of the fluid streams within the vessel, retaining, however, a form similar to that of the orifice. Afterwards it expands into sheets in planes perpendicular to the sides of the orifice. Thus the jet from a triangular orifice expands into three sheets, in planes bisecting at right angles the three sides of the triangle. Generally a jet from an orifice, in the form of a regular polygon of n sides, forms n sheets in planes perpendicular to the sides of the polygon.

Bidone explains this by reference to the simpler case of meeting streams. If two equal streams having the same axis, but moving in opposite directions, meet, they spread out into a thin disk normal to the common axis of the streams. If the directions of two streams intersect obliquely they spread into a symmetrical sheet perpendicular to the plane of the streams. Now those portions of a jet which proceed from different portions of an orifice are conceived to behave in some degree like independent meeting streams.

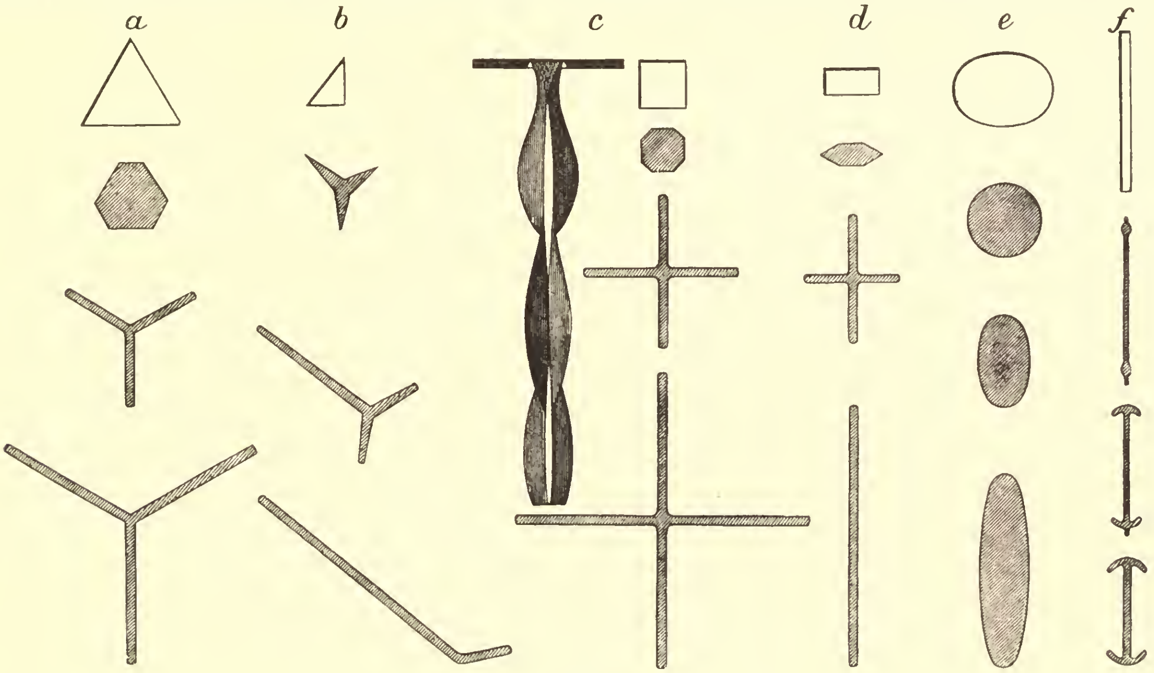

Fig. 28.

Let a_1, a_2 (fig. 29) be two points in an orifice at depths h_1, h_2 from the free surface. The filaments issuing at a_1, a_2 will have the different velocities $\sqrt{2gh_1}$ and $\sqrt{2gh_2}$. Consequently they will tend to describe parabolic paths a_1cb_1 and a_2cb_2 of different horizontal range, and intersecting in the point c. But since two filaments cannot simultaneously flow through the same point, they must exercise mutual pressure, and will be deflected out of the paths they tend to describe. It is this mutual pressure which causes the expansion of the jet into sheets.

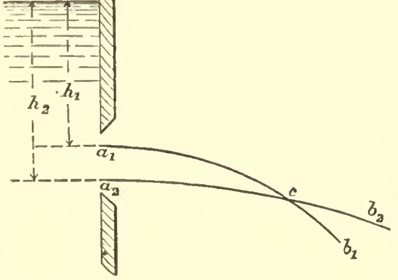

Fig. 29.

Lord Rayleigh has pointed out that, when the orifices are small and the head is not great, the expansion of the sheets in directions perpendicular to the direction of flow reaches a limit. Sections taken at greater distance from the orifice show a contraction of the sheets until a compact form is reached similar to that at the first contraction. This is shown in the elevation of the jet c. Beyond this point, if the jet retains its coherence, sheets are thrown out again, but in directions bisecting the angles between the previous sheets. Lord Rayleigh accepts an explanation of this contraction first suggested by Buff, namely, that it is due to surface tension or capillarity. The fluid is enclosed in an envelope of constant tension, and the recurrent form of the jet is due to vibrations of the fluid column, about a circular figure of equilibrium, superposed on the general progressive motion. Since the phase of vibration depends on the time elapsed, it is always the same at the same point in space, and thus the motion is steady and the boundary of the jet is a fixed surface.

In so far as the vibrations may be considered isochronous, the distance between consecutive corresponding points of the recurrent figure, or, as it may be termed, the wave length of the figure, is directly proportional to the velocity of the jet, that is, to the square root of the head of water. For low heads the measurements confirm this law. For higher heads there is an increase of the wave lengths in a higher ratio than the velocity of the jet. This points to a departure from isochronous vibration, the nature of which is investigated in Lord Rayleigh's paper.

IV. THEORY OF THE STEADY MOTION OF FLUIDS.

25. The general equation of the steady motion of a fluid given under Hydrodynamics furnishes immediately three results as to the distribution of pressure in a stream which may here be assumed.

(*a.*) If the motion is rectilinear and uniform, the variation of pressure is the same as in a fluid at rest. In a stream flowing in an open channel, for instance, when the effect of eddies produced by the roughness of the sides is neglected, the pressure at each point is simply the hydrostatic pressure due to the depth below the free surface.

(*b.*) If the velocity of the fluid is very small, the distribution of pressure is approximately the same as in a fluid at rest.

(*c.*) If the fluid molecules take precisely the accelerations which they would have if independent and submitted only to the external forces, the pressure is uniform. Thus in a jet falling freely in the air the pressure throughout any cross section is uniform and equal to the atmospheric pressure.

(*d.*) In any bounded plane section traversed normally by streams which are rectilinear for a certain distance on either side of the section, the distribution of pressure is the same as in a fluid at rest.

Distribution of Energy in Incompressible Fluids.

26. *Application of the Principle of the Conservation of Energy to Cases of Stream Line Motion.*—The external and internal work done on a mass is equal to the change of kinetic energy produced. In many hydraulic questions this principle is difficult to apply, because from the complicated nature of the motion produced it is difficult to estimate the total kinetic energy generated, and because in some cases the internal work done in overcoming frictional or viscous resistances cannot be ascertained; but in the case of stream line motion it furnishes a simple and important result known as Bernouilli's theorem.

Let AB (fig. 30) be any one elementary stream, in a steadily moving fluid mass. Then, from the steadiness of the motion, AB is a fixed

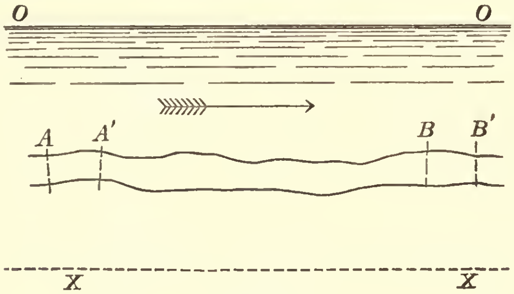

Fig. 30.

path in space through which a stream of fluid is constantly flowing. Let OO be the free surface and XX any horizontal datum line. Let ω be the area of a normal cross section, v the velocity, p the intensity of pressure, and z the elevation above XX, of the elementary stream AB at A, and ω_1, p_1, v_1, z_1 the same quantities at B. Suppose that in a short time t the mass of fluid initially occupying AB comes to A'B'. Then AA', BB' are equal to vt, v_1t, and the volumes of fluid AA', BB' are the equal inflow and outflow $= Qt = \omega vt = \omega_1 v_1 t$, in the given time. If we suppose the filament AB surrounded by other filaments moving with not very different velocities, the frictional or viscous resistance on its surface will be small enough to be neglected, and if the fluid is incompressible no internal work is done in change of volume. Then the work done by external forces will be equal to the kinetic energy produced in the time considered.

The normal pressures on the surface of the mass (excluding the ends A, B) are at each point normal to the direction of motion, and do no work. Hence the only external forces to be reckoned are gravity and the pressures on the ends of the stream.

The work of gravity when AB falls to A'B' is the same as that of transferring AA' to BB'; that is, $GQt\,(z-z_1)$. The work of the pressures on the ends, reckoning that at B negative, because it is opposite to the direction of motion, is $(p\omega \times vt) - (p_1\omega_1 \times v_1 t) = Qt\,(p-p_1)$. The change of kinetic energy in the time t is the difference of the kinetic energy originally possessed by AA' and that finally acquired by BB', for in the intermediate part A'B there is no change of kinetic energy, in consequence of the steadiness of the motion. But the mass of AA' and BB' is $\frac{G}{g}Qt$, and the change of kinetic energy is therefore $\frac{G}{g}Qt\left(\frac{v_1^2}{2}-\frac{v^2}{2}\right)$. Equating this to the work done on the mass AB,

$$GQt(z-z_1)+Qt(p-p_1)=\frac{G}{g}Qt\left(\frac{v_1^2}{2}-\frac{v^2}{2}\right).$$

Dividing by GQt and rearranging the terms,

$$\frac{v^2}{2g}+\frac{p}{G}+z=\frac{v_1^2}{2g}+\frac{p_1}{G}+z_1 \quad . \quad . \quad . \quad . \quad . \quad (1);$$

or, as A and B are any two points,

$$\frac{v^2}{2g}+\frac{p}{G}+z=\text{constant}=H \quad . \quad . \quad . \quad . \quad (2).$$

Now $\frac{v^2}{2g}$ is the head due to the velocity v, $\frac{p}{G}$ is the head equivalent to the pressure, and z is the elevation above the datum (see § 15). Hence the terms on the left are the total head due to velocity, pressure, and elevation at a given cross section of the filament. z is easily seen to be the work in foot-pounds which would be done by 1 lb of fluid falling to the datum line, and similarly $\frac{p}{G}$ and $\frac{v^2}{2g}$ are the quantities of work which would be done by 1 lb of fluid due to the pressure p and velocity v. The expression on the left of the equation is, therefore, the total energy of the stream at the section considered, per lb of fluid, estimated with reference to the datum line XX. Hence we see that in stream line motion, under the restrictions named above, the total energy per lb of fluid is uniformly distributed along the stream line. If the free surface of the fluid OO is taken as the datum, and $-h$, $-h_1$ are the depths of A and B measured down from the free surface, the equation takes the form

$$\frac{v^2}{2g}+\frac{p}{G}-h=\frac{v_1^2}{2g}+\frac{p_1}{G}-h_1 \quad . \quad . \quad . \quad . \quad . \quad (3);$$

or generally

$$\frac{v^2}{2g}+\frac{p}{G}-h=\text{constant} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3a).$$

27. *Second Form of the Theorem of Bernoulli.*—Suppose at the two sections A, B (fig. 31) of an elementary stream small vertical pipes are introduced, which may be termed pressure columns

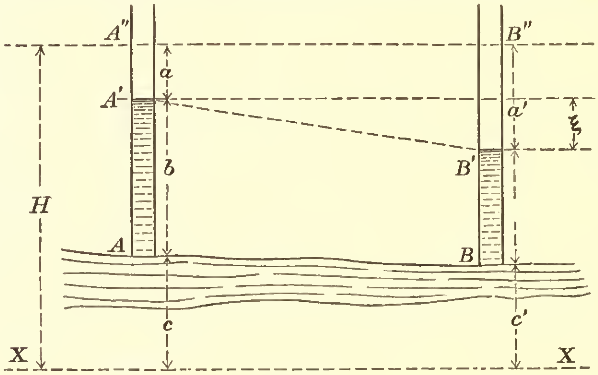

Fig. 31.

(§ 8), having their lower ends accurately parallel to the direction of flow. In such tubes the water will rise to heights corresponding to the pressures at A and B. Hence

$$b=\frac{p}{G}, \quad \text{and } b'=\frac{p_1}{G}$$

Consequently the tops of the pressure columns A' and B' will be at total heights $b+c=\frac{p}{G}+z$ and $b'+c'=\frac{p_1}{G}+z_1$ above the datum line XX. The difference of level of the pressure column tops, or the fall of free surface level between A and B, is therefore

$$\xi=\frac{p-p_1}{G}+(z-z_1);$$

and this by equation (1), § 26, is

$$=\frac{v_1^2-v^2}{2g}.$$

That is, the fall of free surface level between two sections is equal to the difference of the heights due to the velocities at the sections. The line A'B' is sometimes called the line of hydraulic gradient, though this term is also used in cases where friction needs to be taken into account. It is the line the height of which above datum is the sum of the elevation and pressure head at that point, and it falls below a horizontal line A″B″ drawn at H feet above XX by the quantities $a=\frac{v^2}{2g}$ and $b=\frac{v_1^2}{2g}$, when friction is absent.

28. *Illustrations of the Theorem of Bernoulli.*—In a lecture to the mechanical section of the British Association in 1875, the late Mr W. Froude gave some experimental illustrations of the principle of Bernoulli. Mr Froude remarked that it was a common but erroneous impression that a fluid exercises in a contracting pipe A (fig. 32) an excess of pressure against the entire converging surface which it meets, and that, conversely, as it enters an enlargement B, a relief of pressure is experienced by the entire diverging surface of the pipe. Further it is commonly assumed that when passing through a contraction C, there is in the narrow neck an excess of pressure due to the squeezing together of the liquid at that point. These impressions are in no respect correct; the pressure is smaller as the section of the pipe is smaller and conversely.

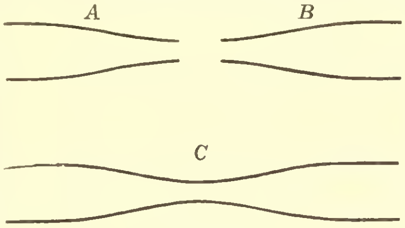

Fig. 32

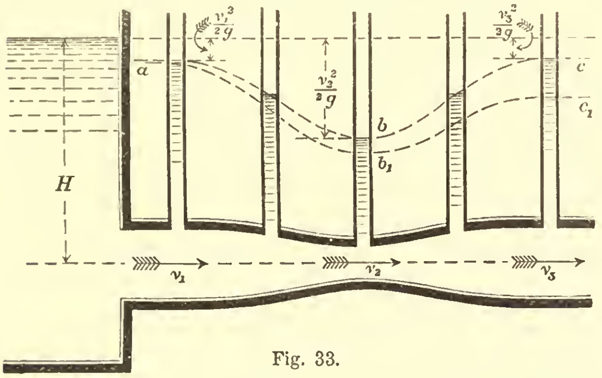

Fig. 33.

Fig. 33 shows a pipe so formed that a contraction is followed by an enlargement, and fig. 34 one in which an enlargement is followed by a contraction. The vertical pressure columns show the decrease of pressure at the contraction and increase of pressure at the enlargement.

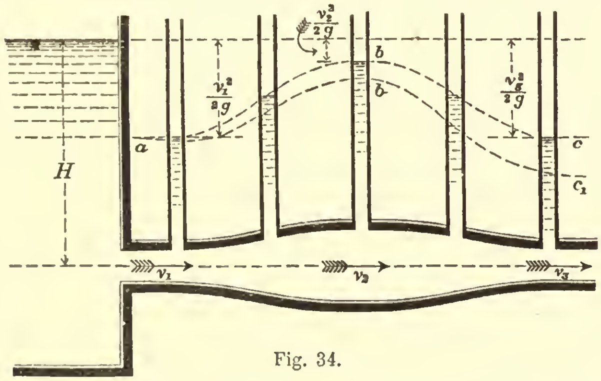

Fig. 34.

The line *abc* in both figures shows the variation of free surface level, supposing the pipe frictionless. In actual pipes, however, work is expended in friction against the pipe; the total head diminishes in proceeding along the pipe, and the free surface level is a line such as ab_1c_1, falling below *abc*.

Mr Froude further points out that, if a pipe contracts and enlarges again to the same size, the resultant pressure on the converging part exactly balances the resultant pressure on the diverging part so that there is no tendency to move the pipe bodily when water flows through it. Thus the conical part AB (fig. 35) presents the same projected surface as HI, and the pressures parallel to the axis of the pipe, normal to these projected surfaces, balance each other.

