year olds, $47\frac{3}{4}$ s ; older horses have no record at this distance.
Three quarters of a mile.—Two year olds, 1 m. 15 s.; three year olds, 1 m. $15\frac{1}{4}$ s.; four year olds and upwards, 1 m. 15 s.
One mile.—Two year olds, 1 m. $43\frac{1}{4}$ s.; three year olds, 1 m. $41\frac{3}{4}$ s.; four years and upwards, 1 m. $39\frac{3}{4}$ s.
One mile and a furlong.—Three year olds, 1 m. 54 s.; four years and upwards, 1 m. $55\frac{1}{4}$ s.
One mile and a quarter.—Three year olds, 2 m. $8\frac{1}{2}$ s.; four years and upwards, 2 m. $8\frac{3}{4}$ s.
One mile and a half.—Three year olds, 2 m. 37 s.; four year olds and upwards, 2 m. $34\frac{3}{4}$ s.
One mile and five furlongs.—Three year olds, 2 m. $49\frac{1}{4}$ s.; four years and upwards, 2 m. 53 s.
One mile and three quarters.—Three year olds, 3 m. $5\frac{1}{4}$ s.; four years and upwards, 3 m. 4 s.
Two miles.—Three year olds, 3 m. $30\frac{1}{2}$ s.; four years and upwards, 3 m. $27\frac{1}{2}$ s.
Two miles and a furlong.—Three year olds, 3 m. 50 s ; four years and upwards, 3 m. $45\frac{1}{2}$ s
Two miles and a quarter.—Three year olds, 4 m. 2 s.; four years and upwards, 3 m. $56\frac{1}{4}$ s.
Two miles and a half.—Three year olds, 4 m. $31\frac{3}{4}$ s.; four years and upwards, 4 m. $27\frac{1}{2}$ s.
Two miles and three quarters.—Four year olds and upwards, 4 m. $58\frac{3}{4}$ s.
Three miles.—Three year olds, 5 m. 28 s.; four years and upwards, 5 m. $26\frac{1}{4}$ s.
Four miles.—Three year olds, 7 m. $31\frac{3}{4}$ s. · four years and upwards, 7 m. $15\frac{3}{4}$ s.

(J. R. H.)

American trotting.

Trotting.—The development of speed in the trotting-horse through systematic breeding and training is one of the great industries of the United States of America and the Dominion of Canada, and in no other portion of the world is it pursued to any great extent, except in Russia. This interest, which has attained vast proportions, is entirely the growth of a century, dating back to the importation to Philadelphia from England, in 1788, of the thoroughbred horse Messenger. This was a grey stallion, by Mambrino, 1st dam by Turf, 2d dam by Regulus, 3d dam by Starling, 4th dam by Fox, 5th dam Gipsey, by Bay Bolton, 6th dam by duke of Newcastle's Turk, 7th dam by Byerly Turk, 8th dam by Taffolet Barb, 9th dam by Place's White Turk. He was eight years old when imported to the United States. He was at the stud for twenty years, in the vicinity of Philadelphia and New York, serving a number of thoroughbred mares, but a far greater number of cold-blooded mares, and in the progeny of the latter the trotting instinct was almost invariably developed, while his thoroughbred sons, who became scattered over the country, were also noted for transmitting the trotting instinct. That Messenger was the fountain-head of American trotting is shown by the fact that almost every trotter of merit in that country, whose pedigree is reasonably well established, traces to him in one or more lines, and the more Messenger strains there are in a pedigree the greater is its esteemed value. It was years after the death of Messenger, however, before these facts became apparent ; the taste of the country in racing matters was confined to running contests, and systematic trotting breeding is of much later growth. The first public trotting race of which there is any account in the United States was in 1818, when the grey gelding Boston Blue was matched to trot a mile in 3 minutes, a feat deemed impossible, but he won, though the time of his performance has not been preserved. From about that date, interest in this gait began to increase ; breeders of trotters, in a small way, sprang up, and horses were trained for trotting contests. The problem of breeding trotters has been necessarily found to be a much more complex one than that of breeding the thoroughbred, as in the latter case pure blood lines of long recognized value could be relied upon, while in the former the best results were constantly being obtained from most unexpected sources. At the present day, the leading families are the Hambletonian, of which the modern head was Rysdyk's Hambletonian, a bay horse foaled in 1849, got by Abdallah (traced to imp. Messenger on the side of both sire and dam) out of the Charles Kent mare, by imp. (*i.e.*, imported) Bellfounder, with two crosses to imp. Messenger on her dam's side ; the Mambrinos, whose modern head was Mambrino Chief, foaled 1844, by Mambrino Paymaster, a grandson of imp. Messenger ; the Bashaws, founded by Young Bashaw, foaled 1822, by Grand Bashaw, an Arabian horse, dam Pearl, by First Consul; the Clays, springing from Henry Clay, a grandson of Young Bashaw through Andrew Jackson, and properly a branch of the Bashaw Family, but arbitrary usage, of which there is much in American trotting lineage, makes them distinct ; the Stars, springing from Stockholm's American Star, by Duroc, son of imp. Diomed ; the Morgans, whose founder was Justin Morgan, foaled 1793, by a horse called True Briton, or Beautiful Bay, who was probably thoroughbred ; the Black Hawks, a branch of the Morgan family ; the Blue Bulls, descended from Doyle's Blue Bull, foaled 1855, a pacer, sired by a pacer of the same name, dam by Blacknose, son of Medoc ; the Canadians, whose best representatives were St Lawrence and pacing Pilot, horses of unknown pedigree ; the Gold Dusts, another branch of the Morgan family ; and the Royal Georges, springing from Tippoo, a horse who was probably by Ogden's Messenger, son of imp. Messenger. There are many subordinate branches of these leading families not named here, and in some cases trotters of great speed have been produced which do not trace to any of the sources mentioned. It follows that the breeder has an extensive field before him, and the questions of in-breeding or out-crossing, of the value of thoroughbred crosses, pacing crosses, &c., have to be considered, and are abundantly discussed. There are many large and successful establishments for breeding trotters at the present day. All of them are extensive in acreage, while on several a hundred or more brood mares are kept, besides a number of stallions. As a rule, the stallions do service outside the farms of their owner, but in some cases they are reserved strictly for home use. Very large prices are frequently paid for youngsters, solely on the strength of their breeding. In 1876 $13,000 was paid for two two year old fillies, and $41,200 for a lot of thirteen, nearly all young. Steinway, a three year old colt, was sold in 1879 to go to California, for $13,000; and in 1878 $21,000 was paid for the four year old filly Maud S., after she had trotted a mile in public in 2 m. $17\frac{1}{4}$ s. Much larger sums have been paid, however, for matured trotters, such as $40,000 for the stallion Smuggler, $38,000 for Pocahontas, $35,000 for Dexter, $36,000 for Rarus, and long prices for many others ; St Julien, the trotter with the fastest record at the close of 1879, was held at $50,000, while Rysdyk's Hambletonian, Messenger, Duroc, and Volunteer were valued, in their prime, at $100,000 each.

Since the early days of American trotting, the advance has been rapid and the changes marked. After the performance of Boston Blue, mentioned above, more attention was paid to the gait, but for a long time the races were generally under saddle, and at long distances, 3 miles being rather the favourite. The best of the old time trotters were Edwin Forrest, who trotted a mile in 2 m. $31\frac{1}{2}$ s. in 1834; Dutchman, whose 3 miles under saddle, in 7 m. $32\frac{1}{2}$ s., is still the best on record ; Ripton ; Lady Suffolk, who trotted a mile in 2 m. $26\frac{1}{2}$ s. in 1843, and headed the list of performers; Mac, Tacony, &c. Since 1850, however, the taste of the people has settled upon the style of race called "mile heats, best three out of five, in harness," as the favourite, and nine out of ten contests are of this character. By "in harness" is meant that the horse draws a sulky, a light two-wheeled vehicle in which the driver sits close to the horse, with his legs on each side of his flanks. These sulkies often weigh less than 40 lb. The driver is required to weigh, with the blanket on which he sits, 150 lb, while for saddle races the regulation weight is 145 lb, or 10 st. 5 lb. Each heat of a mile is a separate race ; 20 minutes is allowed between heats ; and the horse that first places three heats to his credit wins the race. There are various penalties imposed upon a horse that breaks into a run in a trotting race. The driver is required to pull him to a trot as quickly as possible ; if the horse gains by running, the judges set him back at the finish twice the distance he has gained, in their estimation, by running ; and for repeated "breaks" they can declare him distanced. The first-class tracks are of oval shape, with long stretches and easy curves, measuring 1 mile at 3 feet distance from the "pole," as the inner railing of the track is called. The time in which the leading horse trots each heat is accurately kept, placed on a blackboard in front of the judges' stand for the information of the public, and also placed in the book of the course. The fastest time that any trotter has is thus entered as his "record." This is one of the distinctive features of trotting in America. The purses that are given by the association owning tracks are generally divided into classes, such as for horses that have never beaten 3 minutes, that have never beaten 2 m. 40 s., 2 m. 20s., &c. Hence it is an object, as a rule, for the record of a trotter to be kept as slow as possible, that he may be eligible to compete in slow classes, and as the purses are divided into three or four monies, and the second money is usually half as large as the first, drivers frequently "pull" a superior animal, and content themselves with an inferior portion of the purse for the sake of avoiding a record, which attaches only to the winner of a heat, and from this cause springs a great deal of dishonest racing. It is in the power of the judges, when they think that a horse is not being driven to win, to substitute another driver, and this is often done.

Prior to 1866 purses for trotters were small ; match races were more in vogue, and the trotting turf was in bad odour. In that year an association was formed at Buffalo, N.Y., which undertook to remedy the evil, and inaugurated its efforts by offering the then unprecedented sum of $10,500 for a trotting meeting of four days' duration. The experiment was successful ; other cities followed the example of Buffalo; larger and larger purses were given; and at Buffalo in 1872 the prizes amounted to $70,000. Twice at this point $20,000 has been given for a single race, a sum nearly equal to an average Derby winning. Other cities are also in the habit of giving large purses, and the amount offered in the United States and Canada, during a single year, has reached nearly $1,500,000. Individual trotters, in the course of a long turf career, earn enormous amounts. The most remarkable instance of this was the mare Goldsmith Maid, by Alexander's Abdallah (a son of Rysdyk's Hambletonian), out of an Abdallah mare. She began trotting in 1866, and left the turf in 1878, when twenty-one years old, and her winnings amounted to over $200,000.

In 1869 the organization now known as the National Trotting Association was formed, and it embraces in its membership all the principal tracks of the continent. All members of this association respect the penalties imposed by any other member, and exclusion from the privileges of one is exclusion from the privileges of all. This has had a great tendency to reform abuses on the trotting turf, enabling severe penalties to be inflicted for infractions of the rules, a very elaborate code of which has been published by the National Trotting Association, and is revised triennially.

In trotting races, it will be noted, the time test is supreme, differing from running races, in which time is of comparatively little consequence. The animal which has the fastest record for 1 mile in harness is, until deposed, the king or queen of the trotting turf. Lady Suffolk, with her record of 2 m. 26½ s., in 1843, held this honour until 1853, when Tacony trotted in 2 m. 25½ s. under saddle; Flora Temple wrested it from him in 1856 by trotting in 2 m. 24½ s. in harness. This latter mare, in 1859, trotted a mile in 2 m. 19¾ s., a feat which the best horsemen thought would never be repeated, but since that time forty-two trotters have beaten 2 m. 20 s. Dexter's record was 2 m. 17¼ s. in 1867, and Goldsmith Maid's in 1871 was 2 m. 17 s., which she reduced, by successive efforts, to 2 m. 16¾ s., 2 m. 16 s., 2 m. 15 s., 2 m. 14¾ s., and finally, in 1874, to 2 m. 14 s. In 1878 Rarus trotted a mile in 2 m. 13¼ s., and in October 1879 the bay gelding St Julien, by Volunteer, son of Rysdyk's Hambletonian, dam by Henry Clay, trotted a mile in California in 2 m. 12¾ s. There is a great diversity of opinion among the best informed horsemen as to the limit of trotting speed, but none fix it slower than 2 m. 10s., while the more sanguine believe that a mile will yet be made by a trotter in 2 minutes. The pacing gait, in which the front and hind legs on the same side are moved in the same direction simultaneously, is admitted to be faster than the trotting, in which the near fore leg and the off hind leg move together, but as pacing is not fashionable, and small purses are given for contests between pacers, a great deal of skill has been expended, of late years, in converting pacers to trotters. This is done by means of toe-weights on the forward feet, which are knobs of brass or iron screwed into the hoof or fastened to the shoe, by means of which a competent trainer can not only change a pacing into a trotting horse, but can correct any errors of gait in a natural trotter. With inveterate pacers very heavy weights have to be used, but these can gradually be lessened as the horse becomes accustomed to the trot. So effective are these weights found that there are very few fast trotters upon whom they are not used to some extent, unless the same object is effected by wearing a very heavy forward shoe.

The market for American trotters is by no means confined to those intending to use them for track purposes. While there are probably ten thousand in training, at least an equal number are used by gentlemen for road purposes; and there is great rivalry among millionaires with a taste for driving to secure the best stable, and especially the fastest double team. In September 1877 Mr W. H. Vanderbilt drove his team, composed of Small Hopes and Lady Mac, a full mile over Fleetwood Park track, near New York city, in 2 m. 23 s., which is 3½ seconds faster than the best record for a mile by a double team, the 2 m. 23 s. performance not being a technical record.

As an indication of the rapid advance that has been made in the general speed of the American trotter, a table recently published in the United States, giving the names of all horses that had trotted 1 mile in harness in 2 m. 25 s., or better, up to the close of 1879, includes 317 performers, and all these, except 25, were living when the table was published. This shows that a 2 m. 25 s. record was a very unusual occurrence only a horse generation since, while now an animal who cannot show that rate of speed is not considered a promising competitor in turf contests.

Every year a book is published containing summaries of all the trotting and pacing events of the preceding year. The record for 1875 showed 3304 events, amount of purses and stakes, $1,418,971; for 1876, 3484 races, $1,078,449; for 1877, 2802, $951,137; for 1878, 2737, $817,629; and for 1879, 2246 races, amount of purses and stakes, $750,000.

We give, in conclusion, a table of the fastest trotting and pacing records, at all distances, ages, and ways of going, complete up to July 1880:—

Trotting in Harness.

One mile—St Julien, Oakland Park, Cal., Oct. 25, 1879, 2 m. 12¾ s., in a first heat.
One mile (second heat)—Rarus, Hartford, Conn., August 23, 1878, 2 m. 13½ s.
One mile (third heat)—Rarus, Buffalo, N.Y., August 3, 1878, 2 m. 13¼ s.
One mile (fourth heat)—Lula, Rochester, N.Y., August 14, 1875, 2 m. 17 s.
One mile (fifth heat)—Smuggler, Cleveland, O., July 27, 1876, 2 m. 17½ s.
One mile (sixth heat)—Goldsmith Maid, Hartford, Conn., Aug 31, 1876, 2 m. 19¾ s.
One mile—Smuggler, Hartford, Conn., August 31, 1876, 2 m. 15¼ s., the fastest heat by a stallion.
Half-mile, by a yearling—Memento, Lexington, Ky., October 10, 1877, 1 m. 30½ s.
One mile, by a two year old—So-So, Lexington, Ky., October 12, 1877, 2 m. 31 s.
One mile, three year old—Jewett, Lexington, Ky., Oct. 15, 1879, 2 m. 23½ s.
One mile, four year old—Trinket, Louisville, Ky, July 10, 1879, 2 m. 19¾ s.
One mile, five year old—Santa Claus, Sacramento, Cal., Sept 11, 1879, 2 m. 18 s.
One mile, over half-mile track—Rarus, Toledo, O., July 20, 1878, 2 m. 16 s.
One mile, fastest two consecutive heats—Rarus, Hartford, Conn., August 23, 1878, 2 m. 13½ s., 2 m 13¾ s.
One mile, fastest three consecutive heats—Rarus, Hartford, Conn., August 23, 1878, 2 m. 15 s., 2 m. 13½ s., 2 m. 13¾ s.
One mile, fastest four consecutive heats—Gloster, Rochester, N.Y., August 14, 1874, 2 m. 18 s., 2 m. 17¾ s., 2 m. 17 s., 2 m. 19 s.,; and Goldsmith Maid, Hartford, Conn., August 31, 1876, 2 m. 16¾ s., 2 m. 17¼ s., 2 m. 18 s., 2 m. 19¾ s. The aggregate times of these two performances are equal.
Two miles—Flora Temple, Eclipse Course, L. I., August 16, 1859, 4 m. 50½ s.
Three miles—Huntress, Prospect Park, Brooklyn, N.Y., Sept 23, 1872, 7 m. 21¼ s.
Four miles—Trustee, Union Course, L. I., June 13, 1849, 11 m 6 s.
Five miles—Lady Mack, San Francisco, Cal., April 2, 1874, 13 m
Ten miles—Controller, San Francisco, Cal., November 23, 1878, 27 m. 28¼ s.
Fifteen miles—Girda, San Francisco, Cal., August 6, 1874, 47 m. 20 s.
Twenty miles—Capt. McGowan, Boston, Mass, 1865, 58 m. 25 s.
Fifty miles—Ariel, Albany, N.Y., 1846, 3 h 55 m. 40½ s.
One hundred miles—Conqueror, Long Island, November 12, 1853, 8 h. 55 m. 53 s.

Trotting to Waggon.

One mile—Hopeful, Chicago, Ill., October 12, 1878, 2 m. 16¾ s., in a first heat.
One mile (second heat)—Hopeful, Chicago, Ill., October 12, 1878, 2 m 17 s.
One mile (third heat)—Hopeful, Chicago, Ill., October 12, 1878, 2 m. 17 s.
One mile, drawing 2000 lb—Mountain Maid, Long Island, 1865, 3 m. 24½ s.
Two miles—Gen. Butler, Long Island, 1863, first heat, 4 m. 56¼ s.; Dexter, Long Island, October 27, 1865, second heat, 4 m. 56¼ s.
Three miles—Kemble, Jackson, June 1, 1853, 8 m. 3 s.
Four miles—Longfellow, California, December 31, 1869, 10 m. 34½ s.
Five miles—Little Mack, Fashion Course, L I., October 29, 1863, 13 m. 43½ s.
Twenty miles—Controller, San Francisco, Cal., April 20, 1878, 58 m. 57 s.
Fifty miles—Spangle, October 15, 1855, 3 h. 49 m. 4 s.

Trotting, Double Teams.

One mile—Gen. Cobb and Lulu May, San Francisco, Cal., 1877, 2 m. 26½ s., in a third heat
One mile, with running mate—Ethan Allen and mate, Fashion Course, L.I., June 21, 1867, 2 m. 15 s., in a first heat.
One hundred miles—Master Burke and Robin, 10 h. 17 m. 22 s.

Trotting under Saddle.

One mile—Great Eastern, Fleetwood Park, N.Y., September 22, 1877, 2 m. 15¾ s.
Two miles—Dexter, Long Island, 1865, 5 m. 0¾ s.
Three miles—Dutchman, Beacon Park, N J., August 1, 1839, 7 m. 32½ s.
Four miles—Dutchman, 1836, 10 m. 31 s.

Pacing.

One mile, in harness—Sleepy Tom, Chicago, Ill., July 25, 1879, 2 m. 12¼ s.
One mile, under saddle—Billy Boyce, Buffalo, N.Y., August 1, 1868, 2 m. 14½ s.
One mile, to waggon—Pocahontas, June 21, 1855, 2 m. 17½ s.
Two miles, under saddle—Bowery Boy, Long Island, 1839, 5 m. 4½ s.
Two miles, in harness—Hero, May 17, 1853, 4 m. 56½ s.
Three miles, under saddle—Oneida Chief, Beacon Park, N.J., 1843, 7 m. 44 s.
Three miles, in harness—Harry White, San Francisco, Cal., August 8, 1874, 7 m. 57¼ s. (W. T. C.)

HORSE-CHESTNUT, *Æsculus*, L. (Germ., *Rosskastanie*; Fr., *marronnier d' Inde*), a genus of trees or shrubs indigenous to North America and mountainous regions in Mexico, New Granada, Persia, North India, and the Malayan peninsula, of the natural order *Sapindaceæ* and suborder *Sapindeæ*, having exstipulate, opposite, digitate, 5- to 9-lobed leaves, an irregular campanulate or tubular 5-lobed calyx, 4 to 5 petals, 5 to 8 stamens, one style, a 3-celled ovary, with 6 ovules, of which 3 or more abort, exalbuminous seeds, and a smooth or echinate coriaceous capsule. The Common Horse-chestnut, *Æ. Hippocastanum*, L., has been stated to be a native of Thibet, and to have been brought thence to England in 1550; it is now, however, thought to be indigenous in the mountains of northern Greece, where it occurs wild at 3000 to 4000 feet above sea-level (*Gard. Chron.*, 1880, i. 488). Matthiolus, who attributes the origin of the name of the tree to the use of the nuts by the inhabitants of Constantinople for the relief of short-windedness and cough in horses,[1] remarks that no ancient writer appears

[1] *Opera quæ extant omnia*, "Comment.," lib. i. cap. cxxii. p. 184, Frankfort, 1598, fol.; *cf.* Gerard, *Herball*, p. 1443, 2d ed., 1633. For other derivations see *Notes and Queries*, 3d ser., x. 452, 523, and *Gard. Chron.*, 1878, ii. 53.

to have made mention of the horse-chestnut. Clusius (*Rariorum plantarum hist.*, lib. i. p. 8, 1601) describes it as a vegetable curiosity, of which in 1588 he had left in Vienna a living specimen, but of which he had not yet seen either the flowers or recent fruit. The dry fruit, he says, had frequently been brought from Constantinople into Europe. The tree grows rapidly; it flourishes best in a sandy, somewhat moist loam, and attains a height of 50 to 60 or more feet, assuming a pyramidal outline. Its boughs are strong and spreading. The buds, conspicuous for their size, are protected by a coat of a glutinous substance, which is impervious to water; in spring this melts, and the bud-scales are then cast off. The leaves are composed of 7 obovate-cuneate radiating leaflets (see vol. iv. p. 112, fig. 115); when young they are downy and drooping. From the early date of its leafing year by year, a horse-chestnut in the Tuileries is known as the "Marronnier du 20 Mars." The flowers of the horse-chestnut, which are white dashed with red and yellow, appear in May, and sometimes, but quite exceptionally, again in autumn (*Gard. Chron.*, 1868, p. 1116); they are very numerous on each rachis, and form a thyrse. Comparatively few of them afford mature fruit. The fruit is ripe in or shortly before the first week in October, when it falls to the ground, and the three-valved thorny capsule divides, disclosing the brown and at first beautifully glossy seeds or nuts, having a resemblance to sweet chestnuts, and commonly three or else two in number. For propagation of the tree, the nuts may be sown either when fresh, or, if preserved in sand or earth, in spring. Drying by exposure to the air for a month has been found to prevent their germination. The cotyledons do not rise to the surface of the soil. Rooks are wont to remove the nuts from the tree just before they fall, and to disperse them in various directions (R. Ellison, *Berwickshire Naturalist*, quoted in *J. of Forestry*, Apr. 1880, pp. 877, 878).

The bark of the horse-chestnut contains a greenish oil, resin, a yellow body, a tannin, $C_{26}H_{24}O_{12}$, existing likewise in the seeds and various parts of the tree, and decomposable into *phloroglucin* and *æsciglyoxalic acid*, $C_7H_6O_3$, also *æsculetin hydrate*, and the crystalline fluorescent compound *æsculin*, of the formula $C_{21}H_{24}O_{13}$ (Rochleder and Schwarz), with which occurs a similar substance *fraxin*, the *paviin* of Stokes (*Q. J. Chem. Soc.*, xi. 17, 1859; xii. 126, 1860), who suggests that its presence may perhaps account for the discrepancies in the analyses of æsculin given by different authors. From the seeds have been obtained starch (about 14 per cent.). gum, mucilage, a non-drying oil, phosphoric acid, salts of calcium, *saponin*, by boiling which with dilute hydrochloric or sulphuric acid *æsculic acid* is obtained, *quercitrin*, present also in the fully developed leaves, *æscigenin*, $C_{12}H_{20}O_2$, and *æsculetin*, $C_9H_6O_4$, which is procurable also, but in small quantity only, from the bark. Rochleder has described as constituent principles of the cotyledons *aphrodæscin*, $C_{52}H_{82}O_{23}$, a bitter glucoside, *argyræscin*, $C_{27}H_{42}O_{12}$, *æscinic acid*, $C_{24}H_{40}O_{12}$, and *queræscitrin*, $C_{41}H_{46}O_{25}$, found also in the leaves. To prepare pure starch from the seeds, Flandin (*Compt. Rend.*, xxvii. 391, 1848; xxviii. 138, 1849) recommends kneading them, when peeled and bruised, in an aqueous solution of $\frac{1}{100}$ to $\frac{1}{60}$ of their weight of sodium carbonate. E. Staffel (*Ann. d. Chem. u. Pharm.*, lxxvi., 1850, p. 379) after drying found, in spring and autumn respectively, 10·9 and 3·38 per cent. of ash in the wood, 8·68 and 6·57 in the bark, and 7·68 and 7·52 in the leaves of the horse-chestnut. The ash of the unripe fruit contains 58·77, that of the ripe kernel 61·74, and that of the green shell 75·91 per cent. of potash (E. Wolff).

The wood of the horse-chestnut is soft, and serves only for the making of water-pipes, for turner's work and common carpentry, as a source of charcoal for gunpowder, and as fuel. Newly cut it weighs 60 ℔, and dry 35 ℔ per cubic foot approximately. The bark has been employed for dyeing yellow and for tanning, and was formerly in popular repute as a febrifuge and tonic. The powder of the dried nuts was at one time prescribed as a sternutatory in the Edinburgh *Pharmacopœia*. It is stated to form with alum-water a size or cement highly offensive to vermin, and with two parts of wheaten flour the material for a strong bookbinder's paste. Infusion of horse-chestnuts is found to expel worms from soil, and soon to kill them if they are left in it (*The Garden*, xiii. 198, 1878). The nuts furthermore have been applied to the manufacture of an oil for burning, cosmetic preparations, and starch (*v. sup.*), and in Switzerland, France, and Ireland, when rasped or ground, to the bleaching of flax, hemp, silk, and wool. In Geneva horse-chestnuts are largely consumed by grazing stock, a single sheep receiving 2 ℔ crushed morning and evening. Given to cows in moderate quantity, they have been found to enhance both the yield and flavour of milk. Deer readily eat them, and, after a preliminary steeping in lime-water, pigs also. For poultry they should be used boiled, and mixed with other nourishment. The fallen leaves are relished by sheep and deer, and afford a good litter for flocks and herds.

One variety of the horse-chestnut has variegated leaves, and another double flowers. Darwin has observed that *Æ. Pavia*, L., the Red Buckeye of North America, exhibits a special tendency, under unfavourable conditions, to be double-blossomed (*Anim. and Pl.*, ii. 168). The seeds of this species are used to stupefy fish. The Scarlet-flowered Horse-chestnut, *Æ. rubicunda*, is a handsome tree, less in height, and having a rounder head than the common form. Another species, possessing flowers with the lower petals white with a red tinge, and the upper yellow and red with a white border, and fruit unarmed, is *Æ. indica*. Among the North American species are the Fœtid or Ohio Buckeye, *Æ. glabra*, Willd., and *Æ. flava*, Ait., the Sweet Buckeye. *Æ. californica*, Nutt., when full-grown and in flower, is a beautiful tree, but its leaves often fall before midsummer.

Chron.*, 1843, pp. 7, 737; 1878, i. 768, 828, and ii. 53; *Technologist*, 1865, p. 3; Asa Gray, *Man. of Bot.*, p. 117, 5th ed., 1872; Brewer and Watson, *Geol. Surv. Calif.*, "Bot." i. 106; ARBORICULTURE, vol. ii. p. 319; and, for the chemistry, Rochleder and Schwarz, *Ann. d. Chem. u. Pharm.*, lxxxvii., 1853, p. 186, and lxxxviii. 356; C. Zwenger, *Ib.*, xc., 1854, p. 63; and Rochleder, *Wien. Akad. Sitzungsber.*, xl., 1860, xlv., 1862, xlviii., 1863, liv.-lvii., 1866-68. (F. H. B.)

HORSE-MACKEREL is the name applied to a genus of fishes (*Caranx*) found in abundance in almost all temperate and especially in tropical seas. The designation "cavalli," given to them by the early Portuguese navigators, and often met with in the accounts of the adventures of the buccaneers, is still in frequent use among the sailors of all nations. Some ninety different kinds are known,—the majority being wholesome food, and some of the species attaining a length of 3 feet and more. The fish to which the name horse-mackerel is applied in Great Britain is *Caranx trachurus*, distinguished by having the lateral line in its whole length armed with large but narrow bony plates. Horse-mackerel are found singly on the coast all the year round, but sometimes they congregate in shoals of many thousands. Although well-flavoured, they are much more frequently used for bait than for food. This species has a most extraordinary range, being found almost everywhere within the temperate and tropical zones of the northern and southern hemispheres.

HORSEMANSHIP. See HORSE, p. 195.

HORSENS, a seaport town of Denmark, in the province of Aarhuus and amt of Skanderborg, is situated at the head of the Horsens-fiord on the east coast of Jutland, and on the railway from Fridericia to Langaa, 25 miles south-west of Aarhuus. It is a well-built town, and contains a Latin school and two market-places. In the neighbourhood there is a large prison. The town possesses a large foundry, machine shops, shipbuilding yards, lime-works, and manufactures of cloth and of woodwares; it has also a good harbour. It is the birthplace of the navigator Vitus Bering or Behring, the discoverer of Behring Straits. The population in 1870 was 10,501.

HORSE-POWER is the name given to the unit in terms of which engineers measure the power of steam-engines, water-wheels, and other prime movers. It is defined to be the rate at which an engine works when it does 33,000 foot-pounds of work per minute, a foot-pound being the amount of work necessary to raise a pound weight a foot high. We must go back to the early history of the steam-engine to discover the reason why this number was adopted. The first steam-engines were employed to drive mills, pumps, and other machinery which had previously been driven by horses; and it seemed natural to express their working-power in terms of the number of horses whose work they were got to accomplish. This led to experiments being made in order to get an estimate of the average working-power of a horse. Several such estimates have been given, all differing considerably from each other; but the one adopted whereby to express horse-power is that obtained by Boulton and Watt from observations on the strong dray horses employed at the London breweries working eight hours a day. They found that a horse was able to go at the rate of $2\frac{1}{2}$ miles per hour and at the same time raise a weight of 150 ℔ by means of a rope led over a pulley. This is easily seen to be equivalent to 33,000 ℔ raised one foot per minute, and hence the number given above. In connexion with this subject it is necessary to distinguish clearly between "horse-power indicated" and "horse-power nominal" as applied to steam-engines. The horse-power indicated is got from an examination of the indicator diagram (see DIAGRAMS, vol vii. p. 152). The area of the closed curve traced on the diagram, or "card" as it is technically called, gives the work done by the steam on the piston during each complete stroke. This divided by the difference between the extreme abscissæ gives the average pressure (p) on the piston. If we multiply this by the area of the piston (A) and by the length of stroke (x), we get the number of foot-pounds of work done during each stroke, and this multiplied by the number (n) of strokes per minute and divided by 33,000 gives the indicated horse-power. Thus—

$$\text{Indicated H.P.} = \frac{pAnx}{33,000}.$$

Nominal horse-power is a purely conventional term adopted by makers of steam-engines, and has no fixed relation to indicated horse-power. The method of calculating it dates from the time of Boulton and Watt. In their engines they supposed the average pressure on the piston to be 7 ℔ on the square inch, and the velocity of the piston in feet per minute to be 128 times the cube root of the length of stroke in feet. Computing from these supposed data, we get the nominal horse-power. Thus—

$$\text{Nominal H.P.} = \frac{7 \times A \times 128 \times \sqrt[3]{x}}{33,000}.$$

The British Admiralty rule for nominal horse-power differs from this in using the actual velocity of the piston instead of the above supposed velocity. These rules only apply to low-pressure engines; for high-pressure engines it is usual, after Bourne, to assume 21 ℔ as the average pressure on the piston, the other data remaining as before. See Rankine's *Steam-Engine*.

HORSE-RACING. See HORSE, p. 199.

HORSERADISH (Ger., *Meerrettig*; Fr., *raifort = racine forte, cran de Bretagne*; Swed., *Peppar-rot*; Russ., *chren*), *Cochlearia Armoracia*, L., a perennial plant of the natural order *Cruciferæ* and tribe *Alyssineæ*, having radical leaves on long stalks, ovate or oval-oblong, 4 to 6 inches broad, about a foot in length, subcoriaceous, crenate or serrate, and coarsely veined; stem-leaves short-stalked or sessile, elongate, and tapering to their attachment, the lower ones often deeply toothed; flowers, which appear in May and June, $\frac{3}{8}$-inch in width, in flat-topped panicles, with sepals purplish, and petals white; and fruit a small silicula, which in the climate of England seldom bears seed. The horseradish is indigenous to eastern Europe. Into western Europe and Great Britain, where it is to be met with on waste ground, it was probably introduced from Russia (De Candolle, *Géogr. Botan.*, ii. 654, 1855). It was wild in various parts of England in Gerard's time. The root, the *armoraciæ radix* of pharmacy, is $\frac{1}{2}$ to 2 inches or more in diameter, and commonly a foot, sometimes 3 feet in length; the upper part is enlarged into a crown, which is annulated with the scars of fallen leaves; and from the numerous irregular lateral branches are produced vertical stolons, and also adventitious buds, which latter render the plant very difficult of extirpation. From the root of ACONITE (*q. v.*, vol. i. p. 98), which has occasionally been mistaken for it, horseradish root differs in being more or less cylindrical from a little below the crown, and in its pale yellowish (or brownish) white hue externally, acrid and penetrating odour when scraped or bruised, and pungent and either sweetish or bitter taste (see Bentley, *Pharm. Journ.*, 1st ser., xv. 449, 1856). The fresh root yields on distillation with water about ·05 per cent. of a volatile oil identical with that of black mustard, resulting from the mutual reaction of sinigrin (potassium myronate) and myrosin in the presence of the water. After drying, the root has been found to afford 11·15 per cent. of ash. Horseradish root is an ingredient in the *spiritus armoraciæ compositus* of the British Pharmacopœia. It possesses stomachic, diaphoretic, and diuretic properties, and hence is administered in atonic dyspepsia, chronic rheumatism, and dropsies. As a masticatory, or in the form of syrup or infusion, it is used for hoarseness. Gerard speaks of it as anthelmintic and emetic. Externally applied it acts as a rubefacient; and the juice with vinegar is a popular remedy for freckles. In common with other species of *Cochlearia*, the horseradish was formerly in high repute as an antiscorbutic. The root was, as well as the leaves, taken with food by the Germans in the Middle Ages, whence the old French name for it, *moutarde des Allemands*; and Coles, writing in 1657, mentions its use with meat in England, where it is now chiefly employed as a condiment with beef. For the successful cultivation of the horseradish, a light and friable damp soil is the most suitable; this having been trenched 3 feet deep in autumn, and the surface turned down with a liberal supply of farm-yard manure, a second dressing of decomposed manure should in the ensuing spring be dug in 2 feet deep, and pieces of the root 6 inches in length may then be planted a foot apart in narrow trenches. During summer the ground requires to be kept free of weeds; and the application of liquid manure twice or thrice in sufficient quantity to reach the lowest roots is an advantage. When dug the root may be long preserved in good condition by placing it in sand. The horseradish tree is the *Moringa pterygosperma* of Gärtner.