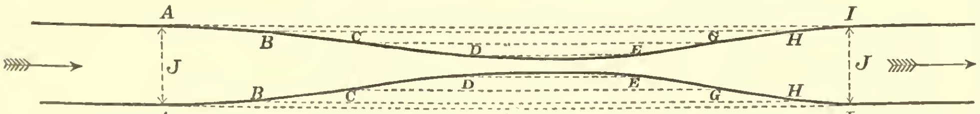

Fig. 35.

Similarly the pressures on BC, CD balance those on GH, EG. In the same way, in any combination of enlargements and contractions, a balance of pressures, due to the flow of liquid parallel to the axis of the pipe, will be found, provided the sectional area and direction of the ends are the same.

The following experiment is interesting. Two cisterns provided with converging pipes were placed so that the jet from one was exactly opposite the entrance to the other. The cisterns being filled very nearly to the same level, the jet from the left hand cistern A entered the right hand cistern B (fig. 36), shooting across the free

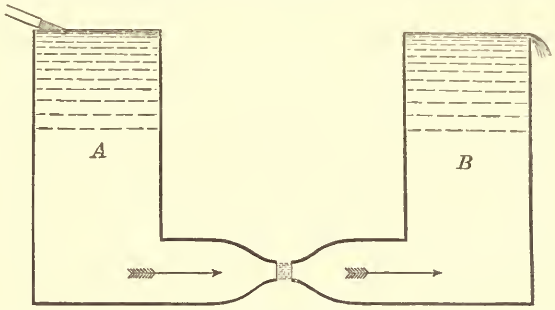

Fig. 36.

space between them without any waste, except that due to indirectness of aim and want of exact correspondence in the form of the orifices. In the actual experiment there was 18 inches of head in the right and $20\frac{1}{2}$ inches of head in the left hand cistern, so that about $2\frac{1}{2}$ inches were wasted in friction. It will be seen that in the open space between the orifices there was no pressure, except the atmospheric pressure acting uniformly throughout the system.

29. *Pressure, Velocity, and Energy in Different Stream Lines.*—The equation of Bernouilli gives the variation of pressure and velocity from point to point along a stream line, and shows that the total energy of the flow across any two sections is the same. Two other directions may be defined, one normal to the stream line and in the plane containing its radius of curvature at any point, the other normal to the stream line and the radius of curvature. For the problems most practically useful it will be sufficient to consider the stream lines as parallel to a vertical or horizontal plane. If the motion is in a vertical plane, the action of gravity must be

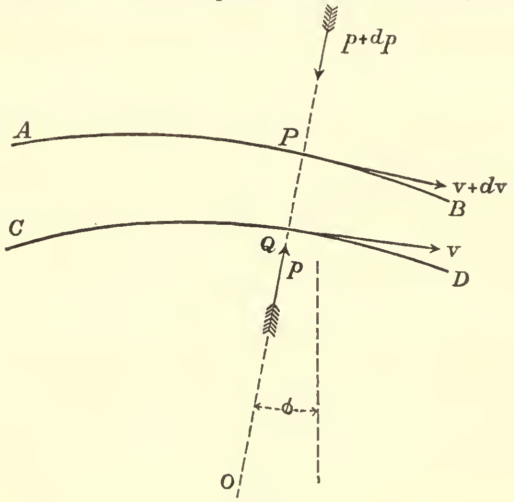

Fig. 37.

taken into the reckoning; if the motion is in a horizontal plane, the terms expressing variation of elevation of the filament will disappear.[1]

Let AB, CD (fig. 37) be two consecutive stream lines, at present assumed to be in a vertical plane, and PQ a normal to these lines making an angle ϕ with the vertical. Let P, Q be two particles moving along these lines at a distance $PQ=ds$, and let z be the height of Q above the horizontal plane with reference to which the energy is measured, v its velocity, and p it

[1] The following theorem is taken from a paper by Professor Cotterill, "On the Distribution of Energy in a Mass of Fluid in Steady Motion," *Phil. Mag.*, February 1876.

pressure. Then, if H is the total energy at Q per unit of weight of fluid,

$$\mathrm{H} = z + \frac{p}{\mathrm{G}} + \frac{v^2}{2g}.$$

Differentiating, we get

$$d\mathrm{H} = dz + \frac{dp}{\mathrm{G}} + \frac{vdv}{g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

for the increment of energy between Q and P. But

$$dz = \mathrm{PQ} \cos \phi = ds \cos \phi ;$$

$$\therefore d\mathrm{H} = \frac{dp}{\mathrm{G}} + \frac{vdv}{g} + ds \cos \phi \quad . \quad . \quad . \quad . \quad . \quad . \quad (1a),$$

where the last term disappears if the motion is in a horizontal plane.

Now imagine a small cylinder of section ω described round PQ as an axis. This will be in equilibrium under the action of its centrifugal force, its weight and the pressure on its ends. But its volume is ωds and its weight $\mathrm{G}\omega ds$. Hence, taking the components of the forces parallel to PQ—

$$\omega dp = \frac{\mathrm{G}}{g} \frac{v^2}{\rho} \omega ds - \mathrm{G}\omega \cos \phi \, ds.$$

where ρ is the radius of curvature of the stream line at Q. Consequently, introducing these values in (1),

$$d\mathrm{H} = \frac{v^2}{g\rho} ds + \frac{vdv}{g} = \frac{v}{g} \left\{ \frac{v}{\rho} + \frac{dv}{ds} \right\} ds \quad . \quad . \quad . \quad (2).$$

Now it is already known that if, through any particle A, lines be drawn through B and C two particles near to A, such that AB and AC are at right angles at the instant considered, then the mean angular velocity of these lines is the same in whatever direction they are drawn, and is equal to the angular velocity with which a small cylindrical element described round A would rotate if supposed suddenly solidified. This mean angular velocity may be conveniently called the molecular rotation, and will be denoted by $\circlearrowleft$. In the present case $\frac{v}{\rho}$ is the angular velocity of the tangent at Q, and $\frac{dv}{ds}$ is the angular velocity, reckoned in the same direction, of a line perpendicular to the tangent through P and Q. The sum of these is, therefore, twice the molecular rotation, and

$$d\mathrm{H} = 2\frac{v}{g} \circlearrowleft ds \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Now vds is constant, being the flow in an elementary stream of breadth unity, and thickness ds. Therefore the difference of energy between two consecutive elementary streams is proportional to the molecular rotation at any point of either.

Currents.

30. *Rectilinear Current.*—Suppose the motion is in parallel straight stream lines (fig. 38) in a vertical plane. Then ρ is infinite, and from eq. (2), § 29,

$$d\mathrm{H} = \frac{vdv}{g}.$$

Comparing this with (1) we see that

$$dz + \frac{dp}{\mathrm{G}} = 0 ;$$

$$\therefore z + \frac{p}{\mathrm{G}} = \text{constant} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4);$$

or the pressure varies hydrostatically as in a fluid at rest. For two stream lines in a horizontal plane, z is constant, and therefore p is constant.

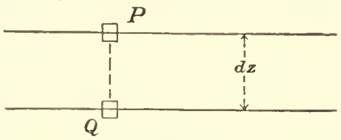

Fig. 38.

Radiating Current.—Suppose water flowing radially between horizontal parallel planes, at a distance apart $= \delta$. Conceive two cylindrical sections of the current at radii r_1 and r_2, where the velocities are v_1 and v_2, and the pressures p_1 and p_2. Since the flow across each cylindrical section of the current is the same,

$$\mathrm{Q} = 2\pi r_1 \delta v_1 = 2\pi r_2 \delta v_2$$

$$r_1 v_1 = r_2 v_2$$

$$\frac{r_1}{r_2} = \frac{v_2}{v_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

The velocity would be infinite at radius 0, if the current could be conceived to extend to the axis. Now, if the motion is steady,

$$\mathrm{H} = \frac{p_1}{\mathrm{G}} + \frac{v_1^2}{2g} = \frac{p_2}{\mathrm{G}} + \frac{v_2^2}{2g},$$

$$= \frac{p_2}{\mathrm{G}} + \frac{r_1^2}{r_2^2} \frac{v_1^2}{2g};$$

$$\frac{p_2 - p_1}{\mathrm{G}} = \frac{v_1^2}{2g} \left(1 - \frac{r_1^2}{r_2^2}\right) \quad . \quad . \quad . \quad . \quad (6);$$

$$\frac{p_2}{\mathrm{G}} = \mathrm{H} - \frac{r_1^2}{r_2^2} \frac{v_1^2}{2g} \quad . \quad . \quad . \quad . \quad (6a).$$

Hence the pressure increases from the interior outwards, in a way indicated by the pressure columns in fig. 39, the curve through the free surfaces of the pressure columns being, in a radial section, the

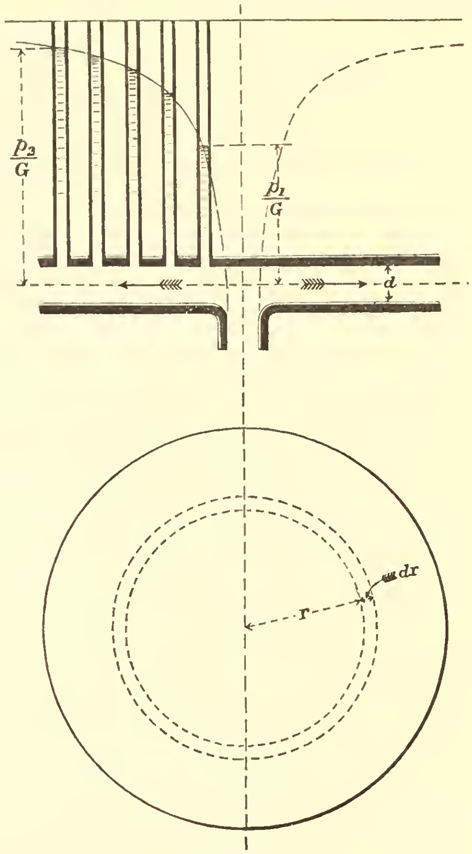

Fig. 39.

quasi-hyperbola of the form $xy^2 = c^3$. This curve is asymptotic to a horizontal line, H feet above the line from which the pressures are measured, and to the axis of the current.

Free Circular Vortex.—A free circular vortex is a revolving mass of water, in which the stream lines are concentric circles, and in which the total head for each stream line is the same. Hence, if by any slow radial motion portions of the water strayed from one stream line to another, they would take freely the velocities proper to their new positions under the action of the existing fluid pressures only.

For such a current, the motion being horizontal, we have for all the circular elementary streams

$$\mathrm{H} = \frac{p}{\mathrm{G}} + \frac{v^2}{2g} = \text{constant};$$

$$\therefore d\mathrm{H} = \frac{dp}{\mathrm{G}} + \frac{vdv}{g} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

Consider two stream lines at radii r and $r + dr$ (fig. 39). Then in (2), § 29, $\rho = r$ and $ds = dr$,

$$\frac{v^2}{gr} dr + \frac{vdv}{g} = 0,$$

$$\frac{dv}{v} = -\frac{dr}{r},$$

$$v \propto \frac{1}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

precisely as in a radiating current; and hence the distribution of pressure is the same, and formulæ 6, $6a$ are applicable to this case.

Free Spiral Vortex.—As in a radiating and circular current the equations of motion are the same, they will also apply to a vortex in which the motion is compounded of these motions in any proportions, provided the radial component of the motion varies inversely as the radius as in a radial current, and the tangential component varies inversely as the radius as in a free vortex. Then the whole velocity at any point will be inversely proportional to the radius of the point, and the fluid will describe stream lines having a constant inclination to the radius drawn to the axis of the current. That is, the stream lines will be logarithmic spirals. When water is delivered from the circumference of a centrifugal pump or turbine into a chamber, it forms a free vortex of this kind. The water flows spirally outwards, its velocity diminishing and its pressure increasing according to the law stated above, and the head along each spiral stream line is constant.

31. *Forced Vortex.*—If the law of motion in a rotating current is different from that in a free vortex, some force must be applied to cause the variation of velocity. The simplest case is that of a rotating current in which all the particles have equal angular velocity, as for instance when they are driven round by radiating paddles revolving uniformly. Then in equation (2), § 29, considering two circular stream lines of radii r and $r+dr$ (fig. 40), we have $\rho=r$, $ds=dr$. If the angular velocity is α, then $v=\alpha r$ and $dv=\alpha dr$. Hence

$$dH=\frac{\alpha^2 r}{g}dr+\frac{\alpha^2 r dr}{g}=\frac{2\alpha^2 r}{g}dr \; .$$

Comparing this with (1), § 29, and putting $dz=0$, because the motion is horizontal,

$$\frac{dp}{G}+\frac{\alpha^2 r dr}{g}=\frac{2\alpha^2 r}{g}dr \; ,$$

$$\frac{dp}{G}=\frac{\alpha^2 r}{g}dr \; ,$$

$$\frac{p}{G}=\frac{\alpha^2 r^2}{2g}+\text{constant} \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Let p_1, r_1, v_1 be the pressure, radius, and velocity of one cylindrical section, p_2, r_2, v_2 those of another; then

$$\frac{p_1}{G}-\frac{\alpha^2 r_1^2}{2g}=\frac{p_2}{G}-\frac{\alpha^2 r_2^2}{2g} \; ;$$

$$\frac{p_2-p_1}{G}=\frac{\alpha^2}{2g}(r_2^2-r_1^2)=\frac{v_2^2-v_1^2}{2g} \quad . \quad . \quad . \quad . \quad (10).$$

That is, the pressure increases from within outwards in a curve which in radial sections is a parabola, and surfaces of equal pressure are paraboloids of revolution (fig. 40).

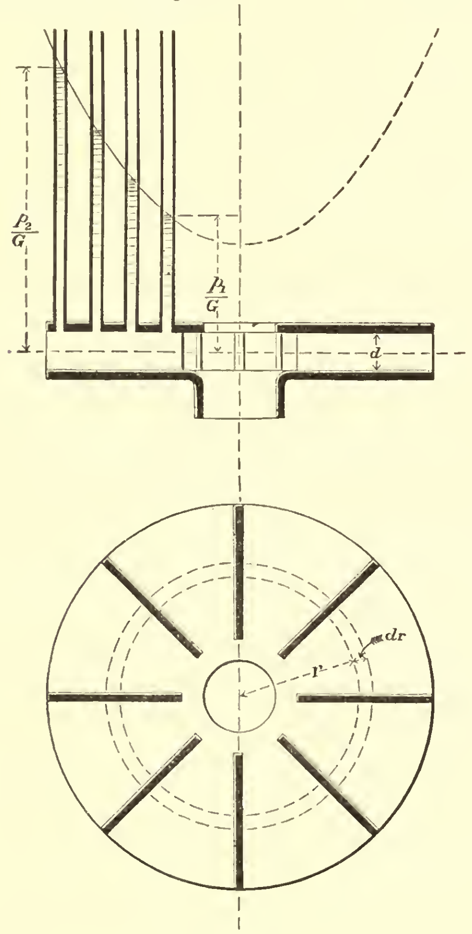

Fig. 40.

Dissipation of Head in Shock.

32. *Relation of Pressure and Velocity in a Stream in Steady Motion when the Changes of Section of the Stream are Abrupt.*—When a stream changes section abruptly, rotating eddies are formed which dissipate energy. The energy absorbed in producing rotation is at once abstracted from that effective in causing the flow, and sooner or later it is wasted by frictional resistances due to the rapid relative motion of the eddying parts of the fluid. In such cases the work thus expended internally in the fluid is too important to be neglected, and the energy thus lost is commonly termed energy lost in shock. Suppose fig. 41 to represent a stream having such an abrupt change of section. Let AB, CD be normal sections at points where ordinary stream line motion has not been disturbed and where it has been re-established. Let ω, p, v be the area of section, pressure, and velocity at AB, and ω_1, p_1, v_1 corresponding quantities at CD. Then if no work were expended internally, and assuming the stream horizontal, we should have

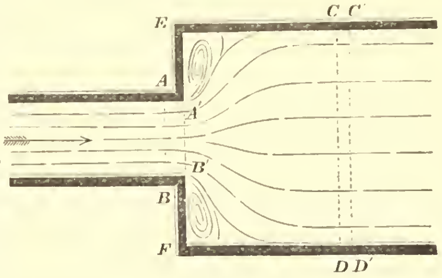

Fig. 41.

$$\frac{p}{G}+\frac{v^2}{2g}=\frac{p_1}{G}+\frac{v_1^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

But if work is expended in producing irregular eddying motion, the head at the section CD will be diminished.