See Gerard, *Herball*, p. 240, ed. Johnson, 1636; Syme, *Sowerby's Eng. Bot.*, i. 183, pl. cxxix., 1863; *Florist*, 1875, p. 191; *Floral World*, 1879, p. 149; Flückiger and Hanbury, *Pharmacographia*, p. 71, 2d ed., 1879; Bentley and Trimen, *Med. Pl.*, i. 21, 1880.

HORSETAIL, *Equisetum*, the sole genus of the natural order *Equisetaceæ*, consists of a group of vascular cryptogamous plants remarkable for its resemblance in general appearance to the phanerogamic genera *Casuarina* and *Ephedra*. The stem is jointed, consisting of numerous easily separable tubular sheaths toothed at the apex, and is generally furnished with whorls of similar but more slender branches. The fructification is borne at the apex of the stem in the form of a dense oval, oblong, or cylindrical spike, consisting of a number of shortly-stalked peltate scales, each of which has attached to its under surface a circle of spore cases. These open by a longitudinal slit on their inner side. The spores differ from those of ferns in their outer coat being split up into four club-shaped hygroscopic threads or elaters, which are curled when moist, but become straightened when dry. The apparent roots consist of underground stems, any portion of which broken off is capable of producing a new plant; hence the difficulty of eradicating them when once established. There are 25 known species of the horsetail, and the genus is universally distributed.

The Corn Horsetail, *E. arvense*, L., one of the commonest species, is a troublesome weed in clayey cornfields. The fructification appears in March and April, terminating in short unbranched stems. It is said to produce diarrhœa in such cattle as eat it. The Bog Horsetail, *E. palustre*, is said to possess similar properties. It grows in marshes, ditches, pools, and drains in meadows, and sometimes obstructs the flow of water with its dense matted roots. The fructification in this species is cylindrical, and in that of *E. limosum*, L., which grows in similar situations, it is ovate in outline. The largest British species, *E. maximum*, L., grows in wet sandy declivities by railway embankments or streams, &c., and is remarkable for its beauty, due to the abundance of its elegant branches and the alternately green and white appearance of the stem. In this species the fructification is conical or lanceolate, and is found in the month of April, on short stout unbranched stems, which have large loose sheaths. Horses appear to be fond of this species, and in Sweden it is stored for use as winter fodder. *E. hyemale*, L., commonly known as the Dutch rush, is much more abundant in Holland than in Britain; it is used for polishing purposes, and also in medicine by homœopathic practitioners. *E. variegatum*, Sch., grows on wet sandy ground, and serves by means of its fibrous roots to bind the sand together. The horsetails are remarkable for the large quantity of silica they contain, which often amounts to half the weight of the ash yielded by burning them, and the roots contain a quantity of starch.

HORSHAM, a parliamentary borough and market-town of Sussex, England, is pleasantly situated in the midst of a fertile country near the source of the Arun and on the Mid-Sussex Railway, 37½ miles south of London. It consists chiefly of two streets crossing each other at right angles, and a picturesque causeway leading to the church, adorned with rows of trees. Within recent years the town has undergone great improvements, and it now possesses well-paved streets and some handsome buildings. In the vicinity there are several fine mansions. Works were erected in 1865 for supplying the town with water from a well in the neighbourhood. The principal buildings are the parish church, often repaired, and in 1865 entensively restored, a very ancient structure in the Early English style, with the remains of Norman work, having a lofty tower surmounted by a spire, and containing several fine monuments and tombs, and two brasses; the grammar school, founded in 1540 and rebuilt in 1840, recommended to be used as a middle class school by the Endowed Schools Commission; the corn exchange, erected in 1766 in the Italian style, with a room for assemblies and public meetings; the Roman Catholic chapel of St John in the Early English style, erected in 1866 at the cost of the duchess of Norfolk. A school board was formed in 1873, which, besides having the management of most of the schools previously existing, has erected new buildings in the east end of the town, at a cost of above £4000. There are a number of small charities, and almshouses were founded in 1842 by the Rev. Jarvis Kenrick. The town possesses a tannery, a foundry, a carriage factory, and several flour-mills. The area of the parish and parliamentary borough is 10,741 acres, and the population in 1871 was 7831.

There is a tradition which derives the name of Horsham from Horsa the brother of Hengist, who is said to have been slain in the vicinity; others derive it from *horsham*, the horses' meadow; but the most probable derivation is Hurst-Ham or the Ham (village) in the Hurst (forest). The town is a borough by prescription, and returned two members to parliament from the 23d year of the reign of Edward I. to the 2d of William IV., when it was deprived of one of its members. It has never been incorporated, and it is now governed by a local board.

HORSLEY JOHN (*c.* 1685–1732), a distinguished antiquary of the last century, the date and place of whose birth as well as his parentage are uncertain. The late Rev. John Hodgson, the historian of Northumberland, in a short memoir of him published in 1831, countenances the belief that he was born in 1685, at Pinkie, in the parish of Inveresk and county of Midlothian. This statement he reconciles with Horsley's subsequent history, by supposing that his father was a Northumberland Nonconformist, who had migrated to Scotland during the reign of Charles II. or James II., but returned to England soon after the Revolution of 1688. On the other hand, Mr J. H. Hinde, in "Notes" on the life of Horsley, printed in the *Archæologia Æliana* for February 1865, leans to the opinion that he was a native of Newcastle-on-Tyne, and the son of Charles Horsley, a member of the Tailors' Company of that town, an opinion to which colour is given by some expressions of Horsley's own in the *Britannia Romana*.

Horsley undoubtedly received his early education at the grammar school of Newcastle, and completed it at the university of Edinburgh, where he was admitted to the degree of master of arts on the 29th of April 1701. For years afterwards nothing seems to be known of him, though some of them must have been given to the study of theology in connexion with the body of dissenters to which he belonged. There is some evidence tending to show that Horsley "was settled in Morpeth as a Presbyterian minister as early as 1709." Mr Hodgson, however, thinks that up to 1721, at which time he was residing at Widdrington, "he had not received ordination, but preached as a licentiate." Even if he was ordained then his stay at the latter place was probably prolonged beyond that date; for he communicated to the *Philosophical Transactions* notes on the rainfall there in the years 1722 and 1723. Mr Hinde also shows that during these years, in addition to his other duties, whatever their nature, "he certainly followed a secular employment as agent to the York Buildings Company, who had contracted to purchase and were then in possession of the Widdrington estates." Soon after settling at Morpeth, Horsley began to supplement his professional income, probably slender, by opening a private school. The enterprise was successful. Respect for his character and abilities attracted pupils irrespective of religious connexion, one of them becoming afterwards Dean of Westminster. He likewise found time to give courses of lectures on mechanics and hydrostatics in Morpeth, Alnwick, and Newcastle; and it was doubtless in recognition of his scientific tastes and attainments that he was elected on the 23d April 1730 a Fellow of the Royal Society.

It is, however, in connexion with his archæological researches that John Horsley is now so well and so honourably known, though strangely enough no place appears to have been hitherto found for his name in such works as the present. Among those who have investigated the traces left by the Romans of their presence in Britain he stands, and must ever stand, as in many respects the foremost. His great work, *Britannia Romana, or the Roman Antiquities of Britain* (London, 1732), one of the scarcest and most valuable of its class, contains the result of an amount of patient labour in this extensive field that in the case of a man in his position is truly marvellous. Nor was the acuteness of his intellectual powers less remarkable; for so accurately were his researches conducted and so solid was the judgment he brought to bear upon them that a century and a half of subsequent inquiry has invalidated only a few of the conclusions he came to.

Horsley died suddenly, of apoplexy, on the 12th of January 1732, his constitution having been in all likelihood prematurely worn out by the toil he had undergone in the composition of the *Britannia Romana*, then on the eve of publication. The following extract from the burial register of the parish of Morpeth gives the date of his interment: "173½, Jan. 15, Mr John Horsley;" but the site of his grave is unknown. Besides the *Britannia Romana*, Horsley published two sermons and a hand-book to his lectures on mechanics, &c. He also projected a history of Northumberland and Durham, collections for which were found among his papers. By his wife, a daughter of the Rev. William Hamilton, D.D., minister of Cramond, afterwards professor of divinity in the university of Edinburgh, he had one son and two daughters.

HORSLEY, Samuel (1733–1806), a learned Anglican prelate, was born in London in 1733. Entering Trinity College, Cambridge, he became LL.B. in 1758 without graduating in arts, and in the following year succeeded his father in the living of Newington Butts in Surrey. Horsley was elected a Fellow of the Royal Society in 1767; but, in consequence of a difference with the president, he withdrew from it in 1784. He had been secretary since 1773. In 1768 he attended the eldest son of the earl of Aylesford to Oxford as private tutor; and, after receiving through the earl and Bishop Lowth various minor preferments, which by dispensations he combined with his first living, he was installed in 1781 as archdeacon of St Albans. In 1774 the university of Oxford conferred on him the degree of LL.D. Whilst archdeacon, Horsley entered upon his famous controversy with the Socinian, Dr Priestley, who denied that the early Christians held the doctrine of the Trinity. In this controversy, conducted on both sides in the fiercest polemical spirit, Horsley showed the superior learning and ability. His aim was to lessen the influence which the prestige of Priestley's name gave to his views, by proving from his writings the latter's incompetence through ignorance to form an authoritative judgment on the disputed points. For the energy displayed in the contest Horsley was rewarded by Lord Chancellor Thurlow with a prebendal stall at Gloucester; and in 1788 the same patron procured his promotion to the episcopal see of St David's. As a bishop, Horsley was energetic both in his diocese and in parliament. The efficient support which he afforded the Government in the latter place was acknowledged by his successive translations to Rochester in 1793, and to St Asaph in 1802. With the bishopric of Rochester he held the deanery of Westminster. He died at Brighton on October 4, 1806.

Besides the controversial *Tracts*, which appeared in 1783-84-86, and were republished in 1789 and 1812, Horsley's more important works are:—*Apollonii Pergæi Inclinationum Libri duo*, 1770; *Remarks on the Observations . . . for determining the acceleration of the Pendulum in Lat.* 70° 51′, 1774; *Isaaci Newtoni Opera quæ extant Omnia*, with a commentary, 5 vols. 4to, 1779–84; *On the Properties of the Greek and Latin Languages*, 1796; *Disquisitions on Isaiah* xviii., 1796; *Hosea, translated from the Hebrew, with Notes*, 1801; *Elementary Treatises on . . . . Mathematics*, 1801; *Euclidis Elementorum Libri priores XII.*, 1802; *Euclidis Datorum Liber*, 1803; *Virgil's Two Seasons of Honey*, &c., 1805; and papers in the *Philosophical Transactions* from 1767 to 1776. Since his death have appeared—*Sermons*, 1810–12; *Speeches in Parliament*, 1813; *Book of Psalms, translated with Notes*, 1815; *Biblical Criticism*, 1820; *Collected Theological Works*, 6 vols. 8vo, 1845. See Nichol's *Literary Anecdotes*, vol. iv.

HORSLEY, William (1774–1858), an English musician of considerable reputation, was born November 15, 1774, and became in 1790 the pupil of Theodore Smith, an indifferent musician of the time, who, however, taught him sufficient to obtain the position of organist at Ely Chapel, Holborn. This post he resigned in 1798, to become organist at the Asylum for Female Orphans, as assistant to Dr Callcott, with whom he had long been on terms of personal and artistic intimacy, and whose eldest daughter he married. In 1802 he became his friend's successor upon the latter's resignation. Besides holding this appointment he became in 1812 organist of Belgrave Chapel, Halkin Street, and in 1837 of the Charter House. He died June 12, 1858. Horsley's compositions are numerous, and include amongst other instrumental pieces three symphonies for full orchestra. Infinitely more important are his glees, of which he published five books, besides contributing many detached glees and part songs to various collections. Mr Barrett, in his lecture on "English glee and madrigal writers," calls Horsley "one of the princes amongst glee writers," and attributes to him "a fine and powerful dramatic aim and an elegant taste." Horsley's compositions are moreover distinguished by a remarkable purity of style, which sometimes verges on pedantry. His glees, "By Celia's arbour," "O nightingale," "Now the storm begins to lower," and others, are amongst the finest specimens of this peculiarly English class of compositions. Horsley's son (Charles Edward), born in 1822, enjoyed a certain reputation as a musician. He studied in Germany under Hauptmann and Mendelssohn, and on his return to England composed several oratorios and other pieces, none of which had permanent success. In 1868 he emigrated to Australia. He died March 2, 1876, at New York.

HORTEN (Karljohanswærn), a seaport town of Norway, in the amt of Jarlsberg-Laurvig, is beautifully situated on the west bank of the Christiania fjord, opposite Moss, and 32 miles south of Christiania. It is defended by strong fortifications, is the headquarters of the Norwegian fleet, and possesses an arsenal and shipbuilding yards, as well as a real school, a national school of the higher grade, an observatory, a nautical museum, and an infirmary. It also carries on a considerable shipping trade. The population, which in 1836 did not exceed 200, was 5457 in 1875.

HORTENSE (1783–1837), queen of Holland, is familiarly known as La Reine Hortense. Her proper name was Eugénie Hortense de Beauharnais, and she was the only daughter of Alexandre de Beauharnais and Josephine Tascher de la Pagerie. She was born on the 10th of April 1783. When four years old she accompanied her mother to Martinique, and returned with her three years later to be subjected to all the dangers of the Revolution. For a time she was sent with her brother to England, but soon returned. The marriage of her mother to Napoleon Bonaparte naturally altered her prospects altogether, and, as she grew to woman's estate, several marriages of more or less importance were proposed for her. It suited the first consul, however, that she should marry his brother Louis, and despite her tears and entreaties the marriage was concluded. In one of his moments of brutal frankness Napoleon confessed that his brother as a husband was "insupportable," though he characteristically proceeded to charge Hortense with having been the cause of his own misfortunes in not agreeing with her husband. Louis it appears was sincerely anxious to please his young wife. But his health was bad and his temper gloomy, while Hortense was exceptionally lively and fond of gaiety. The natural consequence was an infinity of scandal, some of it of a very grave character. The recent publication of Madame de Rémusat's memoirs has, however, gone far to exonerate Hortense. The writer, equally outspoken and well informed, gives instances of the most fantastic and disgusting exercise of conjugal tyranny on Louis's part, and denies that his wife in any way misconducted herself, the malignant jealousy of the Bonaparte sisters being credited with the accusation. Within seven years of her marriage Hortense had three children, whose nomenclature, unless carefully studied, is somewhat puzzling. The eldest, Napoleon-Louis-Charles, was born in 1802 and died in 1807. The next, Napoleon-Louis, was born in 1804 and died in 1831. The third, Charles-Louis-Napoleon, was born in 1807, and lived to be the late emperor Napoleon III. When Napoleon distributed crowns to his relations Hortense was very anxious that her husband should receive that of Italy. Holland, however, fell to his share, and the ill-matched pair retired thither. The death of her eldest son made Holland intolerable to Hortense, and before long she returned to Paris and established herself in the Rue Cerutti. Nor did she from that time forward ever live in any regular fashion with her husband, whose forced abdication of his crown soon followed. In Paris she was more popular than respected, and her leisure time was filled up with many quasi-literary and artistic employments. It was there that she signalized herself by composing among other airs the famous melody of *Partant pour la Syrie.* The ineffable silliness of the words of this song is not due to her, but to a certain M. de Laborde; and it is only fair to say that it took Frenchmen twenty years to find out that the air was ugly, and that it was possibly stolen. Hortense continued even after her mother's divorce to exercise a certain influence over her stepfather. At the first Restoration she was confirmed in her title and possessions as Duchesse de Saint-Leu. But she ardently welcomed the returning emperor, and thenceforward France was hardly a residence for her, while her private life was disturbed by constant and indecent bickerings with her husband about the custody of her children. She bought a house at Arenenberg on the Lake of Constance and another at Augsburg, for the sake of educating her sons, and from time to time she undertook various journeys in the hope of furthering their interests. The Revolution of July gave her some chance of returning to France, but immediately afterwards grave misfortunes overtook her. Her sons took part in the Italian risings, and the elder died of measles. Scarcely had she recovered from this when the Strasburg attempt was made against her advice. She lived long enough to see the future emperor return from America, and died at Arenenberg on the 3d October 1837. Generally speaking, Hortense appears to have been an amiable woman, whose life was spoilt by the tyrannical egotism of her stepfather. She seems, however, to have been unduly given to intrigue; and she herself admitted that she might have lived on better terms with her husband, upon whom she was forced almost as much as he was forced on her.

HORTENSIUS, Quintus, was one of the first and most famous orators at the Roman bar in the latter days of the republic, when the orator's art was particularly flourishing and was diligently cultivated. His father had been governor of Sicily, and had left behind him a good name for justice and uprightness. He was himself born in 114 B.C., and he lived to the year 50 B.C., so that his life and career ran parallel to that of Cicero, whose senior he was by only eight years. He had the best possible introductions into public life, and at the age of nineteen he made his first speech at the bar, and shortly afterwards successfully conducted the defence of a petty king of Bithynia, one of Rome's many dependants in the East. From that time his reputation as an eloquent advocate was decisively established. As the son-in-law of Catulus he was attached to the aristocratical party of which Sulla was the head, and among his clients he numbered several of its most eminent members. During Sulla's ascendency the courts of law were under the control of the senate, the judges being themselves senators. To this circumstance perhaps as well as to his own merits Hortensius may have been indebted for much of his success. Many of his clients were the governors of provinces which they were accused of having plundered, and such men were generally sure to find themselves brought before a somewhat lenient or even friendly tribunal, one, too, which was shamefully accessible to corruption. Hortensius himself, according to Cicero, was not ashamed to avail himself of this disgraceful weakness, and a good deal of the plunder which his clients had got from the provincials went into the pockets of the judges. Cicero made this statement in open court, and we are thus driven to assume that it must have had some foundation.

Hortensius, like other eminent Roman citizens, passed through the regular succession of public offices, rising from the quæstorship in 81 to the consulship in 69 B.C. In the year before his consulship he came into collision with the now rapidly rising eloquence of Cicero in the memorable case of Verres, and from that time his supremacy at the bar was shaken. In fact his younger rival stepped into his position. Cicero's success against a man who was backed up by all the influence of Sulla's party was a splendid triumph, and it must have been a heavy blow to Hortensius. Shortly afterwards he was again pitted against Cicero, and again failed. In 67 a proposal was made to supersede Lucullus in his command in the East against Mithradates in favour of Pompeius. This was supported by Cicero, and was successfully carried in face of the opposition of Hortensius. From the year 63 B.C., the famous year of Cicero's consulship and of the Catiline conspiracy, we find the two great rivals often associated together as counsel in the same case. The fact was that Cicero was now himself drawn towards the aristocratical party,—the party of Hortensius. Consequently, in the many cases which had more or less of a political complexion as arising out of the disorder and turbulence incident to party quarrels, it was natural that the two men should have the same sympathies and be engaged on the same side. So it happened, for example, in the case of Licinius Murena, whom Cicero defended along with Hortensius against a charge of bribery in canvassing for the consulship. And so strongly declared was his sympathy with Milo against Cicero's bitter enemy Clodius that he was nearly murdered by some of Clodius's gang. After Pompeius's return from the East in 61 B.C., and the political revolution which for a time united him with Cæsar, Hortensius withdrew from public life and devoted himself exclusively to his profession. For nine more years he was in continual employment as an advocate, and won a number of verdicts. In 50 B.C., the last year of his life, he defended successfully one Appius Claudius against Dolabella, Cicero's son-in-law, who prosecuted the man on a serious charge of bribery.

None of Hortensius's speeches have come down to us; and it was, it seems, only on special occasions that he wrote them. Almost all our knowledge of him is derived from Cicero. He was undoubtedly a highly-gifted and accomplished man, and though of course he owed his very early success to his great connexions, yet he was perfectly well able to stand on his own conspicuous merits. His eloquence perhaps was not quite of the highest order;—it was not for the most part what Cicero called "gravis," weighty, dignified, impressive; there was, it may be presumed, an absence of those appeals to great moral principles which give such grandeur to the best speeches of Cicero and Demosthenes, and of our own Burke. His oratory, according to his great rival, was of the Asiatic style, by which appears to be meant a florid rhetoric, better to hear than to read. He had the gift of a marvellously tenacious memory, and could retain every single point in his opponent's argument. His action was highly artificial, and even his manner of folding his toga was noted by eminent tragic actors of the day, and is left on record by Macrobius. He had, too, a fine musical voice, which he could skilfully command.

Cicero sometimes speaks of Hortensius very favourably, and even almost affectionately, though it would appear from some passages in his letters that he never quite trusted him. He could not have thought him a high-principled man, as he openly charged him with bribery, and as he actually mentions a case in which he claimed property under a will which he knew to be a forgery (*De Officiis*, iii. 18). Hortensius, in fact, seems to have been a lax, easygoing, clever man, with very little noble ambition and very little real moral worth. "An amiable Epicurean" is a phrase which describes him not unfairly. The anecdotes we have about him all point to a man of luxurious tastes and a great capacity for enjoyment. The vast wealth he had accumulated during forty-four years of successful practice he spent after the fashion of rich Roman nobles, in splendid villas, in parks, in fish ponds, and costly entertainments. He left his heir an unusually well-stocked cellar of wine, and his park at Laurentum abounded in every variety of game. He was also a great buyer of pictures and works of art. With true consistency he opposed Pompeius and Crassus when they proposed their sumptuary law. He is said to have spoken wittily on the occasion; he was at any rate successful.

There is a good account of Hortensius in Dunlop's *Roman Literature* (ii. 222), and in Smith's *Dictionary of Greek and Roman Biography* his life and career are traced as thoroughly as the materials at our disposal allow. (W. J. B.)

HORTICULTURE

HORTICULTURE embraces both the art and the science of the cultivation of garden plants, whether for utilitarian or for decorative purposes. The subject naturally divides itself into two sections, which we here propose to treat separately, commencing with the science, and passing on to the practice of the cultivation of flowers, fruits, and vegetables as applicable to the home garden.

Part I.—Principles or Science of Horticulture.

Horticulture, apart from the mechanical details connected with the maintenance of a garden and its appurtenances, may be considered as the application of the principles of vegetable physiology to the cultivation of plants. The lessons derived from the abstract principles enunciated by the physiologist, the chemist, and the physicist require, however, to be modified to suit the special circumstances of plants under cultivation. The necessity for this modification arises from the fact that such plants are subjected to conditions more or less unnatural to them, and that they are grown for special purposes which are at variance, in degree at any rate, with their natural requirements.

The life of the plant makes itself manifest in the processes of growth, development, and reproduction. By growth is here meant mere increase in bulk, and by development the series of gradual modifications by which a plant originally simple in its structure and conformation becomes eventually complicated, and endowed with distinct parts or organs. The reproduction of the higher plants takes place either asexually by the formation of buds or organs answering thereto, or sexually by the production of an embryo plant within the seed. The conditions requisite for the growth, development, and reproduction of plants are, in general terms, exposure, at the proper time, to suitable amounts of light, heat, and moisture, and a due supply of appropriate food. The various amounts of these needed in different cases have to be adjusted by the gardener, according to the nature of the plant, its "habit" or general mode of growth in its native country, and the influence to which it is there subjected, as also in accordance with the purposes for which it is to be cultivated, &c. It is but rarely that direct information on all these points can be obtained; but inference from previous experience, especially with regard to allied vegetable forms, will go far to supply such deficiencies. Moreover, it must be remembered that the conditions most favourable to plants are not always those to which they are subjected in nature, for, owing to the competition of other vegetable forms in the struggle for existence, liability to injury from insects, and other adverse circumstances, plants may actually be excluded from the localities best suited for their development. The gardener therefore may, by modifying, improve upon the conditions under which a plant naturally exists. Thus it frequently happens that in our gardens flowers have a beauty and a fragrance, and fruits a size and savour denied to them in their native haunts. It behoves the judicious gardener, then, not to be slavish in his attempts to imitate natural conditions, and to bear in mind that such attempts must sometimes necessarily be failures. The most successful gardening is that which turns to the best account the plastic organization of the plant, and enables it to develop and multiply as perfectly as possible. Experience, coupled with observation and reflexion, as well as the more indirect teachings of tradition, are therefore of primary importance to the practical gardener.

We propose here to notice briefly the several parts of a flowering plant, and to point out the rationale of the cultural procedures connected with them.

The Root.—The root, though not precluded from access of air, is not directly dependent for its growth on the agency of light. The efficiency of drainage, digging, hoeing, and like operations is accounted for by the manner in which they promote aeration of the soil, raise its temperature, and remove its stagnant or superfluous moisture. Owing to their growth in length at, or rather in the immediate vicinity of, their tips, roots are enabled to traverse long distances by surmounting some obstacles, penetrating others, and insinuating themselves into narrow crevices. As they have no power of absorbing solid materials, their food must be of a liquid or gaseous character. It is taken up from the interstices between the particles of soil exclusively by the finest subdivisions of the fibrils, and in many cases by the extremely delicate thread-like cells which project from them, and which are known as root-hairs. The number and density of these latter are in direct proportion to the abundance and suitability of the food of the plant. The importance of the root-fibres, or "feeding roots," justifies the care which is taken by every good gardener to secure their fullest development, and to prevent as far as possible any injury to them in digging, potting, and transplanting, such operations being therefore least prejudicial at seasons when the plant is in a state of comparative rest.

Root-Pruning and Lifting.—In apparent disregard of the general rule just enunciated is the practice of root-pruning fruit trees, when, from the formation of wood being more active than that of fruit, they bear badly. The contrariety is more apparent than real, as the operation consists in the removal of the coarser roots, a process which results in the development of a leash of fine feeding roots. Moreover, there is a generally recognized quasi-antagonism between the vegetative and reproductive processes, so that, other things being equal, anything that checks the one helps forward the other.

Watering.—So far as practical gardening is concerned, feeding by the roots after they have been placed in suitable soil is confined principally to the administration of water and, under certain circumstances, of liquid manure; and no operations demand more judicious management. The amount of water required, and the times when it should be applied, vary greatly according to the kind of plant and the object for which it is grown, the season, the supply of heat and light, and numerous other conditions, the influence of which is to be learnt by experience only. The same may be said with respect to the application of manures. The watering of pot-plants requires especial care. Water should as a rule be used at a temperature not lower than that of the surrounding atmosphere, and preferably after exposure for some time to the air.

Bottom-Heat.—The "optimum" temperature, or that best suited to promote the general activity of roots, and, indeed, of all vegetable organs, necessarily varies very much with the nature of the plant, and the circumstances in which it is placed, and is ascertained by practical experience. Artificial heat applied to the roots, called by gardeners "bottom-heat," is supplied by fermenting materials, dung, tan, flues, or hot-water pipes. In some cases solar heat is as it were entrapped by placing beneath the roots substances such as bricks, the heat previously absorbed by which is slowly radiated. In winter the temperature of the soil, out of doors, beyond a certain depth is usually higher than that of the atmosphere, so that the roots are in a warmer and more uniform medium than are the upper parts of the plant. Often the escape of heat from the soil is prevented by "mulching," *i.e.*, by depositing on it a thick layer of litter, straw, dead leaves, and the like.

The *Stem* and its subdivisions or branches lengthen, not only near the tip, but also lower down, by intercalary growth. They upraise to the light and air the leaves and flowers, and serve as channels for the passage to them of fluids from the roots, and they act as reservoirs for nutritive substances. Their functions in annual plants cease after the ripening of the seed, whilst in plants of longer duration layer after layer of strong woody tissue is formed, which enables them to bear the strains which the weight of foliage and the exposure to wind, &c., entail. The gardener aims usually at producing stout, robust, short-jointed stems, instead of long lanky growths defective in woody tissue. To secure these conditions free exposure to light and air is requisite, but in the case of coppice woods, or where long straight spars are needed by the forester, plants are allowed to grow thickly so as to ensure development in an upward rather than in a lateral direction. This and like matters will, however, be more fitly considered in dealing hereafter with the buds and their treatment.

Leaves.—The work of the leaves may briefly be stated to consist in the processes of nutrition and of respiration. Nutrition by the leaves includes the inhalation of air, and the combination, under the influence of light and in the presence of chlorophyll, of carbon from the carbonic acid gas in the air with hydrogen from the watery vapour it contains, oxygen being exhaled. There is also a process of true respiration, in which atmospheric oxygen unites with a portion of the carbon in the plant, and is evolved as carbonic acid gas.

Syringing, &c.—In certain circumstances water is absorbed by the surface of leaves, especially when the supply of moisture at the root is defective, and when by too long exposure to drought the watery constituents of the plant have evaporated. A certain amount of evaporation of superfluous watery fluid or vapour is a necessary accompaniment of nutrition, but this may easily become excessive, especially where the plant cannot readily recoup itself. In these circumstances such operations as "syringing" and "damping down" are of special value. Evaporating basins or tanks in houses for orchid and other plants are beneficial for like reasons. Following Boussingault and Henslow, by whom the absorption of water by leaves has been proved, we may sum up the advantages of syringing as follows:—it washes off dust and insects from the leaves, and by moistening the cuticle promotes respiration and the absorption of water; it checks loss by transpiration, and so enables terminal shoots and young leaves to receive a sufficiency of sap from the stem; it keeps the air cool by evaporation; and lastly, as moisture is actually imbibed by the green parts of plants, it helps to compensate for any loss from within, and thus supplements root absorption.

In accordance with the facts just cited it is found that the preservation of cut flowers is promoted by inserting some of their leaves as well as their stalks in water. By cutting an herbaceous stem under water, so that the severed end is never exposed to the air, withering can to a large extent be prevented; and a bouquet may be kept fresh for a long time either by immersing the whole in water, or by simply covering the vase of water in which it is placed with a bell-glass. In the case of "cuttings" excessive transpiration is obviated by means of bell-glasses and by shading, and sometimes by burying a portion of the cutting with a leaf attached.

Carnivorous Plants.—Before leaving the subject of nutrition by leaves, reference may be made to the so-called carnivorous plants, *e.g.*, *Drosera*. Substances, particularly such as contain nitrogen, as insects or fragments of meat, when brought into contact with the surface of the leaves, or with certain glands on the leaves, become dissolved by the agency of a digestive ferment secreted therein, are then absorbed and serve as nutriment. See INSECTIVOROUS PLANTS.

Respiration, already alluded to, is not directly connected with exposure to light, since it goes on by night as freely as by day. It is a process requisite for the health of the plant, and contributes to maintain its heat, to perfect its structure, to eliminate some of its secretions, and to destroy effete or impure matters. Chlorophyll, according to Pringsheim, acts as a regulator of the respiration of plants by absorbing some of the luminous rays, and thereby favouring the function of assimilation.

As a result of the processes carried on in the leaves under the influence of light, many of the secretions, as starch, sugar, oils, and colouring and odoriferous matters are formed. These either at once subserve the nutrition of the plant or are stored in its tissues, as in the case of tubers and many seeds. Usually before it can be rendered available as nourishment the stored matter has to undergo a change from a more or less insoluble to a soluble form. The changes which they undergo within the plant require very careful study, and indeed constitute a department of physiology still very greatly in need of elucidation. Pringsheim's recent researches on the action of light on chlorophyll, prosecuted with the aid of a small lens and observed under the microscope, bid fair, if confirmed, materially to change the views of chemists as to the processes which go on in leaves as a consequence of exposure to light; but, although they may change or even reverse our notions as to the mode of action of chlorophyll, they will not detract from its importance.

Buds.—The recognition of the various forms of buds, and their modes of disposition in different plants, on which see BOTANY, vol. iv. pp. 95–99, 118, 119, is a matter of the first consequence in the operations of pruning and training. Flower-buds may be produced on the old wood, *i.e.*, the shoots of the past year's growth, or on a shoot of the present year. The pear and rhododendron develop flower-buds for the next season speedily after blossoming, and these may be stimulated into premature growth. The peculiar short stunted branches or "spurs" which bear the flower-buds of the pear, apple, and their allies, and of the laburnum, deserve special attention. In the rose, in which the flower-buds are developed at the ends of the young shoot of the year, we have an example of a plant destitute of flower-buds during the winter.

Propagation by Buds.—The detached leaf-buds (*gemmæ* or *bulbils*) of some plants are capable under favourable conditions of forming new plants. The edges of the leaves of *Bryophyllum calycinum* (see vol. iv. p. 98, fig. 67) and of *Cardamine pratensis*, and the axils of the leaves of *Lilium bulbiferum* (iv. 99, fig. 71), produce buds of this character. It is a matter of familiar observation that the ends of the shoots of brambles take root when bent down to the ground. In rare instances buds form on the roots, and may be used for purposes of propagation, as in the Japan quince. Of the tendency in buds to assume an independent existence gardeners avail themselves in the operations of striking "cuttings," and making layers and "pipings," as also in budding and grafting. In taking a slip or cutting the gardener removes from the parent plant one or more buds or "eyes," in the case of the vine one only, attached or not to a short shoot, and places them in a moist and sufficiently warm situation, where, as previously mentioned, undue evaporation from the surface of the leaf or leaves is prevented. For some cuttings pots filled with light soil, with the protection of the propagating house and of bell-glasses, are requisite; but for many, such as willows, no such precautions are necessary, and the thrusting of the end of a shoot into moist ground suffices to ensure its growth. In the case of the more delicate plants, the formation of roots is preceded by the production from the cambium of the cuttings of a succulent mass of tissue, the *callus*. It is important in some cases to retain on the cutting some of its leaves, so as to supply the requisite food for storage in the callus. In other cases, where the buds themselves contain a sufficiency of nutritive matter for the young growths, the retention of leaves is not necessary. In the tissues of willow-stakes just referred to there exists an abundance of material available for the supply of the young roots. The most successful mode of forming roots is to place the cuttings in a mild bottom-heat, which expedites their growth, even in the case of many hardy plants whose cuttings strike roots in the open soil. With some hard-wooded trees, as the common white-thorn, roots cannot be obtained without bottom-heat. It is a general rule throughout plant culture that the activity of the roots shall be in advance of that of the leaves. Cuttings of deciduous trees and shrubs succeed best if planted early in autumn while the soil still retains the solar heat absorbed during summer. For evergreens April or May and August or September, and for greenhouse and stove-plants the spring and summer months, are the times most suitable for propagation by cuttings. The great object to be attained is to secure the formation of active roots before the approach of winter.