Suppose the mass ABCD comes in a short time t to A′B′C′D′. The resultant force parallel to the axis of the stream is

$$p\omega+p_0(\omega_1-\omega)-p_1\omega_1,$$

where p_0 is put for the unknown pressure on the annular space between AB and EF. The impulse of that force is

$$\{p\omega+p_0(\omega_1-\omega)-p_1\omega_1\}t.$$

The horizontal change of momentum in the same time is the difference of the momenta of CDC′D′ and ABA′B′, because the amount of momentum between A′B′ and CD remains unchanged if the motion is steady. The volume of ABA′B′ or CDC′D′, being the inflow and outflow in the time t, is $Qt=\omega vt=\omega_1 v_1 t$, and the momentum of these masses is $\frac{G}{g}Qvt$ and $\frac{G}{g}Qv_1 t$. The change of momentum is therefore $\frac{G}{g}Qt(v_1-v)$. Equating this to the impulse,

$$\{p\omega+p_0(\omega_1-\omega)-p_1\omega_1\}t=\frac{G}{g}Qt(v_1-v) \; .$$

Assume that $p_0=p$, the pressure at AB extending unchanged through the portions of fluid in contact with AE, BF which lie out of the path of the stream. Then (since $Q=\omega_1 v_1$)

$$(p-p_1)=\frac{G}{g}v_1(v_1-v) \; ;$$

$$\frac{p}{G}-\frac{p_1}{G}=\frac{v_1(v_1-v)}{g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2) \; ;$$

$$\frac{p}{G}+\frac{v^2}{2g}=\frac{p_1}{G}+\frac{v_1^2}{2g}+\frac{(v-v_1)^2}{2g} \quad . \quad . \quad . \quad (3).$$

This differs from the expression (1), § 26, obtained for cases where no sensible internal work is done, by the last term on the right. That is, $\frac{(v-v_1)^2}{2g}$ has to be added to the total head at CD, which is $\frac{p_1}{G}+\frac{v_1^2}{2g}$, to make it equal to the total head at AB, or $\frac{(v-v_1)^2}{2g}$ is the head lost in shock at the abrupt change of section. But $v-v_1$ is the relative velocity of the two parts of the stream. Hence, when an abrupt change of section occurs, the head due to the relative velocity is lost in shock, or $\frac{(v-v_1)^2}{2g}$ foot-pounds of energy is wasted for each pound of fluid. Experiment verifies this result, so that the assumption that $p_0=p$ appears to be admissible.

If there is no shock,

$$\frac{p_1}{G}=\frac{p}{G}+\frac{v^2-v_1^2}{2g} \; .$$

If there is shock,

$$\frac{p_1}{G}=\frac{p}{G}-\frac{v_1(v_1-v)}{g} \; .$$

Hence the pressure head at CD in the second case is less than in the former by the quantity

$$\frac{(v-v_1)^2}{2g} \; ,$$

or, putting $\omega_1 v_1=\omega v$, by the quantity

$$\frac{v^2}{2g}\left(1-\frac{\omega}{\omega_1}\right)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

V. THEORY OF THE DISCHARGE FROM ORIFICES AND MOUTHPIECES.

33. *Minimum Coefficient of Contraction. Re-entrant Mouthpiece of Borda.*—In one special case the coefficient of contraction can be determined theoretically, and, as it is the case where the convergence of the streams approaching the orifice takes place through the greatest possible angle, the coefficient thus determined is the minimum coefficient.

Let fig. 42 represent a vessel with vertical sides, OO being the free water surface, at which the pressure is p_a. Suppose the liquid issues by a horizontal mouthpiece, which is re-entrant and of the greatest length which permits the jet to spring clear from the inner end of the orifice, without adhering to its sides. With such an orifice the velocity near the points CD is negligible, and the pressure at those points may be taken equal to the hydrostatic pressure due to the depth from the free surface. Let Ω be the area of the mouthpiece AB, ω that of the contracted jet *aa*. Suppose that in a short time t, the mass OO*aa* comes to the position O′O′ *a′a′*; the impulse of the horizontal external forces acting on the mass during that time is equal to the horizontal change of momentum.

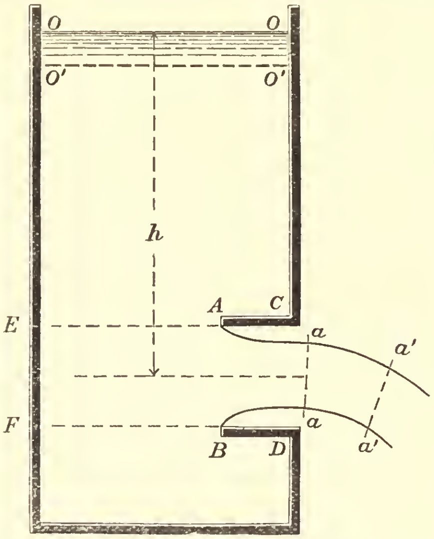

Fig. 42.

The pressure on the side OC of the mass will be balanced by the pressure on the opposite side OE, and so for all other portions of the vertical surfaces of the mass, excepting the portion EF opposite the mouthpiece and the surface *Aaa*B of the jet. On EF the pressure is simply the hydrostatic pressure due to the depth, that is, $(p_a + Gh)\Omega$. On the surface and section *Aaa*B of the jet, the horizontal resultant of the pressure is equal to the atmospheric pressure p_a acting on the vertical projection AB of the jet; that is, the resultant pressure is $-p_a\Omega$. Hence the resultant horizontal force for the whole mass OO*aa* is $(p_a + Gh)\Omega - p_a\Omega = Gh\Omega$. Its impulse in the time t is $Gh\Omega t$. Since the motion is steady there is no change of momentum between O′O′ and *aa*. The change of horizontal momentum is, therefore, the difference of the horizontal momentum lost in the space OOO′O′ and gained in the space *aaa′a′*. In the former space there is no horizontal momentum.

The volume of the space *aaa′a′* is ωvt; the mass of liquid in that space is $\frac{G}{g}\omega vt$; its momentum is $\frac{G}{g}\omega v^2 t$. Equating impulse to momentum gained,

$$Gh\Omega t = \frac{G}{g}\omega v^2 t\ ;$$

$$\frac{\omega}{\Omega} = \frac{gh}{v^2}\ .$$

But
$$v^2 = 2gh, \text{ and } \frac{\omega}{\Omega} = c_c\ ;$$

$$\therefore\ \frac{\omega}{\Omega} = \frac{1}{2} = c_c\ ;$$

a result confirmed by experiment with mouthpieces of this kind. A similar theoretical investigation is not possible for orifices in plane surfaces, because the velocity along the sides of the vessel in the neighbourhood of the orifice is not so small that it can be neglected. The resultant horizontal pressure is therefore greater than $Gh\Omega$, and the contraction is less. The experimental values of the coefficient of discharge for a re-entrant mouthpiece are 0·5149 (Borda), 0·5547 (Bidone), 0·5324 (Weisbach), values which differ little from the theoretical value, 0·5, given above.

34. *Velocity of Filaments issuing in a Jet.*—A jet is composed of fluid filaments or elementary streams, which start into motion at some point in the interior of the vessel from which the fluid is discharged, and gradually acquire the velocity of the jet. Let M*m*, fig. 43, be such a filament, the point M being taken where the velocity is insensibly small, and m at the most contracted section of the jet, where the filaments have become parallel and exercise uniform mutual pressure. Take the free surface AB for datum line, and let

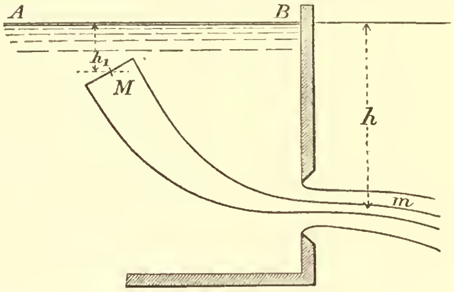

Fig. 43.

p_1, v_1, h_1, be the pressure, velocity, and depth below datum at M; p, v, h, the corresponding quantities at m. Then § 26, eq. (3),

$$\frac{v_1^2}{2g} + \frac{p_1}{G} - h_1 = \frac{v^2}{2g} + \frac{p}{G} - h\ . \quad . \quad . \quad . \quad . \quad (1).$$

But at M, since the velocity is insensible, the pressure is the hydrostatic pressure due to the depth; that is, $v_1 = 0$, $p_1 = p_a + Gh_1$. At m, $p = p_a$, the atmospheric pressure round the jet. Hence, inserting these values,

$$0 + \frac{p_a}{G} + h_1 - h_1 = \frac{v^2}{2g} + \frac{p_a}{G} - h\ ;$$

$$\frac{v^2}{2g} = h\ . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2);$$

or
$$v = \sqrt{2gh} = 8{\cdot}025\sqrt{h} \quad . \quad . \quad (2a).$$

That is, neglecting the viscosity of the fluid, the velocity of filaments at the contracted section of the jet is simply the velocity due to the difference of level of the free surface in the reservoir and the orifice. If the orifice is small in dimensions compared with h, the filaments will all have nearly the same velocity, and if h is measured to the centre of the orifice, the equation above gives the mean velocity of the jet.

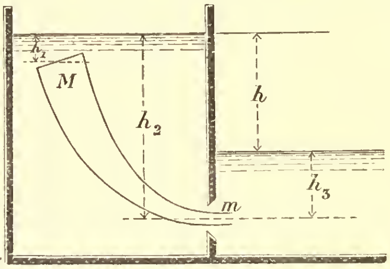

Fig. 44.

Case of a Submerged Orifice.—Let the orifice discharge below the level of the tail water. Then using the notation shown in fig. 44, we have at M, $v_1 = 0$, $p_1 = Gh_1 + p_a$; at m, $p = Gh_3 + p_a$. Inserting these values in (3), § 26,

$$0 + h_1 + \frac{p_a}{G} - h_1 = \frac{v^2}{2g} + h_3 - h_2 + \frac{p_a}{G}\ ;$$

$$\frac{v^2}{2g} = h_2 - h_3 = h \quad . \quad . \quad . \quad . \quad . \quad (3),$$

where h is the difference of level of the head and tail water, and may be termed the *effective head* producing flow.

Case where the Pressures are different on the Free Surface and at the Orifice.—Let the fluid flow from a vessel in which the pressure is p_0 into a vessel in which the pressure is p, fig. 45. The pressure p_0 will produce the same effect as a layer of fluid of thickness $\frac{p_0}{G}$ added to the head water; and the pressure p will produce the same effect as a layer of thickness $\frac{p}{G}$ added to the tail water. Hence the effective difference of level, or effective head producing flow, will be

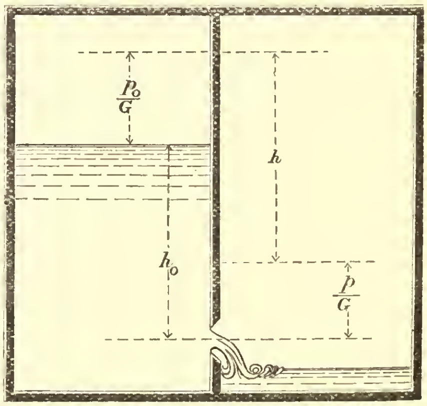

Fig. 45.

$$h = h_0 + \frac{p_0}{G} - \frac{p}{G}\ ;$$

and the velocity of discharge will be

$$v = \sqrt{2g\left\{h_0 + \frac{p_0 - p}{G}\right\}} \quad . \quad . \quad . \quad . \quad . \quad (4).$$

We may express this result by saying that differences of pressure at the free surface and at the orifice are to be reckoned as part of the effective head.

Hence in all cases thus far treated the velocity of the jet is the velocity due to the effective head, and the discharge, allowing for contraction of the jet, is

$$Q = c\omega v = c\omega\sqrt{2gh} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

where ω is the area of the orifice, $c\omega$ the area of the contracted section of the jet, and h the effective head measured to the centre of the orifice. If h and ω are taken in feet, Q is in cubic feet per second.

It is obvious, however, that this formula assumes that all the filaments have sensibly the same velocity. That will be true for horizontal orifices, and very approximately true in other cases, if the dimensions of the orifice are not large compared with the head h. In large orifices in say a vertical surface, the value of h is different for different filaments, and then the velocity of different filaments is not sensibly the same.

Simple Orifices—Head Constant.

35. *Large Rectangular Jets from Orifices in Vertical Plane Surfaces.*—Let an orifice in a vertical plane surface be so formed that it produces a jet having a rectangular contracted section with vertical and horizontal sides. Let b (fig. 46) be the breadth of the jet, h_1 and h_2 the depths below the free surface of its upper and lower surfaces. Consider a lamina of the jet between the depths h and $h+dh$.

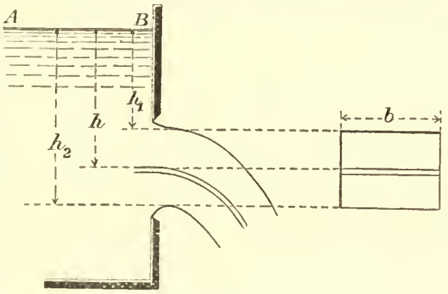

Fig. 46.

Its normal section is bdh, and the velocity of discharge $\sqrt{2gh}$. The discharge per second in this lamina is therefore $b\sqrt{2gh}\,dh$, and that of the whole jet is therefore

$$Q = \int_{h_1}^{h_2} b\sqrt{2gh}\,dh$$

$$= \tfrac{2}{3}\,b\sqrt{2g}\left\{h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}}\right\} \quad . \quad . \quad . \quad . \quad . \quad (6),$$

where the first factor on the right is a coefficient depending on the form of the orifice.

Now an orifice producing a rectangular jet must itself be very approximately rectangular. Let B be the breadth, H_1, H_2, the depths to the upper and lower edges of the orifice. Put

$$\frac{b(h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}})}{B(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}})} = c \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

Then the discharge, in terms of the dimensions of the orifice, instead of those of the jet, is

$$Q = \tfrac{2}{3}cB\sqrt{2g}(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}) \quad . \quad . \quad . \quad . \quad . \quad (8),$$

the formula commonly given for the discharge of rectangular orifices. The coefficient c is not, however, simply the coefficient of contraction, the value of which is

$$\frac{b(h_2 - h_1)}{B(H_2 - H_1)},$$

and not that given in (7). It cannot be assumed, therefore, that c in equation (8) is constant, and in fact it is found to vary for different values of $\frac{B}{H_2}$ and $\frac{B}{H_1}$, and must be ascertained experimentally.

Relation between the Expressions (5) and (8).—For a rectangular orifice the area of the orifice is $\omega = B(H_2 - H_1)$, and the depth measured to its centre is $\frac{1}{2}(H_2 + H_1)$. Putting these values in (5),

$$Q_1 = cB(H_2 - H_1)\sqrt{g(H_2 + H_1)}.$$

From (8) the discharge is

$$Q_2 = \tfrac{2}{3}cB\sqrt{2g}(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}).$$

Hence, for the same value of c in the two cases,

$$\frac{Q_2}{Q_1} = \frac{2}{3}\,\frac{H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}}{(H_2 - H_1)\sqrt{\frac{1}{2}(H_2 + H_1)}},$$

$$= 0{\cdot}9427\,\frac{1 - \frac{H_1}{H_2}\sqrt{\frac{H_1}{H_2}}}{1 - \frac{H_1}{H_2}\sqrt{\left(1 + \frac{H_1}{H_2}\right)}} \quad . \quad . \quad . \quad (9).$$

If H_1 varies from 0 to ∞, $\frac{H_1}{H_2}$ varies from 0 to 1. The following table gives values of the two estimates of the discharge for different values of $\frac{H_1}{H_2}$:—

$\frac{H_1}{H_2}$.	$\frac{Q_2}{Q_1}$.	$\frac{H_1}{H_2}$.	$\frac{Q_2}{Q_1}$.
0·0	·943	0·8	·999
0·2	·979	0·9	·999
0·5	·995	1·0	1·000
0·7	·998		

Hence it is obvious that, except for very small values of $\frac{H_1}{H_2}$, the simpler equation (5) gives values sensibly identical with those of (8). When $\frac{H_1}{H_2} < 0{\cdot}5$ it is better to use equation (8) with values of c determined experimentally for the particular proportions of orifice which are in question.

36. *Large Jets having a Circular Section from Orifices in a Vertical Plane Surface.*—Let fig. 47 represent the section of the jet,

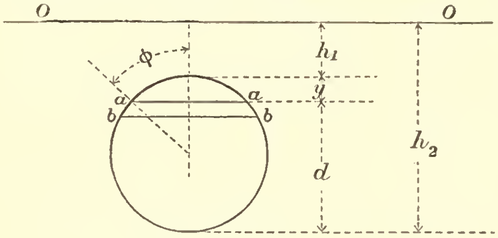

Fig. 47.

OO being the free surface level in the reservoir. The discharge through the horizontal strip $aabb$, of breadth $aa = b$, between the $h_1 + y$ and depths $h_1 + y + dy$, is

$$dQ = b\sqrt{\{2g(h_1 + y)\}}dy\,.$$

The whole discharge of the jet is

$$Q = \int_0^d b\sqrt{\{2g(h_1 + y)\}}dy\,.$$

But $b = d\sin\phi$; $y = \frac{1}{2}d(1 - \cos\phi)$; $dy = \frac{1}{2}d\sin\phi\,d\phi$. Let

$$\epsilon = \frac{d}{2h_1 + d},$$

then

$$Q = \frac{d^2}{2}\sqrt{\left\{2g\left(h_1 + \frac{d}{2}\right)\right\}}\int_0^\pi \sin^2\phi\sqrt{1 - \epsilon\cos\phi}\,d\phi\,.$$

From eq. (5), putting $\omega = \frac{\pi}{4}d^2$, $h = h_1 + \frac{d}{2}$, $c = 1$ when d is the diameter of the jet and not that of the orifice,

$$Q_1 = \frac{\pi}{4}d^2\sqrt{\left\{2g\left(h_1 + \frac{d}{2}\right)\right\}},$$

$$\frac{Q}{Q_1} = \frac{2}{\pi}\int_0^\pi \sin^2\phi\sqrt{\{1 - \epsilon\cos\phi\}}d\phi\,.$$

For $\quad h_1 = \infty$, $\epsilon = 0$ and $\frac{Q}{Q_1} = 1$;

and for $\quad h_1 = 0$, $\epsilon = 1$ and $\frac{Q}{Q_1} = 0{\cdot}96$.

So that in this case also the difference between the simple formula (5) and the formula above, in which the variation of head at different parts of the orifice is taken into account, is very small.

Notches and Weirs.

37. *Notches, Weirs, and Bycwashes.*—A notch is an orifice extending up to the free surface level in the reservoir from which the discharge takes place. A weir is a structure over which the water flows, the discharge being in the same conditions as for a notch. The formula of discharge for an orifice of this kind is ordinarily deduced by putting $H_1 = 0$ in the formula for the corresponding orifice, ob-

tained as in the preceding section. Thus for a rectangular notch, put $H_1=0$ in (8). Then

$$Q=\tfrac{2}{3}\,c\,B\sqrt{2g}\;H^{\frac{3}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11),$$

where H is put for the depth to the crest of the weir or the bottom of the notch. Fig. 48 shows the mode in which the discharge occurs in the case of a rectangular notch or weir with a level crest. As the free surface level falls very sensibly near the notch, the head H should be measured at some distance back from the notch, at a point where the velocity of the water is very small.

Since the area of the notch opening is BH, the above formula is of the form

$$Q=c\times BH\times k\sqrt{2gH}\,,$$

where k is a factor depending on the form of the notch and expressing the ratio of the mean velocity of discharge to the velocity due to the depth H.

38. *Francis's Formula for Rectangular Notches.*—The jet discharged through a rectangular notch has a section smaller than BH, (*a*) because of the fall of the water surface from the point where H is measured towards the weir, (*b*) in consequence of the crest contraction, (*c*) in consequence of the end contractions. It may be pointed out that while the diminution of the section of the jet due to the surface fall and to the crest contraction is proportional to the length of the weir, the end contractions have nearly the same effect whether the weir is wide or narrow.

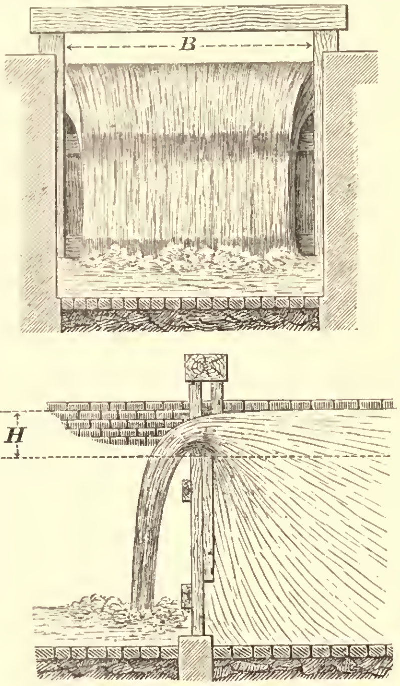

Fig. 48.

Mr Francis's experiments showed that a perfect end contraction, when the heads varied from 3 to 24 inches, and the length of the weir was not less than three times the head, diminished the effective length of the weir by an amount approximately equal to one-tenth of the head. Hence, if l is the length of the notch or weir, and H the head measured behind the weir where the water is nearly still, then the width of the jet passing through the notch would be $l-0{\cdot}2H$, allowing for two end contractions. In a weir divided by posts there may be more than two end contractions. Hence, generally, the width of the jet is $l-0{\cdot}1nH$, where n is the number of end contractions of the stream. The contractions due to the fall of surface and to the crest contraction are proportional to the width of the jet. Hence, if cH is the thickness of the stream over the weir, measured at the contracted section, the section of the jet will be $c(l-0{\cdot}1nH)H$ and (§ 37) the mean velocity will be $\tfrac{2}{3}\sqrt{2gH}$. Consequently the discharge will be given by an equation of the form

$$Q=\tfrac{2}{3}c(l-0{\cdot}1nH)H\sqrt{2gH}$$

$$=5{\cdot}35c(l-0{\cdot}1nH)H^{\frac{3}{2}}\,.$$

This is Francis's formula, in which the coefficient of discharge c is much more nearly constant for different values of l and h than in the ordinary formula. Francis found for c the mean value 0·622, the weir being sharp-edged.

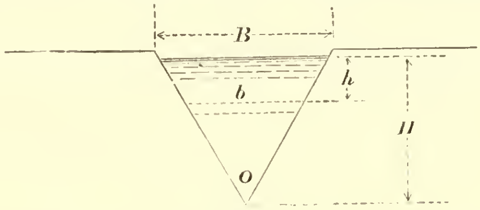

Fig. 49.

39. *Triangular Notch* (fig. 49).—Consider a lamina issuing between the depths h and $h+dh$. Its area, neglecting contraction, will be bdh, and the velocity at that depth is $\sqrt{2gh}$. Hence the discharge for this lamina is

$$b\sqrt{2gh}\,dh\,.$$

But

$$\frac{B}{b}=\frac{H}{H-h}\,;$$

$$b=B\frac{H-h}{H}\,.$$

Hence discharge of lamina

$$=B\,\frac{H-h}{H}\sqrt{2gh}\,dh\,;$$

and total discharge of notch

$$=Q=B\sqrt{2g}\int_0^H\frac{H-h}{H}h^{\frac{1}{2}}\,dh$$

$$=\tfrac{4}{15}B\sqrt{2g}\,H^{\frac{5}{2}}\,,$$

or, introducing a coefficient to allow for contraction,

$$Q=\tfrac{4}{15}cB\sqrt{2g}\,H^{\frac{5}{2}}\,.$$

When a notch is used to gauge a stream of varying flow, the ratio $\frac{B}{H}$ varies if the notch is rectangular, but is constant if the notch is triangular. This led Professor James Thomson to suspect that the coefficient of discharge, c, would be much more constant with different values of H in a triangular than in a rectangular notch, and this has been experimentally shown to be the case. Hence a triangular notch is more suitable for accurate gaugings than a rectangular notch. For a sharp-edged triangular notch Professor J. Thomson found $c=0{\cdot}617$. It will be seen, as in § 37, that since $\tfrac{1}{2}BH$ is the area of section of the stream through the notch, the formula is again of the form

$$Q=c\times\tfrac{1}{2}BH\times k\sqrt{2gH}\,,$$

where $k=\tfrac{8}{15}$ is the ratio of the mean velocity in the notch to the velocity at the depth H. It may easily be shown that for all notches the discharge can be expressed in this form.

40. *Weir with a Broad Sloping Crest.*—Suppose a weir formed with a broad crest so sloped that the streams flowing over it have a movement sensibly rectilinear and uniform (fig. 50). Let the inner edge be

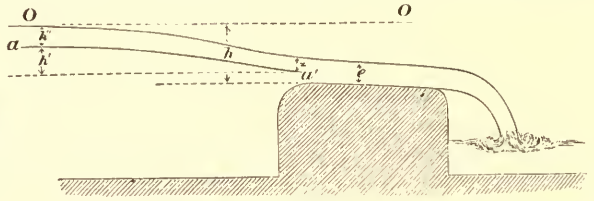

Fig. 50.

so rounded as to prevent a crest contraction. Consider a filament aa', the point a being so far back from the weir that the velocity of approach is negligible. Let OO be the surface level in the reservoir, and let a be at a height h'' below OO, and h' above a'. Let h be the distance from OO to the weir crest and e the thickness of the stream upon it. Neglecting atmospheric pressure, which has no influence, the pressure at a is Gh''; at a' it is Gz. If v be the velocity at a',

$$\frac{v^2}{2g}=h'+h''-z=h-e\,;$$

$$Q=be\sqrt{2g(h-e)}\,.$$

Theory does not furnish a value for e, but $Q=0$ for $e=0$ and for $e=h$. Q has therefore a maximum for a value of e between 0 and h, obtained by equating $\frac{dQ}{de}$ to zero. This gives $e=\tfrac{2}{3}h$, and, inserting this value,

$$Q=0{\cdot}385\,bh\sqrt{2gh}\,,$$

as a maximum value of the discharge with the conditions assigned. Experiment shows that the actual discharge is very approximately equal to this maximum, and the formula is more legitimately applicable to the discharge over broad-crested weirs and to cases such as the discharge with free upper surface through large masonry sluice openings than the ordinary weir formula for sharp-edged weirs. It should be remembered, however, that the friction on the sides and crest of the weir has been neglected, and that this tends to reduce a little the discharge. The formula is equivalent to the ordinary weir formula with $c=0{\cdot}577$.

Coefficients for the Discharge over Weirs, derived from the Experiments of Mr Blackwell. When more than one experiment was made with the same head, and the results were pretty uniform, the resulting coefficients are marked with an (*). The effect of the converging wing-boards is very strongly marked.

[1] The discharge per second varied from ·461 to ·665 cubic feet in two experiments. The coefficient ·435 is derived from the mean value.

Special Cases of Discharge from Orifices.

41. *Cases in which the Velocity of Approach needs to be taken into Account. Rectangular Orifices and Notches.*—In finding the velocity at the orifice in the preceding investigations, it has been assumed that the head h has been measured from the free surface of still water above the orifice. In many cases which occur in practice the channel of approach to an orifice or notch is not so large, relatively to the stream through the orifice or notch, that the velocity in it can be disregarded.

Let h_1, h_2 (fig. 51) be the heads measured from the free surface to the top and bottom edges of a rectangular orifice, at a point in the

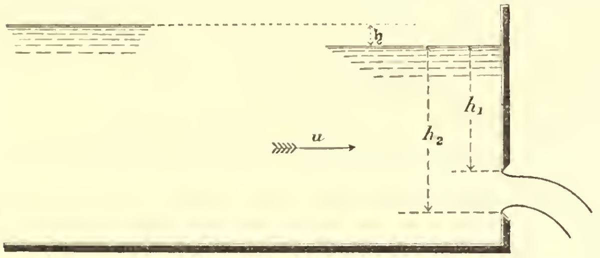

Fig. 51.

channel of approach where the velocity is u. It is obvious that a fall of the free surface,

$$\mathfrak{h} = \frac{u^2}{2g}$$

has been somewhere expended in producing the velocity u, and hence the true heads measured in still water would have been $h_1 + \mathfrak{h}$ and $h_2 + \mathfrak{h}$. Consequently the discharge, allowing for the velocity of approach, is

$$Q = \tfrac{2}{3} cb \sqrt{2g} \left\{ (h_2 + \mathfrak{h})^{\frac{3}{2}} - (h_1 + \mathfrak{h})^{\frac{3}{2}} \right\} \quad . \quad . \quad . \quad . \quad (1).$$

And for a rectangular notch for which $h_1 = 0$, the discharge is

$$Q = \tfrac{2}{3} cb \sqrt{2g} \left\{ (h_2 + \mathfrak{h})^{\frac{3}{2}} - \mathfrak{h}^{\frac{3}{2}} \right\} \quad . \quad . \quad . \quad . \quad . \quad (2).$$

In cases where u can be directly determined, these formulæ give the discharge quite simply. When, however, u is only known as a function of the section of the stream in the channel of approach, they become complicated. Let Ω be the sectional area of the channel where h_1 and h_2 are measured. Then $u = \dfrac{Q}{\Omega}$ and $\mathfrak{h} = \dfrac{Q^2}{2g\Omega^2}$.

This value introduced in the equations above would render them excessively cumbrous. In cases therefore where Ω only is known, it is best to proceed by approximation. Calculate an approximate value Q′ of Q by the equation

$$Q' = \tfrac{2}{3} cb \sqrt{2g} \left\{ h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}} \right\} .$$

Then $\mathfrak{h} = \dfrac{Q'^2}{2g\Omega^2}$ nearly. This value of $\mathfrak{h}$ introduced in the equations above will give a second and much more approximate value of Q.

42. *Partially Submerged Rectangular Orifices and Notches.*—When the tail water is above the lower but below the upper edge of the orifice, the flow in the two parts of the orifice, into which it is divided by the surface of the tail water, takes place under different conditions. A filament M_1m_1 (fig. 52) in the upper part of the orifice issues with a head h' which may have any value between h_1 and h. But a filament M_2m_2 issuing in the lower part of the orifice has a velocity due to $h'' - h'''$, or h, simply. In the upper part

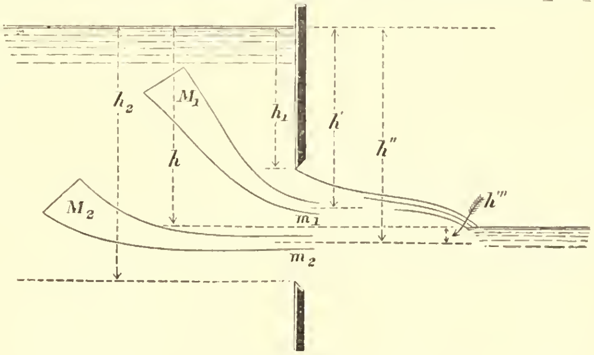

Fig. 52.

of the orifice the head is variable, in the lower constant. If Q_1, Q_2 are the discharges from the upper and lower parts of the orifice, b the width of the orifice, then

$$\left. \begin{aligned} Q_1 &= \tfrac{2}{3} cb \sqrt{2g} \left\{ h^{\frac{3}{2}} - h_1^{\frac{3}{2}} \right\} \\ Q_2 &= cb(h_2 - h)\sqrt{2gh} \end{aligned} \right\} \quad . \quad . \quad . \quad . \quad . \quad (3).$$

In the case of a rectangular notch or weir, $h_1 = 0$. Inserting this value, and adding the two portions of the discharge together, we get for a drowned weir

$$Q = cb\sqrt{2gh}\left(h_2 - \frac{h}{3} \right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

where h is the difference of level of the head and tail water, and h_2 is the head from the free surface above the weir to the weir crest. If velocity of approach is taken into account, let $\mathfrak{h}$ be the head due to that velocity; then, adding $\mathfrak{h}$ to each of the heads in the equations (3), and reducing, we get for a weir

$$Q = cb\sqrt{2g}\left[(h_2 + \mathfrak{h})(h + \mathfrak{h})^{\frac{1}{2}} - \tfrac{1}{3}(h + \mathfrak{h})^{\frac{3}{2}} - \tfrac{2}{3}\mathfrak{h}^{\frac{3}{2}} \right] \quad . \quad . \quad (5);$$

an equation which may be useful in estimating flood discharges.

Bridge Piers and other Obstructions in Streams.—When the piers of a bridge are erected in a stream they create an obstruction to the flow of the stream, which causes a difference of surface-level above

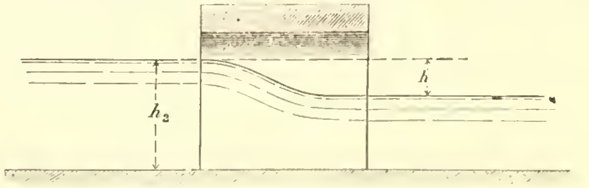

Fig. 53.

and below the pier (fig. 53). If it is necessary to estimate this difference of level, the flow between the piers may be treated as if it occurred over a drowned weir. But the value of c in this case is imperfectly known.

43. *Separating Weirs.*—Many towns derive their water supply from streams in high moorland districts, in which the flow is extremely variable. The water is collected in large storage reservoirs, from which an uniform supply can be sent to the town. In such cases it is desirable to separate the coloured water which comes down the streams in high floods from the purer water of ordinary flow. The latter is sent into the reservoirs; the former is allowed to flow away down the original stream channel, or is stored in separate reservoirs and used as compensation water. To accomplish the separation of the flood and ordinary water, advantage is taken of the different horizontal range of the parabolic path of the water falling over a weir, as the depth on the weir and, consequently, the velocity change. Fig. 54 shows one of these separating weirs in the form in which they were first introduced on the Manchester Waterworks; fig 55 a more modern weir of the same kind designed by Mr Binnie for the Bradford Waterworks. When the quantity of water coming

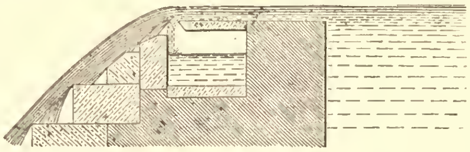

Fig. 54.