Layering consists simply in bending down a branch and keeping it in contact with or buried to a small depth in the soil until roots are formed; the connexion with the parent plant may then be severed. Many plants can be far more easily propagated thus than by cuttings.

Grafting or "*working*" consists in the transfer of a branch, the "graft" or "scion," from one plant to another, which latter is termed the "stock." The operation must be so performed that the growing tissues, or cambium-layer of the scion, may fit accurately to the corresponding layer of the stock. In *budding*, as with roses and peaches, a single bud only is implanted. *Inarching* is essentially the promotion of the union of one shoot to another of a different plant. The outer bark of each being removed, the two shoots are kept in contact by ligature until union is established, when the scion is completely severed from its original attachments. This operation is varied in detail according to the kind of plant to be propagated, but it is essential in all cases that the affinity between the two plants be near, that the union be neatly effected, and that the ratio as well as the season of growth of stock and scion be similar.

The selection of suitable stocks is a matter still requiring much scientific experiment. The object of grafting is to expedite and increase the formation of flowers and fruit. Strong-growing pears, for instance, are grafted on the quince stock in order to restrict their tendency to form "gross" shoots, and a superabundance of wood in place of flowers and fruit. Apples, for the same reason, are "worked" on the "paradise" or "doucin" stocks, which from their influence on the scion are known as dwarfing stocks. Scions from a tree which is weakly, or liable to injury by frosts, are strengthened by engrafting on robust stocks. Lindley has pointed out that, while in Persia, its native country, the peach is probably best grafted on the peach, or on its wild type the almond, in England, the summer temperature of whose soil is much lower than that of Persia, it might be expected, as experience has proved, to be most successful on stocks of the native plum.

The soil on which the stock grows is a point demanding attention. From a careful series of experiments made in the Horticultural Society's Garden at Chiswick, it was found that where the soil is loamy, or light and slightly enriched with decayed vegetable matter, the apple succeeds best on the doucin stock, and the pear on the quince; and where it is chalky it is preferable to graft the apple on the crab, and the pear on the wild pear. For the plum on loamy soils the plum, and on chalky and light soils the almond, are the most desirable stocks, and for the cherry on loamy or light rich soils the wild cherry, and on chalk the "mahaleb" stock.

The form and especially the quality of fruit is more or less affected by the stock upon which it is grown. The Stanwick nectarine, so apt to crack and not to ripen when worked in the ordinary way, is said to be cured of these propensities by being first budded close to the ground, on a very strong-growing Magnum Bonum plum, worked on a Brussels stock, and by then budding the nectarine on the Magnum Bonum about a foot from the ground. The fruit of the pear is of a higher colour and smaller on the quince stock than on the wild pear; still more so on the medlar. On the mountain ash the pear becomes earlier.

The effects produced by stock on scion, and more particularly by scion on stock, are as a rule with difficulty appreciable. Nevertheless, in exceptional cases modified growths, termed "graft-hybrids," have been obtained which have been attributed to the commingling of the characteristics of stock and scion. Of these the most remarkable example is *Cytisus Adami*, a tree which year after year produces some shoots, foliage, and flowers like those of the common laburnum, others like those of the very different looking dwarf shrub *C. purpureus*, and others again intermediate between these. We may hence infer that *C. purpureus* was grafted or budded on the common laburnum, and that the intermediate forms are the result of graft-hybridization. Numerous similar facts have been recorded. Among gardeners the general opinion is against the possibility of graft-hybridization. The wonder, however, seems to be that it does not occur more frequently, seeing that fluids must pass from stock to scion, and matter elaborated in the leaves of the scion must certainly to some extent enter the stock. It is clear, nevertheless, from examination that as a rule the wood of the stock and the wood of the scion retain their external characters year by year without change. Still, as in the laburnum just mentioned, in the variegated jasmine and in *Abutilon Darwinii*, in the copper beech and in the horse-chestnut, the influence of a variegated scion has occasionally shown itself in the production from the stock of variegated shoots. At a meeting of the Scottish Horticultural Association (see *Gard. Chron.*, Jan. 10, 1880, fig. 12-14) specimens of a small roundish pear, the "Aston Town," and of the elongated kind known as "Beurré Clairgeau," were exhibited. Two more dissimilar pears hardly exist. The result of working the Beurré Clairgeau upon the Aston Town was the production of fruits precisely intermediate in size, form, colour, speckling of rind, and other characteristics. Similar, though less marked, intermediate characters were obvious in the foliage and flowers.

Double grafting (French, *greffe sur greffe*) is sufficiently explained by its name. By means of it a variety may often be propagated, or its fruit improved in a way not found practicable under ordinary circumstances. For its successful prosecution prolonged experiments in different localities and in gardens devoted to the purpose are requisite.

Planting.—By removal from one place to another the growth of every plant receives a check. How this check can be obviated or reduced, with regard to the season, the state of atmosphere, and the condition and circumstances of the plant generally, is a matter to be considered by the practical gardener.

As to season, it is now admitted with respect to deciduous trees and shrubs that the earlier in autumn planting is performed the better; although some extend it from the period when the leaves fall to the first part of spring, before the sap begins to move. If feasible, the operation should be completed by the end of November, whilst the soil is still warm with the heat absorbed during summer. Attention to this rule is specially important in the case of rare and delicate plants. Early autumn planting enables wounded parts of roots to be healed over, and to form fibrils, which will be ready in spring, when it is most required, to collect food for the plant. Planting late in spring should, as far as possible, be avoided, for the buds then begin to awaken into active life, and the draught upon the roots becomes great. It has been supposed that because the surface of the young leaves is small transpiration is correspondingly feeble; but it must be remembered, not only that their newly-formed tissue is unable without an abundant supply of sap from the roots to resist the excessive drying action of the atmosphere, but that, in spring, the lowness of the temperature at that season in Great Britain prevents the free circulation of the sap. The comparative dryness of the atmosphere in spring also causes a greater amount of transpiration then than in autumn and winter. Another fact in favour of autumnal planting is the production of roots in winter.

The best way of performing transplantation depends greatly on the size of the trees, the soil in which they grow, and the mechanical appliances made use of in lifting and transporting them. The smaller the tree the more successfully can it be removed. The more argillaceous and the less siliceous the soil the more readily can balls of earth be retained about the roots. All planters lay great stress on the preservation of the fibrils; all indeed admit them to be indispensable for the absorption of nutriment. The point principally disputed is to what extent they can with safety be allowed to be cut off in transplantation. Trees and shrubs in thick plantations, or in sheltered warm places, are ill fitted for planting in bleak and cold situations. During their removal it is important that the roots be covered, if only to prevent desiccation by the air. Damp days are therefore the best for the operation; the dryest months are the most unfavourable. Though success in transplanting depends much on the humidity of the atmosphere, the most important requisite is warmth in the soil; humidity can be supplied artificially, but heat cannot.

Pruning, or the removal of superfluous growths, is practised in order to equalize the development of the different parts of trees, or to promote it in particular directions so as to secure a certain form, and, by checking undue luxuriance, to promote enhanced fertility. In the rose-bush, for instance, in which, as we have seen, the flower-buds are formed on the new wood of the year, pruning causes the old wood to "break," *i.e.*, to put forth a number of new buds, some of which will produce flowers at their extremities. The manner and the time in which pruning should be accomplished, and its extent, vary with the plant, the objects of the operation, *i.e.*, whether for the production of timber or fruit, the season, and various other circumstances. So much judgment and experience does the operation call for that it is a truism to say that bad pruning is worse than none. The removal of weakly, sickly, overcrowded, and gross infertile shoots is usually, however, a matter about which there can be few mistakes when once the habit of growth and the form and arrangement of the buds are known. Winter pruning is effected when the tree is comparatively at rest, and is therefore less liable to "bleeding" or outpouring of sap. Summer pruning or pinching off the tips of such of the younger shoots as are not required for the extension of the tree, when not carried to too great an extent, is preferable to the coarser more reckless style of pruning. The injury inflicted is less and not so concentrated; the wounds are smaller, and have time to heal before winter sets in. The effects of badly-executed pruning, or rather hacking, are most noticeable in the case of forest trees, the mutilation of which often results in rotting, canker, and other diseases. Judicious and timely thinning so as to allow the trees room to grow, and to give them sufficiency of light and air, will generally obviate the need of the pruning-saw, except to a relatively small extent.

Training is a procedure adopted when it is required to grow plants in a limited area, or in a particular shape, as in the case of many plants of trailing habit. Judicious training also may be of importance as encouraging the formation of flowers and fruit. Growth in length is mainly in a vertical direction, or at least at the ends of the shoots; and this should be encouraged, in the case of a timber tree, or of a climbing plant which it is desired should cover a wall quickly; but where flowers or fruit are specially desired, then, when the wood required is formed, the lateral shoots may often be trained more or less downward to induce fertility. The refinements of training, as of pruning, may, however, be carried too far; and not unfrequently the symmetrically trained trees of the French excite admiration in every respect save fertility.

Sports or Bud Variations.—Here we may conveniently mention certain variations from the normal condition in the size, form, or disposition of buds or shoots on a given plant. An inferior variety of pear, for instance, may suddenly produce a shoot bearing fruit of superior quality; a beech tree, without obvious cause, a shoot with finely divided foliage; or a camellia an unwontedly fine flower. When removed from the plant and treated as cuttings or grafts, such sports may be perpetuated. Many garden varieties of flowers and fruits have thus originated. The cause of their production is very obscure. In certain instances where plants have been "crossed" or hybridized, perhaps for generations, the phenomenon may be explained on the supposition of a dissociation of previously mixed elements, or of a reversion to some ancestral conditions.

Formation of Flowers.—Flowers, whether for their own sake or as the necessary precursors of the fruit and seed, are objects of the greatest concern to the gardener. As a rule they are not formed until the plant has arrived at a certain degree of vigour, or until a sufficient supply of nourishment has been stored in the tissues of the plant. The reproductive process of which the formation of the flower is the first stage being an exhaustive one, it is necessary that the plant, as gardeners say, should get "established" before it flowers. Moreover, although the green portions of the flower do indeed perform the same office as the leaves, the more highly coloured and more specialized portions, which are further removed from the typical leaf-form, do not carry on those processes for which the presence of chlorophyll is essential; and the floral organs may, therefore, in a rough sense, be said to be parasitic upon the green parts. A check or arrest of growth in the vegetative organs seems to be a necessary preliminary to the development of the flower. The flower itself is always the modified extremity of a shoot or stalk, which only exceptionally lengthens beyond the flower, as, for example, in "proliferous" roses. See BOTANY, vol. iv. p. 119, fig. 145.

A diminished supply of water at the root is requisite, so as to check energy of growth, or rather to divert it from leaf-making. Partial starvation will sometimes effect this; hence the grafting of free-growing fruit trees upon dwarfing stocks, as before alluded to, and also the "ringing" or girdling of fruit trees, *i.e.*, the removal from the branch of a ring of bark, or the application of a tight cincture, in consequence of which the growth of the fruits above the wound or the obstruction is enhanced. On the same principle the use of small pots to confine the roots, root-pruning and lifting the roots, and exposing them to the sun, as is done in the case of the vine in some countries, are resorted to. A higher temperature, especially with deficiency of moisture, will tend to throw a plant into a flowering condition. This is exemplified by the fact that the temperature of the climate of Great Britain is too low for the flowering, though sufficiently high for the growth of many plants. Thus the Jerusalem artichoke, though able to produce stems and tubers abundantly, only flowers in exceptionally hot seasons.

Forcing.—The operation of forcing is based upon the facts just mentioned. By subjecting a plant to a gradually increasing temperature, and supplying water in proportion, its growth may be accelerated; its season of development may be, as it were, anticipated; it is roused from a dormant to an active state. Forcing therefore demands the most careful adjustment of temperature and supplies of moisture and light.

Deficiency of light is less injurious than might at first be expected, because the plant to be forced has stored up in its tissues, and available for use, a reserve stock of material formed through the agency of light in former seasons. The intensity of the colour of flowers and the richness of flavour of fruit are, however, deficient where there is feebleness of light. Recent experiments of Dr Siemens have shown that the gardener may avail himself of the electric light, which is proved to exercise on chlorophyll the same kind of influence as do the solar rays, and that he may thus supply the deficiencies of natural illumination. The employment of that light for forcing purposes would seem to be at present a question of expense. The great advantage hitherto obtained from its use has consisted in the rapidity with which flowers have been formed and fruits ripened under its influence, circumstances which go towards compensating for the extra cost of production.

Double Flowers.—The taste of the day demands that "double flowers" should be largely grown. Though in some instances, as in hyacinths, they are decidedly less beautiful than single ones, they always present the advantage of being less evanescent. Under the vague term "double" many very different morphological changes are included. The flower of a double dahlia, *e.g.*, offers a totally different condition of structure from that of a rose or a hyacinth. The double poinsettia, again, owes its so-called double condition merely to the increased number of its scarlet involucral leaves, which are not parts of the flower at all. It is reasonable, therefore, to infer that the causes leading to the production of double flowers are varied. A good deal of difference of opinion exists as to whether they are the result of arrested growth or of exuberant development, and accordingly whether restricted food or abundant supplies of nourishment are the more necessary for their production. It must suffice here to say that double flowers are most commonly the result of the substitution of brightly-coloured petals for stamens or pistils or both, and that a perfectly double flower where all the stamens and pistils are thus metamorphosed is necessarily barren. Such a plant must needs be propagated by cuttings. It rarely happens, however, that the change is quite complete throughout the flower, and so a few seeds may be formed, some of which may be expected to reproduce the double-blossomed plants. By continuous selection of seed from the best varieties, and "roguing" or eliminating plants of the ordinary type, a "strain" or race of double flowers is gradually produced.

Formation of Seed—Fertilization.—In fertilization—the influence in flowering plants of the sperm-cell, or its contents upon the germ-cell (see BOTANY, vol. iv. 147, and BIOLOGY, vol. iii. 695)—there are many circumstances of importance horticulturally, to which therefore brief reference must be made. Flowers, generally speaking, are either self-fertilized, cross-fertilized, or hybridized. Self-fertilization occurs when the pollen of a given flower affects the germ-cell of the same individual flower. Such a flower is hermaphrodite functionally as well as structurally. In self-fertilizing flowers the structure is such that the pollen inevitably comes in contact with the stigma; but fertilization is also dependent on the simultaneous maturity of pollen and stigma. Cross-fertilization varies both in manner and degree. In the simplest instances the pollen of one flower fertilizes the ovules of another on the same plant, owing to the stamens arriving at maturity in any one flower earlier or later than the pistils. Such flowers though structurally hermaphrodite are, at any given time, functionally unisexual. In many plants a polymorphic condition occurs: thus, in the same species of primrose some flowers have the stamens short, and within the tube of the corolla, with the style projecting beyond the mouth, giving the appearance termed "pin-eyed," while others, known as "thrum-eyed," present exactly reverse conditions of stamens and style. In the common loose-strife, *Lythrum Salicaria*, the stamens are of three lengths, and the styles differ correspondingly. In such di- or tri-morphic flowers, as Mr Darwin's experiments have shown, the most complete fertility occurs when a cross is effected between a flower having short stamens and one with short styles. It is asserted that, not only is such a union more fertile than when pollen from a short stamen is placed on a long style, or *vice versa*, but the seedling plants are as a rule more vigorous.

Cross-fertilization must of necessity occur when the flowers are structurally unisexual, as in the hazel, in which the male and female flowers are monoecious, or separate on the same plant, and in the willow, in which they are diœcious, or on different plants. A conspicuous example of a diœcious plant is the common aucuba, of which for years only the female plant was known in Britain. When, through the introduction of the male plant from Japan, its fertilization was rendered possible, ripe berries, before unknown, became common ornaments of the shrub.

The conveyance of pollen from one flower to another in cross-fertilization is effected naturally by the wind, or by the agency of insects and other creatures. Flowers that require the aid of insects usually offer some attraction to their visitors in the shape of bright colour, fragrance, or sweet juices. The colour and markings of a flower often serve to guide the insects to the honey, in the obtaining of which they are compelled either to remove or to deposit pollen. The reciprocal adaptations of insects and flowers demand attentive observation on the part of the gardener concerned with the growing of grapes, cucumbers, melons, and strawberries, or with the raising of new and improved varieties of plants. Scarcely less remarkable, though not so important in the present connexion, are the means by which the visits of such insects as are useless for the purpose of fertilization, or even injurious to the plant, as preying without advantage to it on its secretions, are prevented or rendered ineffective. In wind-fertilized plants the flowers are comparatively inconspicuous and devoid of much attractions for insects; and their pollen-cells are smoother and smaller, and better adapted for transport by the wind, than those of insect-fertilized plants, the roughness of which adapt them for attachment to the bodies of insects.

Although the general facts with respect to fertilization are as above stated, it must be remembered that probably self-fertilization is not constant in any plant under all circumstances, and that it certainly does sometimes take place in flowers which are usually cross-fertilized. It may be that, while continued self-fertilization ensures the perpetuation of certain qualities, cross-fertilization induces beneficial variation. Some botanists doubt the injurious effects attributed to self-fertilization, and, so long as a plant is healthy, it can be attended with but little disadvantage; but after a time in any case a cross is probably useful, and sometimes fertility is found to be much greater, and, in rare instances, only possible, when impregnation is effected by pollen not produced by a flower's own stamens.

It is very probable that the same flower at certain times and seasons is self-fertilizing, and at others not so. The defects which cause gardeners to speak of certain vines as "shy setters," and of certain strawberries as "blind," may be due either to unsuitable conditions of external temperature, or to the non-accomplishment, from some cause or other, of cross-fertilization. In a vinery or a peach-house it is often good practice at the time of flowering to tap the branches smartly with a stick so as to ensure the dispersal of the pollen. Sometimes more delicate and direct manipulation is required, and the gardener has himself to convey the pollen from one flower to another, for which purpose a small camel's-hair pencil is generally suitable. The degree of fertility varies greatly according to external conditions, the structural and functional arrangements just alluded to, and other causes which may roughly be called constitutional. Thus, it often happens that an apparently very slight change in climate alters the degree of fertility. Certain plants which seem almost sterile with their own pollen become fertile if grafted on some others. In a particular country or at certain seasons one flower will be self-sterile or nearly so, and another just the opposite. The influence of conditions on the formation of "races," and the consequent importance to the horticulturist seeking to obtain new and improved strains of crossing-plants grown in different localities, have been specially insisted on by Darwin. The advantages of this practice are analogous to those accruing from what gardeners call "change of seed," *i.e.*, the sowing of seed or the planting of tubers, say of potatoes, in localities and on soils other than those in which they themselves were produced.

Hybridization.—Some of the most interesting results and many of the gardener's greatest triumphs have been obtained by hybridization, *i.e.*, the crossing two individuals, not of the same but of two distinct species of plants, as, for instance, two species of rhododendron or two species of orchid. It is obvious that hybridization differs more in degree than in kind from cross-fertilization. The occurrence of hybrids in nature explains the difficulty experienced by botanists in deciding on what is a species, and the widely different limitations of the term adopted by different observers in the case of willows, roses, brambles, &c. The artificial process is practically the same in hybridization as in cross-fertilization, but usually requires more care. To prevent self-fertilization, or the access of insects, it is advisable to remove the stamens and even the corolla from the flower to be impregnated, as its own pollen or that of a flower of the same species is often found to be "prepotent." There are, however, cases, *e.g.*, some passion-flowers and rhododendrons, in which a flower is more or less sterile with its own, but fertile with foreign pollen, even when this is from a distinct species. It is a singular circumstance that reciprocal crosses are not always or even often possible; thus, one rhododendron may afford pollen perfectly potent on the stigma of another kind, by the pollen of which latter its own stigma is unaffected. With respect to the relations of the hybrid offspring, which partakes sometimes more of the characteristics of the male or pollen parent, sometimes more of those of the female or seed-parent, the opinions of practical experimenters are so diverse that at present no general rule can be established. A valuable essay on the subject is the presidential address read by Mr Anderson-Henry at the annual meeting of the Botanical Society of Edinburgh in 1867. A general *résumé* of the facts will be found in Darwin's *Origin of Species*, his *Variations of Animals and Plants under Domestication*, and his works on the fertilization of flowers. See also HYBRIDISM.

The object of the hybridizer is to obtain varieties exhibiting improvements in hardihood, vigour, size, shape, colour, fruitfulness, or other attributes. His success depends not alone on skill and judgment, for some seasons, or days even, are found more propitious than others. Although promiscuous and hap-hazard procedures no doubt meet with a measure of success, the best results are those which are attained by systematic work with a definite aim. To secure early and free-flowering varieties, Mr Henry advises "violent" crosses, *i.e.*, crosses between varieties or species as distantly related as is practicable. Careful experiments are still greatly needed for the elucidation of the mysteries and the development of the resources of hybridization. It is difficult to understand why some very closely-related species, *e.g.*, the apple and pear, the currant and gooseberry, refuse to intercross, while much more remote species, or even members of different genera, can be made to do so, as in the case of the hybrid *Philageria* (see *Gardeners' Chronicle*, 1872, p. 358), which is the result of a cross between the climbing plant *Lapageria rosea* and the dwarf bush *Philesia buxifolia*.

Hybrids are usually less fertile than pure-bred species, and are occasionally quite sterile. Some hybrids, however, are as fertile as pure-bred plants. Hybrid plants may be again crossed, or even re-hybridized, so as to produce a progeny of very mixed parentage. This is the case with many of our roses, dahlias, begonias, pelargoniums, and other long or widely cultivated garden plants.

Reversion.—In modified forms of plants there is frequently a tendency to "sport" or revert to parental or ancestral characteristics. So markedly is this the case with hybrids that in a few generations all traces of a hybrid origin may disappear. The dissociation of the hybrid element in a plant must be obviated by careful selection.

Germination.—The length of the period during which seeds remain dormant after their formation is very variable. The conditions for germination are much the same as for growth in general. Access to light is not required, because the seed contains a sufficiency of stored-up food. The temperature necessary varies according to the nature and source of the seed. Some seeds require prolonged immersion in water to soften their shells; others are of so delicate a texture that they would dry up and perish if not kept constantly in a moist atmosphere. Seeds buried too deeply receive a deficient supply of air. As a rule, seeds require to be sown more deeply in proportion to their size and the lightness of the soil.

The time required for germination in the most favourable circumstances varies very greatly, even in the same species, and in seeds taken from one pod. Thus the seeds of *Primula japonica*, though sown under precisely similar conditions, yet come up at very irregular intervals of time. Germination is often slower where there is a store of available food in the perisperm or albumen, or in the embryo itself, than where this is scanty or wanting. In the latter case the seedling has early to shift for itself, and to form roots and leaves for the supply of its needs.

Selection.—Supposing seedlings to have been developed, it is found that a large number of them present considerable variations, some being especially robust, others peculiar in size or form. Those most suitable for the purpose of the gardener are carefully selected for propagation, while others not so desirable are destroyed; and thus after a few generations a fixed variety, race, or strain superior to the original form is obtained. Many garden plants have originated solely by selection; and it is certain that, quite independently of cross-breeding, much could still be done to improve our breeds of vegetables, flowers, and fruit by more systematic selection. The remarkable results obtained in the case of Major Hallett's pedigree wheat and Mr Bennett's hybrid tea-roses are instances in point. Two robust-growing varieties of potato, the "Magnum Bonum" and the "Champion," have been found to resist better than others the attacks of fungus to which the plant is liable. Whatever may be the cause, whether the possession by the tuber of a more than ordinarily thick skin, or other peculiarity, it is obvious that selection with a view to the development of this quality might be productive of the most important results. Darwin recommends, as a means of improving health and fertility by intercrossing without loss of purity of race, to sow in alternate rows seeds grown under as different conditions as possible.

Large and well-formed seeds are to be preferred for harvesting. The seeds should be kept in sacks or bags in a dry place, and if from plants which are rare, or liable to lose their vitality, they are advantageously packed for transmission to a distance in bottles or jars filled with earth or sphagnum moss, without the addition of moisture. Cuttings and entire plants may be transported in wide-mouthed bottles.

It will have been gathered from what has been said that seeds cannot always be depended on to reproduce exactly the characteristics of the plant which yielded them; for instance, seeds of the greengage plum or of the Ribston pippin will produce a plum or an apple, but not these particular varieties, to perpetuate which grafts or buds must be employed. (M. T. M.)

Part II.—The Practice of Horticulture.

The details of horticultural practice naturally range under the three heads of flowers, fruits, and vegetables. There are, however, certain general aspects of the subject which will be more conveniently noticed apart, since they apply alike to each department. We shall therefore first treat of these under four headings:—formation and preparation of the garden, garden structures and edifices, garden materials and appliances, and garden operations.

I. *Formation and Preparation of the Garden.*

1. *Site.*—The site chosen for the mansion will more or less determine that of the garden, the pleasure grounds and flower garden being placed so as to surround or lie contiguous to it, while the fruit and vegetable gardens, either together or separate, should be placed on one side or in the rear, according to fitness as regards the nature of the soil and subsoil, the slope of the surface, or the general features of the park scenery. In the case of villa gardens there is usually little choice: the land to be occupied is cut up into plots, usually rectangular, and of greater or less breadth, and in laying out these plots there is generally a smaller space left in the front of the villa residence and a larger one behind, the front plot being usually devoted to approaches, shrubbery, and plantations, flower beds being added if space permits, while the back or more private plot has a piece of lawn grass with flower beds next the house, and a space for vegetables and fruit trees at the far end, this latter being shut off from the lawn by an intervening screen of evergreens. Between these two classes of gardens there are many gradations, but our remarks will chiefly apply to those of larger extent. Site.

The almost universal practice is to have the fruit and vegetable gardens combined; and the flower garden may sometimes be conveniently placed in juxtaposition with them. When the fruit and vegetable gardens are combined, the smaller and choicer fruit trees only should be admitted, such larger-growing hardy fruits as apples, pears, plums, cherries, &c., being relegated to the orchard.

Ground possessing a gentle inclination toward the south is desirable for a garden. On such a slope effectual draining is easily accomplished, and the greatest possible benefit is derived from the sun's rays. It is well also to have an open exposure towards the east and west, so that the garden may enjoy the full benefit of the morning and evening sun, especially the latter; but shelter is desirable on the north and north-east, or in any direction in which the particular locality may happen to be exposed.

2. *Soil and Subsoil.*—A hazel-coloured loam, moderately light in texture, is well-adapted for most garden crops, whether of fruits or culinary vegetables, especially a good warm deep loam resting upon chalk; and if such a soil occurs naturally in the selected site, but little will be required in the way of preparation. If the soil is not moderately good and of fair depth, the situation is not an eligible one for gardening purposes. Wherever the soil is not quite suitable, but is capable of being made so, it is best to remedy the defect at the outset; and as it will be found easier to render a light soil sufficiently retentive than to make a tenacious clay sufficiently porous, a light soil is to be preferred to one which is excessively stiff and heavy. It is advantageous to possess a variety of soils; and if the garden be on a slope, it will often be practicable to render the upper part light and dry, while the lower remains of a heavier and damper nature. Soil.

Natural soils consist of substances derived from the decomposition of various kinds of rocks, the bulk consisting of clay, silica, and lime, in various proportions. As regards preparation, draining is of course of the utmost importance.

The ground should also be trenched to the depth of 3 feet at least, but the deeper the better, provided the good soil be not buried under a mass of inferior quality. In this operation all stones larger than a man's fist must be taken out, and all roots of trees and of perennial weeds carefully cleared away. When the whole ground has been thus treated, a moderate liming will, in general, be useful. After this, supposing the work to have occupied most of the summer, the whole may be laid up in ridges, to expose as great a surface as possible to the action of the winter's frost.

Argillaceous or clay soils are those which contain a large percentage (45–50) of clay, and a small percentage (5 or less) of lime. These are unfitted for garden purposes until improved by draining, liming, trenching, and the addition of porous materials, such as ashes, burnt ballast, or sand, but when thoroughly improved they are very fertile and less liable to become exhausted than most other soils. Loamy soils contain a considerable quantity (30–45 per cent.) of clay, and smaller quantities (5 or less) of lime and humus. Such soils properly drained and prepared are very suitable for orchards, and when the proportion of clay is smaller (20–30 per cent.) they form excellent garden soils, in which the better sort of fruit trees luxuriate. Marly soils are those which contain a considerable percentage (10–20) of lime, and are called clay marls, loamy marls, and sandy marls, according as these several ingredients preponderate. The clay marls are, like clay soils, too stiff for garden purposes until ameliorated; but loamy marls are fertile and well suited to fruit trees, and sandy marls are adapted for producing early crops. Calcareous soils, which may also be heavy, intermediate, or light, are those which contain more than 20 per cent. of lime, their fertility depending on the proportions of clay and sand which enter into their composition; they are generally cold and wet. Vegetable soils or moulds, or humus soils, contain a considerable percentage (more than 5) of humus, and embrace both the rich productive garden moulds and those known as peaty soils.

Subsoil. The nature of the subsoil is of scarcely less importance than that of the surface soil. If an unsuitable subsoil has to be dealt with, it must be removed or ameliorated. An uneven subsoil, especially if retentive, is most undesirable, as water is apt to collect in the hollows, and thus affect the upper soil. The remedy is to make the plane of its surface agree with that of the ground. When there is a hard pan this should be broken up, and if of bad quality the material should be removed altogether. When there is an injurious preponderance of metallic oxides or other deleterious substances, the roots of trees would be affected by them, and they must therefore be removed. When the subsoil is too compact to be pervious to water, effectual drainage must be resorted to; when it is very loose, so that it drains away the fertile ingredients of the soil as well as those which are artificially supplied, the compactness of the stratum must be increased. The best of all subsoils is a dry bed of clay overlying sandstone.

Size. 3. *Size and Form.*—The general size of a garden adjoining a mansion is from 4 to 6 acres; but in many places the extent varies from 12 to 20 or even 30 acres. A garden of 2 to 3 acres, enclosed by walls and surrounded by slips, will, however, suffice for the supply of a moderate establishment.

Plan. In laying out the garden, the plan should be prepared in minute detail before commencing operations. The form of the kitchen and fruit garden should be square or oblong, rather than curvilinear, since the working and cropping of the ground can thus be more easily carried out. The whole should be compactly arranged, so as to facilitate working, and to afford convenient access for the carting of the heavy materials. This access is especially desirable as regards the store-yards and framing ground, where fermenting manures and tree leaves for making up hot beds, coals or wood for fuel, and ingredients for composts, together with flower pots and the many necessaries of garden culture, have to be accommodated. In the case of villas or picturesque residences, gardens of irregular form may be permitted; when adapted to the conditions of the locality, they associate better with surrounding objects, but in such gardens wall space is usually limited.

The distribution of the garden area in walks, borders, and compartments must be partly regulated by the outline of the ground. In general, a gravel walk, 6 or 8 feet broad, is led quite round the garden, both within and without the walls. A walk of similar dimensions is often constructed in the centre of the garden in the direction of the glazed houses, and this is sometimes crossed by another at right angles, which is far preferable to having the walks led diagonally from the corners, since this throws the enclosed plots out of the square. The space between the wall and the walk that skirts it is called the wall-border, and is commonly from 15 to 20 feet broad. On the interior of the walk there is usually another border 5 or 6 feet broad, which is generally occupied by fruit trees, trained either as espaliers, as dwarfs, or as pyramids. The middle part of the garden is divided into rectangular compartments for raising the various culinary crops. It is advantageous to have several small beds, in which to cultivate the less bulky subjects, such as basil, sage, tarragon, &c., which, in large spaces, are apt to be overlooked or neglected.

A considerable portion of the north wall is usually covered in front with the glazed structures called forcing-houses, and to these the houses for ornamental plants are sometimes attached; but a more appropriate site for the latter is the flower garden, when that forms a separate department. It is well, however, that everything connected with the forcing of fruits or flowers should be concentrated in one place. The frame ground, including melon and pine pits, should occupy some well-sheltered spot in the slips, or on one side of the garden, and adjoining to this may be found a suitable site for the compost ground, in which the various kinds of soils are kept in store, and in which also composts may be prepared.

As the walls afford valuable space for the growth of the choicer kinds of hardy fruits, the direction in which they are built is of considerable importance. In the warmer parts of the country the wall on the north side of the garden should be so placed as to face the sun at about an hour before noon, or a little to the east of south; in less favoured localities it should be made to face direct south, and in still more unfavourable districts it should face the sun an hour after noon, or a little west of south. The east and west walls should run parallel to each other, and at right angles to that on the north side, in all the most favoured localities; but in colder or later ones, though parallel, they should be so far removed from a right angle as to get the sun by eleven o'clock. On the whole, the form of a parallelogram with its longest sides in the proportion of about five to three of the shorter, and running east and west, may be considered the best form, since it affords a greater extent of south wall than any other. Mr Thompson, in the *Gardener's Assistant*, gives a figure which is nearly in this proportion (fig. 1), representing a small garden 272¼ feet by 160, and therefore containing exactly an acre. This figure admits of nearly double the number of trees on the south aspect as compared with the east and west; it allows a greater number of espalier or pyramid trees to face the south; and it admits of being divided into equal principal compartments, each of which forms nearly a square. The size of course can be increased to any requisite extent. That of the royal gardens at Frogmore,

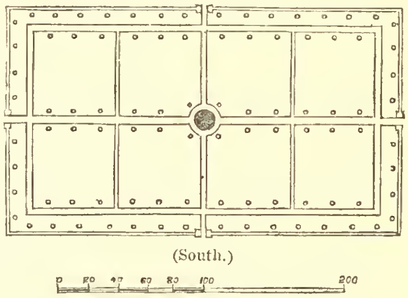

Fig. 1.—Plan of Garden an acre in area.

760 feet from east to west, and 440 feet from north to south, is nearly of the same proportions.

Slips. The spaces between the walls and the outer fence are called slips. A considerable extent is sometimes thus enclosed, and utilized for the growth of such vegetables as potatoes, winter greens, and sea-kale, for the small bush fruits, and for strawberries. The slips are also convenient as affording a variety of aspects, and thus helping to prolong the season of particular vegetable crops.