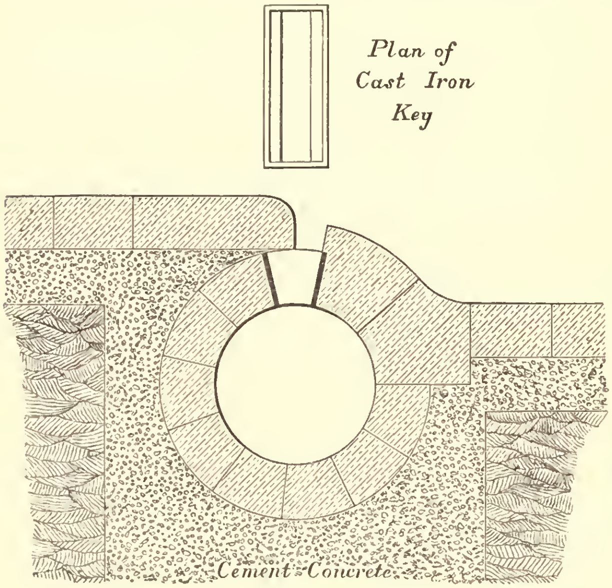

Fig, 55.

down the stream is not excessive, it drops over the weir into a transverse channel leading to the reservoirs. In flood, the water springs over the mouth of this channel and is led into a waste channel.

It may be assumed, probably with accuracy enough for practical purposes, that the particles describe the parabolas due to the mean velocity of the water passing over the weir, that is, to a velocity

$$\tfrac{2}{3}\sqrt{2gh}\,,$$

where h is the head above the crest of the weir.

Let $eb = x$ be the width of the orifice and $ac = y$ the difference of level of its edges (fig. 56). Then, if a particle passes from a to b in t seconds,

$$x = \tfrac{1}{2}gt^2\,,$$
$$y = \tfrac{2}{3}\sqrt{2gh}\,t\,;$$
$$\therefore \quad x = \tfrac{9}{16}\frac{y^2}{h}\,,$$

which gives the width x for any given difference of level y and head h, which the jet will just pass over the orifice. Set off ad vertically and equal to $\frac{1}{2}g$ on any scale; af horizontally and equal to $\frac{2}{3}\sqrt{gh}$. Divide af, fe into an equal number of equal parts. Join a with the divisions on ef. The intersections of these lines with verticals from the divisions on af give the parabolic path of the jet.

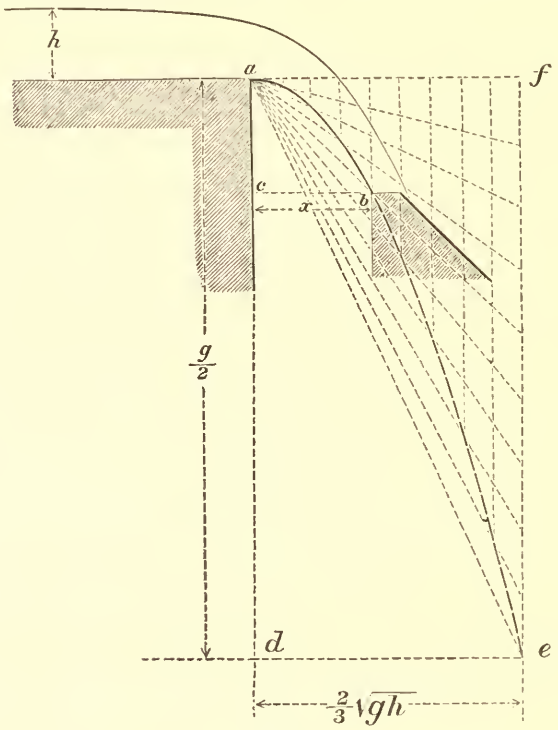

Fig. 56.

Mouthpieces—Head Constant.

44. *Cylindrical Mouthpieces.*—When water issues from a short cylindrical pipe or mouthpiece of a length at least equal to $1\frac{1}{2}$ times its smallest transverse dimension, the stream, after contraction within the mouthpiece, expands to fill it and issues full bore, or without contraction, at the point of discharge. The discharge is found to be about one-third greater than that from a simple orifice of the same size. On the other hand, the energy of the fluid per unit of weight is less than that of the stream from a simple orifice with the same head, because part of the energy is wasted in eddies produced at the point where the stream expands to fill the mouthpiece, the action being something like that which occurs at an abrupt change of section.

Let fig. 57 represent a vessel discharging through a cylindrical mouthpiece at the depth h from the free surface, and let the axis of the jet XX be taken as the datum with reference to which the head is estimated. Let Ω be the area of the mouthpiece, ω the area of the stream at the contracted section EF. Let v, p be the velocity and pressure at EF, and v_1, p_1 the same quantities at GH. If the discharge is into the air, p_1 is equal to the atmospheric pressure p_a.

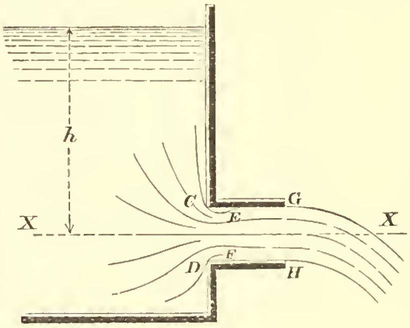

Fig. 57.

The total head of any filament which goes to form the jet, taken at a point where its velocity is sensibly zero, is $h + \frac{p_a}{G}$; at EF the total head is $\frac{v^2}{2g} + \frac{p}{G}$; at GH it is $\frac{v_1^2}{2g} + \frac{p_1}{G}$.

Between EF and GH there is a loss of head due to abrupt change of velocity, which from eq. (3), § 32, may have the value

$$\frac{(v - v_1)^2}{2g}\,.$$

Adding this head lost to the head at GH, before equating it to the heads at EF and at the point where the filaments start into motion,—

$$h + \frac{p_a}{G} = \frac{v^2}{2g} + \frac{p}{G} = \frac{v_1^2}{2g} + \frac{p_1}{G} + \frac{(v - v_1)^2}{2g}\,.$$

But $\omega v = \Omega v_1$, and $\omega = c_c\Omega$, if c_c is the coefficient of contraction within the mouthpiece. Hence

$$v = \frac{\Omega}{\omega}v_1 = \frac{v_1}{c_c}\,.$$

Supposing the discharge into the air, so that $p_1 = p_a$,

$$h + \frac{p_a}{G} = \frac{v_1^2}{2g} + \frac{p_a}{G} + \frac{v_1^2}{2g}\left(\frac{1}{c_c} - 1\right)^2 ;$$

$$\frac{v_1^2}{2g}\left\{1 + \left(\frac{1}{c_c} - 1\right)^2\right\} = h ;$$

$$\therefore \quad v_1 = \frac{1}{\sqrt{1 + \left(\frac{1}{c_c} - 1\right)^2}} \sqrt{2gh} \quad . \quad . \quad . \quad . \quad (1);$$

where the first term on the right is evidently the coefficient of velocity for the cylindrical mouthpiece in terms of the coefficient of contraction at EF. Let $c_c = 0{\cdot}64$, the value for simple orifices, then the coefficient of velocity is

$$c_v = \frac{1}{\sqrt{1 + \left(\frac{1}{c_c} - 1\right)^2}} = 0{\cdot}87 \quad . \quad . \quad . \quad . \quad (2).$$

The actual value of c_v found by experiment is 0·82, which does not differ more from the theoretical value than might be expected if the friction of the mouthpiece is allowed for. Hence, for mouthpieces of this kind, and for the section at GH,

$$c_v = 0{\cdot}82 \quad c_c = 1{\cdot}00 \quad c = 0{\cdot}82,$$

$$Q = 0{\cdot}82\,\Omega\sqrt{2gh}$$

It is easy to see from the equations that the pressure p at EF is less than atmospheric pressure. Eliminating v_1, we get

$$\frac{p_a - p}{G} = \tfrac{3}{4}h \text{ nearly} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3);$$

or

$$p = p_a - \tfrac{3}{4}Gh \text{ lb per sq. ft.}$$

If a pipe connected with a reservoir on a lower level is introduced into the mouthpiece at the part where the contraction is formed (fig. 58), the water will rise in this pipe to a height

$$KL = \frac{p_a - p}{G} = \tfrac{3}{4}h \text{ nearly.}$$

If the distance X is less than this, the water from the lower reservoir will be forced continuously into the jet by the atmospheric pressure, and discharged with it. This is the crudest form of a kind of pump known as the jet pump.

45. *Convergent Mouthpieces.*—With convergent mouthpieces there is a contraction within the mouthpiece causing a loss of head, and a diminution of the velocity of discharge, as with cylindrical mouthpieces. There is also a second contraction of the stream outside the mouthpiece. Hence the discharge is given by an equation of the form

$$Q = c_v c_c \Omega \sqrt{2gh} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

where Ω is the area of the external end of the mouthpiece, and $c_c\Omega$ the section of the contracted jet beyond the mouthpiece.

Convergent Mouthpieces (Castel's Experiments).—Smallest diameter of orifice = 0·05085 feet. Length of mouthpiece = 2·6 diameters.

Angle of Convergence.	Coefficient of Contraction, c_c	Coefficient of Velocity, c_v	Coefficient of Discharge, c
0° 0′	·999	·830	·829
1° 36′	1·000	·866	·866
3° 10′	1·001	·894	·895
4° 10′	1·002	·910	·912
5° 26′	1·004	·920	·924
7° 52′	·998	·931	·929
8° 58′	·992	·942	·934
10° 20′	·987	·950	·938
12° 4′	·986	·955	·942
13° 24′	·983	·962	·946
14° 28′	·979	·966	·941
16° 36′	·969	·971	·938
19° 28′	·953	·970	·924
21° 0′	·945	·971	·918
23° 0′	·937	·974	·913
29° 58′	·919	·975	·896
40° 20′	·887	·980	·869
48° 50′	·861	·984	·847

The maximum coefficient of discharge is that for a mouthpiece with a convergence of 13° 24′.

The values of c_v and c_c must here be determined by experiment. The above table gives values sufficient for practical purposes. Since the contraction beyond the mouthpiece increases with the convergence, or, what is the same thing, c_c diminishes, and on the other hand the loss of energy diminishes, so that c_v increases with the convergence, there is an angle for which the product $c_c\, c_v$, and consequently the discharge, is a maximum.

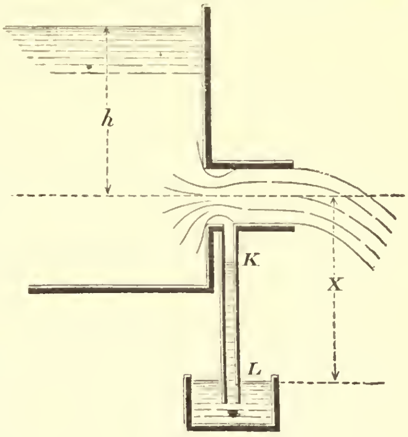

Fig. 58.

46. *Divergent Conoidal Mouthpiece.*—Suppose a mouthpiece so designed that there is no abrupt change in the section or velocity of the stream passing through it. It may have a form at the inner end approximately the same as that of a simple contracted vein, and may then enlarge gradually, as shown in fig. 59. Suppose that at EF it becomes cylindrical, so that the jet may be taken to be of the diameter EF. Let ω, v, p be the section, velocity, and pressure at CD, and Ω, v_1, p_1 the same quantities at EF, p_a being as usual the atmospheric pressure, or pressure on the free surface AB. Then, since there is no loss of energy, except the small frictional resistance of the surface of the mouthpiece,

$$h + \frac{p_a}{G} = \frac{v^2}{2g} + \frac{p}{G} = \frac{v_1^2}{2g} + \frac{p_1}{G}.$$

If the jet discharges into the air, $p_1 = p_a$; and

$$\frac{v_1^2}{2g} = h ;$$

$$v_1 = \sqrt{2gh} ;$$

or, if a coefficient is introduced to allow for friction,

$$v_1 = c_v\sqrt{2gh} ;$$

where c_v is about 0·97 if the mouthpiece is smooth and well-formed.

$$Q = \Omega v_1 = c_v \Omega \sqrt{2gh}.$$

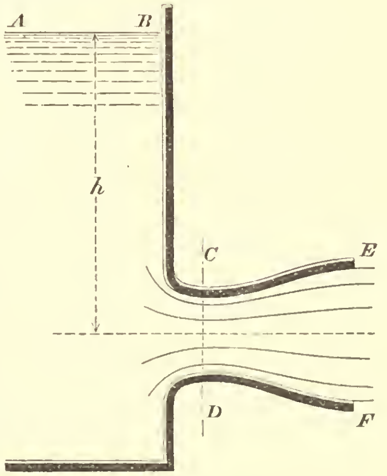

Fig. 59.

Hence the discharge depends on the area of the stream at EF, and not at all on that at CD, and the latter may be made as small as we please without affecting the amount of water discharged.

There is, however, a limit to this. As the velocity at CD is greater than at EF the pressure is less, and therefore less than atmospheric pressure, if the discharge is into the air. If CD is so contracted that $p = 0$, the continuity of flow is impossible. In fact the stream disengages itself from the mouthpiece for some value of p greater than 0 (fig. 60).

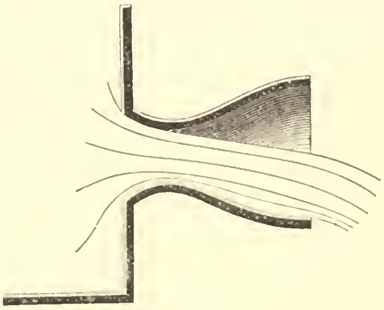

Fig. 60.

From the equations,

$$\frac{p}{G} = \frac{p_a}{G} - \left(\frac{v^2 - v_1^2}{2g}\right).$$

Let $\frac{\Omega}{\omega} = m$. Then

$$v = v_1 m ;$$

$$\frac{p}{G} = \frac{p_a}{G} - \frac{v_1^2}{2g}(m^2 - 1)$$

$$= \frac{p_a}{G} - (m^2 - 1)h ;$$

whence we find that $\frac{p}{G}$ will become zero or negative if

$$\frac{\Omega}{\omega} \geqq \sqrt{\frac{h+\frac{p_a}{G}}{h}} = \sqrt{1+\frac{p_a}{Gh}}\,;$$

or, putting $\frac{p_a}{G}=34$ feet, if

$$\frac{\Omega}{\omega} \geqq \sqrt{\frac{h+34}{h}}\,.$$

In practice there will be an interruption of the full bore flow with a less ratio of $\frac{\Omega}{\omega}$, because of the disengagement of air from the water. But, supposing this does not occur, the maximum discharge of a mouthpiece of this kind is

$$Q=\omega\sqrt{2g\left(h+\frac{p_a}{G}\right)}\,;$$

that is, the discharge is the same as for a well-bellmouthed mouthpiece of area ω, and without the expanding part, discharging into a vacuum.

47. *Jet Pump.*—A divergent mouthpiece may be arranged to act as a pump, as shown in fig. 61. The water which supplies the energy

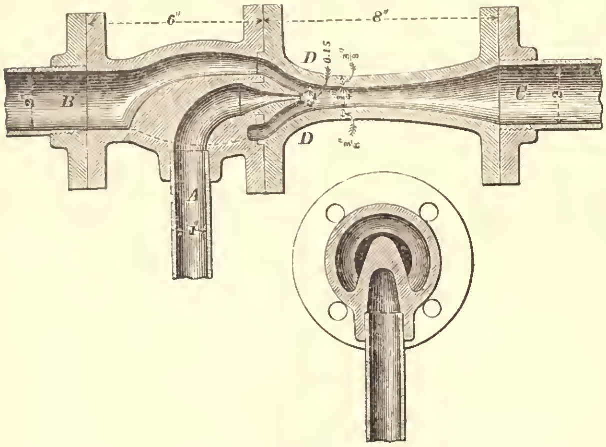

Fig. 61

required for pumping enters at A. The water to be pumped enters at B. The streams combine at DD where the velocity is greatest and the pressure least. Beyond DD the stream enlarges in section, and its pressure increases, till it is sufficient to balance the head due to the height of the lift, and the water flows away by the discharge pipe C.

Fig. 62 shows the whole arrangement in a diagrammatic way. A is the reservoir which supplies the water that effects the pump-

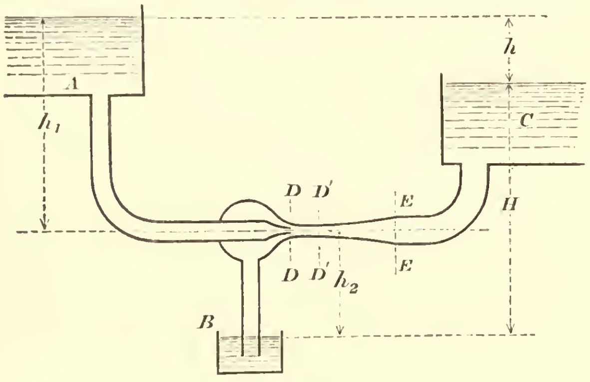

Fig. 62.

ing; B is the reservoir of water to be pumped; C is the reservoir into which the water is pumped.

Discharge with Varying Head.