Shelter. 4. *Shelter.*—A screen of some kind to temper the fury of the blast is absolutely necessary. If the situation is not naturally well sheltered, the defect may be remedied by masses of forest trees disposed at a considerable distance so as not to shade the walls or fruit trees. They should not be nearer than say 50 yards, and may vary from that to 100 or 150 yards distance according to circumstances, regard being had especially to peculiarities occasioned by the configuration of the country, as for instance to aerial currents from adjacent eminences. Care should be taken, however, not to hem in the garden by crowded plantations, shelter from the prevailing strong winds being all that is required, while the more open it is in other directions the better. The trees employed for screens should include both those of deciduous and of evergreen habit, and should suit the peculiarities of local soil and climate. Of deciduous trees the sycamore, wych-elm, horse-chestnut, beech, lime, plane, and poplar may be used,—the *Populus canadensis nova* being one of the most rapid-growing of all trees, and, like other poplars, well-suited for nursing other choicer subjects; while of evergreens, the holm oak, holly, laurel (both common and Portugal), and such conifers as the Scotch, Weymouth, and Austrian pines, with spruce and silver firs and yews, are suitable. The conifers make the most effective screens.

Extensive gardens in exposed situations are often divided into compartments by hedges, so disposed as to break the force of high winds. Where these are required to be narrow as well as lofty, holly, yew, or beech is to be preferred; but, if there is sufficient space, the beautiful laurel and the bay may be employed where they will thrive. Smaller hedges may be formed of evergreen privet, or of tree-box. These subordinate divisions furnish, not only shelter, but also shade, which, at certain seasons, is peculiarly valuable.

Belts of shrubbery may be placed round the slips outside the walls; and these may in many cases, or in certain parts, be of sufficient breadth to furnish pleasant retired promenades, at the same time that they serve to mask the formality of the walled gardens, and are made to harmonize with the picturesque scenery of the pleasure ground.

Water Supply. 5. *Water Supply.*—Although water is one of the most important elements in vegetable life, we do not find one garden in twenty where even ordinary precautions have been taken to secure a competent supply. Rain-water is the best, next to that river or pond water, and last of all that from springs; but a chemical analysis should be made of the last before introducing it, as some spring waters contain mineral ingredients injurious to vegetation. Iron pipes are the best conductors; they should lead to a capacious open reservoir placed outside the garden, and at the highest convenient level, in order to secure sufficient pressure for effective distribution, and so that the wall trees also may be effectually washed. Stand pipes should be placed at intervals beside the walks and in other convenient places from which water may at all times be drawn; and short flexible tubes should be made to fit on to them, to which a garden hose can be attached, so as to permit of the whole garden being readily and when necessary profusely watered. The mains should be placed under the walks for safety, and also that they may be easily reached when repairs are required. Pipes should also be laid having a connexion with all the various greenhouses and forcing-houses, each of which should be provided with a cistern for aerating the daily supplies. In fact, every part of the garden, including the working sheds and offices, should have water supplied without stint. At the same time it is not expedient to admit of large basins or ponds, and far less of a running stream in a garden.

Entrance. 6. *Approach and Fence.*—The entrance to the garden from without is a matter requiring the exercise of some taste and of sound judgment. If possible, it should be from the south and front, so that the pleasing effect of the range of glazed houses may be realized by the visitor on entering. Sometimes a lateral entrance, leading from the flower-garden through an intermediate shrubbery, and coming upon the hot-houses in flank, may be necessary. The worst of all entrances is from the back or north, everything being then viewed in reverse.

Enclosure. All gardens of large extent should be encircled by an outer boundary, which is often formed by a sunk wall or ha-ha surrounded by an invisible wire fence to exclude ground game, or consists of a hedge with low wire fence on its inner side. Occasionally this sunk wall is placed on the exterior of the screen plantations, and walks lead through the trees, so that views are obtained of the adjacent country. Although the interior garden receives its form from the walls, the ring fence and plantations may be adapted to the shape and surface of the ground. In smaller country gardens the enclosure or outer fence is often a hedge, and there is possibly no space enclosed by walls, but some divisional wall having a suitable aspect is utilized for the growth of peaches, apricots, &c., and the hedge merely separates the garden from a paddock used for grazing. The still smaller gardens of villas are generally bounded by a wall or wood fence, the inner side of which is appropriated to fruit trees. For the latter, walls are much more convenient and suitable than a boarded fence, but in general these are too low to be of much value as aids to cultivation, and they are best covered with bush fruits or with ornamental plants of limited growth.

Walks. 7. *Walks and Edgings.*—The best material for the construction of garden walks is good binding gravel. The ground should be excavated to the depth of a foot or more,—the bottom being made firm and slightly concave, so that it may slope to the centre, where a drain should be introduced; or the bottom may be made convex and the water allowed to drain away at the sides. The bottom 9 inches should be filled in compactly with hard coarse materials, such as stones, brickbats, clinkers, burned clay, &c., on which should be laid two or three inches of coarse gravel, and then an inch or two of firm binding gravel on the surface. The surface of the walks should be kept well rolled, for nothing contributes more to their elegance and durability.

All the principal lines of walk should be broad enough to allow at least three persons to walk abreast; the others may be narrower, but a multitude of narrow walks has a puny effect. Much of the neatness of walks depends upon the material of which they are made. Gravel from an inland pit is to be preferred; though occasionally very excellent varieties are found upon the sea-coast. The gravels of Kensington and Blackheath have attained considerable celebrity, and have been frequently employed in remote parts of the kingdom, the expense being lessened by their being conveyed to different sea-ports as ballast for ships. Gravel walks must be kept free from weeds, either by hand weeding, by occasionally salting the surface, or by watering with boiling salt water. In some parts of the country the available material does not bind to form a close even surface, and such walks are kept clean by hoeing.

Grass walks were common in English gardens during the prevalence of the Dutch taste, but, owing to the frequent humidity of the climate, they have in a great measure been discarded. Their disuse is perhaps to be regretted, as in some situations, particularly behind lengthened screens of trees, they form very agreeable promenades in dry, hot weather. Grass walks were made in the same way as grass lawns. When the space to be thus occupied had been prepared, a thin layer of sand or poor earth was laid upon the surface, and over this a similar layer of good soil. This arrangement was adopted in order to prevent excessive luxuriance in the grass.

Edgings.—Walks are separated from the adjoining beds and borders in a variety of ways. If a living edging is adopted, by far the best is afforded by the dwarf Dutch box planted closely in line. It is of extremely neat growth, and, when annually clipped, will remain in good order for many years. Very good edgings, but of a less durable character, are formed by thrift (*Statice Armeria*), double daisy (*Bellis perennis*), gentianella (*Gentiana acaulis*), and London pride (*Saxifraga umbrosa*); or by some of the finer grasses very carefully selected, such as the sheep's fescue (*Festuca ovina*) or its glaucous-leaved variety. Indeed, any low-growing herbaceous plant, susceptible of minute division, is suitable for an edging. Edgings may also be formed of narrow slips of sandstone flag, slate, fire-clay tiles, bricks, glass, or cast-iron. An excellent form of edging tile is that invented by Mr Stevens of Trentham Gardens (fig. 2), which is made of a very durable kind of clay, and is remarkably neat in appearance. It is 18 inches long, 5 inches deep, and 5 inches broad, and, resting on the broad base, is held firmly by the gravel used for filling up the walk. One advantage of using edgings of this kind, especially in kitchen gardens, is that they do not harbour slugs and similar vermin, which all live edgings do, and often to a serious extent, if they are left to grow large. In shrubberies and large flower-plots, verges of grass-turf, from 1 to 3 feet in breadth, according to the size of the border and width of the walk, make a very handsome edging, but they should not be allowed to rise more than an inch and a half above the gravel, the grass being kept short by repeated mowings, and the edges kept trim and well-defined by frequently clipping with shears, and cutting once a year with an edging iron.

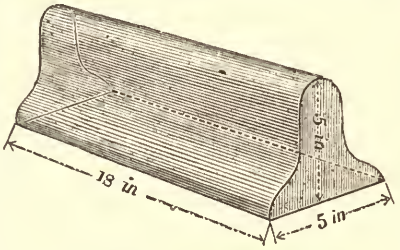

FIG. 2.—Stevens's Edging Tile.

II. *Garden Structures.*

8. *Gardener's Residence.*—The gardener's residence and the apartments for the workmen should be within convenient distance of each other and of the forcing-houses. The gardener's house may stand in the centre of the range of hot-houses, or it may be placed in one corner of the walled garden. In either case it should communicate on the one side with the best part of the garden, and on the other with the yard in which the garden offices are placed.

9. *Walls.*—The position to be given to the garden walls has been already referred to under par. 3. The shelter afforded by a wall, and the increased temperature secured by its presence, are indispensable in the climate of Great Britain, for the production of all the finer kinds of outdoor fruits; and hence, the inner side of a north wall, having a southern aspect, is appropriated to the more tender kinds. It is, indeed, estimated that such positions enjoy an increased temperature equal to 7° of latitude; that is to say, the mean temperature within a few inches of the wall is equal to the mean temperature of the open plain 7° farther south. The eastern and western aspects are set apart for fruits of a somewhat hardier character.

Where the inclination of the ground is considerable, and the presence of high walls would be objectionable, the latter may be replaced by sunk walls. These should not rise more than 3 feet above the level of the ground behind them. As dryness is favourable to an increase of heat, such walls should be either built hollow, or packed behind to the thickness of 3 or 4 feet with rubble stones, flints, brickbats, or similar material, thoroughly drained at bottom. For mere purposes of shelter a height of 6 or 7 feet will generally be sufficient for the walls of a garden, but for the training of fruit trees it is found that an average height of 12 feet is most suitable. In gardens of large size the northern or principal wall may be 14 feet, and the side walls 12 feet in height; while smaller areas of an acre or so should have the principal walls 12 and the side walls 10 feet in height. As brick is more easily built hollow than stone, it is to be preferred for garden walls. A 14-inch hollow wall will take in its construction 12,800 bricks, while a solid 9-inch one, with piers, will take 11,000; but the hollow wall, while thus only a little more costly, will be greatly superior, being drier and warmer, as well as more substantial. Bricks cannot be too well burnt for garden walls; the harder they are the less moisture will they absorb. The darker colour they acquire when the process of burning is prolonged is also more in harmony with the surrounding objects. At one time brick walls were preferred on account of the facility they afforded for training trees, but now cast-iron studs (fig. 3) or sometimes nails are placed in the wall during its erection, being pushed into the joints before the mortar becomes set, and ranged in straight lines, both vertically and horizontally; for peaches, &c., they are placed 9 inches apart, and for pears, &c., 15 inches. The trees are fastened to them by soft ligatures of twine or matting, which should be twisted after being tied to the stud or nail, so as to prevent contact between the branch and the metal. Many excellent walls are built of stone. The best is dark-coloured whinstone, because it absorbs very little moisture, or in Scotland Caithness pavement 4 inches thick. The stones can be cut (in the quarries) to any required length, and built in regular courses. Stone walls should always be built with thin courses for convenience of training over their surface. Concrete walls, properly coped and provided with a trellis, may in some places be cheapest, and they are very durable. Common rubble walls are the wors of all.

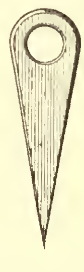

FIG. 3.—Cast-Iron Wall Stud.

The coping of garden walls is important, both for the preservation of the walls and for throwing the rain-water off their surfaces. It should not project less than from 2 to 2½ inches, but in wet districts may be extended to 6 inches. Stone copings are best, but they are costly, and Portland cement is sometimes substituted. Temporary copings of wood, which may be fixed by means of permanent iron brackets just below the stone coping, are extremely useful in spring for the protection of the blossoms of fruit trees. They should be 9 inches or a foot wide, and should be put on during spring before the blossom buds begin to expand; they should have attached to them scrim cloth (a sort of thin canvas), which admits light pretty freely, yet is sufficient to ward off ordinary frosts; this canvas is to be let down towards evening, and drawn up again in the morning. These copings should be removed when they are of no further utility as protectors, so that the foliage may have the full benefit of rain and dew. Any contrivance that serves to interrupt radiation, though it may not keep the temperature much above freezing, will be found sufficient. Standard fruit trees must be left to take their chance; and, indeed from the lateness of their flowering, they are generally more injured by blight, and by drenching rains, which wash away the pollen of the flowers, than by the direct effects of cold.

[H]ot [w]alls. Hot walls, whether constructed to be warmed by flues or hot-water pipes, are nearly or quite obsolete. Their chief use is to assist in ripening the young wood and the crops of the later varieties of tender fruits by the aid of artificial heat, but the expenditure would be more usefully directed to the construction of a glazed house for that purpose.

[E]spalier [ra]ils. *Espalier Rails.*—Subsidiary to walls as a means of training fruit trees, espalier rails were formerly much employed, and are still used in many gardens. In their simplest form, they are merely a row of slender stakes of larch or other wood driven into the ground, and connected by a slight rod or fillet at top. The use of iron rails has now been almost wholly discontinued on account of metallic substances acting as powerful conductors of both heat and cold in equal extremes. Trees trained to espalier rails have some advantages, as they are easily got at for all cultural operations, space is saved, and the fruit, while freely exposed to sun and air, is tolerably secure against wind. They form, moreover, neat enclosures for the vegetable quarters, and, provided excess of growth from the centre is successfully grappled with, they are productive in soils and situations which are suitable.

[Pl]ant [h]ouses. 10. *Plant Houses.*—These include all those structures which are more intimately associated with the growth of ornamental plants and flowers, and comprise conservatory, plant stove, greenhouse, and the subsidiary pits and frames. They should be so erected as to present the smallest extent of opaque surface consistent with stability. With this object in view, the early improvers of hot-house architecture substituted metal for wood in the construction of the roofs, and for the most part dispensed with back walls; but the conducting power of the metal caused a great irregularity of temperature, which it was found difficult to control; and, notwithstanding the elegance of metallic houses, this circumstance, together with their greater cost, and some doubt as to their durability, has induced most recent authorities to give the preference to wood. The combination of the two, however, as in the Crystal Palace at Sydenham, shows clearly that, without much variation of heat or loss of light, any extent of space may be covered, and houses of any altitude constructed.

The earliest notice we have of such structures is given in the Latin writers of the 1st century (Mart., *Epigr.*, viii. 14 and 68); the Ἀδώνιδος κῆποι, to which allusion is made by various Greek authors, have no claim to be mentioned in this connexion. Columella (xi. 3, 51, 52) and Pliny (*H.N.*, xix. 23) both refer to their use in Italy for the cultivation of the rarer and more delicate sorts of plants and trees. Seneca has given us a description of the application of hot water for securing the necessary temperature. The botanist Jungermann had plant houses at Altdorf in Switzerland; those of Loader, a London merchant, and the conservatory in the Apothecaries' Botanic Garden at Chelsea, were the first structures of the kind erected in British gardens. These were, however, ill adapted for the growth of plants, as they consisted of little else than a huge chamber of masonry, having large windows in front, with the roof invariably opaque. The next step was taken when it became fashionable to have conservatories attached to mansions, instead of having them in the pleasure grounds. This arrangement brought them within the province of architects, and for nearly a century utility and fitness for the cultivation of plants were sacrificed, as still is often the case, to the unity of architectural expression between the conservatory and the mansion.

Plant houses must be as far as possible impervious to wet and cold air from the exterior, provision at the same time being made for ventilation, while the escape of warm air from the interior must also be under control. The most important part of the enclosing material is necessarily glass. But as the rays of light, even in passing through transparent glass, lose much of their energy, which is further weakened in proportion to the distance it has to travel, the nearer the plant can be placed to the glass the more perfectly will its functions be performed; hence the importance of constructing the roofs at such an angle as will admit the most light, especially sunlight, at the time it is most required. Plants in glass houses require for their fullest development more solar light probably than even our best hot-houses transmit,—certainly much more than is transmitted through the roofs of houses as generally constructed.[1]

Plant houses should be constructed of the best Baltic pine timber, as being the most durable, but the whole of the parts should be kept as light as possible. In many houses, especially those where ornament is of no consequence, the rafters are now omitted, or only used at wide intervals, somewhat stouter sash-bars being adopted, and

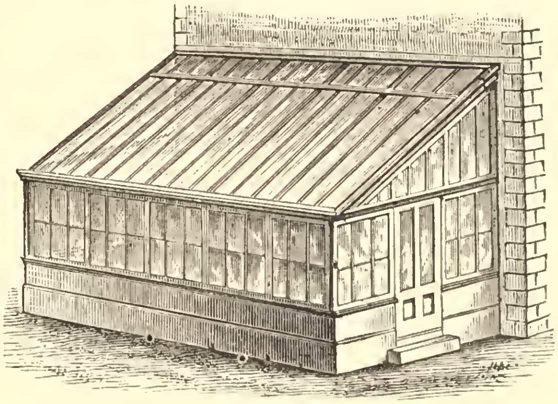

Fig. 4.—Lean-to Plant House.

stout panes of glass, 8 to 12 inches wide, made use of. Such houses are very light; being also very close, they require careful ventilation. The glass roof is commonly designed so as to form a uniform plane or slope from back to front in lean-to houses (fig. 4), and from centre to sides in span-roofed houses. In some cases, however, the roof sashes are fitted up on the ridge-and-furrow principle invented by Sir Joseph Paxton, shown in fig. 5, which represents the original ridge-and-furrow house erected by him at Chatsworth. To secure the greatest possible influx of light, some scientific horticulturists recommend curvilinear roofs; but the superiority of these is largely

[1] Mr Knight, an unquestionable authority, proposed a general pitch or elevation of 34° for the latitude of London, the angle at which the rays of the mid-day sun are perpendicular to the surface on the 20th of May and 21st of July. This would afford four months, from the 20th of April to the 21st of August, during which the angle of incidence at mid-day would not at any time amount to 9°, while the deviation at the winter solstice would be 43°, and the loss of light from reflexion would be little more than $\frac{1}{30}$. The angle of 45° has been recommended as a pitch extremely suitable for early vineries and pine stoves, in which case the midsummer deviation would be 19°, and the loss $\frac{1}{40}$, and the winter deviation 30°, the loss being nearly the same. Greater exactness, however, has been sought in this matter than is at all necessary. The reduction of the opacity of the roof arising from the breadth and depth of rafters and astragals is of much more consequence. The massive rafters, framed sashes, and inferior glass inserted in small fragments, with numerous overlaps liable to be choked with dirt, intercept a large proportion of the solar light and heat in ordinary glass houses.

due to the absence of rafters, which may also be dispensed with in plain roofs. Span and ridge-and-furrow roofs, the forms now mostly preferred, are exceedingly well adapted for the admission of light, especially when they are glazed to within a few inches of the ground. They can be made, too, to cover in any extent of area without sustaining walls. Indeed, it has been proposed to support such roofs to a great extent upon suspension principles, the internal columns of support being utilized for conducting the rain-water off the roof to underground drains or reservoirs. The lean-to is the least desirable form, since it scarcely admits of elegance of design, but it is necessarily adopted in some cases.

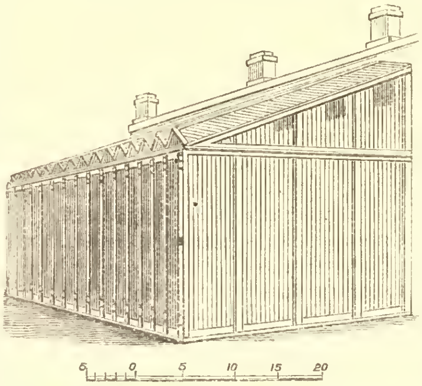

FIG. 5.—Ridge-and-Furrow Plant House.

azing. In glazing, the greater the surface of glass, and the less space occupied by rafters and astragals as well as overlaps, the greater the admission of light. Some prefer that the sash-bars should be grooved instead of rebated, and this plan exposes less putty to the action of the weather. The simple bedding of the glass, without the use of over putty, seems to be widely approved; but the glass may be fixed in a variety of other ways, some of which are patented. In Beard's method (a very good one) the glass is fixed between strips of felt, the covering bar being held in position by white metal nuts tightly screwed. Good results have also been obtained from the system introduced and improved by Rendle, which covers all the framework of the roof, so that the timber is not exposed to the vicissitudes of weather.

nser-tory. The *Conservatory* is often built in connexion with the mansion, so as to be entered from the drawing-room or boudoir. But when so situated it is apt to suffer from the shade of the building, and is objectionable on account of admitting damp to the drawing-room. Where circumstances will admit, it is better to place it at some distance from the house, and to form a connexion by means of a glass corridor. In order that the conservatory may be kept gay with flowers, there should be a subsidiary structure to receive the plants as they go out of bloom. The conservatory may also with great propriety be placed in the flower garden, where it may occupy an elevated terrace, and form the termination of one of the more important walks.

Great variety of design is admissible in the conservatory, but it ought always to be adapted to the style of the mansion of which it is a prominent appendage. Some very pleasing examples are to be met with which have the form of a parallelogram with a lightly rounded roof; others of appropriate character are square or nearly so, with a ridge-and-furrow roof. Whatever the form, there must be light in abundance; and the shade both of buildings and of trees must be avoided. A southern aspect, or one varying to south-east or south-west, is preferable; if these aspects cannot be secured, the plants selected must be adapted to the position. The central part of the house may be devoted to permanent plants; the side tables and open spaces in the permanent beds should be reserved for the temporary plants.

The kind of plants adapted for planting out in conservatories are palms, cycads, dracænas, aralias, luculias, camellias, &c., with fuchsias, habrothamnus, plumbago, strong-growing scarlet pelargoniums, &c., on the pillars, and tacsonias, passifloras, lapagerias, &c., on the roof.

reen-use. The *Greenhouse* is a structure designed for the growth of such exotic plants as require to be kept during winter in a temperature considerably above the freezing-point. The best form is the span-roofed, a single span being better even than a series of spans such as form the ridge-and-furrow roof. For plant culture, houses at a comparatively low pitch are better than higher ones where the plants have to stand at a greater distance from the glass, and therefore in greater gloom. Fig. 6 represents a form of house adopted by a most successful cultivator, Mr B. S. Williams, of Holloway. It is 20 feet wide and 12 feet high, the length in this case being 50 feet, but of course any other convenient length could be adopted. The side walls are surmounted by short upright sashes which open outwards by machinery *a*, and the roof is provided with sliding upper sashes for top ventilation. In the centre is a two-tier stage for plants, 6 feet wide, with a pathway on each side 3 feet wide, and a side table 4 feet wide, the side tables being flat, and the centre stage having the middle portion one-third of the width elevated 1 foot above the rest, so as to lift up the middle row of plants nearer the light. Span-roofed houses of this character should run north and south so as to secure an equalization of light, and should be warmed by two 4-inch hot-water pipes carried under the side tables along each side and across each end. Where it is desired to cultivate a large number of plants, it is much better to increase the number of such houses than to provide larger structures. The smaller houses are far better for cultural purposes, while the plants can be classified, and the little details of management more conveniently attended to. Pelargoniums, cinerarias, calceolarias, cyclamens, camellias, heaths, Australian plants, roses, and other specialities might thus have to themselves either a whole house or part of a house, the conditions of which could then be more accurately fitted to the wants of the inmates.

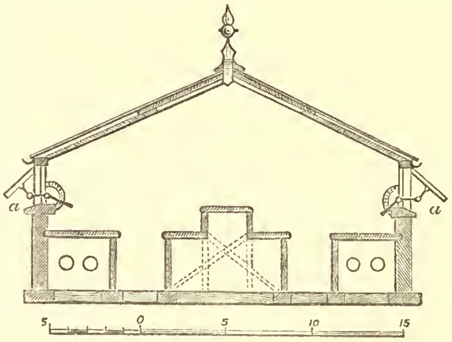

FIG. 6.—Section of Greenhouse.

The lean-to house is in most respects inferior to the span-roofed; one of the latter could be converted into two of the former of opposite aspects by a divisional wall along the centre. Except where space does not permit a span-roofed building to be introduced, a lean-to is not to be recommended; but a house of this class may often be greatly improved by adopting a half-span or hipped roof (as in fig. 9), that is, one with a short slope behind and a longer in front.

Where the cultivation of large specimens of heaths, Australian plants, Indian azaleas, &c., has to be carried on, a span-roofed house of greater height and larger dimensions may sometimes prove useful; but space for this class of plants may generally be secured in a house of the smaller elevation, simply by lowering or removing altogether the staging erected for smaller plants, and allowing the larger ones to stand on or nearer the floor.

The *Plant Stove* differs in no respect from the greenhouse except in having a greater extent of hot-water pipes for the purpose of securing a greater degree of heat, although, as the plants in stove houses often attain a larger size, and many of them require a tan bed to supply them with bottom heat, a somewhat greater elevation may perhaps be occasionally required in some of the houses. For the smaller plants, and for all choicer subjects, the smaller size of house already recommended for greenhouses, namely, 20 feet wide and 12 feet high, with a side table of 4 feet on each side, a pathway of 3 feet, and a central stage on two levels of 6 feet wide, will be preferable, because more easily managed as to the supply of heat and moisture. Mr Williams's plant stove (fig. 7), which is a very good model, is of the foregoing dimensions. It has, however, a different arrangement from the greenhouse as to ventilation. It will be seen that along the ridge of the roof a raised portion or lantern light *b*, *b* is introduced, which permits of the fixing of two continuous ventilators, one along each side, for the egress of heated and foul air, openings *a*, *a* being also provided in the side walls opposite the hot-water pipes for the admission of pure cold air. Plant stove.

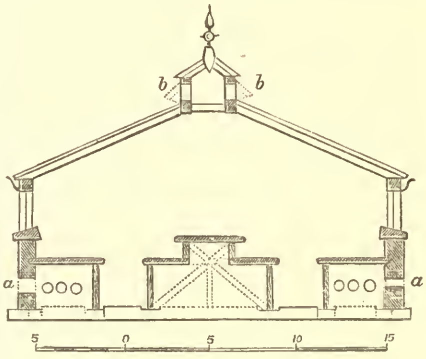

FIG. 7.—Section of Plant Stove.

Three or four rows of pipes will be required on each side, according to the heat proposed to be maintained.

In their interior fittings plant stoves require more care than greenhouses, which are much drier, and in which consequently the staging does not so soon decay. In stoves the tables should always be of slate or stone, and the supports of iron; slate is now most commonly used. This should be covered with a layer of 2 or 3 inches of some coarse gritty material, such as pounded spar, or the shell sand obtained on the sea-coast, on which the pots are to stand; its use is to absorb moisture and gradually give it out for the benefit of the plants. The pathways should be paved, or made of concrete and cement, and the surface should be gently rounded so that the water required for evaporation may drain to the sides while the centre is sufficiently dry to walk upon; they should also have brick or stone edgings to prevent the water so applied soaking away at the sides and thus being wasted.

sition plant uses. The greenhouses, if large and ornamental, should be contiguous to the flower garden or pleasure ground; but if of the simple character employed only for growing decorative plants, it is better to associate them with similar houses set apart for other purposes, in an enclosed portion of the grounds contiguous to the potting sheds, where fuel and other materials required can be conveniently stored, and where all the untidiness of the workshops may be masked. For this reason it is a very convenient plan to place side by side a series of small span-roofed houses for growing plants, where they can be connected by a glazed passage-way at the back. The glazed way may be utilized for the cultivation of plants requiring less light than others, such as ferns, camellias, &c.; it should communicate with the workmen's offices, which are commonly placed on the north side of the garden wall, so that potting and other cultural operations may be carried on without creating a block or confusion in the several houses. Wherever placed, it is imperative that all plant houses should have a free and abundant admission of light.

uit uses. 11. *Fruit Houses.*—The principal of these are the vinery, pinery, peach house, cucumber and melon house, and orchard house. These or a portion of them, especially the vineries and peacheries, are frequently brought together into a range along the principal interior or south wall of the garden, where they are well exposed to sun and light, an ornamental plant house being sometimes introduced into the centre of the range in order to give effect to the outline of the buildings. When thus associated, the houses are usually of the lean-to class, which have the advantage of being more easily warmed and kept warm than buildings having glass on both sides, a matter of great importance for forcing purposes.

ery. The *Vinery* is a house devoted to the culture of the grape-vine, which is by far the most important exotic fruit cultivated in English gardens. When forming part of a range a vinery would in most cases be a lean-to structure, with a sharp pitch (45°–50°) if intended for early forcing, and a flatter roof (40°) with longer rafters if designed for the main or late crops. Mr A. F. Barron, a recognized authority on grape growing, recommends in the *Florist and Pomologist* (1879, p. 37) three classes of

FIG. 8.—Lean-to Vinery.

vineries, namely, *early* for the production of early or forced grapes, *general-crop* for all unheated grape houses, and *late* for producing and keeping grapes till late in the season, each requiring its own special arrangements. The following are the three forms of houses recommended by him. (1) The *lean-to* (fig. 8) is the simplest form, often erected against some existing wall, and the best for early forcing, being warmer on account of the shelter afforded by the back wall. In this house the principal part of the roof is a fixture, ventilation being provided for by small lifting sashes against the back wall, and by the upright front sashes being hung on a pivot so as to swing outwards on the lower side. The necessary heat is provided by four 4-inch hot-water pipes, which would perhaps be best placed if all laid side by side, while the vines are planted in front, and trained upwards under the roof. A second set of vines may be planted against the back wall, and will thrive there until the shade of the roof becomes too dense. (2) The *hipped-roofed* or three-quarter span (fig. 9) is a combination of the lean-to and the span-roofed, uniting to a great degree the advantages of both, being warmer than the span and lighter than the lean-to. The heating and ventilating arrangements are much the same as in the lean-to, only the top sashes which open are on the back slope, and therefore do not interfere so much with the vines on the front slope. In both this and the lean-to the aspect should be as nearly due south as possible. Houses of this form are excellent for general purposes, and they are well adapted both for muscats, which require a high temperature, and for late-keeping grapes. (3) The *span-roofed* (fig. 10), the most elegant and ornamental

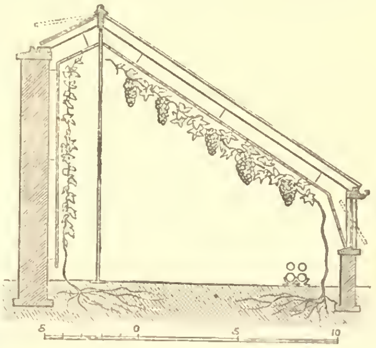

FIG. 9.—Hipped-Roofed Vinery.

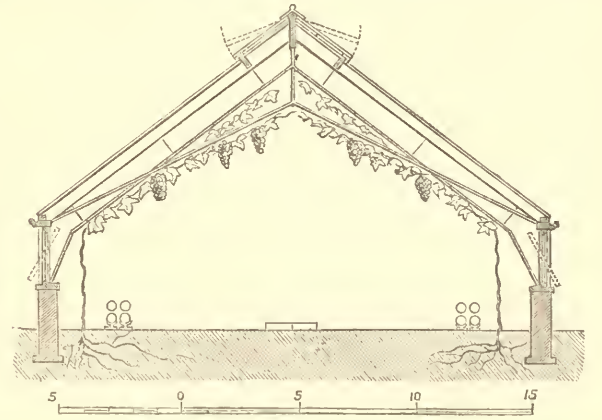

FIG. 10.—Span-Roofed Vinery.

form, is especially adapted for isolated positions; indeed, no other form affords so much roof space for the development of the vines. The amount of light admitted being very great, these houses answer well for general purposes and for the main crop. The large amount of glass or cooling surface, however, makes it more difficult to keep up a high and regular temperature in them, and from this cause they are not so well adapted for very early or very late crops. They are best, nevertheless, when grapes and ornamental plants are grown in the same house, except, indeed, in very wet and cold districts, where, in consequence of its greater warmth, the lean-to is to be preferred.

The *Pinery* is a house devoted to the cultivation of the pine-apple. The pineries or pine stoves of former times were generally large lofty structures of the lean-to vinery fashion, and heated by smoke flues; but these were superseded by buildings of more compact form, such as that of Baldwin, a noted pine grower of his day, in which the low roof was hipped, the short or northern slope being of slate, and the glazed sashes being fixtures. These were again improved by the substitution of glass for slate in the back slope, and of hot-water pipes for smoke flues as the heating medium, openings being provided at back and front, as at *a*, *a* (fig. 11), for ventilation. Such houses as these are low, and therefore are more economically kept at the high temperature necessary for pine growing. The best form of pinery is a low structure of this kind, but somewhat wider, so as to permit of the utilization of the front and back Pinery.

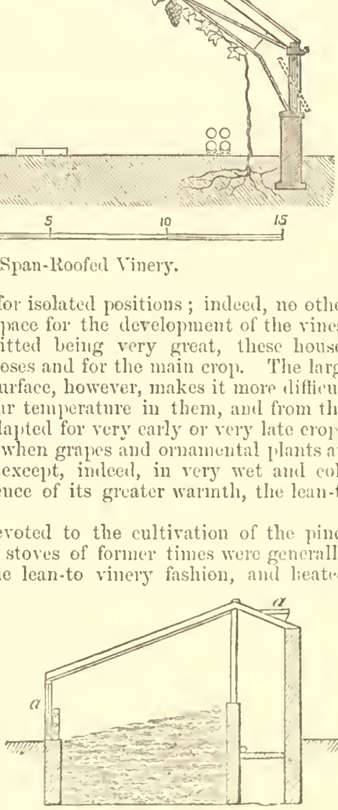

FIG. 11.—Section of Pinery.

spaces for general forcing purposes (fig 12). Such a house might be 14 feet wide, consisting of a plunging bed for bottom heat 8 feet wide, a back path of 2 feet provided with a shelf for strawberries near the glass, a front path of 2 feet, and between that and the front wall a stage for pots, which might be used for forcing French beans, and which should be on the same level as the front curb of the centre pit, and about 2½ feet from the glass. The height of the back wall should be 15 feet. The house should be heated by three or four hot-water pipes placed beneath the front stage, and two placed close to the wall in the back path; and the

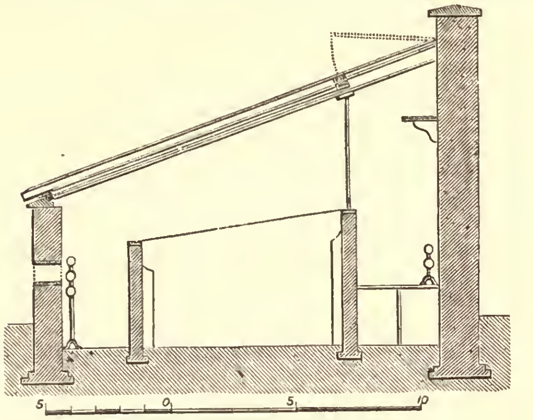

FIG. 12.—Modern Pinery.

necessary bottom heat should be provided by fermenting tan or leaves, or by hot-water pipes or a hot-water tank placed beneath the plunging bed. Ventilators should be fixed at short intervals in the front wall beneath the stage and opposite the heating pipes; and the alternate upper sashes should be made to open, or corresponding ventilators close to the top of the back wall should be provided.

If the stock of pine plants is not extensive, certain and abundant crops of fruit cannot be expected; and it is therefore necessary to have not only fruiting pineries but pineries for succession plants. These are generally called *pine pits*, and differ little from the pits used for accommodating other tender plants. Two or three succession pits are required to provide a stock of plants to keep the fruiting-house filled. Low-roofed pits are to be preferred, not only on account of their appearance, but because the pine can only be cultivated in its highest state of perfection when grown in pits just sufficient for the full development of the foliage and crown of the fruit. These pits, if span-roofed, should be provided with a central path under the ridge, just high enough for a workman to stand upright, and a plunging-pit on each side; but any ordinary well-constructed pit will answer the purpose if sufficiently heated.

Peach house.

The *Peach House* is a structure in which the ripening of the fruit is accelerated by the judicious employment of artificial heat. For early forcing, as in vineries, the lean-to form is to be preferred, and the house may have a tolerably sharp pitch. A width of 7 or 8 feet, with the glass slope continued down to within a foot or two of the ground, and without any upright front sashes, will be suitable for such a house, which may also be conveniently divided into compartments of from 30 to 50 feet in length according to the extent of the building, small houses being preferable to larger ones. As a very high temperature is not required, two or three pipes running the whole length of the house will suffice. The front wall should be built on piers and arches to allow the roots to pass outwards into a prepared border, the trees being planted just within the house. Abundant means of ventilation should be provided.

For more general purposes the house represented in fig. 13 will be found more useful. One set of trees is planted near the front, and trained to an arched trellis *b*. Another set is planted at the back, and trained on a trellis *c*, which is nearly upright, and leans against the back wall; or the back wall itself may be used for training. There are no upright front sashes, but to facilitate ventilation there are ventilators *d* in the front wall, and the upper roof sashes are made to move up and down for the same object. Two or three hot-water pipes are placed near the front wall. The back wall is usually planted with dwarf and standard trees alternately, the latter being temporary, and intended to furnish the upper part of the trellis, while the permanent dwarfs are gradually filling up the trellis from below. In any case the front trellis should stop conveniently short of the top of the sashes if there are trees against the back wall, in order to admit light to them. They would also be better carried up nearly parallel to the roof, and at about 1 foot distant from it, supposing there were no trees at the back.

A span-roofed house, being lighter than a lean-to, would be so much the better for peach culture, especially for the crop grown just in anticipation of those from the open walls, since a high temperature is not required. A low span, with dwarf side walls, and a lantern ventilator along the ridge, the height in the centre being 9 feet, would be very well adapted for the purpose. The trees should be planted inside and trained up towards the ridge on a trellis about a foot from the glass, the walls being arched to permit the egress of the roots. A trellis path should run along the centre, and movable pieces of trellis should

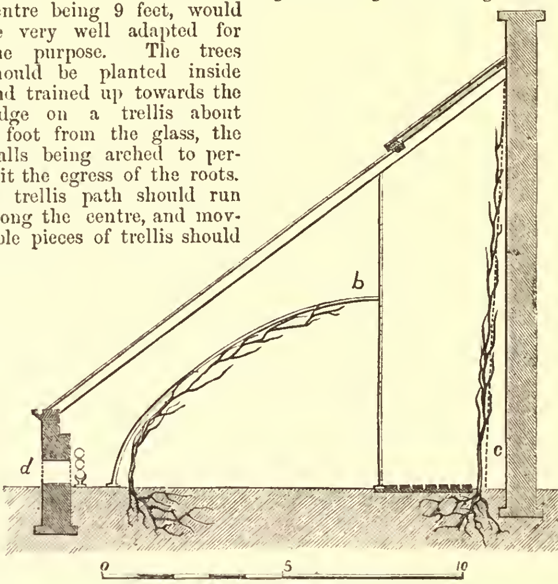

FIG. 13.—Peach House.

be provided to prevent trampling on the soil while dressing and tying in the young wood.

Cucumber and melon house.

The Cucumber and Melon House.—Wherever a continuous supply of cucumbers and a considerable number of melons are required, it is found most convenient to grow them in houses, the attention required and the risk of failures being much less than when hot-beds and pits heated by fermenting materials are employed. The best form of house is a narrow span (fig. 14), on account of the much greater amount of light which it admits. The width should be 12 feet, the height about 10 feet, and the length divided into short portions so as to be worked in succession; a 60-feet house divided into three 20-feet portions would be found very useful, as

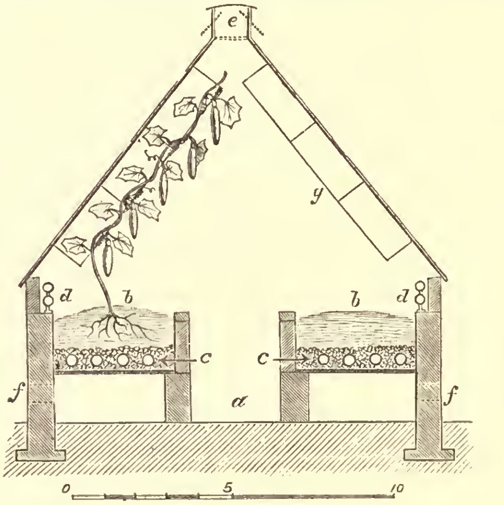

FIG. 14.—Span-Roofed Cucumber House.

one or more could be taken for either crop according to the demand. The inside arrangements should include a pathway *a* of 3 feet in the centre, two beds *b*, *b* provided with hot-water pipes *c*, *c* or hot-water tank for bottom heat, two pipes *d*, *d* on each side for warming the atmosphere, a lantern ventilator *e* at the ridge, and openings in the wall *f* beneath the beds to admit fresh air, and a trellis *g* for training the plants, fixed at 12 or 18 inches from the roof.

Where the house is built against a wall, the hipped form of roof is to be preferred, as it will admit more light, and also allows more space for the cucumber or melon vines. Fig. 15, from Moore's *Treatise on the Cucumber*, shows such a structure, in which *b* is the pathway, *c* front ventilator, *d* back ventilator, *e* hot-water pipes, and *f* tank for bottom heat. The cold air admitted at *c* enters a chamber *g*; thence it passes into the space *h* over the water in the tank, and is admitted through a tube *m*, which passes up through the bed of soil, into the house near the front; similar tubes *n*, inserted at intervals along the front of the bed, are intended for supplying water amongst the rubble, to keep the soil about the roots constantly moistened.

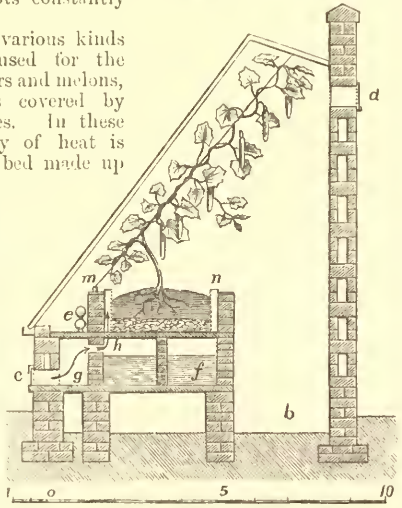

FIG. 15.—Moore's Cucumber House.

Pits and frames of various kinds are also frequently used for the cultivation of cucumbers and melons, as well as hot beds covered by ordinary garden frames. In these cases the first supply of heat is derived from the hot bed made up within the pit (fig. 17, *a*), which is all the better for having a layer or two of faggot-wood worked into it to facilitate the distribution of the heat from the linings later on. When the heat of the original bed subsides, linings of fermenting dung *b, b* must be added, and these must be kept active by occasional turnings and the addition of fresh material as often as required. Figs. 16 and 17 show different forms of pits of this character. It is, however, a vast improvement upon the old system to effect both top and bottom heating by hot-water pipes (fig. 16, *a, a*), in which case the width of the pits may be increased by at least 2 feet. Where there is much forcing carried on, the judicious arrangement of the several structures, permitting of their being worked from one boiler, should be carefully seen to.

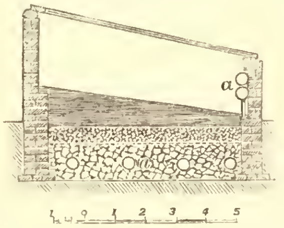

FIG. 16.—Cucumber Pit heated by Hot Water.

Orchard Houses. *Orchard Houses* are the invention of the late Mr Rivers of Sawbridgeworth. In all the more genial portions of England and Scotland they may be used without fire-heat, and chiefly for potted fruit trees; and if the trees are well managed, a very large quantity and variety of fruit can be produced, of excellent if not first-rate quality. These houses will be found useful adjuncts to

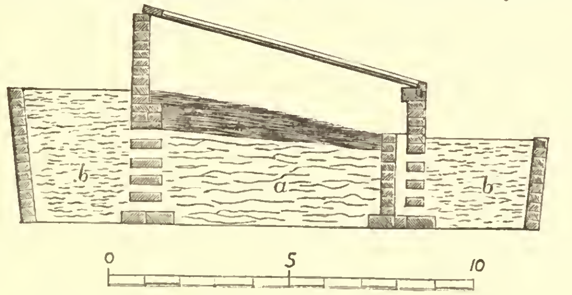

FIG. 17.—Cucumber Pit heated by Fermenting Dung.

other structures even in large gardens, while they are of the utmost value to amateurs, who would otherwise be dependent on outdoor crops. They are, moreover, exceedingly economical, and may be turned to a variety of uses, being just as suitable for the growth of half-hardy flowers as for our less hardy fruits. For fruit trees the orchard houses are of most value in spring, not to excite but to protect the blossom buds, and in autumn to assist in ripening both fruit and wood. While peaches, nectarines, and apricots are the permanent occupants of the house, except in late autumn, when they may be set out of doors, plums, pears, and apples may all by this means be assisted to produce good crops. During winter and spring (when they should be kept cool) the trees may be stored as closely as possible, and in this state they may remain until after blooming is over and the fruits are set, when the hardier kinds should be gradually drawn out and hardened in sheltered spots, and eventually plunged in the open garden to swell their fruits, this thinning out affording room for the tenderer kinds.

The orchard house may be of the lean-to form or a span; but the latter is much to be preferred. Fig. 18 is a sketch of Mr Rivers's small span-roofed orchard house, which is built of wood and glass. Two rows, 14 feet apart, of oak posts *a, a*, 5 by 3 inches and 9 feet long, or of deal posts set in cast-iron sockets, are firmly fixed 3 feet in the ground and 5 feet apart. On each of these should be firmly nailed the plate *b*, 4 inches by 3, to receive the ends of the rafters *c, c*, which should be 8 feet long and 3 inches by $1\frac{1}{2}$. The ridge board *d* should be 3 inches by 1, to which the upper ends of the rafters, after being sloped, should be nailed. At the lower end a drip board, 5 inches by 1, placed sloping to receive the lower ends of the glass, must be fixed on the plate the full length of the house; and on the ridge board a small ledge must be nailed for the upper ends of the glass panes to rest upon. On the upper edge of the ridge board a cap, 3 inches by 1, shaped thus ∧, should be nailed, to shoot off the water and prevent its entrance at the ridge. The sides *i* are boarded, and the roof is of 21 oz. glass, the rafters (stout sash-bars) being 20 inches apart, and the panes 15 inches long, set end to end in glazing. Under the glass *g* on each side is a ventilating shutter *h*, $\frac{3}{4}$ inch broad and 1 foot wide, hinged and opening downwards. The roof is stayed by irons screwed to every fourth rafter. The angular space over the door forms a ventilator. A house of this form should have a central path *e*, the two beds or spaces on each side *f, f* accommodating the fruit trees either planted out or grown in pots. These beds may be raised above the path if used for dwarf trees.

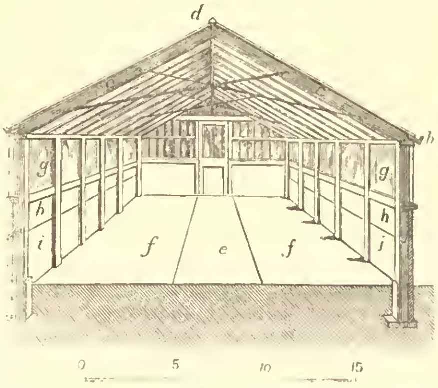

FIG. 18.—Rivers's Span-Roofed Orchard House.

As a larger house, one of 24 feet width (fig. 19) might be recommended. The oak posts or deal posts in sockets, 6 inches by 4, must be set in two rows *a, a*, 24 feet asunder, 6 feet apart in the rows, and the plates, rafters, ridge board, and drip board should be as described above. The apex of the ridge *d* should be 12 feet from the surface. The roof itself *c* is supported and steadied by two rows of iron pillars *k* connected by tie rods, and glazed with 21 oz. glass,

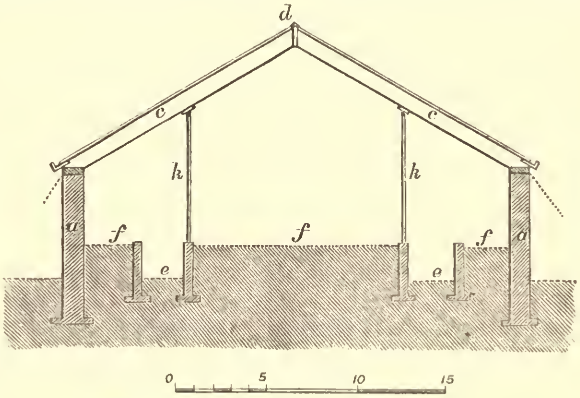

FIG. 19.—Orchard House with Raised Beds.

the rafters being 20 inches apart. The sides and ends are boarded, and provided with hinged ventilators as in the smaller house. The floor may be level with the ground, and with a central path or two side paths *e, e*. For dwarfer and more bushy plants, and for general purposes, the beds may be slightly raised, as *f, f, f* in fig. 19. When the trees are planted out the raised beds would be objectionable as diminishing the available height, but for potted plants they are an advantage, raising the trees nearer to the light.

In the north of England, and in all moist and cold districts of Scotland or Ireland, Mr Rivers recommends the introduction of a hot-water pipe or two into houses in which peaches, nectarines, and apricots are to be grown, not to force them, but to ensure the ripening of both wood and fruit.

12. *Pits and Frames.*—These are used both for the summer growth and winter protection of various kinds of ornamental plants, for the growth of such fruits as cucumbers, melons, and strawberries, and for the forcing of vegetables. When heat is required, it is sometimes supplied by means of fermenting dung, or dung and leaves, or Pits.

tanner's bark, but it is much more economically provided, on the score of labour at least, by hot-water pipes. Pits of many different forms have been designed, but it may be sufficient here to describe one or two which can be recommended for general purposes.

Fig. 20 represents a simple and useful form of pit designed for the Chiswick garden by Mr Sibthorpe, and published by Mr R. Thompson (*Gardener's Assistant*, 499). It is 7 feet wide, the front wall 2 feet high, the back wall 3½ feet. The walls are one brick thick, or 4½ inches, with a 4-inch pier *a* at every third rafter, the

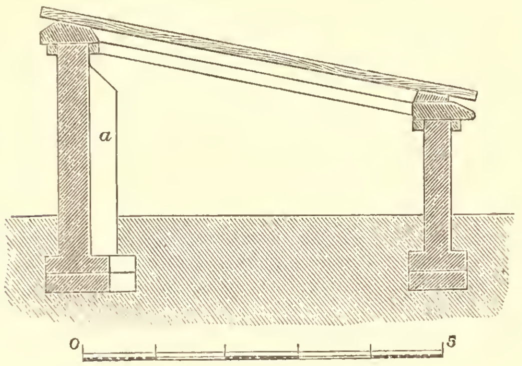

Fig. 20.—Sibthorpe's Plant Pit.

foundations being respectively 9 and 14 inches. The wall plates both at front and back project so as to allow the drip to fall clear of the walls; and fillets of wood fixed to their under surfaces and close up to the wall on each side serve to maintain both the wall plate and top of the wall steadily in their positions. Such a pit used for cucumbers or melons might be excavated slightly below the ground level to admit of bottom heat being supplied by a bed of fermenting dung, over which the soil should be placed in the usual way, bringing the plants up near to the glass; or the bottom heat might be supplied by the tank system of heating or by hot-water pipes. For small store plants of any kind the interior might be filled up with any porous materials, finishing off with a surface of fine coal-ashes at a suitable height, or larger plants might be accommodated by using it as shown, without any filling up. Heat can easily be supplied by one or two 4-inch pipes, front and back, according to the temperature required; but if fermenting material be used for this purpose, the lower portion of the walls, as far up as will be covered by the interior filling, should be pigeon-holed.

An excellent pit for wintering bedding-out plants or young greenhouse stock is shown at fig. 21. It is built upon the pigeon-hole principle as high as the ground level *a*, *a*, and above that in 9-inch brickwork. At a distance of 9 inches retaining walls *b*, *b* are built up to the ground level, and the spaces between the two are covered by thick boarding, which is to be shut down as shown at *c* in cold weather to exclude frost, and opened as shown at *d* in mild weather to promote a free circulation of air through the pit. The height of the pit might be reduced according to the size of the plants; and, to secure the interior against frost, a flow and return hot-water pipe *e* should pass along beneath the staging, which

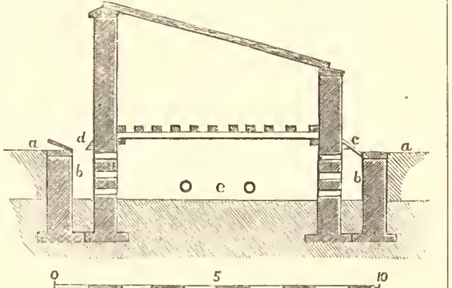

Fig. 21.—Ventilated Plant Pit.

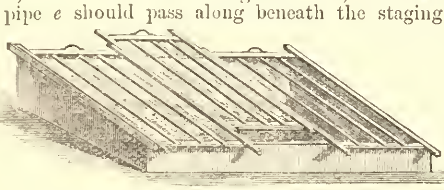

Fig. 22.—Hot-Bed Three-Light Frame.

should be a strong wooden trellis supported by projections in the brickwork. The water which drains from the plants or is spilt in watering would fall on the bottom, which should be made porous to carry it away. For many plants this under current of ventilation would be exceedingly beneficial, especially when cold winds prevented the sashes from being opened. A pit of this character may be sunk into the ground deeper than is indicated in the figure if the subsoil is dry and gravelly, but in the case of a damp subsoil it should rather be more elevated, as the soil could easily be sloped up to meet the retaining wall.

For all useful purposes these two forms of pits will suffice, but there will always be found occupation for some of the common hot-bed frames (fig. 22). They should be made of the best red deal, 1¼ inch thick. A convenient size is 6 feet wide, 24 inches high at the back and 15 in front; and they are usually 12 feet long, which makes three lights and sashes, though they can be made with two lights or one light for particular purposes. Indeed, a one-light frame (fig. 23) is often found very convenient for many purposes. The lights should be 2 inches thick, and glazed with 21 oz. sheet glass, in broad panes four or five to the breadth of a light, and of a length which will work in conveniently and economically, very long panes being undesirable from the havoc caused by accidents, and very short ones being objectionable as multiplying the chances of drip; panes of from 6 or 8 to 12 inches long are of convenient size for garden lights of this character. In all gardens the frames and lights should be of one size so as to be interchangeable, and a good supply of extra lights (sashes) may always be turned to good account for various purposes. Fran

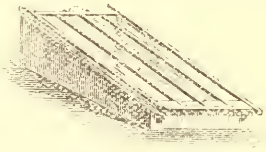

Fig. 23.—One-Light Frame.

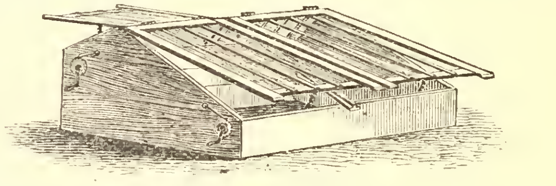

Fig. 24.—Span-Roof Frame.

Boulton and Paul's span-roof garden frame (fig. 24) may under some circumstances be useful as a substitute for the three-light frame. It is adapted for storing plants in winter, for nursing small plants in summer, and for the culture of melons and other crops requiring glass shelter. These frames are made 11 inches high in front, 22 at the back, and 32 at the ridge, with ends of 1½-inch red deal; the sashes, which are 2 inches thick, open by gearing, the front and back separately. The lights are hinged so that they can be turned completely back when necessary. This more direct and ready access to the plants within is one of the principal recommendations of this form of pit.

13. *Mushroom House.*—Mushrooms may be grown in sheds and cellars, or even in protected ridges in the open ground, but a special structure is usually devoted to them. A lean-to against the north side of the garden wall will be found suitable for the purpose, though a span-roofed form may also be adopted, especially if the building stands apart. Mus room hous

The internal arrangement of a lean-to mushroom house is shown in fig. 25. The length may vary from 30 feet to 60 feet; a convenient width is 10 feet, which admits of a 3½ feet central path, and beds 3 feet wide on each side. The shelves should be of slate *a*, *a*, supported by iron uprights *b*, *b*, each half having a front ledge of bricks set on edge in cement *c*, *c*. The slabs of slate forming the shelves should not be too closely fitted, as a small interval will prevent the accumulation of moisture at the bottom of the bed. They may be supported

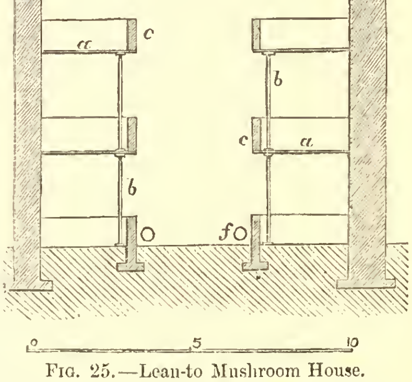

Fig. 25.—Lean-to Mushroom House.

by iron standards or brick piers, back and front, bearing up a flat bar of iron on which the slates may rest; the use of the bar will give wider intervals between the supports, which will be found convenient for filling and emptying the beds. The roof may be tiled or slated; but, to prevent the injurious influence of hot sun, there should be an inner roof or ceiling *d*, the space between which and the outer roof *e* should be packed with sawdust. A hot-water pipe *f* should run along both sides of the pathway, close to the front ledge of the lowest beds. The different shelves can be planted in succession; and the lower ones, especially those on the floor level, as being most convenient, can be utilized for forcing sea-kale and rhubarb.

Another style of house which answers remarkably well may be formed by an arch of brickwork, making a kind of tunnel, or by a semi-arch projected against a brick wall or against the side of a bank (fig. 26). In either case the arch *d* should be covered with

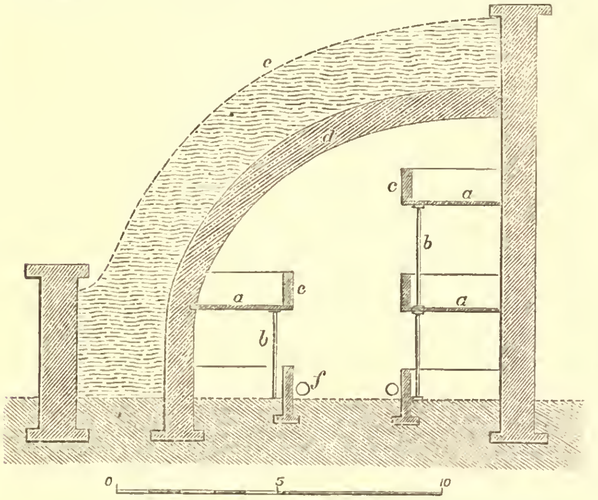

FIG. 26.—Semi-Arch Mushroom House.

a thick bank of earth *e*, and planted with spreading shrubs to keep it cool and shaded. The size of the beds and the fitting up may be exactly the same as in fig. 25 already described, except that on one side the available height will be necessarily less.

14. *Fruit Room.*—In many gardens a portion of the shed accommodation behind the ranges of glass-houses is made to do service as a fruit room, but it is sometimes difficult to secure in this way the conditions favourable for the conservation of fruit. The main requisites are coolness and a steady uniform temperature, combined with darkness and moderate but not excessive dryness. A dry cool cellar makes an excellent fruit room.

One of the most successful examples of a fruit room is that of Mr Moorman of Clapham, described by Mr Robert Thompson in the *Journal of the Horticultural Society* (vi. 110), of which figs. 27 and 28 represent a plan and section. The building in this case

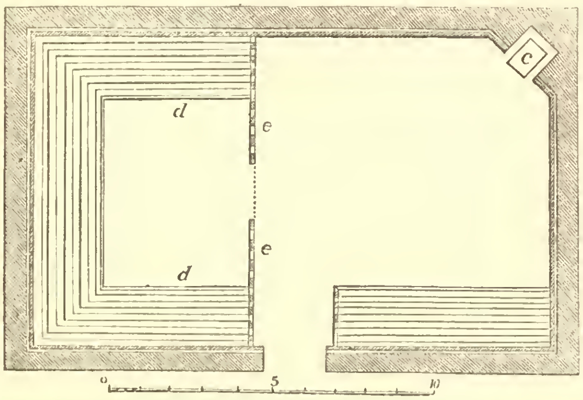

FIG. 27.—Moorman's Fruit Room (plan).

was not specially erected for a fruit room, having been originally a loft over a coach-house. The walls have an inner lining of board enclosing a cavity, which is probably one cause of the efficiency of the apartment, since the wood lining and the cavity containing air both act as slow conductors of heat. The ceiling on the north side is double, which also conduces to the same end. There is a swing window *b*, opened a little occasionally, but always covered with a roller blind so as to shut out light, and there is a small stove *c*, but seldom used, and never for the sake of warming the air, unless the temperature is below freezing; if damp is observed a little fire is lighted on a dry day, and this with ventilation soon dissi-

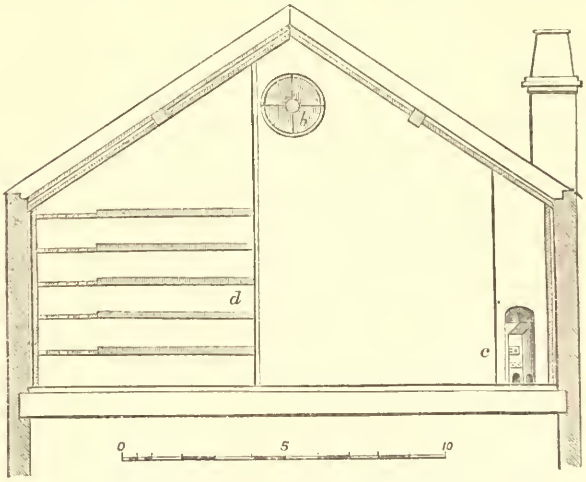

FIG. 28.—Moorman's Fruit Room (section).

pates it. The fruit shelves *d*, *d* are made with battens $1\frac{1}{2}$ inch wide and $1\frac{1}{4}$ inch apart, with a layer of clean straw placed across them, and on this the fruit is laid out singly. The shelves are enclosed by a partition of open work *e*, *e*, which is made of battens similar to the shelves themselves.

The fruit room in the Royal Horticultural Garden at Chiswick is a very good example of one on a larger scale. The floor of this is sunk about 18 inches below the ground level, and is concreted to keep out rats and mice. It is built against a north wall, and has a low sloping roof of slate. Three or four ranges of shelves are fixed all round against the walls, and there is a table occupying the centre for the display of samples of the different kinds grown. Such an apartment would form a convenient fruit room in a private garden establishment. The walls should be hollow; and a ventilator made to open and shut, and communicating obliquely with the external air, should be inserted in the ceiling near each end, the interval between ceiling and roof being packed with dry sawdust to assist in keeping up a uniform temperature. The shelves should be made of narrow battens of wood laid somewhat apart, as in Mr Moorman's house, and the central table should be fitted with shallow drawers in which to store the very choicest fruits, such as the finer dessert pears, which should be individually wrapped in tissue paper and laid in a single tier. The better kinds of fruits on the open shelves should be laid out singly. It is a wise economy not to stint space in such a structure, as many things can be accommodated for a time in a room of this sort; for example, the floor space beneath the shelves forms a good place for storing seed potatoes, especially those for the early crops. A window is necessary, as light will be occasionally required to examine and to select the fruits, but it should be tight-fitting, and on all other occasions closed by shutters so as to keep the interior dark. The door should also be closely fitted, to exclude the external air; indeed it is better if the fruit room itself can be entered from an adjoining apartment, from which light need not be excluded, and which may serve as a seed room and store room for many of the smaller garden requisites. If a hot-water pipe can be run round these apartments from some neighbouring apparatus, so much the better, but in the fruit room proper it should only be used occasionally to dispel damp, or, in the case of very severe weather, to keep out frost.

15. *Heating Apparatus.*—Plant houses are heated in a Heating.
variety of ways, but practically smoke flues and hot-water pipes are principally made use of. The cost of erection is a little more for hot-water pipes than for flues, but the former are the cheaper in the end. Steam is not now used as a heating medium, except where the waste steam of a manufactory is turned to account in some adjoining garden. The use of fermenting vegetable substances in the production of heat is rapidly disappearing from our best gardens before the application of hot water, which is far more economical and certain in its effects.

The *Smoke Flue*, that is, the continuous cavity commencing at Smoke
the back of the furnace and ending at the chimney, when used as flue.

a source of heat, should be carried along the front of the house, returning near the back; by the time it has run thus far most of the heat taken up from the fuel will be in course of transmission to the enclosed atmosphere of the house to be heated. There should be a gradual rise for some distance after leaving the furnace, which should be from 1 to 2 feet below the level of the front flue; and there should be no sharp angles or turnings. Earthenware pipes may be substituted when appearance is not a consideration. Smoke flues should be cleaned out at least once a year. When properly constructed, they answer their purpose sufficiently well; but this mode of heating is now virtually superseded in all gardens of note by the hot-water system.

Hot water. *Hot Water.*—The diffusion of heat in plant houses by causing hot water to circulate in iron pipes or vessels was brought into notice in 1827, and has gradually superseded all other modes. The apparatus is more durable than flues, occupies less space, can be placed in situations where flues cannot, is more elegant in appearance, gives out a more steady and uniform heat, and can seldom be overheated. The true cause of the circulation of the water in the pipes may be explained by fig. 29. When the water in the boiler

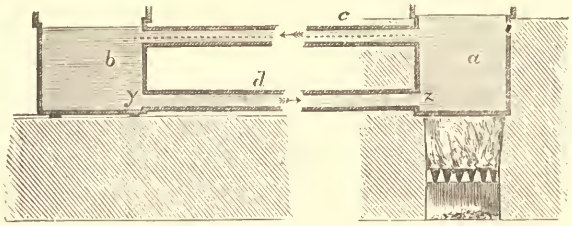

Fig. 29.—Diagram of Tank Boiler showing Circulation in Pipes.

a is heated up, it expands and so becomes lighter than that in the cistern *b*; the pressure at *z* in the horizontal pipe *d* is thus less than at *y*, so that the water flows through *d* from *b* to *a*, and *b* is kept supplied from the pipe *c*. In this arrangement, which represents the common tank boiler, with a cistern at the extremity of the pipes, the process of heating was slow, and many changes have consequently been made.

The furnace. *The Furnace.*—The most perfect furnace is that in which the combustion is most complete. On this account the fire should be surrounded by slow conductors of heat, such as Welsh lumps or other kinds of fire-brick; and the sides of the furnace should not be formed by any part of the boiler, nor should the furnace bars be tubular and connected with the boiler, though this latter plan is sometimes adopted to prevent the burning out of the bars. All the air necessary for maintaining combustion should enter from below, that is, through the ash-pit, and not through the door or sides of the furnace; but to produce this effect the furnace should be fitted with double doors and ash-pit registers, for thus only can

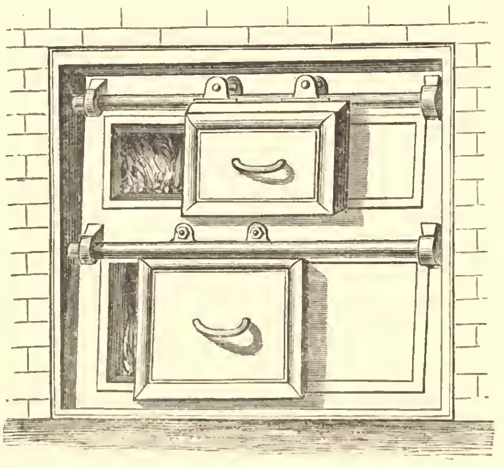

Fig. 30.—Sliding Furnace Doors.

the stoker have control over his furnace. By shutting the ash-pit and furnace door closely combustion is lessened, and the fire may be kept almost in a state of quiescence for many hours together; while, on opening either the door or ash-pit register, air is admitted and combustion goes on. Sylvester's furnace doors or doors of similar sliding form (fig. 30) are preferable to the ordinary hinged doors, because they can be opened to any extent, and are less liable to get out of order. These doors are faced with fire-brick, and run on rollers on an iron rod, or slide by means of a ledge. Mr Taplin recommended, in the *Florist and Pomologist* (1868, p. 32), that, to prevent the burning away of the furnace bars and the formation of clinkers, the ash-pit should be kept filled with water, and states that the bars will then last three times as long as with the ordinary dry ash-pit. The ash-pit may be built in cement for this purpose, or fitted with a cast-iron pan for the water.

Hot-Water Boilers.—Only a few of the principal types of the very diverse kinds of boilers can be noticed here. The simpler the form and the less complicated the whole apparatus is the better. It is essential that a large area of the boiler surface should be brought within the direct action of the fire.

Rogers's Conical Boiler (fig. 31), which has long been in use, is very suitable for heating pits and small houses, since it is econo-

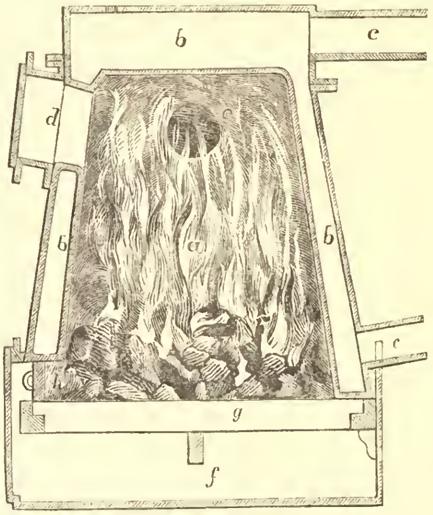

Fig. 31.—Rogers's Conical Boiler.

mical of fuel, and gives out a steady heat for a long time—15 to 20 hours. It is formed of two truncated concentric cones, with a space of 2 or 3 inches between them for the water, the furnace being in the inner cone, and the fuel supplied from the top. It was originally surrounded with brickwork, but several improvements have been introduced. In fig. 31 the boiler is placed in a cast-iron stand, with ground circular furnace, and register ash-pit doors,—*a* being the furnace, *b* the boiler, *c* flow and return pipes, *d* the furnace door, *e* smoke-pipe to the vent, *f* ash-pit, *g* grating, *h* hole for cleaning the furnace. The best kinds of fuel are coke, gas cinders, and anthracite; but common coal which does not cake very much is also suitable, as it is soon formed into coke.