48. *Flow from a Vessel when the Effective Head varies with the Time.*—Various useful problems arise relating to the time of emptying and filling vessels, reservoirs, lock chambers, &c., where the flow is dependent on a head which increases or diminishes during the operation. The simplest of these problems is the case of filling or emptying a vessel of constant horizontal section.

Time of Emptying or Filling a Vertical-sided Lock Chamber.—Suppose the lock chamber, which has a water surface of Ω square feet, is emptied through a sluice in the tail gates, of area ω, placed below the tail-water level. Then the effective head producing flow through the sluice is the difference of level in the chamber and tail bay. Let H (fig. 63) be the initial difference of level, h the difference

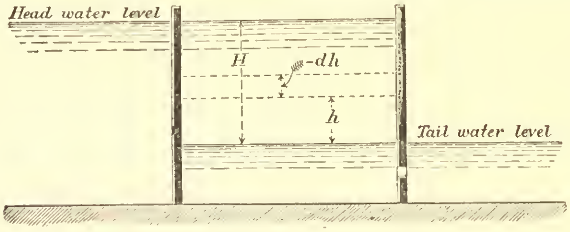

Fig. 63.

of level after t seconds. Let $-dh$ be the fall of level in the chamber during an interval dt. Then in the time dt the volume in the chamber is altered by the amount $-\Omega dh$, and the outflow from the sluice in the same time is $c\omega\sqrt{2gh}\,dt$. Hence the differential equation connecting h and t is

$$c\omega\sqrt{2gh}\,dt+\Omega h=0.$$

For the time t, during which the initial head H diminishes to any other value h,

$$-\frac{\Omega}{c\omega\sqrt{2g}}\int_H^h\frac{dh}{\sqrt{h}}=\int_0^t dt.$$

$$\therefore\ t=\frac{\Omega}{c\omega\sqrt{2g}}\,2\left(\sqrt{H}-\sqrt{h}\right)$$

$$=\frac{\Omega}{c\omega}\left\{\sqrt{\frac{2H}{g}}-\sqrt{\frac{2h}{g}}\right\}.$$

For the whole time of emptying, during which h diminishes from H to 0,

$$T=\frac{\Omega}{c\omega}\sqrt{\frac{2H}{g}}\,.$$

Comparing this with the equation for flow under a constant head, it will be seen that the time is double that required for the discharge of an equal volume under a constant head.

The time of filling the lock through a sluice in the head gates is exactly the same, if the sluice is below the tail-water level. But if the sluice is above the tail-water level, then the head is constant till the level of the sluice is reached, and afterwards it diminishes with the time.

Practical Use of Orifices in Gauging Water.

49. If the water to be measured is passed through a known orifice under an arrangement by which the constancy of the head is ensured, the amount which passes in a given time can be ascertained by the formulæ already given. It will obviously be best to make the orifices of the forms for which the coefficients are most accurately determined; hence sharp-edged orifices or notches are most commonly used.

Water Inch.—For measuring small quantities of water circular sharp-edged orifices have been used. The discharge from a circular orifice one French inch in diameter, with a head of one line above the top edge, was termed by the older hydraulic writers a water-inch. A common estimate of its value was 14 pints per minute, or 677 English cubic feet in 24 hours. An experiment by Bossut gave 634 cubic feet in 24 hours (see Navier's edition of *Belidor's Arch. Hydr.*, p. 212).

Weisbach points out that measurements of this kind would be made more accurately with a greater head over the orifice, and he proposes that the head should be equal to the diameter of the orifice. Several equal orifices may be used for larger discharges.

50. *Pin Ferrules or Measuring Cocks.*—To give a tolerably definite supply of water to houses, without the expense of a meter, a ferrule with an orifice of a definite size, or a cock, is introduced in the service-pipe. If the head in the water main is constant, then a definite quantity of water would be delivered in a given time. The arrangement is not a very satisfactory one, and acts chiefly as a check on extravagant use of water. It is interesting here chiefly as an example of regulation of discharge by means of an orifice. Fig. 64 shows a cock of this kind used at Zurich. It consists of three cocks, the middle one having the orifice of the predetermined size in a small circular plate, protected by wire gauze from stoppage by impurities in the water. The cock on the right hand can be used by the consumer for emptying the pipes. The one on the left and the measuring cock are connected by a key which can be locked by a padlock, which is under the control of the water company.

51. *Measurement of the Flow in Streams.*—To determine the quantity of water flowing off the ground in small streams, which is available for water supply or for obtaining water power, small temporary weirs are often used. These may be formed of planks supported by piles and puddled to prevent leakage. The measurement of the head may be made by a thin-edged scale at a short distance behind the weir, where the water surface has not begun to slope down to the weir and where the velocity of approach is not high. The measurements are conveniently made from a short pile driven into the bed of the river, accurately level with the crest of the weir (fig. 65). Then if at any moment the head is h, the discharge is, for a rectangular notch of breadth b,

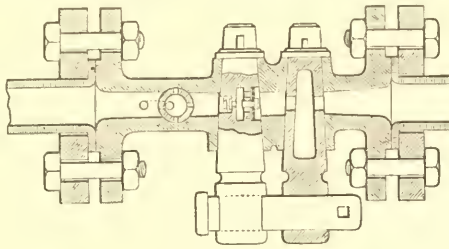

Fig. 64.

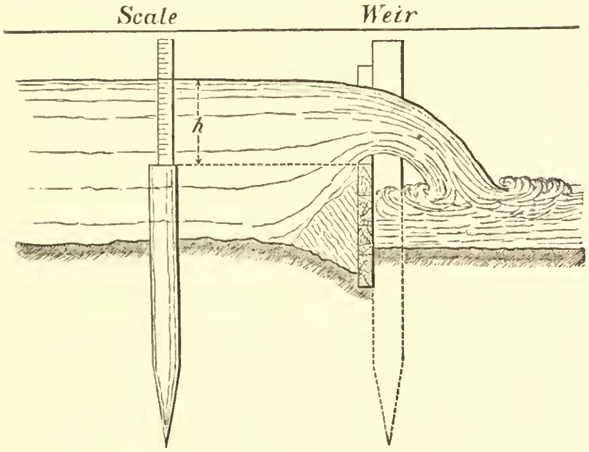

Fig. 65.

$$Q = \tfrac{2}{3} c b h \sqrt{2gh}$$

where $c = 0\cdot62$; or, better, the formula in § 38 may be used.

Gauging weirs are most commonly in the form of rectangular notches; and care should be taken that the crest is accurately horizontal, and that the weir is normal to the direction of flow of the stream. If the planks are thick, they should be bevelled (fig. 66), and then the edge may be protected by a metal plate about $\frac{1}{16}$th inch thick to secure the requisite accuracy of form and sharpness of edge. In permanent gauging weirs a cast steel plate is sometimes used to form the edge of the weir crest. The weir should be large enough to discharge the maximum volume flowing in the stream, and at the same time it is desirable that the minimum head should not be too small (say half a foot) to decrease the effects of errors of measurement. The section of the jet over the weir should not exceed one-fifth the section of the stream behind the weir, or the velocity of approach will need to be taken into account. A triangular notch is very suitable for measurements of this kind.

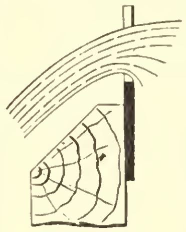

Fig. 66.

If the flow is variable, the head h must be recorded at equidistant intervals of time, say twice daily, and then for each 12 hour period the discharge must be calculated for the mean of the heads at the beginning and end of the time. As this involves a good deal of troublesome calculation, Mr Sang has proposed to use a scale so graduated as to read off the discharge in cubic feet per second. The lengths of the principal graduations of such a scale are easily calculated by putting $Q = 1, 2, 3 \ldots$ in the ordinary formulæ for notches; the intermediate graduations may be taken accurately enough by subdividing equally the distances between the principal graduations.

The accurate measurement of the discharge of a stream by means of a weir is, however, in practice, rather more difficult than might be inferred from the simplicity of the principle of the operation. Apart from the difficulty of selecting a suitable coefficient of discharge, which need not be serious if the form of the weir and the nature of its crest are properly attended to, other difficulties of measurement arise. The length of the weir should be very accurately determined, and if the weir is rectangular its deviations from exactness of level should be tested. Then the agitation of the water, the ripple on its surface, and the adhesion of the water to the scale on which the head is measured, are liable to introduce errors. Upon a weir 10 feet long, with 1 foot depth of water flowing over an error of 1-1000th of a foot in measuring the head, or an error of 1-100th of a foot in measuring the length of the weir, would cause an error in computing the discharge of 2 cubic feet per minute.

52. *Hook Gauge.*—For the determination of the surface level of water, the most accurate instrument is the hook gauge used first by Mr U. Boyden of Boston, in 1840. It consists of a fixed frame with scale and vernier. In the instrument in fig. 67 the vernier is fixed to the frame, and the scale slides vertically. The scale carries at its lower end a hook with a fine point, and the scale can be raised or lowered by a fine pitched screw. If the hook is depressed below the water surface and then raised by the screw, the moment of its reaching the water surface will be very distinctly marked, by the reflexion from a small capillary elevation of the water surface over the point of the hook. In ordinary light, differences of level of the water of ·001 of a foot are easily detected by the hook gauge. If such a gauge is used to determine the heads at a weir, the hook should first be set accurately level with the weir crest, and a reading taken. Then the difference of the reading at the water surface and that for the weir crest will be the head at the weir.

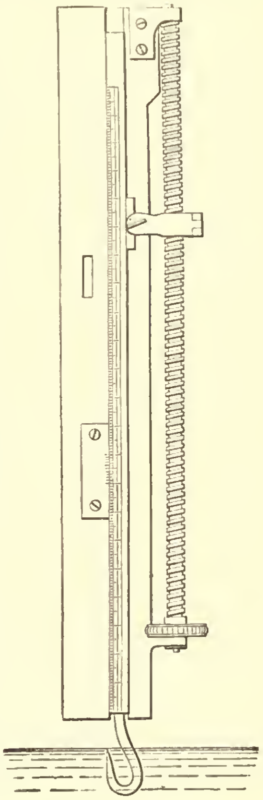

Fig. 67.

53. *Modules used in Irrigation.*—In distributing water for irrigation, the charge for the water may be simply assessed on the area of the land irrigated for each consumer, a method followed in India; or a regulated quantity of water may be given to each consumer, and the charge may be made proportional to the quantity of water supplied, a method employed for a long time in Italy and other parts of Europe. To deliver a regulated quantity of water from the irrigation channel, arrangements termed modules are used. These are constructions intended to maintain a constant or approximately constant head above an orifice of fixed size, or to regulate the size of the orifice so as to give a constant discharge, notwithstanding the variation of level in the irrigating channel.

54. *Italian Module.*—The Italian modules are masonry constructions, consisting of a regulating chamber, to which water is admitted by an adjustable sluice from the canal. At the other end of the chamber is an orifice in a thin flagstone of fixed size. By means of the adjustable sluice a tolerably constant head above the fixed orifice is maintained, and therefore there is a nearly constant discharge of ascertainable amount through the orifice, into the channel leading to the fields which are to be irrigated.

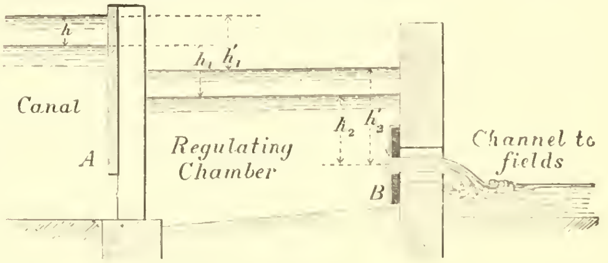

Fig. 68.

In fig. 68 A is the adjustable sluice by which water is admitted to the regulating chamber, B is the fixed orifice through which the water is discharged. The sluice A is adjusted from time to time by the canal officers, so as to bring the level of the water in the regulating chamber to a fixed level marked on the wall of the chamber. When adjusted it is locked. Let ω_1 be the area of the orifice through the sluice at A, and ω_2 that of the fixed orifice at B; let h_1 be the difference of level between the surface of the water in the canal and regulating chamber; h_2 the head above the centre of the discharging orifice, when the sluice has been adjusted and the flow has become steady; Q the normal discharge in cubic feet per second. Then, since the flow through the orifices at A and B is the same,

$$Q = c_1\omega_1\sqrt{2gh_1} = c_2\omega_2\sqrt{2gh_2}\,,$$

where c_1 and c_2 are the coefficients of discharge suitable for the two orifices. Hence

$$\frac{c_1\omega_1}{c_2\omega_2} = \sqrt{\left(\frac{h_2}{h_1}\right)}\,.$$

Suppose now that in the interval between the visits of the canal officer the level of the canal rises h feet, causing the heads relatively to the orifices A and B to become h'_1 and h'_2. Since the areas of the orifices are unchanged

$$\sqrt{\frac{h'_2}{h'_1}} = \frac{c_1\omega_1}{c_2\omega_2}\,,$$

and therefore

$$\frac{h'_1}{h'_2} = \frac{h_1}{h_2}\,;$$

or the ratio of the effective heads above the orifices A and B is unaffected by the change of level of the canal. Also

$$h'_1 + h'_2 = h_1 + h_2 + h\,.$$

Eliminating h'_1, we get

$$h'_2 = \frac{(h_1+h_2+h)h_2}{h_1+h_2}\,;$$

and the discharge in the altered conditions is

$$Q' = c_2\omega_2\sqrt{2gh'_2}$$

$$= c_2\omega_2\sqrt{\left\{2g\frac{(h_1+h_2+h)h_2}{h_1+h_2}\right\}}\,.$$

That is,

$$\frac{Q'}{Q} = \sqrt{\frac{h_1+h_2+h}{h_1+h_2}}\,.$$

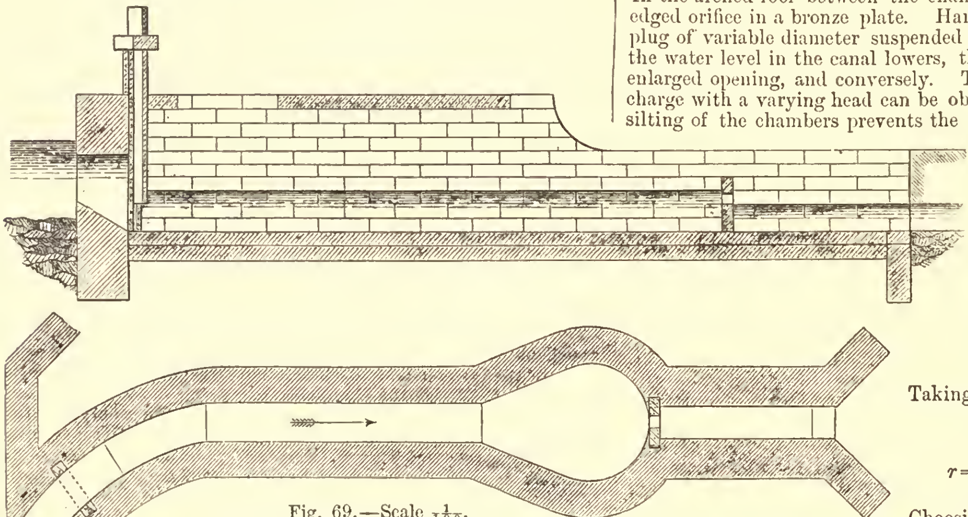

Fig. 69.—Scale $\frac{1}{100}$.

If the orifice at B opened directly into the canal without any intermediate regulating chamber, the discharge would increase for a given change of level in the canal in exactly the same ratio. Consequently the Italian module in no way moderates the fluctuations of discharge, except so far as it affords means of easy adjustment from time to time. It has further the advantage that the cultivator, by observing the level of the water in the chamber, can always see whether or not he is receiving the proper quantity of water.

On each canal the orifices are of the same height, and intended to work with the same normal head, the width of the orifices being varied to suit the demand for water. The unit of discharge varies on different canals, being fixed in each case by legal arrangements. Thus on the Canal Lodi the unit of discharge or one module of water is the discharge through an orifice 1·12 feet high, 0·12416 feet wide, with a head of 0·32 feet above the top edge of the orifice, or ·88 feet above the centre. This corresponds to a discharge of about 0·6165 cubic feet per second. Two modules would be the discharge of a similar orifice of twice the width. The following table gives some examples of different units of discharge.