Saddle Boilers.—The saddle boiler is a very efficient form, steady and sure in its working. In its improved forms it is, perhaps, the best for general purposes. It should be set over a furnace, the sides and end of which should be of fire-brick. It may be quite plain, or with the inner surface ribbed or corrugated (fig. 32), a modification adopted by Mr Gray of Chelsea. In all saddle boilers,

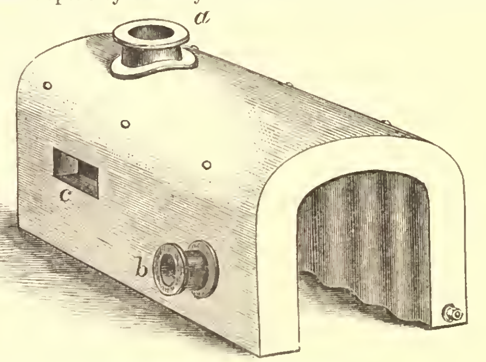

Fig. 32.—Gray's Saddle Boiler.

which should be deep from front to back, and set well back from the doors of the furnace, the full force of the fire strikes the dome of the boiler directly, and so long as the fire continues this is the part most directly influenced by its heat. The flow pipe is shown at *a*, and the return pipe at *b*, while *c* represents an opening (one on each side) for the passage of the smoke into the flues, the end being a water-way, and forming part of the boiler. The boiler is emptied by a small tap affixed to the pipe shown in the front.

There are many forms of what are called *Flued Saddle Boilers*, all of them good and thoroughly efficient if properly set. One of these, with a terminal water-way, is shown in elevation at fig. 33, and in section, showing the mode of setting, at fig. 34. The fire is made under the principal arch *a*; the flame and smoke return through the flue *b*, and then turn back over the top of the boiler

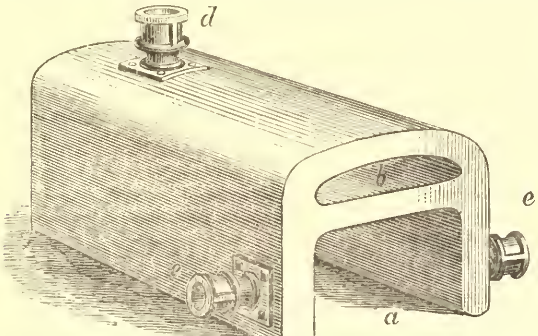

FIG. 33.—Flued Saddle Boiler.

to the outlet *c*, which can be placed at whatever point is in each case most convenient. The other parts referred to are—*d* flow pipe, *e* return pipes, *i* soot-door for cleaning flues, *g* furnace door, *h* ash-pit door.

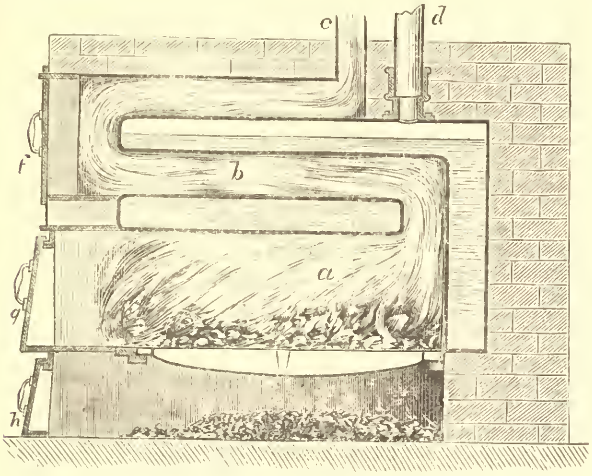

FIG. 34.—Flued Saddle Boiler (section).

The *Gold Medal Boiler* (figs. 35–38) is perhaps one of the best of these modified saddles, and like the others has a dome or arch *a*, and back water-way *b*; the heated products of combustion striking against this back are sent up the central flue *c*, and then diverted into the side flues *d*, *d*, before passing into the chimney shaft *e*. Fig. 36 shows a transverse section, and fig. 37 a longitudinal section set in brickwork, which is shown in elevation in fig. 38.

FIG. 35.—Gold Medal Boiler.

The ash-pit is shown at *f*, the furnace door at *h*, the centre and side flues at *c* and *d*, the water-way end at *b*, the soot-door at *i*, the sludge-plugs for cleaning out the interior at *g*, the flow pipe at *m*, the return at *n*, while *l* shows a hollow space around the boiler for utilizing the heat given off by its exterior surface. This boiler is named from its having won the gold medal in a boiler competition at Birmingham in 1872. The Witley Court boiler and the Glasgow boiler are both excellent forms of the flued saddle type.

Stevens's Trentham Boiler (fig. 39) is a very powerful and economical one, for large establishments especially. It is a modification of the well-known Cornish boiler, and consists of two wrought-iron cylinders substantially rivetted together, and having Trentham boiler.

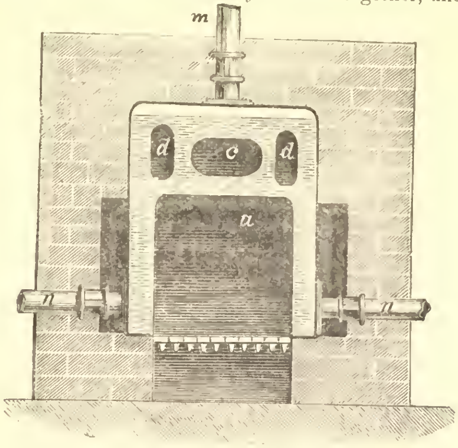

FIG. 36.—Gold Medal Boiler (transverse section).

a water space of about 2 inches between them. The frame for the furnace doors *d* is attached to the front. It is supported by two cast-iron chairs *a*, *a*, the front chair forming the frame for the lower flue doors *b*, which fasten by a simple catch, and can readily

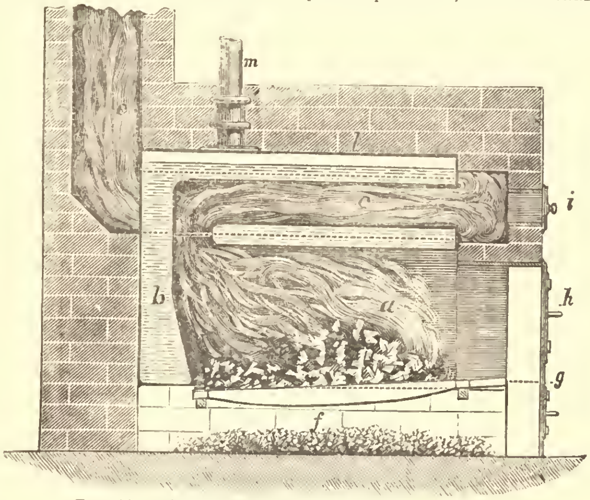

FIG. 37.—Gold Medal Boiler (longitudinal section).

be lifted off for cleaning the flues. The plug *c*, opened by unscrewing it, is for the purpose of clearing out all interior accumulations of dirt, which should be done thoroughly at short intervals. The flow pipe is at *e*, the return at *f*. In setting, the chairs are placed

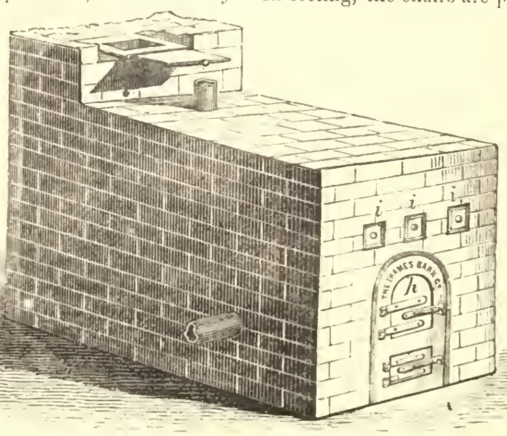

FIG. 38.—Gold Medal Boiler (brickwork setting).

level on a solid foundation, and two 9-inch walls are built up so as just to clear the boiler, and about level with the centre of the cylinder; on these a course of fire-brick lumps is laid, and brought close up to the side of the cylinder, and resting on the lumps an arch is turned leaving a space the depth of the top flue doors *b*, to serve as an upper flue, while the space below forms a lower flue. The grate bars are inside the cylinder towards the lower part, the space above them forming the furnace, and that below them the

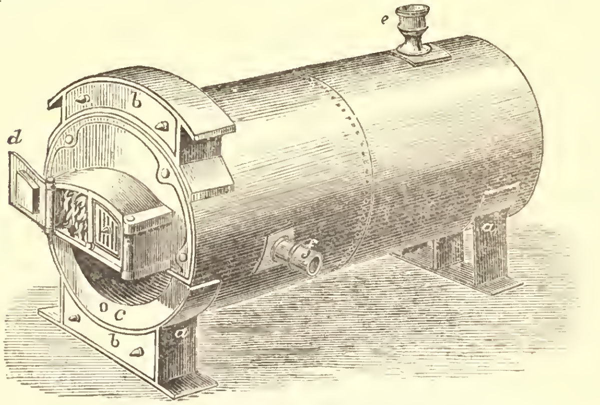

Fig. 39.—Stevens's Trentham Boiler.

ash-pit. The heat thus passes through the centre of the cylinder, then returns by the upper flue over its top, and is conducted to the chimney by the lower flue, which arrangement is found to work better than when the heated air is made to pass through the lower flue first.

Tubular boilers.

Tubular Boilers.—While the action of tubular boilers is rapid, and they are undoubtedly very powerful, they are said to be prodigal in their consumption of fuel, and liable to crack. In many cases, however, they have done good work for many years, and they are consequently employed to a considerable extent. The original tubular boilers were horizontal, but the upright form has nearly superseded this, and the *Upright Oval Tubular* of Mr Gray, and the *Duplex Upright Tubular* of Messrs Weeks & Co., both of Chelsea,—the latter marked by improvements introduced specially to meet the foregoing objections,—are the best forms at present in use. The Duplex (fig. 40) is made in two equal parts, each being capable of

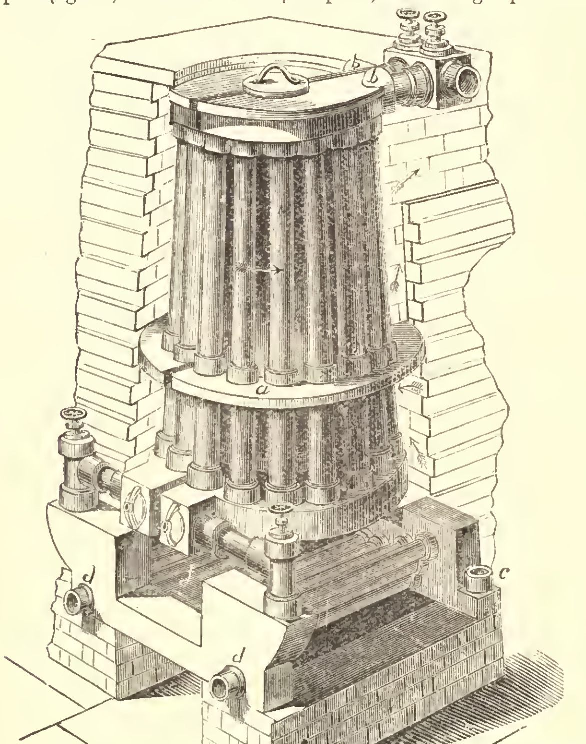

Fig. 40.—Weeks's Duplex Tubular Boiler.

being worked alone. Each section consists of a semicircle of upright tubes forming the boiler proper, fitted with the diaphragm *a*, by which more perfect combustion of the fuel is secured, a series of horizontal pipes forming the furnace *f*, a flow pipe *b* and a return pipe *c*, and an outlet *d* for removing sedimentary deposits from the interior.

Ladds's Boiler (fig. 41) is a horizontal tubular, which is found to be extremely powerful as well as economical. It is a rectangular box 6 feet long, made of 2-inch iron pipes, fixed into hollow water spaces which form the ends; these pipes act as fire bars, and form the sides of the furnace. Above the fire there are three series of horizontal pipes, each covered by a layer of tiles so placed as to convert the two intervening spaces into flues, along which the flames and smoke travel for 18 feet, the smoke escaping at the far end by an opening in the upper layer of tiles. Each tier of pipes

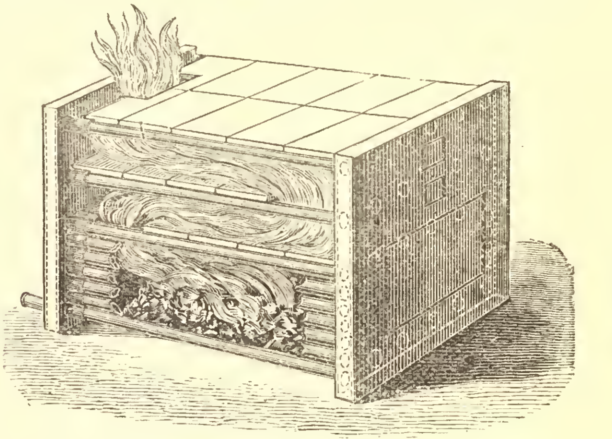

Fig. 41.—Ladds's Boiler.

in its turn therefore gets its share of heat from the burning fuel, and the consequence is that the apparatus is very quick in its action. The tubes are fitted in with Portland cement and hempen cord packing—tar ropes being found to destroy the cement. These boilers each heat 3000 feet or more of 4-inch piping. On the top of the upper layer of tiles are placed about 9 inches of ashes, then ordinary inch boards which rest on 4½-inch retaining walls, and on these 8 or 10 inches more of ashes, which very efficiently prevents any loss of heat.

Stoves, &c.—In the case of very small houses petroleum stoves or lamps are sufficient to keep out all ordinary frosts, but they are attended with a disagreeable smell. A small conical or cylindrical boiler attached to a system of piping is by far the safest and best in such cases. The furnace heating may also be effected either with petroleum, or, better still, as requiring no attendance, with gas. The furnace should be accessible from the outside only, so that none of the products of combustion may enter the house. A small conservatory might be readily heated in this way from a furnace fixed in a recess of the back wall or in the basement of the house, and placed near one of the fire-places, so that the outlet may be conducted into the chimney. A flow and return passing along under the side and front stage (avoiding doorways) might be kept heated by means of a small boiler of any form set over a circlet of gas jets. If on the level, the arrangement would be more simple still, since the boiler could be set in the house without brickwork, and the furnace constructed beneath it by piercing through the exterior wall, and fitting the opening with an ordinary furnace door.

Hot-water pipes are best made of cast-iron. Tow or rope, and a mixture of red and white lead, are generally used for packing or caulking the joints, though some prefer vulcanized india-rubber rings, which make good sound joints, and are very easily removable; for the joints near the fire iron cement must, however, be used. Flat pipes, and fluted or semi-circular pipes have sometimes been used, but the cylindrical form is much to be preferred. The number of pipes must be regulated by the extent to be heated, and the degree of temperature required; it is often well to have three or even four flow pipes and only one return pipe.

Pipes of 4-inch bore are almost universally employed, but 3-inch pipes may often be used in small houses. It is a mistake to stint the quantity of piping, since it is far more economical and better for the plants to have a larger surface heated moderately than a smaller surface heated to the highest possible degree. The pipes should, moreover, be placed near the front or lowest part of the house, and, to prevent loss of heat by conduction, should be supported clear of the ground, not less than 6 inches, upon cast-iron chairs.

Mr Cannell of Swanley has adopted the plan of fixing two or three distinct lines of small piping close under the roof glass, so as to prevent the air near the glass from getting cold. This contrivance is particularly useful in repelling damp during winter; and it may also be adopted for warming pits intended for the growth of half-hardy plants.

Hot water may be beneficially applied to garden walls, not, however, for the purpose of forcing the blossoms, but to assist in maturing late fruit and the young wood in unpropitious seasons.

To this end the walls must be built hollow, and the pipes placed near the bottom of the cavity, and supported on cast-iron chairs placed on the top of the foundation course of material. This method was first exemplified by Mr Atkinson in the gardens of the duke of Bedford at Woburn Abbey in 1828.

Heating by tanks. The *Tank System* of heating garden structures was introduced some years since by Mr W. E. Rendle. It consists in circulating hot water in broad shallow tanks instead of closed pipes. It will be obvious that as the water is to flow along these open (or only loosely covered) conduits, they must themselves be level, and the boiler must be either at the same level or below it, the connexion between the two being made in either case by hot-water pipes of suitable length. The tanks are formed of wood, brick, stone, or cast-iron. When of wood, they require to be made of good sound plank, not less than 2 inches thick, and properly jointed, and they are usually covered with slates. Stone or brick tanks require to be lined with a thick coating of Roman cement, while stone, slate, or brick pavement may be employed for covers. The cast-iron tanks have covers of the same material.

When one tank only is employed, as for example in supplying bottom heat to the front bed of a propagating pit, it should be constructed with a division along the centre, running to within about a foot of the end, which should be left open to allow of the water passing to the other side; the flow pipe from the boiler should be connected with the end of the tank on one side of the central division, and the return pipe for leading the water back to the boiler should be connected at the same end on the other side of the division, a sufficient number of pipes being also connected with the flow and return pipes to heat the atmosphere to the temperature desired. It is convenient to have valves fixed in the flow and return pipes, so as to shut off bottom or top heat as may be required. In a larger house a tank may run along the front, across the end, and along the back to the end whence it started; and this may be either divided along the centre as in the former case, the water flowing the whole distance on one side the division and returning on the other, or a broad tank may occupy the front and back, and be connected at the end by an ordinary 4-inch pipe, the flow from the boiler being united with the front tank, and the return carried from the back tank into the boiler.

The tank system of heating is perhaps one of the readiest modes of supplying bottom heat to plunging beds either for propagating or for growing plants, though the same end is practically attained by running some of the ordinary 4-inch pipes connected with the heating apparatus through a tank which can be charged with water when necessary, and emptied when heat is not required. When the plan is used for supplying both top and bottom heat, provision must be made to prevent too much of the steam or vapour from passing into the house; and, on account of the danger of having too much damp at certain seasons, it is perhaps preferable to have a separate set of pipes for the supply of atmospheric heat.

Solar heat. *Solar Heat.*—The rays of the sun reflected from walls and other surfaces become a source of artificial heat. This species of heat, however, is materially affected by the admission of the air necessary to the health of the plants. Solar heat, if properly regulated by ventilation, is of immense importance in the ripening of all the finer fruits, as well as for the abundant development of blossoms in the case of flowering plants. In the orchard house, fruits are ripened by the influence of solar heat alone. To secure as much solar heat during the day as possible, the ventilators should be opened early in the morning, and closed early in the afternoon.

Ventilation. 16. *Ventilating Apparatus.*—The object of ventilation is not so much to aid the respiration of the plants as to carry off noxious vapours and to regulate the moisture and temperature. The mechanical agitation both of the atmosphere and of the foliage caused by a free circulation, provided it be not too cold or too rudely admitted, has also a beneficial influence on the health of the plants. All ventilation, observes Mr M'Intosh (*Book of the Garden*, i. 271), "is founded upon the simple principle that cold air is heavier and has a tendency to sink downwards, while hot air is light and rises to the top. At first sight it may appear that, for the purpose of ventilating any building, it is only necessary that holes should be made at the bottom of the apartment for the air to enter, and other holes be placed in the upper part for the air to escape. Practically, however, ventilation is far from being so simple an affair," since currents of air are very difficult to direct or control, to moderate, or even to regulate with very great nicety. Too frequently air is given only during the day, and is excluded at night, often with an increase of fire-heat. Judicious horticulturists will reverse this, since plants require fresh air by night as well as by day, and in all countries cool nights succeed even the hottest days.

The mode of ventilating plant houses formerly in use was by letting down the top roof sashes; this was often supplemented by having the front or upright sashes also made movable, and more or less widely opened either outwards or laterally during the daytime. It is much more economical, however, and equally efficacious, to have the roof sashes fixed, and the top ventilation effected by means of a lantern in the case of a span-roofed house, or by horizontal ventilators near the top of the back wall in a lean-to. The front ventilation may be effected by openings in the front wall opposite the heating pipes, by which means the cold air is warmed, which is the best plan in all houses where a high temperature has to be maintained, and is especially necessary in forcing-houses, on account of the risk of injury to the foliage from cold air; or the front sashes may be made movable, which is better in temperate houses. In the case of pits, where there are no front sashes provided, the ventilators are sufficient for the purpose. The sliding down of one sash over the other, as once generally and even now frequently practised, greatly augments the shade in oblique sunshine, and is strongly objectionable on that account. The lantern mode of construction obviates this, but in a lean-to, and even with span roofs, it is better to have shorter movable sashes, hung so as to open by being elevated at the lower edge instead of sliding one over the other. A very slight elevation is sufficient for the egress of vitiated air.

A successful plan of warming the fresh air, recommended many years ago by Mr T. Moore (*Journ. Hort. Soc.*, i. 110), consists in passing the air after its admission by front ventilators through a heated chamber separate from the tank used as the heating medium, but admitting of communication with the tank chamber if necessary for the purpose of supplying moisture. The warmed fresh air is then led out in front of the tank, and carried forwards by the circulation up the slope of the roof, descending near the back wall to the floor, whence it is sucked into the heated chamber, mingling with the fresh air as it enters to repeat the circuit. A ventilator in the back wall provides the means of egress when this is required. Another plan, well adapted for forcing-houses, consists in fixing from end to end, below the hot-water pipes used for heating the structure, a zinc pipe of 6-inch or 8-inch diameter, and perforated with small holes, one end of the tube passing through an outer wall, and being fitted with a valve which can be wholly or partly closed at pleasure. Other means of accomplishing the same end may be adopted to suit particular cases.

In order to secure the circulation of the confined air during the night, and thus to prevent an injurious rise of the temperature, and also to economize fuel, it is of advantage where practicable to use shutters. These should consist of a light frame, readily movable, and fitted so as to slide readily in grooves on a skeleton roof; and they should be covered with asphalted felt, or strong brown paper coated with tar, which is much used in Germany for covering purposes, and is both durable and cheap. This should form a close outer covering, the ventilators being set open at bottom and top.

Formerly all ventilation had to be effected by the hand unaided, each sash being opened or shut separately, a matter of some urgency on the sudden outburst of sunshine. In all good ranges of glass, and in detached houses also, the work is now effected by machinery, many ingenious combinations of which are in use for this purpose.

17. *Hygrometry.*—For the healthy growth of plants, the regulation of the moisture is as necessary as the regulation of the heat. A considerable degree of moisture is Hygrometry.

necessary in the cases of most plants cultivated in a high temperature; but the amount varies of course in different cases, and this presents one of the principal difficulties in the management of what is called a mixed collection, whether of stove or greenhouse plants. In the case of fruits, where a house is mostly devoted to one subject, whether grapes, peaches, pines, or melons, the requisite conditions can be more readily secured. The instrument with which the amount of moisture present in the atmosphere is measured is the hygrometer. The two hygrometers most generally used are Daniell's and the dry and wet bulb, the former a more delicate instrument, best adapted for scientific observations, the latter a simpler instrument, better adapted for horticultural purposes, because requiring less delicate manipulation. It consists of two thermometers mounted on one frame, the readings of which when uncovered should correspond. One bulb is left uncovered, the other is covered with muslin, and a few threads of cotton, with their other ends immersed in water, keep it constantly moist. The temperature is lowered by the evaporation from the moistened bulb, and the difference in the readings of the two thermometers shows the degree of dryness. Mr Glaisher's instructions, which accompany the set of hygrometrical tables published by him, will be found of great assistance by every one making use of this instrument.

III. *Garden Materials and Appliances.*

Soils. 18. *Soils and Composts.*—The principal soils used in gardens, either alone, or mixed to form what are called composts, are—loam, sand, peat, leaf-mould, and various mixtures and combinations of these made up to suit the different subjects under cultivation.

Loam is the staple soil for the gardener; it is not only used extensively in the pure and simple state, but enters into most of the composts prepared specially for his plants. For garden purposes loam should be rather unctuous or soapy to the touch when moderately dry, not clinging nor adhesive, and should readily crumble when a compressed handful is thrown on the ground. If it clings together closely it is too heavy and requires amelioration by the admixture of gritty material; if it has little or no cohesion when squeezed tightly in the hand, it is too light, and needs to be improved by the addition of heavier or clayey material. Sound friable loam cut one sod deep from the surface of a pasture, and stacked up for twelve months in a heap or ridge, is invaluable to the gardener. When employed for making vine borders, loam of a somewhat heavier nature can be used with advantage, on account of the porous materials which should accompany it. For stone fruits a calcareous loam is best; indeed, for these subjects a rich calcareous loam used in a pure and simple state cannot be surpassed. Somewhat heavy loams are best for potting pine apples, for melons and strawberries, and may be used with the addition of manures only; but for ornamental plants a loam of a somewhat freer texture is preferable and more pleasant to work. Loam which contains much red matter (iron) should be avoided.

Sand is by itself of little value except for striking cuttings, for which purpose fine clean sharp silver sand is the best; and a somewhat coarser kind, if it is gritty, is to be preferred to the comminuted sands which contain a large proportion of earthy matter. River sand and the sharp grit washed up sometimes by the road side are excellent materials for laying around choice bulbs at planting time to prevent contact with earth which is perhaps manure-tainted. Sea sand may be advantageously used both for propagating purposes and for mixing in composts. For the growth of pot plants sand is an essential part of most composts, in order to give them the needful porosity to carry off all excess of moisture from the roots. If the finer earthy sands only are obtainable, they must be rendered sharper by washing away the earthy particles. Washed sand is best for all plants like heaths, which need a pure and lasting compost.

Peat soil is largely employed for the culture of American plants, as rhododendrons, azaleas, heaths, &c. In districts where heather and gritty soil predominate, the peat soil is poor and unprofitable, but selections from both the heathy and the richer peat soils, collected with judgment, and stored in a dry part of the compost yard, are essential ingredients in the cultivation of many choice pot plants, such as the Cape heaths and many of the Australian plants. Most monocotyledons do well in peat, even if they do not absolutely require it.

Leaf-mould is eminently suited for the growth of many free-growing plants, especially when it has been mixed with stable manure and has been subjected to fermentation for the formation of hot beds. In any state most plants feed greedily upon it, and when pure or free from decaying wood or sticks it is a very safe ingredient in composts; but it is so liable to generate fungus, and the mycelium or spawn of certain fungi is so injurious to the roots of trees, attacking them if at all sickly or weakened by drought, that many cultivators prefer not to mix leaf-mould with the soil used for permanent plants, as peaches or choice ornamental trees. For quick growing plants, however, as for example most annuals cultivated in pots, such as balsams, cockscombs, globe-amaranths, and the like, for cucumbers, and for young soft-wooded plants generally, it is exceedingly useful, both by preventing the consolidation of the soil and as a manure. The accumulations of light earth formed on the surface in woods where the leaves fall and decay annually are leaf-mould of the finest quality.

The material known as cocoa-nut fibre refuse is analogous to leaf soil, and may be employed for similar purposes. It should be mixed with gritty matter to favour the passage of water, and indeed requires to be so mixed when in an advanced stage of decay, in order to prevent its collapse into a close pasty mass. This cocoa-nut refuse is also a useful light material into which to plunge pots containing plants, as a preservative of the roots from the drying effects of the sun or the chilling effects of frost.

Composts are mixtures of the foregoing ingredients in varying proportions, and in combination with manures if necessary, so as to suit particular plants or classes of plants. Composts. The chief point to be borne in mind in making these mixtures is not to combine in the same compost any bodies that are antagonistic in their nature, as for example lime and ammonia. In making up composts for pot plants, the fibrous portion should not be removed by sifting, except for small sized pots, but the turfy portions should be broken up by hand and distributed in smaller or larger lumps throughout the mass. When sifting is had recourse to, the fibrous matter should be rubbed through the meshes of the sieve along with the earthy particles. Before being used the turfy ingredients of composts should lie together in a heap only long enough for the roots of the herbage to die, not to decompose.

19. *Manures.*—These are of two classes, organic and inorganic—the former being of animal and vegetable, the latter of mineral origin. Manures.

Farm-yard manure consists of the mixed dung of horses and cattle thrown together, and more or less soaked with liquid drainings of the stable or byre. It is no doubt the finest stimulant for the growth of plants, and that most adapted to restore the fertile elements which the plants have abstracted from exhausted soils. This manure is best fitted for garden use when in a moderately fermented state. Organic manures.

Horse dung is generally the principal ingredient in all hot bed manure; and, in its partially decomposed state, as afforded by exhausted hot beds, it is well adapted for garden use. It is most beneficial on cold stiff soils. It should not be allowed to lie too long unmoved when fresh, as it will then heat violently, and the ammonia is thus driven off. To avoid this, it should be turned over two or three times if practicable, and well moistened—preferably with farm-yard drainings.

Cow dung is less fertilizing than horse dung, but being slower in its action it is more durable; it is also cooler, and therefore better for hot dry soils. Thoroughly decayed, it is one of the best of all manures for mixing in composts for florists' flowers and other choice plants.

Pig dung is very powerful, containing more nitrogen than horse dung; it is therefore desirable that it should undergo moderate fermentation, which will be secured by mixing it with litter and a portion of earth. When weeds are thrown to the pigs, this fermentation becomes specially desirable to kill their seeds. The drainings of a pig-stye form a most valuable liquid manure for vegetable crops.

Night-soil is an excellent manure for all bulky crops, but requires to be mixed with earth or peat, or coal-ashes, so as both to deodorize it and to ensure its being equally distributed. Quick lime should not be used, as it dispels the greater part of the ammonia. When prepared by drying and mixing with various substances, night-soil is sold as poudrette, or desiccated night-soil, the value of which depends upon the materials used for admixture.

Malt-dust is an active manure frequently used as a top-dressing, especially for fruit trees in pots. It is rapid in its action, but its effects are not very permanent. *Rape dust* is somewhat similar in its character and action.

Bones are employed as a manure with decided advantage both to vegetable crops and to fruit trees, as well as to flowers. For turnips bone manure is invaluable. The effects of bones are no doubt mainly due to the phosphates they contain, and they are most effectual on dry soils. They are most quickly available when dissolved in sulphuric acid.

Guano is a valuable manure now much employed, and may be applied to almost every kind of crop with decided advantage. It should be mixed with six or eight times its weight of loam or ashes, charred peat, charcoal-dust, or some earthy matter, before it is applied to the soil, as from its causticity it is otherwise not unlikely to kill or injure the plants to which it is administered.

Pigeon dung approaches guano in its power as manure. It should be laid up in ridges of good loamy soil in alternate layers to form a compost, which becomes a valuable stimulant for any very choice subjects if cautiously used. The dung of the domestic fowl is very similar in character.

Horn, hoof-parings, woollen rags, fish, blubber, and *blood* are all good manures, and should be utilized if readily obtainable. *Sawdust* and *tan* are of less value.

Liquid manure, consisting of the drainings of dung-heaps, stables, cowsheds, &c., or of urine collected from dwelling houses or other sources, is a most valuable and powerful stimulant, and can be readily applied to the roots of growing plants. The urine should be allowed to putrefy, as in its decomposition a large amount of ammonia is formed, which should then be fixed by sulphuric acid or gypsum; or it may be applied to the growing crops after being freely diluted with water or absorbed in a compost heap. Liquid manures can be readily made from most of the solid manures when required, simply by admixture with water. When thus artificially compounded, unless for immediate use, they should be made strong for convenience of storage, and applied as required much diluted.

Inorganic manures. *Ammonia* is the most powerful of the manures of the inorganic series, and one of the most important of the constituents of manures generally, since it is the chief source whence plants derive their nitrogen. It is largely supplied in all the most fertilizing of organic manures, but when required in the inorganic state must be obtained from some of the salts of ammonia, as the sulphate, the muriate, or the phosphate, all of which, being extremely energetic, require to be used with great caution. These salts of ammonia may be used at the rate of from 2 to 3 cwt. per acre as a top-dressing in moist weather. When dissolved in water they form active liquid manures.

Potash and *soda* are also valuable inorganic manures in the form of carbonates, sulphates, silicates, and phosphates, but the most extensively employed is the nitrate of potash. The manures of this class are of course of value only in cases where the soil is naturally deficient in them. On this account the salts of soda are of less importance than those of potash. The value of wood ashes as a manure very much depends upon the carbonate and other salts of potash which they contain.

Lime in the caustic state is beneficially applied to soils which contain an excess of inert vegetable matter, and hence may be used for the improvement of old garden soils saturated with humus, or of peaty soils not thoroughly reclaimed. It does not supply the place of organic manures, but only renders that which is present available for the nourishment of the plants. It also improves the texture of clay soils.

Gypsum, or sulphate of lime, applied as a top-dressing at the rate of 2 to 3 cwt. per acre, has been found to yield good results, especially on light soils. It is also employed in the case of liquid manures to fix the ammonia.

Burnt clay has a very beneficial effect on clay land by improving its texture and rendering soluble the alkaline substances it contains. The clay should be only slightly burnt, so as to make it crumble down readily; in fact, the fire should not be allowed to break through, but should be constantly repressed by the addition of material. The burning should be effected when the soil is dry.

Vegetable refuse of all kinds, when smother-burned in a similar way, becomes a valuable mechanical improver of the soil; but the preferable course is to decompose it in a heap with quick lime and layers of earth, converting it into leaf-mould.

Soot forms a good top-dressing; it consists principally of charcoal, but contains ammonia, whence its value as a manure is derived. It should be kept dry until required for use. It may also be used beneficially in preventing the attacks of insects, such as the onion gnat and turnip fly, by dusting the plants or dressing the ground with it.

Common salt acts as a manure when used in moderate quantities, but in strong doses is injurious to vegetation. It suits many of the esculent crops, as onions, beans, cabbages, carrots, beet-root, asparagus, &c.; the quantity applied varies from 5 to 10 bushels per acre. It is used as a top-dressing sown by the hand. Hyacinths and other bulbs derive benefit from slight doses, while to asparagus as much as 20 lb to the rood has been used with beneficial effect. At the rate of from 6 to 10 bushels to the acre it may be used on garden lawns to prevent worm casts. For the destruction of weeds on gravel walks or in paved yards a strong dose of salt, applied either dry or in solution, is found very effective, especially a hot solution, but after a time much of it becomes washed down, and the residue acts as a manure; its continued application is undesirable, as gravel so treated becomes pasty.

20. *Tools, Implements, &c.*—With regard to garden tools, instruments, implements, and machinery, it is only some of the more modern inventions and improvements that can be touched on here. The two indispensable tools are the spade and the knife. The spade is commonly used for digging and trenching, but much of this work is now better done by means of Parkes's digging-fork (fig. 42), which is both handier and lighter, and breaks up the ground better than the spade. The pickfork or Canterbury hoe (fig. 43) is a very useful tool for breaking up the surface soil, the three-pronged end being used for the looser parts, and the mattock end for breaking clods, or when the surface has become much consolidated. The drag (fig. 44) is also useful—a light three-pronged tool, which may be used for loosening the soil amongst vegetable crops as well as flower garden plants, and may also be sometimes employed, if the tines are sufficiently narrow and pointed, to drag off weeds from the surface. The hand-fork (fig. 45), a short-

Tools.

Fig. 43.—Pickfork.

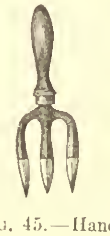

Fig. 45.—Hand-Fork.

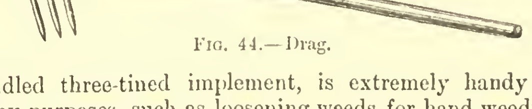

Fig. 44.—Drag.

handled three-tined implement, is extremely handy for many purposes, such as loosening weeds for hand-weeding, or for planting or transplanting small subjects; it is also very handy for plunging pots, either indoors or out, in tan-beds, ash-beds, or common soil. Hoes and rakes made with a tapered neck and socket, into which the handle is fitted, do not clog so readily as when they are driven into a ferruled handle.

For pruning purposes a variety of instruments have been invented, under the names of sécateurs, pruning-shears, pruning-scissors, &c., but nothing equals a well-tempered old-fashioned knife, varied in form, strength, and size to suit the particular object to be operated on. The averruncator is a useful instrument for cutting branches at a considerable elevation (12 to 15 feet) from the ground. Selby's flower gatherer (fig. 46), which cuts and holds the

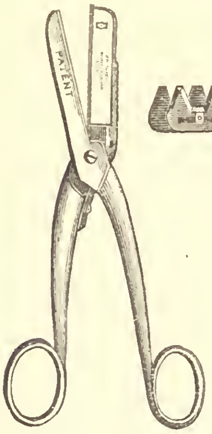

Fig. 46.—Selby's Flower Gatherer.

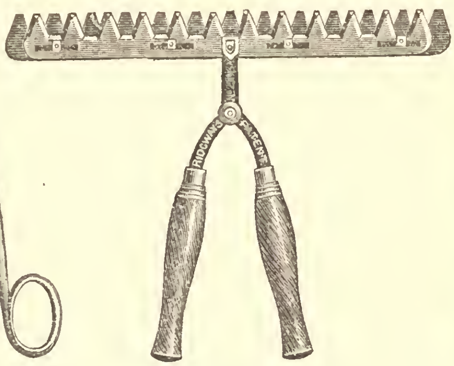

Fig. 47.—Ridgway's Hedge-Cutter.

flower at the same time, may be recommended, especially for the use of ladies. Some of the fruit gatherers also are ingenious and useful. A new instrument for clipping hedges, Ridgway's hedge-cutter (fig. 47), does its work quickly and well; and the same can be said for Adie's new lawn-edging machine.

For the destruction of insects Dean's and Appleby's and Dreschler's fumigators are all useful, but an equally efficient plan is to put a few live embers in a flower-pot, raised on two bricks so placed as not to close the hole at the bottom; on these embers moistened tobacco or tobacco paper is to be put, and over all damped moss. This will burn slowly and fill the house with smoke, care being taken that the material, as it dries, is lightly sprinkled with water, so that it does not burst into a flame.

Sulphurators are instruments for distributing flowers of sulphur, for the purpose of destroying mildew. In the case of greenhouse plants, such as heaths, simply dusting with sulphur through a muslin bag or dredger is sufficient; but in cases where vines are attacked with the *Oidium* or vine-mildew, the saving of the crop depends on the prompt diffusion of sulphur over all the affected parts, and this could not be so readily done by any other contrivance as by some one of the various forms of sulphurator (figs. 48, 49).

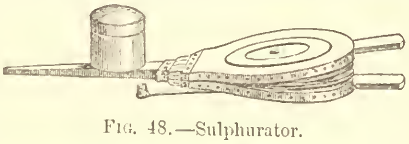

Fig. 48.—Sulphurator.

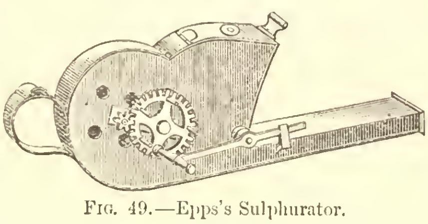

Fig. 49.—Epps's Sulphurator.

For the distribution of water in the form of spray, syringes are used, and of these there are none better than Read's patent, which acts by a piston and ball valve; while for the more powerful garden engines, those manufactured by Read (fig. 50) and Warner have the preference.

Fig. 50.—Read's Garden Engine.

Tallies. *Tallies* of wood should be slightly smeared with white paint and then written on while damp with a black-lead pencil. To preserve them from decay they should first be soaked in linseed oil. Zinc tallies are the best, on account of their durability, if written upon with a proper ink,—12 grains of bichloride of platinum dissolved in 1 oz. of distilled water. Larger labels of various materials and patterns are provided for trees and shrubs, and other permanent outdoor plants. Lead labels with stamped figures are very useful. For numbering pot plants, these may be wedge-shaped and bent over close to the pot-rim; for collections of plants they should be small and light, so that the suspending wire may not cut into the bark of the plants. Zinc labels with the names shown in relief are to be recommended when they can be obtained ready made, but are too expensive when they have to be specially prepared.

IV. *Garden Operations.*

Propagation. 21. *Propagation.*—The increase of plants, so far as the production of new individuals of particular kinds is concerned, is one of the most important and constantly recurring of gardening operations. In effecting this, various processes are adopted, which will now be described.

Seeds. (1) *By Seeds.*—This may be called the natural means of increasing the number of any particular kind of plant, but it is to be remembered that we do not by that means secure an exact reproduction of the parent. We may get a progeny very closely resembling it, yet each plant possessing a distinct individuality of its own; or we may get a progeny very unlike the parent, or a mixed progeny showing various degrees of divergence. Many seeds will grow freely if sown in a partially ripened state; but as a general rule seeds have to be kept for some weeks or months in store, and hence they should be thoroughly ripened before being gathered. They should be sown in fine rich soil, and such as will not readily get consolidated. In the case of outdoor crops, if the soil is inclined to be heavy, it is a good plan to cover all the smaller seeds with a light compost. Very small seeds should only have a sprinkling of light earth or of sand, and sometimes only a thin layer of soft moss to exclude light and preserve an equable degree of moisture. Somewhat larger seeds sown indoors may be covered to the depth of one-eighth or one-fourth of an inch, according to their size. Outdoor crops require to be sown, the smaller seeds from half an inch to an inch, and the larger ones from 2 to 4 inches under the surface, the covering of the smaller ones especially being light and open. Many seeds grow well when raked in; that is, the surface on which they are scattered is raked backwards and forwards until most of them are covered. Whatever the seeds, the ground should be made tolerably firm both beneath and above them; this may be done by treading in the case of most kitchen garden crops, which are also better sown in drills, this admitting the more readily of the ground being kept clear from weeds by hoeing. All seeds require a certain degree of heat to induce germination. For tropical plants the heat of a propagating house—75° to 80°, with a bottom heat of 80° to 90°—is desirable, and in many cases absolutely necessary; for others, such as half-hardy annuals, a mild hot bed, or a temperate pit ranging from 60° to 70°, is convenient; while of course all outdoor crops have to submit to the natural temperature of the season. It is very important that seeds should be sown when the ground is in a good working condition, and not clammy with moisture.

Offsets.

(2) *By Offsets.*—This mode of increase applies specially to bulbous plants, such as the lily and hyacinth, which produce little bulbs on the exterior round their base. Most bulbs do so naturally to a limited but variable extent; when more rapid increase is wanted the heart is destroyed, and this induces the formation of a larger number of offsets. The stem bulbs of lilies are similar in character to the offsets from the parent bulb. The same mode of increase occurs in the gladiolus and crocus, but their bulb-like permanent parts are called corms, not bulbs. After they have ripened in connexion with the parent bulb, the offsets are taken off, stored in appropriate places, and at the proper season planted out in nursery beds.

Tubers.

(3) *By Tubers.*—The tuber is a fleshy underground stem, furnished with eyes which are either visible, as in the potato and in some familiar kinds of *Tropæolum* (*T. tuberosum*) and of *Oxalis* (*O. crenata*), or latent, as in the Chinese yam (*Dioscorea Batatas*). For a fuller description see BOTANY, vol. iv. p. 98. When used for propagation, the tubers are cut up into what are called "sets," every portion having an eye attached being capable of forming an independent plant. The cut portions of bulky sets should be suffered to lie a short time before being planted, in order to dry the surface and prevent rotting; this should not, however, be done with such tropical subjects as caladiums, the tubers of which are often cut up into very small fragments for propagation, and of course require to be manipulated in a properly heated propagating pit. No eyes are visible in the Chinese yam, but slices of the long club-shaped tubers will push out young shoots and form independent plants, if planted with ordinary care.

Division.

(4) *By Division.*—Division, or partition, is usually resorted to in the case of tufted growing plants, chiefly perennial herbs; they may be evergreen, as chamomile or thrift, or when dormant may consist only of underground crowns, as larkspur or lily-of-the-valley; but in either case the old tufted plant being dug up may be divided into separate pieces, each furnished with roots, and, when replanted, generally starting on its own account without much check. Suffruticose plants and even small shrubs may be propagated in this way, by first planting them deeper than they are ordinarily grown, and then after the lapse of a year, which time they require to get rooted, taking them up again and dividing them into parts or separate plants. Box-edging and southernwood are examples. The same ends may sometimes be effected by merely working fine soil in amongst the base of the stems, and giving them time to throw out roots before parting them.

Suckers.

(5) *By Suckers.*—Root suckers are young shoots from the roots of plants, chiefly woody plants, as may often be seen in the case of the elm and the plum. The shoots when used for propagation must be transplanted with all the roots attached to them, care being taken not to injure the parent plant. If they spring from a thick root it is not to be wantonly severed, but the soil should be removed and the sucker taken off by cutting away a clean slice of the root, which will then heal and sustain no harm. Stem suckers are such as proceed from the base of the stem, as is often seen in the case of the currant and lilac. They should be removed

FIG. 51.—Suckering Iron.

in any case; when required for propagation they should be taken with all the roots attached to them, and they should be as thoroughly disbudded below ground as possible, or they are liable to continue the habit of suckering. In this case, too, the soil should be carefully opened and the shoots removed with a suckering iron, a sharp concave implement with long iron handle (fig. 51). When the number of roots is limited, the tops should be shortened, and some care in watering and mulching should be bestowed on the plant if it is of value.

(6) *By Runners.*—A definition of runners will be found in BOTANY, vol. iv. p. 97. The young string-like shoots produced by the strawberry are a well-known example of them. The process of rooting these runners should be facilitated by fixing them close down to the soil, which is done by small wooden hooked pegs or by stones; hair-pins, short lengths of bent wire, &c., may also be used. After the roots are formed, the strings are cut through, and the runners become independent plants.

Prolif- ousbu

(7) *By Proliferous Buds.*—Not unlike the runner, though growing in a very different way, are the bud-plants formed on the fronds of several kinds of ferns belonging to the genera *Asplenium*, *Woodwardia*, *Polystichum*, *Lastrea*, *Adiantum*, *Cystopteris*, &c. In some of these (*Adiantum caudatum*, *Polystichum lepidocaulon*) the rachis of the frond is lengthened out much like the string of the strawberry runner, and bears a plant at its apex. In others (*Polystichum angulare proliferum*), the stipes below and the rachis amongst the pinnæ develop buds, which are often numerous and crowded. In others again (*Woodwardia orientalis*, *Asplenium bulbiferum*), buds are numerously produced on the upper surface of the fronds. These will develop on the plant if allowed to remain. For propagation the bulbiferous portion is pegged down on the surface of a pot of suitable soil; if kept close in a moist atmosphere, the little buds will soon strike root and form independent plants. In the *Cystopteris* the buds are deciduous, falling off as the fronds acquire maturity, but, if collected and pressed into the surface of a pot of soil and kept close, they will grow up into young plants the following season.

Layer

(8) *By Layers.*—Layering consists in preparing the branch of a plant while still attached to the parent, bending it so that the part operated on is brought under ground, and then fixing it there by means of a forked peg. Some plants root so freely that they need only pegging down; but in most cases the arrest of the returning sap to form a callus, and ultimately young roots, must be brought about artificially, either by twisting the branch, by splitting it, by girding it closely with wire, by taking off a ring of bark, or by "tonguing." In tonguing the leaves are cut off the portion which has to be brought under ground, and a tongue or slit is then cut from below upwards close beyond a joint, of such length that, when the cut part of the layer is pegged an inch or two (or in larger woody subjects 3 or 4 inches) below the surface, the elevation of the point of the shoot to an upright position may

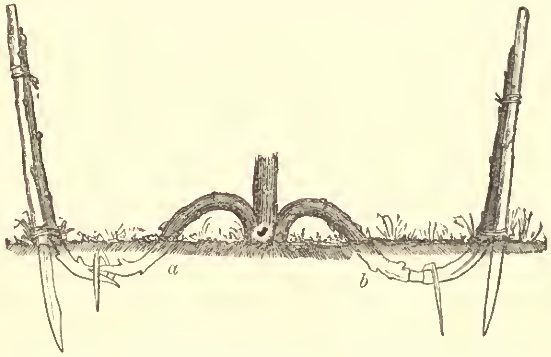

FIG. 52.—Propagation by Layers—*a*, tonguing; *b*, ringing.

open the incision, and thus set it free, so that it may be surrounded by earth to induce it to form roots. The whole branch, except a few buds at the extremity, is covered with soil. The best seasons for these operations are early spring and midsummer, that is, before the sap begins to flow, and after the first flush of growth has passed off. One whole summer, sometimes two, must elapse before the layers will be fully rooted in the case of woody plants; but such plants as carnations and picotees, which are usually propagated in this way, in favourable seasons take only a few weeks to root, as they are layered towards the end of the blooming season in July, and are taken off and planted separately early in the autumn. Fig. 52 shows a woody plant with one layer prepared by tonguing and another by ringing.

In general, each shoot makes one layer, but in plants like the *Wistaria* or *Clematis*, which make long shoots, what is called serpentine layering may be adopted; that is, the shoot is taken alternately below and above the surface, as frequently as its length permits. There must, however, be a joint at the underground part where it is to be tongued and pegged, and at least one sound bud in each exposed part, from which a shoot may be developed to form the top of the young plant.

Circu posit

(9) *By Circumposition.*—When a plant is too high or its habit does not conveniently admit of its being layered, it may often be increased by what is called circumposition, the soil being carried up to the branch operated on. The branch is to be prepared by ringing or notching or wiring as in layering, and a temporary stand made to support the vessel which is to contain the soil. The vessel may be a flower-pot sawn in two, so that the halves may be bound together when used, or it may be a flower-pot or box with a side slit which will admit the shoot; this vessel is to be

filled compactly with suitable porous earth, the opening at the slit being stopped by pieces of slate or tile. The earth must be kept moist, which is perhaps best done by a thick mulching of moss, the moss being also bound closely over the openings in the vessel, and all being kept damp by frequent syringings. Reid remarks of this method of propagation that he has effected it with clay and cow dung, well mixed, after the bark had been taken off all round, and wrapped about with a double or triple swaddling of straw or hay ropes (*Scots Gardener*, 1721).

This process is sometimes found very useful in the case of choice conservatory plants which may be getting too tall for the house, such as a fine *Dracæna* (fig. 53) or *Yucca*. Such a plant may be operated on wherever the stem has become firm and woody; the top will not fail to make a fine young specimen plant, which might be removed in the course of about twelve months, while other shoots would no doubt be obtained from the old stem, which, with its head thus reduced, might be removed to quarters where it would not be an eyesore. The head would perhaps require steadying if the stem were loaded with a pot or box of soil, as at *a* in the figure. Mr Bain records (*Paxt. Mag. Bot.*, xvi. 46) a successful experiment of this kind with a *Dracæna Draco* which was getting too tall for its position. An incision was made in the stem half an inch deep to the extent of half its circumference, lime being applied to the wound to dry up the sap. This incision was from time to time deepened (and lime-dried) until severed, the top being suspended from the roof. After some months roots were protruded from between the woody structure and its bush-like covering, and the gigantic cutting was lowered into its place, and grew away freely. In this case Mr Bain was of opinion that success was due to the slowness of the process and the precautions taken to dry and harden the stem.

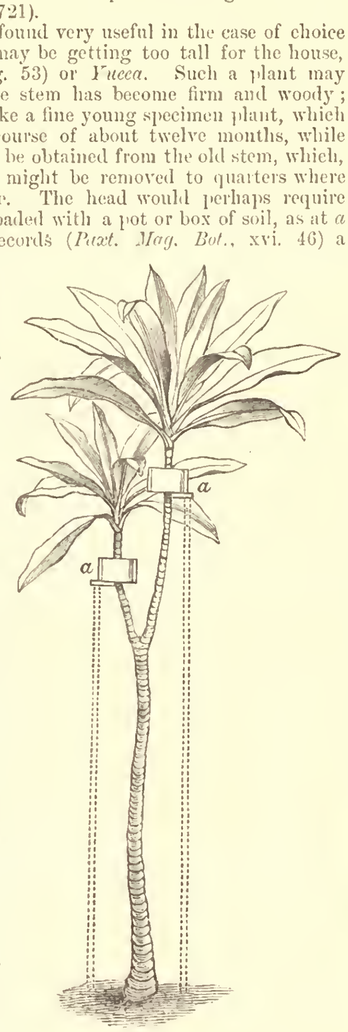

Fig. 53.

rafts. (10) *By Grafts.*—Grafting is so extensively resorted to that it is impossible here to notice all its phases. It is perhaps of most importance as the principal means of propagating our hardy kinds of fruit, especially the apple and the pear; but the process is the same with most other fruits and ornamental hardy trees and shrubs that are thus propagated. The stocks are commonly divided into two classes:—(1) free stocks, which consist of seedling plants, chiefly of the same genus or species as the trees from which the scions are taken; and (2) dwarfing stocks, which are of more diminutive growth, either varieties of the same species or species of the same or some allied genus as the scion, which have a tendency to lessen the expansion of the engrafted tree. The French Paradise is the best dwarfing stock for apples, and the quince for pears. In determining the choice of stocks, the nature of the soil in which the grafted trees are to grow should have full weight. In a soil, for example, naturally moist, it is proper to graft pears on the quince, because this plant not only thrives in such a soil, but serves to check the luxuriance thereby produced. The scions should always be portions of the wood of the preceding year, selected from healthy parents; in the case of shy-bearing kinds, it is better to obtain them from the fruitful branches. The scions should be taken off some weeks before they are wanted, and half-buried in the earth, since the stock at the time of grafting should in point of vegetation be somewhat in advance of the graft. During winter, grafts may be conveyed long distances, if carefully packed. If they have been six weeks or two months separated from the parent plant, they should be grafted low on the stock, and the earth should be ridged up round them, leaving only one bud of the scion exposed above ground. The best season for grafting apples and similar hardy subjects is the month of March; but it may be commenced as soon as the sap in the stock is fairly in motion, and may be continued during the first half of April.

Whip-grafting or *Tongue-grafting* (fig. 54) is the most usual mode of performing the operation. The stock is headed off by an oblique transverse cut as shown at *a*, a slice is then pared off the side as at *b*, and on the face of this a tongue or notch is made, the cut being in a downward direction; the scion *c* is pared off in a similar way by a single clean sharp cut, and this is notched or tongued in the opposite direction as the figure indicates; the two are then fitted together as shown at *d*, so that the inner bark of each may come in contact at least on one side, and then tied round with damp soft bast as at *e*; next some grafting clay is taken on the forefinger and

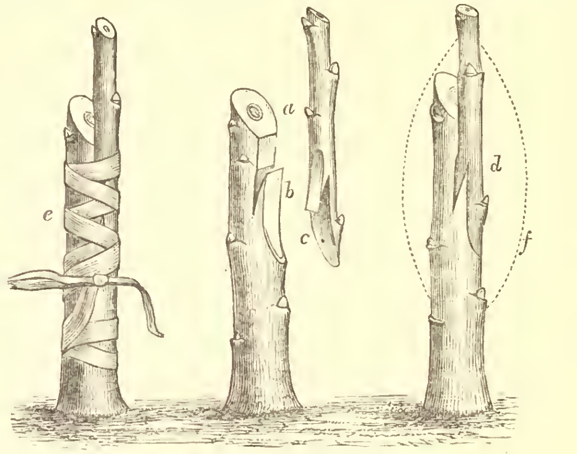

Fig. 54.—Whip-Grafting or Tongue-Grafting.

pushed down on each side so as to fill out the space between the top of the stock and the graft, and a portion is also rubbed over the ligatures on the side where the graft is placed, a handful of the clay is then taken, flattened out, and rolled closely round the whole point of junction, being finished off to a tapering form both above and below, as shown by the dotted line *f*. To do this deftly, the hands should be plunged from time to time in dry ashes, to prevent the clay from sticking to them.

Cleft-grafting (fig. 55) is another method in common use. The stock *a* is cleft down from the horizontal cut *d*, and the scion, when cut to a thin wedge form, as shown at *c* and *e*, is inserted into the cleft; the whole is then bound up and clayed as in the former case. This is not so good a plan as whip-grafting; it is improved by sloping the stock on one side to the size of the graft.

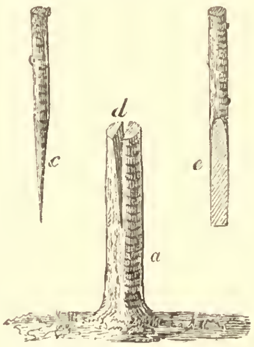

Fig. 55.—Cleft-Grafting.

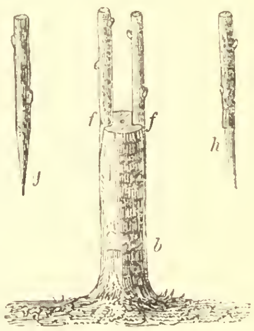

Fig. 56.—Crown-Grafting.

Crown-grafting or *Rind-grafting* (fig. 56) is preferable to cleft-grafting, inasmuch as it leaves no open spaces in the wood. The stock *b* is cut off horizontally or nearly so, and a slit is then cut in the bark *f, f*, a wedge-shaped piece of ivory being inserted to raise the bark; the scion is then cut to the same wedge-shaped form *g, h*, and inserted in the space opened for it between the albumen and the bark, after which it is tied down and clayed over in the manner already described.

Side-grafting is performed like whip-grafting, the graft being inserted on the side of a branch and not at the cut end of the stock. It may be practised for the purpose of changing a part of the tree, and is sometimes very useful for filling out vacant spaces, in trained trees especially.

Inarching is another form of side-grafting. Here the graft is fixed to the side of the stock, which is planted or potted close to the plant to be worked. The branches are applied to the stock while yet attached to the parent tree, and remain so until united. In the case of trained trees, a young shoot is sometimes inarched to its parent stem to supply a branch where one has not been developed in the ordinary way.

For the propagation by grafts of stove and greenhouse plants the process adopted is whip-grafting or a modification of it. The parts are, however, sometimes so small that the tongue of the graft is dispensed with, and the two stems simply pared smooth and bound together. In this way hardy rhododendrons of choice sorts, greenhouse azaleas, the varieties of the orange family, camellias, roses, rare conifers, and numerous other plants are increased. In small subjects soft cotton is used for tying instead of bast, and grafting-wax is substituted for grafting-clay. The best is the French cold mastic "L'Homme Lefort." All grafting of this kind is done in the propagating house, at any season when grafts are obtainable in a fit state,—the plants when operated on being placed in close frames warmed to a suitable temperature.

Root-grafting is sometimes resorted to where extensive increase is an object, or where stem-grafting or other means of propagation are n t available. In this case the scion is grafted directly on to a portion of the root of some appropriate stock, both graft and stock being usually very small; the grafted root is then potted so as to cover the point of junction with the soil, and is plunged in the bed of the propagating house, where it gets the slight stimulus of a gentle bottom heat. Dahlias (fig. 57) and pæonies may be grafted

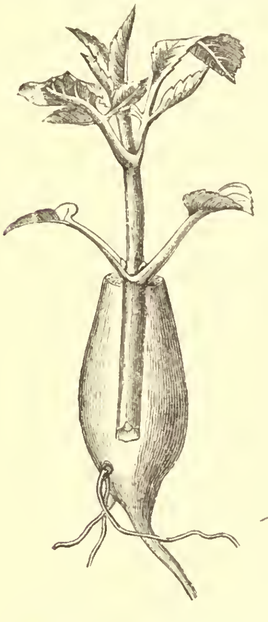

Fig. 57.—Root-Grafting of Dahlia.

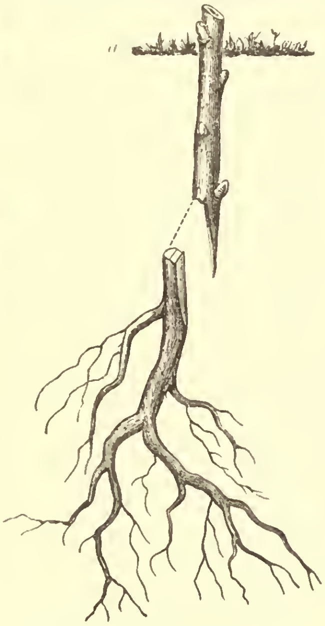

Fig. 58.—Root-Grafting of Woody Plant.

by inserting young shoots into the neck of one of the fleshy roots of each kind respectively—the best method of doing so being to cut a triangular section near the upper end of the root, just large enough to admit the young shoot when slightly pared away on two sides to give it a similar form. In the case of large woody plants thus worked (fig. 58) the grafted roots, after the operation is completed, are planted in nursery beds, so that the upper buds only are exposed to the atmosphere, as shown at *c* in the figure.

uds. (11) *By Buds.*—Budding is the inserting of a bud cut with a portion of bark of the plant to be propagated into the bark of the stock, where it is bound gently but firmly. Stone fruits, such as peaches, apricots, plums, cherries, &c., are propagated in this way, as well as roses, and many other plants. In the propagating house budding may be done at any season when the sap is in motion; but for fruit trees, roses, &c., in the open air, it is usually done in July or August, when the buds destined for the following year are completely formed in the axils of the leaves, and when the bark separates freely from the wood it covers. Those buds are to be preferred, as being best ripened, which occur on the middle portion of a young shoot.

The simplest and most generally practised form of budding is that called *Shield-budding or* T-*budding* (fig. 59). The operator should be provided with a budding-knife in which the cutting edge of the blade is rounded off at the point, and which has a thin ivory or bone handle, for raising the bark of the stock. A horizontal incision is made in the bark quite down to the wood, and from this a perpendicular slit is drawn downwards to the extent of perhaps an inch, so that the slit has a resemblance to the letter T, as at *a*. A bud is then cut by a clean incision from the tree intended to be propagated, having a portion of the wood attached to it, and so that the whole may be an inch and a half long, as at *d*. The bit of wood *e* must be gently withdrawn, care being taken that the bud adheres wholly to the bark or shield, as it is called, of which *f* is a side view. The bark on each side of the perpendicular slit being then cautiously opened, as at *b*, with the handle of the knife, the bud and shield are inserted as shown at *c*. The upper tip of the shield is cut off horizontally, and brought to fit the oark of the stock at the transverse incision. Slight ties of soft cotton wool or worsted, or even moist bast-matting, are then applied. In about a month or six weeks the ligatures may be taken away, when, if the operation has been

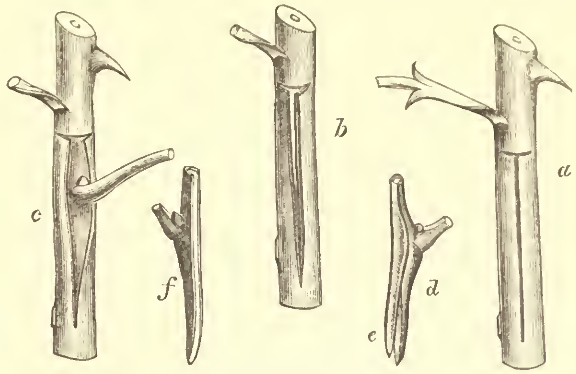

Fig. 59.—Shield-Budding.

successful, the bud will be fresh and full, and the shield firmly united to the wood. In the following spring a strong shoot will be thrown out, and to this the stock is headed down by gradations during the course of the summer.

To be successful the operation should be performed with a quick and light hand, so that no part of the delicate tissues be injured, as would happen if they were left for a time exposed, or if the bud were forced in like a wedge. The union is effected as in grafting, by means of the organizable sap or cambium, and the less this is disturbed until the inner bark of the shield is pressed and fixed against it the better. Inverted T-budding, in which the two incisions are in the form ⊥, is for some reasons preferable to the more ordinary method.

(12) *By Branch Cuttings.*—Propagation by cuttings is the mode of increase most commonly adopted, next to that by seeds. It is effected by taking a portion from a branch or shoot of the plant, and placing it in the soil. There are great differences to be observed in the selection and treatment of cuttings. Sometimes soft green shoots, as in *Verbena* (fig. 60, *a*), are used; sometimes the shoots must be half-ripened, and sometimes fully matured. So of the mode of preparation; some will root if cut off or broken off at any point and thrust into wet earth or sand in a warm place (fig. 60, *a*); others require to be cut with the utmost care just below a joint or leaf-base, and by a keen blade so as to sever the tissues without tearing or bruising; and others again after being cut across require to be split up for a short distance. It is usual and in most cases necessary to cut away the lower portion of a cutting up to just below the Branch cutting

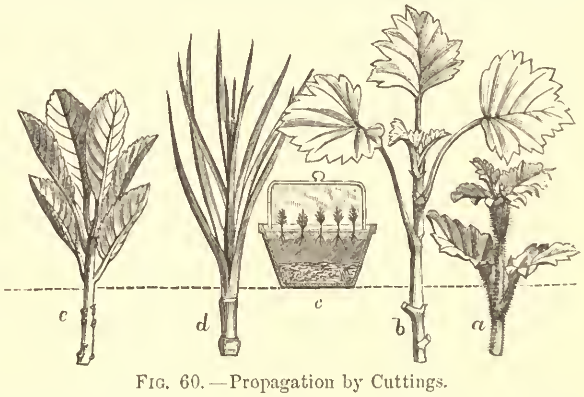

Fig. 60.—Propagation by Cuttings.

node or joint (fig. 60, *b*, *d*, *e*). The internodal parts will not often divide so as to form separate individual plants; sometimes, however, this happens; it is said that the smallest piece of *Torenia asiatica*, for instance, will grow. Then as to position, certain cuttings grow readily enough if planted outdoors in the open soil, some preferring shade, others sunshine, while less hardy subjects must be covered with a bell-glass, or must be in a close atmosphere with bottom heat, or must have the aid of pure silver sand to facilitate their rooting (fig. 60, *c*). Cuttings should in all cases be taken from healthy plants, and from shoots of a moderate degree of vigour. It is also important to select leafy growths, and not such as will at once run up to flower. Young shoots which have become moderately firm generally make the best cuttings, but sometimes the very softest shoots strike more readily. For all plants in a growing state spring is the safest time for taking cuttings.

Cuttings of deciduous plants should be taken off after the fall of the leaf, and should have all underground buds carefully removed so as to prevent as far as possible the formation of suckers. These cuttings should be about one foot in length, and should be planted at once in the ground so as to leave only the top with the two or three preserved buds exposed. If a clean stem, however, is desired, a longer portion may be left uncovered.

Cuttings of growing plants are prepared by removing with a sharp knife, and moderately close, the few leaves which would otherwise be buried in the soil; they are then cut clean across just below a joint; the fewer the leaves thus removed, however, the better, as if kept from being exhausted they help to supply the organizable matter out of which the roots are formed. Free-rooting subjects strike in any lightish sandy mixture; but difficult subjects should have thoroughly well-drained pots, a portion of the soil proper for the particular plants made very sandy, and a surfacing of clean sharp silver sand about as deep as the length of the cutting (fig. 60, *e*). Mr Ayres, writing in the *Gardeners' Chronicle* (1843, p. 116), recommends 5-inch pots for cuttings; and these he prepares by placing over the hole at the bottom of each an inverted 3-inch pot, around it potsherds broken small, over these some moss, and then the compost made up of equal quantities of peat, sand, and leaf-mould, leaving about half an inch at top for white sand, which runs into the holes as the cuttings are inserted. Mr Ayres advises that "a stock of pots thus prepared should be kept in a frame or propagating house, as nothing is so injurious to cuttings taken from plants growing in heat as to put them into cold soil. Cuttings cannot be too short if they have the necessary buds to form a plant; neither can they be inserted too shallow, if they are made firm in the pots."

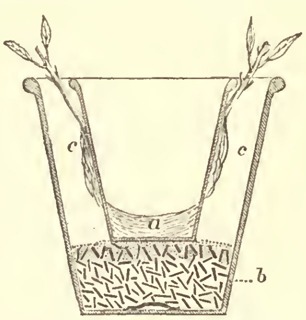

FIG. 61.—Double Cutting Pot.

All plants while striking may be kept in a temperature rather higher than that in which they grow naturally, and the soil about them should be kept moist, although they must not from want of drainage in any degree get sodden with wet. The humidity kept up about the cuttings is maintained by covering them with bell-glasses, or setting them in handlights or small glazed frames of convenient size.

A special contrivance for a cutting pot (fig. 61) was brought into notice many years ago by Mr A. Forsyth. A smaller pot was put into a larger one, the hole at the bottom being closed with clay *a*; the bottom of the outer pot is filled with crocks *b*, so that the small pot is brought up to the level of the larger one; and the space between the two pots *c* is filled with propagating soil, the cuttings being so planted that their ends rest against the sides of the inner pot, which is then filled with water, and this passing slowly through the sides of the pots, just keeps the soil moistened.

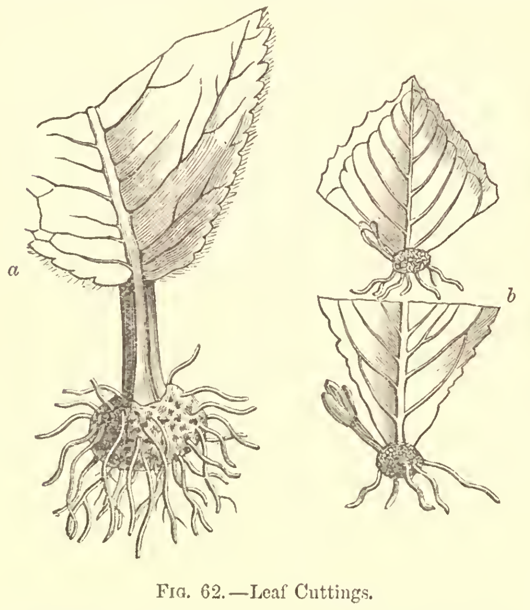

FIG. 62.—Leaf Cuttings.