	Height of Orifice.	Width of Orifice.	Head above top edge of Orifice.	Discharge per sec. in c. feet.
Canal Lodi	1·12	0·12416	0·32	0·6165
Canal of Cremona	1·31816	0·131	0·131	0·7225
Sardinian Module	0·6562	0·6562	0·6562	2·046
Oncia Magistrale of Milan	0·655	0·3426	0·3294	0·866

In the most elaborate Italian modules the regulating chamber is arched over, and its dimensions are very exactly prescribed. Thus in the modules of the Naviglio Grande of Milan, shown in fig. 69, the measuring orifice is cut in a thin stone slab, and so placed that the discharge is into the air with free contraction on all sides. The adjusting sluice is placed with its sill flush with the bottom of the canal, and is provided with a rack and lever and locking arrangement. The covered regulating chamber is about 20 feet long, with a breadth 1·64 feet greater than that of the discharging orifice. At precisely the normal level of the water in the regulating chamber, there is a ceiling of planks intended to still the agitation of the water. A block of stone serves to indicate the normal level of the water in the chamber. The water is discharged into an open channel 0·655 feet wider than the orifice, splaying out till it is 1·637 feet wider than the orifice, and about 18 feet in length. This apparatus was invented in the 16th century, and is still used. The greatest objection to it is the loss of level between the canal and discharging channel. Arrangements precisely similar to an Italian module are in use in England, for discharging compensation water into streams from impounding reservoirs. The fullest account of Italian modules is to be found in Colonel Baird Smith's *Italian Irrigation*.

55. *Spanish Module.*—On the canal of Isabella II., which supplies water to Madrid, a module much more perfect in principle than the Italian module is employed. Part of the water is supplied for irrigation, and as it is very valuable its strict measurement is essential. The module (fig. 71) consists of two chambers one above the other, the upper chamber being in free communication with the irrigation canal, and the lower chamber discharging by a culvert to the fields. In the arched roof between the chambers there is a circular sharp edged orifice in a bronze plate. Hanging in this there is a bronze plug of variable diameter suspended from a hollow brass float. If the water level in the canal lowers, the plug descends and gives an enlarged opening, and conversely. Thus a perfectly constant discharge with a varying head can be obtained, provided no clogging or silting of the chambers prevents the free discharge of the water or the rise and fall of the float. The theory of the module is very simple. Let R (fig. 70) be the radius of the fixed opening, r the diameter of the plug at a distance h from the plane of flotation of the float, and Q the required discharge of the module. Then

$$Q = c\pi(R^2 - r^2)\sqrt{2gh}\,.$$

Taking $c = 0·63$,

$$Q = 15·88(R^2 - r^2)\sqrt{h}\,;$$

$$r = \sqrt{\left\{R^2 - \frac{Q}{15·88\sqrt{h}}\right\}}\,.$$

Choosing a value for R, successive values of r can be found for different values of h, and from these the

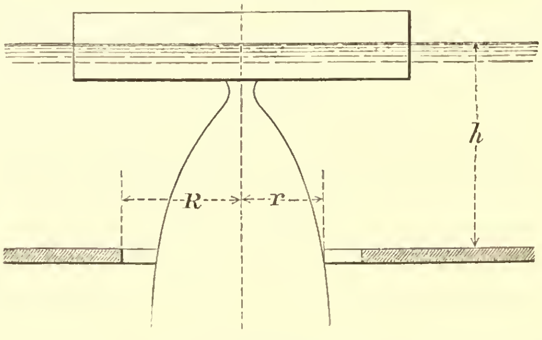

Fig. 70.

curve of the plug can be drawn. The module shown in fig. 71 will discharge 1 cubic metre per second. The fixed opening is 0·2 metre diameter, and the greatest head above the fixed orifice is 1 metre. The use of this module involves a great sacrifice of level between the canal and the fields. The module is described in Lieutenant Scott Moncrieff's *Irrigation in Southern Europe.*

56. *Reservoir Gauging Basins.*—In obtaining the power to store the water of streams in reservoirs, it is usual to concede to riparian owners below the reservoirs a right to a regulated supply through-

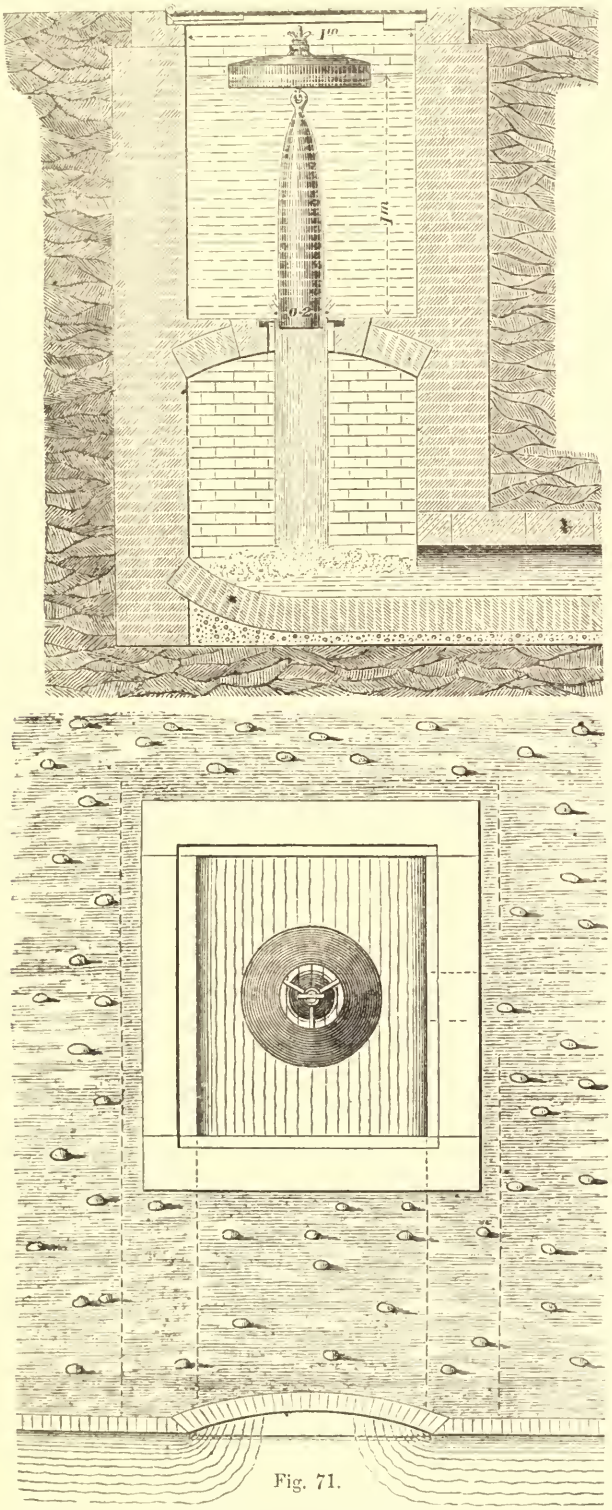

Fig. 71.

out the year. This compensation water requires to be measured in such a way that the millowners and others interested in the matter can assure themselves that they are receiving a proper quantity, and they are generally allowed a certain amount of control as to the times during which the daily supply is discharged into the stream.

Figs. 72 and 73 show an arrangement designed for the Manchester Water Works. The water enters from the reservoir a chamber A, the object of which is to still the irregular motion of the water. The admission is regulated by sluices at *b, b, b*. The water is discharged by orifices or notches at *a, a*, over which a tolerably constant head is maintained by adjusting the sluices at *b, b, b*. At any time the millowners can see whether the discharge is given and whether the proper head is maintained over the orifices. To test at any time the discharge of the orifices, a gauging basin B is

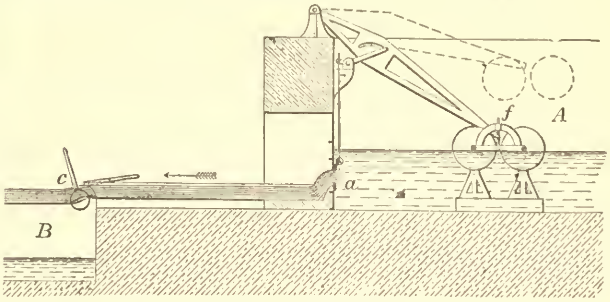

Fig. 72.—Scale $\frac{1}{120}$.

provided. The water ordinarily flows over this, without entering it, on a floor of cast-iron plates. If the discharge is to be tested, the water is turned for a definite time into the gauging basin, by suddenly opening and closing a sluice at *c*. The volume of flow can be ascertained from the depth in the gauging chamber. A mechanical arrangement was designed for securing an absolutely constant head over the orifices at *a, a*. The orifices were formed

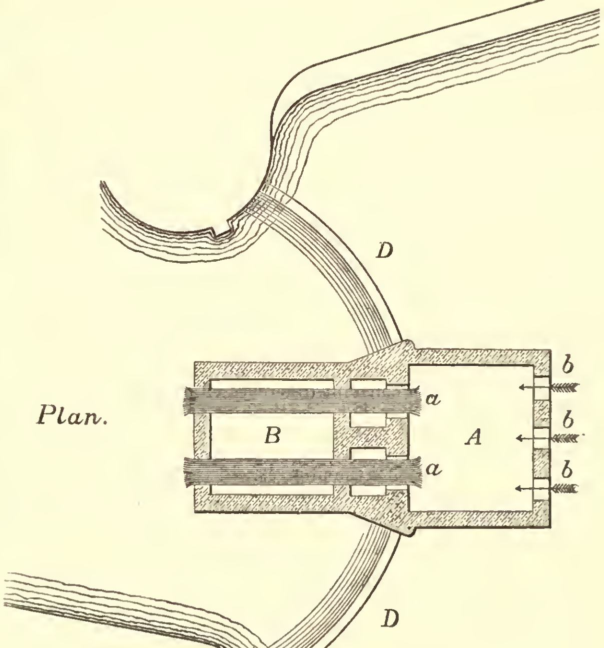

Fig. 73.—Scale $\frac{1}{500}$.

in a cast-iron plate capable of sliding up and down, without sensible leakage, on the face of the wall of the chamber. The orifice plate was attached by a link to a lever, one end of which rested on the wall and the other on floats *f* in the chamber A. The floats rose and fell with the changes of level in the chamber, and raised and lowered the orifice plate at the same time. This mechanical arrangement was not finally adopted, careful watching of the sluices at b, b, b, being sufficient to secure a regular discharge. The arrangement is then equivalent to an Italian module, but on a large scale.

57. *Professor Fleeming Jenkin's Constant Flow Valve.*—In the modules thus far described constant discharge is obtained by varying the area of the orifice through which the water flows. Professor F. Jenkin has contrived a valve in which a constant pressure head is obtained, so that the orifice need not be varied (*Roy. Scot. Society of Arts*, 1876). Fig. 74 shows a valve of this kind suitable for a

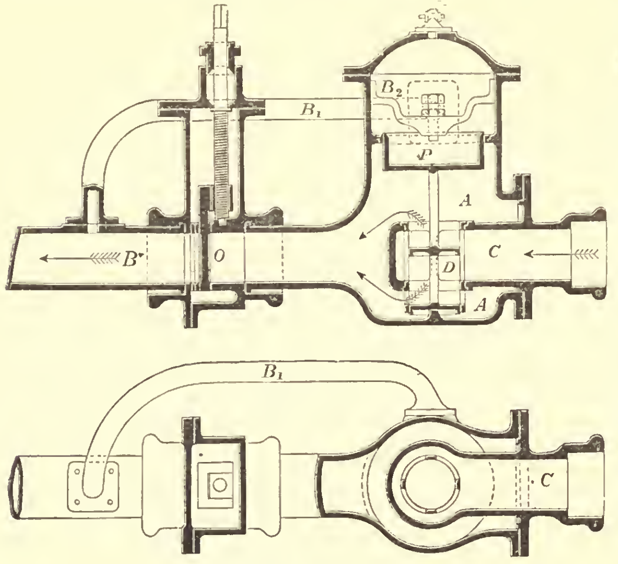

Fig. 74.—Scale $\frac{1}{24}$.

6 inch water main. The water arriving by the main C passes through an equilibrium valve D into the chamber A, and thence through a sluice O, which can be set for any required area of opening, into the discharging main B. The object of the arrangement is to secure a constant difference of pressure between the chambers A and B, so that a constant discharge flows through the stop valve O. The equilibrium valve D is rigidly connected with a plunger P loosely fitted in a diaphragm, separating A from a chamber B_2 connected by a pipe B_1 with the discharging main B. Any increase of the difference of pressure in A and B will drive the plunger up and close the equilibrium valve, and conversely a decrease of the difference of pressure will cause the descent of the plunger and open the equilibrium valve wider. Thus a constant difference of pressure is obtained in the chambers A and B. Let ω be the area of the plunger in square feet, p the difference of pressure in the chambers A and B in pounds per square foot, w the weight of the plunger and valve. Then if at any moment $p\omega$ exceeds w the plunger will rise, and if it is less than w the plunger will descend. Apart from friction, and assuming the valve D to be strictly an equilibrium valve, since ω and w are constant, p must be constant also, and equal to $\frac{w}{\omega}$. By making w small and ω large, the difference of pressure required to ensure the working of the apparatus may be made very small. Valves working with a difference of pressure of $\frac{1}{2}$ inch of water have been constructed.

58. *Appold's Module.*—This acts on the same general principle as the Spanish module, but it secures only an approximately constant discharge. On the other hand it involves no great sacrifice of level, and is not very likely to be affected by silting. It was contrived originally as an air regulator, but it has also been tried with success as a water module. It consists simply of a horizontal pipe with an

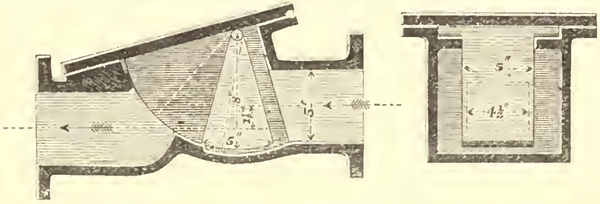

Fig. 75.—Scale $\frac{1}{17}$.

enlarged chamber, in which hangs a heavy wedge-shaped pendulum. The pressure of the water on the upstream side of this pendulum keeps it in a position inclined to the vertical, and partially closing the orifice of discharge as shown by the dotted lines in fig. 75. Any increase of pressure will cause a greater inclination of the pendulum and decrease the orifice of discharge, and *vice versa*.

VI. STEADY FLOW OF COMPRESSIBLE FLUIDS.

59. *External Work during the Expansion of Air.*—If air expands without doing any external work, its temperature remains constant. This result was first experimentally demonstrated by Joule. It leads to the conclusion that, however air changes its state, the internal work done is proportional to the change of temperature. When, in expanding, air does work against an external resistance, either heat must be supplied or the temperature falls.

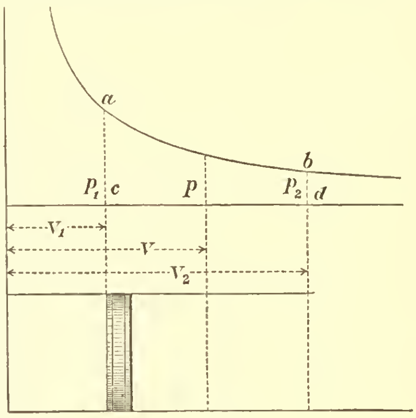

Fig. 76.

To fix the conditions, suppose one pound of air confined behind a piston of one square foot area (fig. 76). Let the initial pressure be p_1 and the volume of the air v_1, and suppose this to expand to the pressure p_2 and volume v_2. If p and v are the corresponding pressure and volume at any intermediate point in the expansion, the work done on the piston during the expansion from v to $v+dv$ is pdv, and the whole work during the expansion from v_1 to v_2, represented by the area *abcd*, is

$$\int_{v_1}^{v_2} pdv.$$

Amongst possible cases two may be selected.

Case 1.—So much heat is supplied to the air during expansion that the temperature remains constant. Hyperbolic expansion. Then

$$pv = p_1 v_1 .$$

Work done during expansion per pound of air

$$= \int_{v_1}^{v_2} pdv = p_1 v_1 \int_{v_1}^{v_2} \frac{dv}{v}$$

$$= p_1 v_1 \log_\epsilon \frac{v_2}{v_1} = p_1 v_1 \log_\epsilon \frac{p_1}{p_2} \quad . \quad . \quad . \quad (1).$$

Since the weight per cubic foot is the reciprocal of the volume per pound, this may be written

$$\frac{p_1}{G_1} \log_\epsilon \frac{G_1}{G_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1a).$$

Then the expansion curve ab is a common hyperbola.

Case 2.—No heat is supplied to the air during expansion. Then the air loses an amount of heat equivalent to the external work done and the temperature falls. Adiabatic expansion.

In this case it can be shown that

$$pv^\gamma = p_1 v_1{}^\gamma ,$$

where γ is the ratio of the specific heats of air at constant pressure and volume. Its value for air is 1·408, and for dry steam 1·135.

Work done during expansion per pound of air

$$= \int_{v_1}^{v_2} pdv = p_1 v_1{}^\gamma \int_{v_1}^{v_2} \frac{dv}{v^\gamma}$$

$$= -\frac{p_1 v_1{}^\gamma}{\gamma - 1} \left\{ \frac{1}{v_2{}^{\gamma-1}} - \frac{1}{v_1{}^{\gamma-1}} \right\}$$

$$= \frac{p_1 v_1{}^\gamma}{\gamma - 1} \left\{ \frac{1}{v_1{}^{\gamma-1}} - \frac{1}{v_2{}^{\gamma-1}} \right\}$$

$$= \frac{p_1 v_1}{\gamma - 1} \left\{ 1 - \left(\frac{v_1}{v_2} \right)^{\gamma-1} \right\} \quad . \quad (2).$$

The value of $p_1 v_1$ for any given temperature can be found from the data already given.