Such delicate plants as heaths are reared in silver sand, a stratum of which is placed over the sandy peat soil in the cutting pot, and thus the cuttings, though rooting in the sand, find at once on the emission of roots congenial soil for them to grow in (fig. 60, *c*).

Hardy plants, such as pinks, pansies, &c., are propagated by cuttings planted during early summer in light rich soil. The cuttings of pinks are called pipings (fig. 60, *d*), and are planted about June, while pansies may be renewed in this way both in spring and in autumn.

(13) *By Leaf Cuttings.*—Many plants may be propagated by planting their leaves or portions of their leaves as cuttings, as, for example, the herbaceous *Gloxinia* (fig. 62, *a*) and *Gesnera*, the succulent *Sempervivum*, *Echeveria*, *Pachyphytum*, and their allies, and such hard-leaved plants as *Theophrasta* (fig. 62, *b*). The leaves are best taken off with the base whole, and should be planted in well-drained sandy soil; in due time they form roots, and ultimately from some latent bud a little shoot which forms the young plant. The treatment is precisely like that of branch cuttings. Gloxinias, begonias, &c., grow readily from fragments of the leaves cut clean through the thick veins and ribs, and planted edgewise like cuttings. This class of subjects may also be fixed flat on the surface of the cutting pot, by means of little pegs or hooks, the main ribs being cut across at intervals, and from these points roots, and eventually young tubers, will be produced (fig. 63). Leaf cuttings.

Fig. 63.—Leaf Propagation.

(14) *By Root Cuttings.*—Some plants which are not easily increased by other means propagate readily from root cuttings. Amongst the indoor plants which may be so treated, the *Bouvardia*, *Pelargonium*, *Aralia*, and *Wigandia* may be mentioned. The *modus operandi* is to turn the plant out of its pot, shake away the soil so as to free the roots, and then select as many pieces of the stouter roots as may be required. These are cut up into half-inch lengths (sometimes less), and inserted in light sandy soil round the margin of a cutting pot, so that the upper end of the root cutting may be level with the soil or only just covered by it. The pots should be watered so as to settle the soil, and be placed in the close atmosphere of the propagating pit or frame, where they will need scarcely any water until the buds are seen pushing through the surface. Root cuttings

There are various herbaceous plants which may be similarly treated, such as sea-kale and horseradish, and, among ornamental plants, the beautiful autumn-blooming *Anemone japonica* and *Senecio pulcher*. The sea-kale and horseradish require to be treated in the open garden, where the cut portions should be planted in lines in well-worked soil; but the roots of the *Anemone* and *Senecio* should be planted in pots and kept in a close frame with a little warmth till the young shoots have started.

Various hardy ornamental trees are also increased in this way, as the quince, elm, robinia, and mulberry, and the rose amongst shrubs. The most important use to which this mode of propagation is put is, however, the increase of roses, and of the various plums used as stocks for working the choicer stone fruits. The method in the latter case is to select roots averaging the thickness of the little finger, to cut these into lengths of about 3 or 4 inches, and to plant them in lines just beneath the surface in nursery beds. The root cuttings of rose-stocks are prepared and treated in a similar way.

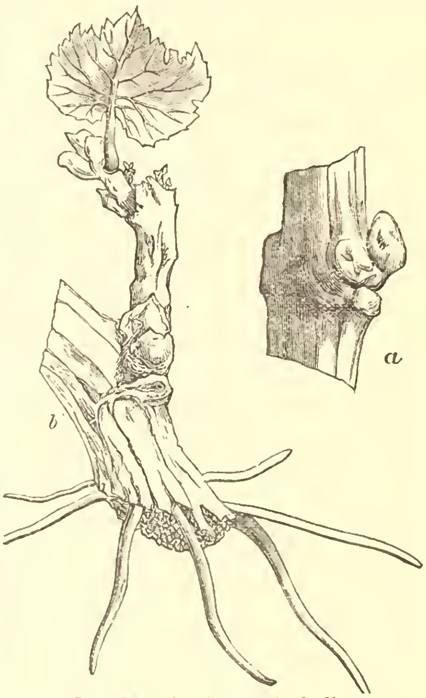

FIG. 64.—Cutting of Single Eye.

(15) *By Cuttings of Single Eyes.*—This mode of propagation is performed by cutting the branches into short lengths, each containing one well-matured bud or eye, with a short portion of the stem above and below. It is a common mode of propagating vines, the eyes Eye cuttings

being in this case cut from the ripened leafless wood. The eyes (fig. 64, *a*) are planted just below the surface in pots of light soil, which are placed in a hot bed or propagating pit, and in due time each pushes up a young shoot which forms the future stem, while from about its base the young roots are produced (fig. 64, *b*) which convert it into an independent plant. In the case of plants with persistent leaves, the stem may be cut through just above and below the bud, retaining the leaf which is left on the cutting, the old wood and eye being placed beneath the oil and the leaf left exposed. In this way the india-rubber tree (*Ficus elastica*), for example, and many other tender plants may be increased with the aid of a brisk bottom heat. Many of the free-growing soft-wooded plants may also be grown from cuttings of single joints of the young wood, where rapid increase is desired; and in the case of opposite-leaved plants two cuttings may often be made from one joint by splitting the stem longitudinally, each cutting consisting of a leaf and a perfect bud attached to half the thickness of the stem.

Trans-planting.

22. *Planting and Transplanting.*—In preparing a fruit tree for transplantation, the first thing to be done is to open a trench round it at a distance of from 3 to 4 feet, according to size. The trench should be opened to about two spades' depth, and any coarse roots which may extend thus far from the trunk may be cut clean off with a sharp knife. The soil between the trench and the stem is to be reduced as far as may seem necessary or practicable by means of a digging fork, the roots as soon as they are liberated being fixed on one side and carefully preserved. By working in this way all round the ball, the best roots will be got out and preserved, and the ball lightened of all superfluous soil. The tree will then be ready to lift if carefully prized up from beneath the ball, and if it does not lift readily, it will probably be found that a root has struck downwards, which will have to be sought out and cut through. Whenever practicable, it is best to secure a ball of earth round the roots. On the tree being lifted from its hole the roots should be examined, and all which have been severed roughly with the spade should have the ends cut smooth with the knife to facilitate the emission of fibres. The tree can then be transported to its new position. The hole for its reception should be of sufficient depth to allow the base of the ball of earth, or of the roots, to stand so that the point whence the uppermost roots spring from the stem may be 2 or 3 inches above the general surface level. Then the bottom being regulated so as to leave the soil rather highest in the centre, the plant is to be set in the hole in the position desired, and steadied there by hand. Next the roots from the lower portion of the ball are to be sought out and laid outwards in lines radiating from the stem, being distributed equally on all sides as nearly as this can be done; some fine and suitable good earth should be thrown amongst the roots as they are thus being placed, and worked in well up to the base of the ball. The soil covering the roots may be gently pressed down, but the tree should not be pulled up and down, as is sometimes done, to settle the soil. This done, another set of roots higher up the ball must be laid out in the same way, and again another, until the whole of the roots, thus carefully laid, are embedded as firmly as may be in the soil, which may now receive another gentle treading. The stem should next be supported permanently, either by one stake or by three, according to its size. The excavation will now be filled up about two-thirds perhaps; and if so the tree may have a thorough good watering, sufficient to settle the soil closely about its roots. After twenty-four hours the hole may be levelled in, with moderate treading, if the water has soaked well in, the surface being left slightly sloping upwards towards the stem of the tree. In transplanting trees of the ornamental class, less need be attempted in respect to providing new soil, although the soil should be made as congenial as practicable.

In transplanting smaller subjects, such as plants for the flower garden, much less effort is required. The plant must be lifted with as little injury to its rootlets as possible, and carefully set into the hole, the soil being filled in round it, and carefully pressed close by the hand. For moving small plants the garden trowel is a very convenient tool, but we are inclined to give the preference to the hand-fork (fig. 45). For larger masses, such as strong-growing herbaceous plants, a spade or digging-fork will be requisite.

When seedlings of vigorous plants have to be "pricked out," a dibble (fig. 64) is the best implement to be used. The ground being prepared and, if necessary, enriched, and the surface made fine and smooth, a hole is made with the dibble deep enough and large enough to receive the roots of the seedling plants without doubling them up, and the hole is filled in by working the soil close to the plant with the point of the dibble. The pricking out of seedlings in pots in the propagating pit is effected in a similar way. The plants, indeed, often require to be removed and set from half an inch to an inch apart before they have become sufficiently developed to admit of being handled with any degree of facility, and for these a pointed stick of convenient size is used as a dibble. In extreme cases it is best to lift the little seedling on the end of a flattish pointed stick, pressing this into the new soil where the plant is to be placed, and liberating it and closing the earth about it by the aid of a similar stick held in the other hand.

Large trees may be successfully transplanted by the aid of transplanting machines, of which different forms are in use. These will be found figured and described in the various horticultural and arboricultural publications. See, *e.g.*, M'Intosh's *Book of the Garden* (ii. p. 374 *sq.*). The best season for transplanting deciduous trees is during the early autumn months. As regards evergreens opinions are divided, some preferring August and September, others April or May. They can be successfully planted at either period, but for subjects which are at all difficult to remove the spring months are to be preferred.

Potting.

23. *Potting and Repotting.*—Garden pots are made with a comparatively large hole in the bottom, and those of the largest size have also holes at the side near the bottom; these openings are to prevent the soil becoming saturated or soured with superabundant water. To prepare the pot for the plant, a broadish piece of potsherd, called a "crock," is placed over the large hole, and if there be side holes they also are covered. The bottom crock is made from a piece of a broken garden pot, and is laid with the convex side upwards; then comes a layer of irregular pieces of crock of various sizes, about an inch deep in a 5-inch pot, 2 inches in an 11-inch or 12-inch pot, &c. The mode of crocking a pot is shown in fig. 65. A few of the coarser lumps from the outer edge of the heap of potting soil are spread over the crocks. The same end, that of keeping the finer particles of the soil from mixing with the drainage crocks, may be attained by shaking in a little clean moss. A handful or two of the soil is then put in, and on this the plant with its roots spread out is to be set a trifle higher than the plant should stand in the pot when finished off; more soil is to be added, and the whole pressed firmly with the fingers, the base of the stem being just below the pot-rim, and the surface being smoothed off so as to slope a little outwards. When finished off, the pots should be well watered, to settle the soil; but they should stand till the water has well drained away, since, if they are moved about while the fresh soil is very wet, there will be a risk of its becoming puddled or too much consolidated. Larger plants do not need quite such delicate treatment,

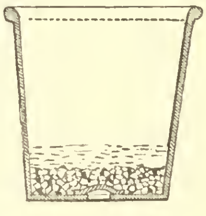

FIG. 65.—Section of Pot showing Crocks.

but care should be taken not to handle the roots roughly. The soil for these should be less comminuted, and the amount of drainage material more ample. Larger bodies of soil also require to be more thoroughly consolidated before watering; otherwise they would settle down so as to leave an unsightly void at the pot-rim.

Some plants, especially when potted temporarily, may be dealt with in a simpler way. A single crock may be used in some cases, and in others no crock at all, but a handful of half-decayed leaves or half-decayed dung thrown into the bottom of the pot. This mode of potting does well for bulbs, such as hyacinths, which are either thrown away or planted out when the bloom is over. The bedding plants generally may be potted in this way, the advantage being that at planting-out time there is less risk of disturbing the roots than if there were potsherds to remove. Plants of this character should be potted a little less firmly than specimens which are likely to stand long in the pot, and indeed the soil should be made comparatively light by the intermixture of leaf-mould or some equivalent, in order that the roots may run freely and quickly into it.

For epiphytal plants like orchids the most thorough drainage must be secured by the abundant use of potsherds, small pots being sometimes inserted inside the larger ones, or by planting in shallow pots or pans, so that there shall be no large mass of soil to get consolidated. For most of these the lightest spongy but sweet turfy peat must be used, this being packed lightly about the roots, and built up above the pot-rim, or in some cases freely mixed before use with chopped sphagnum moss and nodules of broken pots or of charcoal. The plants under these conditions often require to be supported by wooden pegs or sticks. Some of the species grow better when altogether taken out of the soil and fixed to blocks of wood, but in this case they require a little coaxing with moss about the roots until they get established. In other cases they are planted in open baskets of wood or wire, using the porous peat and sphagnum compost. Both blocks and baskets are usually suspended from the roof of the house, hanging free, so that no accumulation of water is possible. In these cases, however, the greatest caution is necessary to prevent the plants from suffering from drought.

When repotting is adopted as a temporary expedient, as in the case of bedding-out plants which it is required to push forward as much as possible, it will suffice if provision is made to prevent the drainage hole from getting blocked, and a rich light compost is provided for the encouragement of the roots. When, however, a hard-wooded plant has to be repotted, the case is different; it may stand without further potting for one year or two years or more, and therefore much more care is necessary. The old ball of earth must be freed from all or most of the old crocks without doing injury to the roots, and the sharp edge of the upper surface gently rubbed off. If there be any sour or sodden or effete soil into which the roots have not run, this should be carefully picked out with a pointed stick. The ball is to be set on the new soil just high enough that when finished the base of the stem may be about level with the pot-rim, towards which the surface should slope gently, and the space between the old ball and the sides of the pot is to be filled in gradually with the prepared compost, which is from time to time to be pressed down with a blunt-ended flat piece of wood called a potting-stick, so as to render the new soil as solid as the old. The object of this is to prevent the plant from starving by the water applied all running off by way of the new soil, and not penetrating the original ball of earth. When this amount of pressure is necessary, especially in the case of loamy composts, the soil itself should be rather inclined to dryness, and should in no case be sufficiently moist to knead together into a pasty mass. In ordinary cases the potting soil should be just so far removed from dryness that when a handful is gently pressed it may hang together, but may lose its cohesion when dropped.

When plants are required to stand in ornamental china pots or vases, it is better both for the plants and for avoiding risk of breakage to grow them in ordinary garden pots of a size that will drop into the more valuable vessels. Slate pots or tubs, usually square, are sometimes adopted, and are durable and otherwise unobjectionable, only, their sides being less porous, the earth does not dry so rapidly, and some modification of treatment as to watering is necessary. For large conservatory specimens wooden tubs, round or square, are frequently used; these should be coated with pitch inside to render them more durable.

Various other contrivances take the place of garden pots for special purposes. Thus shallow square or oblong wooden boxes, made of light inexpensive wood, are very useful for seed-sowing, for pricking out seedlings, or for planting cuttings. When the disturbance of the roots incidental to all transplanting is sought to be avoided, the seed or plant is started in some cases in squares of turf (used grassy-side downwards), which can when ready be transferred to the place the plant is to occupy. Cucumber and melon plants and vines reared from eyes are sometimes started in this way, both for the reason above mentioned, and because it prevents the curling of the roots apt to take place in plants raised in pots. Strips of turf are sometimes used for the rearing of early peas, which are sown in a warmish house or frame, and gradually hardened so as to bear exposure before removal to the open air.

24. *Watering.*—The guiding principle in watering plants is to do it thoroughly when it is required, and to abstain from giving a second supply till the first has been taken up. Watering.

When watering becomes necessary for kitchen-garden crops, the hose should be laid on and the lines of esculents allowed to drink their fill, if fresh succulent vegetables are desired. So also, if well-swelled and luscious fruits, such as strawberries, are required, there must be no parching at the roots. This applies even more strongly to conservatory borders and to forcing-houses than to the outside fruit-tree borders, because from these the natural rain supply is in most cases more distinctly cut off. In the case of forcing-houses, the water should be heated before being applied to the borders containing the roots of the trees.

In the watering of pot plants the utmost care is requisite if the plant be a shy-growing or valuable one, and yet it is almost impossible to give any intelligible instruction for performing the operation. The roots should never be suffered either to get thoroughly dry or to get sodden with excess of water. An adept will know by the ring of the pot on striking it with his knuckles whether water is wanted or not, according as it rings loud and clear or dull and heavy. With very choice subjects watering may be necessary two or three times a day in drying summer weather. It is a wrong though common practice to press the surface of the soil in the pot in order to feel if it is moist enough, as this soon consolidates it, and prevents it from getting the full benefit of aeration.

In all heated houses the water used should be warmed at least up to the temperature of the atmosphere, so as to avoid chilling the roots. This is also necessary in the case of water used for syringing the plants, which should be done two or three times a day in all stoves and forcing-houses, especially during the period when the young growth is being developed. The damping of all absorbent surfaces, such as the floors or bare walls, &c., is frequently necessary several times a day in the growing season, so as to keep up a humid atmosphere; hence the advantage of laying the floors a little rounded, as then the water draws off to the sides against the kerbstone, while the centre remains dry for promenaders.

In cooler structures it becomes necessary in the dull season of the year to prevent the slopping of water over the plants or on the floor, as this tends to cause "damping off,"—the stems assuming a state of mildewy decay, which not unfrequently, if it once attacks a plant, will destroy it piece by piece. For the same reason cleanliness and free ventilation are of great importance.

ning. 25. *Pruning.*—Pruning is a very important operation in the fruit garden, its object being twofold,—(1) to give form to the tree, and (2) to induce the free production of flower buds as the precursors of a plentiful crop of fruit. To form a standard tree, either the stock is allowed to grow up with a straight stem, by cutting away all side branches up to the height required, say about 6 feet, the scion or bud being worked at that point, and the head developed therefrom; or the stock is worked close to the ground, and the young shoot obtained therefrom is allowed to grow up in the same way, being pruned in its progress to keep it single and straight, and the top being cut off when the desired height is reached, so as to cause the growth of lateral shoots. If these are three or four in number, and fairly balanced as to strength and position, little pruning will be required. The tips of unripened wood should be cut back about one-third their length at an outwardly placed bud, and the chief pruning thereafter required will be to cut away inwardly directed shoots which cross or crowd each other and tend to confuse the centre of the tree. Bushy heads should be thinned out, and those that are too large cut back so as to remodel them. If the shoots produced are not sufficient in number, or are badly placed, or very unequal in vigour, the head should be cut back moderately close, leaving a few inches only of the young shoots, which should be pruned back to buds so placed as to furnish shoots in the positions desired. When worked at the top of a stem formed of the stock, the growth from the graft or bud must be pruned in a similar way. Three or four leading shoots should be selected to pass ere long into boughs and form a well-balanced skeleton for the tree; these boughs, however, will soon grow beyond any artificial system the pruner may adopt.

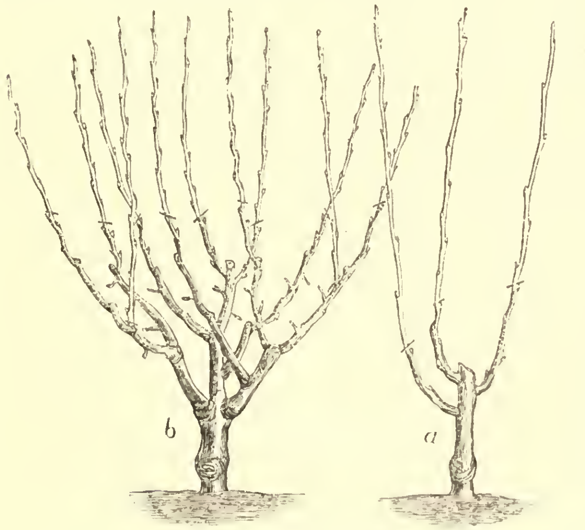

Fig. 66.—Dwarf-Tree Pruning.

To form a dwarf or bush fruit tree the stock must be worked near the ground, and the young shoot produced from the scion or bud must be cut back to whatever height it is desired the dwarf stem should be, say $1\frac{1}{2}$ to 2 feet. The young shoots produced from the portion of the new wood retained are to form the skeleton of the bush tree, and must be dealt with as in the case of standard trees. The growth of inwardly-directed shoots is to be prevented, and the centre kept open, the tree assuming a cup-shaped outline. Fig. 66, reduced from M. Hardy's excellent work, *Traité de la Taille des Arbres Fruitiers*, will give a good idea how these dwarf trees are to be manipulated, *a* showing the first year's development from the maiden tree after being headed back, and *b* the form assumed a year or two later.

In forming a pyramidal tree, the lateral growths, instead of being removed, as in the standard tree, are encouraged to the utmost; and in order to strengthen them the upper part of the leading shoot is removed annually, the side branches being also shortened somewhat as the tree advances in size. In fig. 67, reduced from M. Hardy's work,

Fig. 67.—Pyramid Pruning.

a shows a young tree with its second year's growth, the upright shoot of the maiden tree having been moderately headed back, being left longer if the buds near the base promise to break freely, or cut shorter if they are weak and wanting in vigour. The winter pruning, carried out with the view to shape the tree into a well-grown pyramid, would be effected at the places marked by a cross line. The lowest branch would have four buds retained, the end one being on the lower side of the branch. The two next would be cut to three buds, which here also are fortunately so situated that the upper one is on the lower side of the branches. The fourth is not cut at all, its terminal bud being allowed to grow to draw strength into it. The fifth is an example where the bud to which the shoot should be cut back is wrongly placed; a shoot resulting from such a cut is apt instead of growing outwards to grow erect, and lead to confusion in the form of the tree, to avoid which it is tied down in its proper place during the summer by a small twig. The upper shoots are cut closer in. Near the base of the stem are two prominent buds, which would produce two vigorous shoots, but these would be too near the ground, and the buds should therefore be suppressed; but, to strengthen the lower part, the weaker buds just above and below the lowest branch should be forced into growth, by making a transverse incision close above each. Fig. 67, *b* shows what a similar tree would be at the end of the third year's growth.

In order to bring a young tree into the cordon shape, all its side branches are shortened back, either to form permanent spurs, as in the case of pears, or to yield annual young shoots, as in peaches and nectarines. The single-stemmed cordon may be trained horizontally, obliquely at any required angle, or vertically if required, the first two arrangements being preferable. If a double cordon is required, the original young stem must be headed back, and the two best shoots produced must be selected, trained right and left, and treated as for the single cordon.

The forms chiefly adopted for trees trained to walls and espalier rails are the fan-shaped, the half-fan, and the horizontal, with their various modifications.

Of late years the close pruning of the young trees has been objected to, and the "extension system" has, in many cases, been adopted. The maiden tree is headed down, and two shoots led away right and left. Two laterals should be allowed to grow from the upper side of them, one from near the base, the other from near the middle, all others being pinched out beyond the second or third leaf during summer, but cut away to the last bud in winter. The tree will thus consist of six shoots, probably 3 feet to 4 feet long, which are not to be pruned unless they are unequal in strength, a defect which is rather to be remedied by summer pinching than by winter pruning. The second year three young shoots are to be left on each of the six, one close to the base, one about the middle, and one at the point, the rest being rubbed off. These three shoots will produce laterals, of which one or two may be selected and laid in; and thus a number of moderately strong fertile shoots will be obtained, and at the end of the season a comparatively large tree will be the result.

Fig. 68.—Pruning for Fan-Shaped Tree.

Fig. 69.—The same—third year.

The method of pruning formerly adopted for the formation of a fan-shaped tree was to head down the maiden plant to about two eyes, so placed as to yield a young shoot on each side (fig. 68), the supernumerary shoots being rubbed off while quite young, and the reserved shoots trained against the wall during the summer so as to get them well matured. The next year they were cut back again, often nearly to the base, in order that the lower pair of these shoots might each produce two well-placed young shoots, and the upper pair three young shoots. The tree would thus consist of ten shoots, to be laid out at regular distances, and then if closely cut the skeleton of the tree would be as in fig. 69. These main shoots were not again to be shortened back, but from each of them three young shoots were to be selected and trained in two, on the upper side, one near the base, and the other halfway up, and one on the lower side placed about midway between these two; these with the leading shoot, which was also to be nailed in, made four branches of the current year from each of the ten main branches, and the form of the tree would therefore be that of fig. 70. The other young shoots produced were pinched off while quite young, to throw all the strength of the tree into those which were to form its basis, and to secure abundant light and air. In after years the leading shoot was not to be cut back, but all

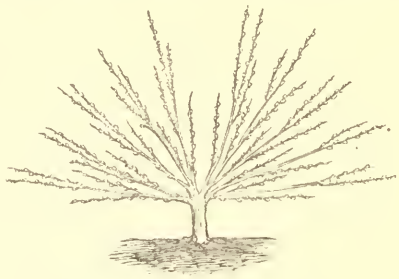

Fig. 70.—The same—fourth year.

the lateral shoots were to be shortened, and from these year by year other shoots were to be selected to fill up the area occupied by the tree.

In pruning for a horizontal tree the young maiden tree has to be headed back nearly to its base, and from the young shoots three are to be selected, the two best placed lower ones to form an opposite or nearly opposite pair of main branches, and the best placed upper one to continue the erect stem (fig. 71). This upper shoot is at the next winter pruning to be cut down to within about a foot of the

Fig. 71.—Pruning for Horizontally-Trained Tree.

Fig. 72.—The same—third year.

point whence it sprung, and its buds rubbed off except the upper one for a leader, and one on each side just below it to furnish another pair of side shoots; these being trained in position, the tree would appear as in fig. 72. The same course is to be followed annually till the space is filled. Sometimes in very favourable soils and with vigorous trees two pairs of branches may be obtained in one season by summer-stopping the erect shoots and selecting others from the young growths thus induced, but more commonly the trees have to be built up by forming one pair of branches

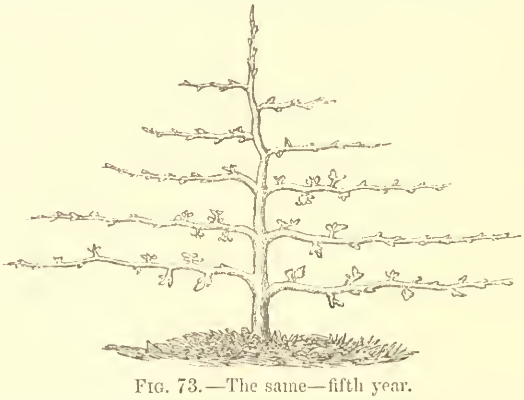

Fig. 73.—The same—fifth year.

annually. The shoots are not at first lowered to the horizontal line, but are brought down gradually; and while the tree is being formed weak shoots may be allowed to grow in a more erect position than it is ultimately intended they should occupy. Thus in four or five years the tree will have acquired something the character of fig. 73, and will go on thus increasing until the space is filled.

The half-fan is a combination of the two forms, but as regards pruning does not materially differ from the horizontal, as two opposite side branches are produced in succession upwards till the space is filled, only they are not taken out so abruptly, but are allowed to rise at an acute angle and then to curve into the horizontal line.

In all the various forms of cordons, in horizontal training, and in fan and half-fan training, the pruning of the main branches when the form of the tree is worked out will vary in accordance with the kind of fruit under treatment. Thus in the peach, nectarine, apricot, plum, and cherry, which are commonly trained fan-fashion, the first two will have to be pruned so as to keep a succession of young annual shoots, these being their fruit-bearing wood. The others are generally pruned so as to combine a moderate supply of young wood with a greater or less number of fruit spurs. In the pear and apple the fruit is borne principally on spurs, and hence what is known as spur-pruning has to be adopted, the young shoots being all cut back nearly to their base, so as to cause fruit buds to evolve from the remaining eyes or buds. Cordons of apples and pears have to be similarly treated, but cordons of peaches and nectarines are pruned so as to provide the necessary annual succession of young bearing wood.

The nature of the cut itself in pruning is of more consequence, especially in the case of fruit trees, than at first sight may appear. The branches should be separated by a clean cut at an angle of about 45°, just at the back of a bud, the cut entering on a level with the base of the bud and passing out on a level with its top (fig. 74, *a*), for when

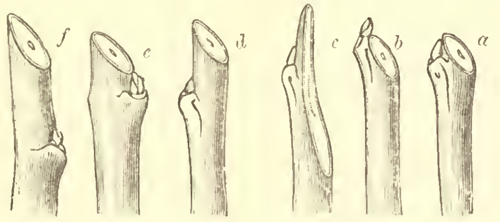

Fig. 74.—Cuts—Good and Bad.

cut in this way the wound becomes rapidly covered with new wood, as soon as growth recommences, whereas if the cut is too close the bud is starved, or if less close an ugly and awkward snag is left. Fig. 74, *b* and *c*, are examples of the former, and *d, e, f* of the latter. Dr Lindley has designated the cut shown at fig. 74, *b* the cut to the quick (*Gardeners' Chronicle*, 1847, p. 19):—

"In order to avoid the risk of the 'cut to the quick,' some gardeners make use of the 'snag cut' (*d, e, f*), in which the wound is made on the same side of the branch as that occupied by the bud, slanting downwards towards it. That plan is objectionable; for it involves the necessity of leaving behind a dead portion of the branch, to be removed at a later pruning, so the work must be done twice over; moreover, it is an admission of a want of the skill required to make the 'clean cut' skilfully. Lastly, there is the 'slivering cut' (*c*), in which a long ragged unequal shave is taken off the branch, much too low in the beginning, and much too high at the end. It is the cut made by garden labourers. It is clumsy, ugly, awkward, and dangerous, for it is apt to injure the branch on which it is made. In all cases, the amputation should be made by one firm-drawn cut. The clean cut can be performed by a dexterous operator to within a shaving of the right line; and the mastery of this art is no mean acquisition."

In the case of fruit trees, and indeed of deciduous plants generally, pruning requires to be done during the winter or resting period, and the earlier in that period the better, as then the buds become plump and full of sap, and produce strong shoots when the time for growth arrives. If, on the contrary, it is done while the plant is in full growth, the whole system of the tree sustains a check, the circulation is deranged, the quality of the sap becomes deteriorated, and a dead stump or unhealthy shoot is the frequent result. This, however, does not apply to the pruning of the herbaceous or succulent growths of the current season, nor to soft-wooded plants generally, for this kind of pruning, called summer pruning, is essential to the formation of handsome specimens of the latter, and is a very important help in the formation of the fruit or blossom buds of fruit trees.

Summer Pruning should be performed while the shoots are yet young and succulent, so that they may in most cases be nipped off with the thumb-nail. It is very necessary in the case of trees trained to a flat surface, as a wall or espalier rail, to prevent undue crowding. In some cases, as, for example, with peaches, the superfluous shoots are wholly removed, and certain selected shoots reserved to supply bearing wood for next year. In others, as pears, the tops of the young shoots are removed, leaving three or four leaves and their buds at the base, to be developed into fruit buds by the additional nourishment thus thrown into them (fig. 75, *a*). One or two may

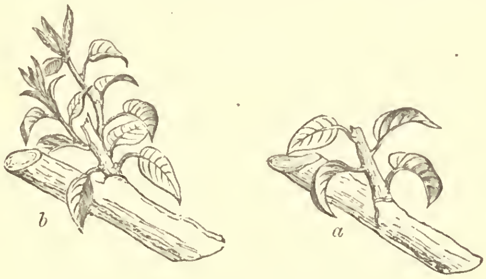

Fig. 75.—Summer Pruning for Spurs.

push out a late summer growth, *b*; this will serve as a vent for the vigour of the tree, and if the lowermost only go to the formation of a fruit spur, the object will have been gained. They are cut to the last dormant bud in winter.

But summer pruning has been much extended since the introduction of restricted growth and the use of dwarfing stocks. Orchard-house trees, and also pyramidal and bush trees of apples, pears, and plums, are mainly fashioned by summer pruning; in fact, the less the knife is used upon them, except in the necessary cutting of the roots in potted trees, the better. In the case of orchard-house plants no shoots are suffered to lengthen out, except as occasionally wanted to fill up a gap in the outline of the tree. On the contrary, the tops of all young shoots are pinched off when some three or four leaves are formed, and this is done again and again throughout the season. When this pruning is just brought to a balance with the vigour of the roots, the consequence is that fruit buds are formed all over the tree, instead of a thicket of sterile and useless wood. Pyramidal and bush trees out of doors are, of course, suffered to become somewhat larger, and sufficient wood must be allowed to grow to give them the form desired; but after the first year or two, when the framework is laid out, they are permitted to extend very slowly, and never to any great extent, while the young growths are continually nipped off, so as to clothe the branches with fruit buds as closely placed as will permit of their healthy development.[1]

The *Pruning of Flowering Plants* is generally a much lighter matter than the pruning of fruit trees. If a young seedling or cutting of any soft-wooded plant is to be bushy, it must have its top nipped out by the thumb-nail or pruning-scissors at a very early stage, and this stopping must be repeated frequently. If what is called a well-furnished plant is required, an average of from 2 to 3 inches is all the extension that must be per-

[1] On the general subject of pruning fruit trees the reader may usefully consult Thompson's *Gardener's Assistant*, Bréhaut's *Modern Peach Pruner*, Forney's *Jardinier Fruitier*, Hardy's *Traité de la Taille des Arbres Fruitiers*, and Dubreuil's *Culture des Arbres et Arbrisseaux à Fruits de Table*.

mitted—sometimes scarcely so much—before the top is nipped out; and this must be continued until the desired size is attained, whether that be large or small. Then generally the plant is allowed to grow away till bloom or blooming shoots are developed. To form a pyramidal plant, which is a very elegant and useful shape to give to a decorative pot plant, the main stem should be encouraged to grow upright, for a length perhaps of 6 or 8 inches before it is topped; this induces the formation of laterals, and favours their development. The best-placed upper young shoot is selected and trained upright to a slender stake, and this also is topped when it has advanced 6 or 8 inches further, in order to induce the laterals on the second portion to push freely. This process is continued till the required size is gained. With all the difficult and slow-growing plants of the hard-wooded section, all the pruning must be done in this gradual way in the young wood as the plant progresses.

Some plants, like pelargoniums, can only be kept handsomely formed and well furnished by cutting them down severely every season, after the blooming is over. The plants should be prepared for this by keeping them rather dry at the root, and after cutting they must stand with little or no water till the stems heal over, and produce young shoots, or "break," as it is technically termed. The appearance of a specimen pelargonium properly pruned is shown in fig. 76, in which *a* shows a young plant, the

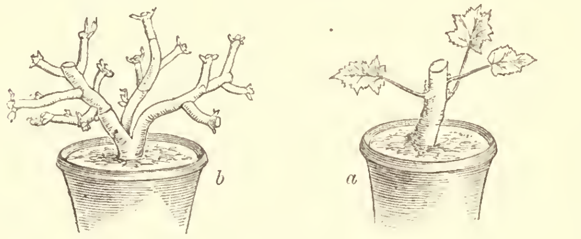

Fig. 76.

head of which has been taken off to form a cutting, and whose buds are ready to break into young shoots. Three shoots will be produced, and these, after growing from 4 to 6 inches in length, should be stopped by pinching out the point, this giving rise to lateral shoots. These will blossom in due course, and, after being ripened thoroughly by full exposure to the sun, should be cut back as shown at *b*. This is the proper foundation for a good specimen, and illustrates how all such subjects should be pruned to keep them stocky and presentable in form.