As before, substituting the weights G_1, G_2 per cubic foot for the volumes per pound, we get for the work of expansion

$$\frac{p_1}{G_1} \cdot \frac{1}{\gamma - 1} \cdot \left\{ 1 - \left(\frac{G_2}{G_1} \right)^{\gamma-1} \right\} \quad . \quad . \quad . \quad (2a),$$

$$= p_1 v_1 \frac{1}{\gamma - 1} \left\{ 1 - \left(\frac{p_2}{p_1} \right)^{\frac{\gamma-1}{\gamma}} \right\} . \quad . \quad . \quad . \quad . \quad (2b).$$

60. *Modification of the Theorem of Bernoulli for the Case of a Compressible Fluid.*—In the application of the principle of work to a filament of compressible fluid, the internal work done by the expansion of the fluid, or absorbed in its compression, must be taken into

account. Suppose, as before, that AB (fig. 77) comes to A'B' in a short time t. Let p_1, ω_1, v_1, G_1 be the pressure, sectional area of stream, velocity, and weight of a cubic foot at A, and p_2, ω_2, v_2, G_2 the same quantities at B. Then, from the steadiness of motion, the weight of fluid passing A in any given time must be equal to the weight passing B:

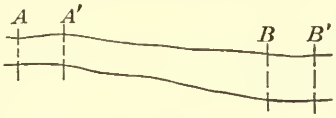

Fig. 77.

$$G_1\omega_1 v_1 t = G_2\omega_2 v_2 t.$$

Let z_1, z_2 be the heights of the sections A and B above any given datum. Then the work of gravity on the mass AB in t seconds is

$$G_1\omega_1 v_1 t(z_1 - z_2) = W(z_1 - z_2)t,$$

where W is the weight of gas passing A or B per second. As in the case of an incompressible fluid, the work of the pressures on the ends of the mass AB is

$$p_1\omega_1 v_1 t - p_2\omega_2 v_2 t,$$
$$= \left(\frac{p_1}{G_1} - \frac{p_2}{G_2}\right) Wt.$$

The work done by expansion of Wt pounds of fluid between A and B is $Wt\int_{v_1}^{v_2} p\,dv$. The change of kinetic energy as before is $\frac{W}{2g}(v_2^2 - v_1^2)t$. Hence, equating work to change of kinetic energy,

$$W(z_1 - z_2)t + \left(\frac{p_1}{G_1} - \frac{p_2}{G_2}\right) Wt + Wt\int_{v_1}^{v_2} p\,dv = \frac{W}{2g}(v_2^2 - v_1^2)t\ ;$$

$$\therefore\ z_1 + \frac{p_1}{G_1} + \frac{v_1^2}{2g} = z_2 + \frac{p_2}{G_2} + \frac{v_2^2}{2g} - \int_{v_1}^{v_2} p\,dv\ . \quad . \quad . \quad (1).$$

Now the work of expansion per pound of fluid has already been given. If the temperature is constant, we get (eq. $1a$, § 59)

$$z_1 + \frac{p_1}{G_1} + \frac{v_1^2}{2g} = z_2 + \frac{p_2}{G_2} + \frac{v_2^2}{2g} - \frac{p_1}{G_1}\log_\epsilon \frac{G_1}{G_2}.$$

But at constant temperature $\frac{p_1}{G_1} = \frac{p_2}{G_2}$;

$$\therefore\ z_1 + \frac{v_1^2}{2g} = z_2 + \frac{v_2^2}{2g} - \frac{p_1}{G_1}\log_\epsilon \frac{p_1}{p_2}, \quad . \quad . \quad . \quad . \quad (2);$$

or, neglecting the difference of level,

$$\frac{v_2^2 - v_1^2}{2g} = \frac{p_1}{G_1}\log_\epsilon \frac{p_1}{p_2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2a).$$

Similarly, if the expansion is adiabatic (eq. $2a$, § 59),

$$z_1 + \frac{p_1}{G_1} + \frac{v_1^2}{2g} = z_2 + \frac{p_2}{G_2} + \frac{v_2^2}{2g} - \frac{p_1}{G_1}\frac{1}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}. \quad (3);$$

or neglecting the difference of level

$$\frac{v_2^2 - v_1^2}{2g} = \frac{p_1}{G_1}\left[1 + \frac{1}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}\right] - \frac{p_2}{G_2}. \quad . \quad (3a).$$

It will be seen hereafter that there is a limit in the ratio $\frac{p_1}{p_2}$ beyond which these expressions cease to be true.

61. *Discharge of Air from an Orifice.*—The form of the equation of work for a steady stream of compressible fluid is

$$z_1 + \frac{p_1}{G_1} + \frac{v_1^2}{2g} = z_2 + \frac{p_2}{G_2} + \frac{v_2^2}{2g} - \frac{p_1}{G_1}\frac{1}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\},$$

the expansion being adiabatic, because in the flow of the streams of air through an orifice no sensible amount of heat can be communicated from outside.

Suppose the air flows from a vessel, where the pressure is p_1 and the velocity sensibly zero, through an orifice, into a space where the pressure is p_2. Let v_2 be the velocity of the jet at a point where the convergence of the streams has ceased, so that the pressure in the jet is also p_2. As air is light, the work of gravity will be small compared with that of the pressures and expansion, so that z_1, z_2 may be neglected. Putting these values in the equation above—

$$\frac{p_1}{G_1} = \frac{p_2}{G_2} + \frac{v_2^2}{2g} - \frac{p_1}{G_1}\frac{1}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\};$$

$$\frac{v_2^2}{2g} = \frac{p_1}{G_1} - \frac{p_2}{G_2} + \frac{p_1}{G_1}\frac{1}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}$$

$$= \frac{p_1}{G_1}\left\{\frac{\gamma}{\gamma - 1} - \frac{1}{\gamma - 1}\left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\} - \frac{p_2}{G_2}.$$

But $$\frac{p_1}{G_1^\gamma} = \frac{p_2}{G_2^\gamma} \quad \therefore \quad \frac{p_2}{G_2} = \frac{p_1}{G_1}\left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}.$$

$$\frac{v_2^2}{2g} = \frac{p_1}{G_1}\frac{\gamma}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}. \quad . \quad . \quad . \quad . \quad (1);$$

or $$\frac{v_2^2}{2g} = \frac{\gamma}{\gamma - 1}\left\{\frac{p_1}{G_1} - \frac{p_2}{G_2}\right\};$$

an equation commonly ascribed to Weisbach (*Civilingenieur*, 1856), though it appears to have been given earlier by St Venant and Wantzel.

It has already (§ 9, eq. $4a$) been seen that

$$\frac{p_1}{G_1} = \frac{p_0}{G_0}\frac{\tau_1}{\tau_0},$$

where for air $p_0 = 2116{\cdot}8$, $G_0 = {\cdot}08075$ and $\tau_0 = 492{\cdot}6$.

$$\frac{v_2^2}{2g} = \frac{p_0}{G_0}\frac{\tau_1}{\tau_0}\frac{\gamma}{\gamma - 1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}, \quad . \quad . \quad . \quad (2);$$

or, inserting numerical values,

$$\frac{v_2^2}{2g} = 183{\cdot}6\tau_1\left\{1 - \left(\frac{p_2}{p_1}\right)^{0{\cdot}29}\right\}, \quad . \quad . \quad . \quad . \quad (2a);$$

which gives the velocity of discharge v_2 in terms of the pressure and absolute temperature, p_1, τ_1, in the vessel from which the air flows, and the pressure p_2 in the vessel into which it flows.

Proceeding now as for liquids, and putting ω for the area of the orifice and c for the coefficient of discharge, the volume of air discharged per second at the pressure p_2 and temperature τ_2 is

$$Q_2 = c\omega v_2 = c\omega\sqrt{2g\frac{\gamma}{\gamma - 1}\frac{p_1}{G_1}\left\{1 - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}}\right\}}$$

$$= 108{\cdot}7c\omega\sqrt{\left[\tau_1\left\{1 - \left(\frac{p_2}{p_1}\right)^{0{\cdot}29}\right\}\right]} \quad . \quad . \quad . \quad (3).$$

If the volume discharged is measured at the pressure p_1 and absolute temperature τ_1 in the vessel from which the air flows, let Q_1 be that volume; then

$$p_1 Q_1^\gamma = p_2 Q_2^\gamma\ ;$$

$$Q_1 = \left(\frac{p_2}{p_1}\right)^{\frac{1}{\gamma}} Q_2\ ;$$

$$Q_1 = c\omega\sqrt{\left[2g\frac{\gamma}{\gamma - 1}\frac{p_1}{G_1}\left\{\left(\frac{p_2}{p_1}\right)^{\frac{2}{\gamma}} - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma+1}{\gamma}}\right\}\right]}.$$

Let $$\left(\frac{p_2}{p_1}\right)^{\frac{2}{\gamma}} - \left(\frac{p_2}{p_1}\right)^{\frac{\gamma+1}{\gamma}} = \left(\frac{p_2}{p_1}\right)^{1{\cdot}41} - \left(\frac{p_2}{p_1}\right)^{1{\cdot}7} = \psi\ ; \text{ then}$$

$$Q_1 = c\omega\sqrt{\left[2g\frac{\gamma}{\gamma - 1}\frac{p_1}{G_1}\psi\right]}$$

$$= 108{\cdot}7c\omega\sqrt{\tau_1\psi}\ . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

The weight of air at pressure p_1 and temperature τ_1 is

$$G_1 = \frac{p_1}{53{\cdot}2\tau_1} \text{ pounds per cubic foot.}$$

Hence the weight of air discharged is

$$W = G_1 Q_1 = c\omega\sqrt{\left[2g\frac{\gamma}{\gamma - 1}p_1 G_1\psi\right]}$$

$$= 2{\cdot}043c\omega p_1\sqrt{\frac{\psi}{\tau_1}}. \quad . \quad . \quad . \quad . \quad . \quad (5).$$

Weisbach has found the following values of the coefficient of discharge c:—

	$c=$
Conoidal mouthpieces of the form of the contracted vein with effective pressures of ·23 to 1·1 atmosphere..................	0·97 to 0·99
Circular sharp-edged orifices	0·563 ,, 0·788
Short cylindrical mouthpieces	0·81 ,, 0·84
The same rounded at the inner end	0·92 ,, 0·93
Conical converging mouthpieces............	0·90 ,, 0·99

62. *Limit to the Application of the above Formulæ.*—In the formulæ above it is assumed that the fluid issuing from the orifice expands from the pressure p_1 to the pressure p_2, while passing from the vessel to the section of the jet considered in estimating the area ω. Hence p_2 is strictly the pressure in the jet at the plane of the external orifice in the case of mouthpieces, or at the plane of the contracted section in the case of simple orifices. Till recently it was tacitly assumed that this pressure p_2 was identical with the general pressure external to the orifice. Mr R. D. Napier first discovered that, when the ratio $\frac{p_2}{p_1}$ exceeded a value which does not greatly differ from 0·5, this was no longer true. In that case the expansion of the fluid down to the external pressure is not completed at the time it reaches the plane of the contracted section, and the pressure there is greater than the general external pressure; or, what amounts to the same thing, the section of the jet where the expansion is completed is a section which is greater than the area $c_c\omega$ of the contracted section of the jet, and may be greater than the area ω of the orifice. Mr Napier made experiments with steam which showed that, so long as $\frac{p_2}{p_1} > 0{\cdot}5$, the formulæ above

were trustworthy, when p_2 was taken to be the general external pressure, but that, if $\frac{p_2}{p_1} < 0{\cdot}5$, then the pressure at the contracted section was independent of the external pressure and equal to $0{\cdot}5p_1$. Hence in such cases the constant value 0·5 should be substituted in the formulæ for the ratio of the internal and external pressures $\frac{p_2}{p_1}$.

It is easily deduced from Weisbach's theory that, if the pressure external to an orifice is gradually diminished, the weight of air discharged per second increases to a maximum for a value of the ratio

$$\frac{p_2}{p_1} = \left(\frac{2}{\gamma+1}\right)^{\frac{\gamma}{\gamma-1}}$$
$$= 0{\cdot}527 \text{ for air}$$
$$= 0{\cdot}58 \text{ for dry steam.}$$

For a further decrease of external pressure the discharge diminishes, —a result no doubt improbable. The new view of Weisbach's formula is that from the point where the maximum is reached, or not greatly differing from it, the pressure at the contracted section ceases to diminish.

Fliegner has shown (*Civilingenieur*, xx., 1874) that for air flowing from well-rounded mouthpieces there is no discontinuity of the law of flow, as Napier's hypothesis implies, but the curve of flow bends so sharply that Napier's rule may be taken to be a good approximation to the true law. The limiting value of the ratio $\frac{p_2}{p_1}$, for which Weisbach's formula, as originally understood, ceases to apply, is for air 0·5767; and this is the number to be substituted for $\frac{p_2}{p_1}$ in the formulæ when $\frac{p_2}{p_1}$ falls below that value. For later researches on the flow of air, reference may be made to Zeuner's paper (*Civilingenieur*, 1871), and Fliegner's papers (*ibid.*, 1877, 1878).

VII. FRICTION OF LIQUIDS.

63. When a stream of fluid flows over a solid surface, or conversely when a solid moves in still fluid, a resistance to the motion is generated, commonly termed fluid friction. It is due to the viscosity of the fluid, but generally the laws of fluid friction are very different from those of simple viscous resistance. It would appear that at all speeds, except the slowest, rotating eddies are formed by the roughness of the solid surface, or by abrupt changes of velocity distributed throughout the fluid; and the energy expended in producing these eddying motions is gradually lost in overcoming the viscosity of the fluid in regions more or less distant from that where they are first produced.

The laws of fluid friction are generally stated thus:—

1. The frictional resistance is independent of the pressure between the fluid and the solid against which it flows. This may be verified by a simple direct experiment. Coulomb, for instance, oscillated a disk under water, first with atmospheric pressure acting on the water surface, afterwards with the atmospheric pressure removed. No difference in the rate of decrease of the oscillations was observed. The chief proof that the friction is independent of the pressure is that no difference of resistance has been observed in water mains and in other cases, where water flows over solid surfaces under widely different pressures.

2. The frictional resistance of large surfaces is proportional to the area of the surface.

3. At low velocities of not more than 1 inch per second for water, the frictional resistance increases directly as the relative velocity of the fluid and the surface against which it flows. At velocities of ½ foot per second and greater velocities, the frictional resistance is more nearly proportional to the square of the relative velocity.

In many treatises on hydraulics it is stated that the frictional resistance is independent of the nature of the solid surface. The explanation of this was supposed to be that a film of fluid remained attached to the solid surface, the resistance being generated between this fluid layer and layers more distant from the surface. At extremely low velocities the solid surface does not seem to have much influence on the friction. In Coulomb's experiments a metal surface covered with tallow, and oscillated in water, had exactly the same resistance as a clean metal surface, and when sand was scattered over the tallow the resistance was only very slightly increased. The earlier calculations of the resistance of water at higher velocities in iron and wood pipes and earthen channels seemed to give a similar result. These, however, were erroneous, and it is now well understood that differences of roughness of the solid surface very greatly influence the friction, at such velocities as are common in engineering practice. Darcy's experiments, for instance, showed that in old and incrusted water mains the resistance was twice or sometimes thrice as great as in new and clean mains.

64. *Ordinary Expressions for Fluid Friction at Velocities not Extremely Small.*—Let f be the frictional resistance estimated in pounds per square foot of surface at a velocity of one foot per second; ω the area of the surface in square feet; and v its velocity in feet per second relatively to the water in which it is immersed. Then, in accordance with the laws stated above, the total resistance of the surface is

$$R = f\omega v^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where f is a quantity approximately constant for any given surface. If

$$\xi = \frac{2gf}{G},$$

$$R = \xi G \omega \frac{v^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

where ξ is, like f, nearly constant for a given surface, and is termed the coefficient of friction.

The following are average values of the coefficient of friction for water, obtained from experiments on large plane surfaces moved in an indefinitely large mass of water.

	Coefficient of Friction, ξ	Frictional Resistance in lb per sq. ft. f
New well-painted iron plate	·00489	·00473
Painted and planed plank (Beaufoy).....	·00350	·00339
Surface of iron ships (Rankine)	·00362	·00351
Varnished surface (Froude)	·00258	·00250
Fine sand surface ,, ...	·00418	·00405
Coarser sand surface ,, ...	·00503	·00488

The distance through which the frictional resistance is overcome is v feet per second. The work expended in fluid friction is therefore given by the equation—

$$\left.\begin{aligned}\text{Work expended} &= f\omega v^3 \text{ foot-pounds per second} \\ &= \xi G \omega \frac{v^3}{2g} \quad ,, \quad ,,\end{aligned}\right\} \quad . \quad . \quad . \quad (3).$$

The coefficient of friction and the friction per square foot of surface can be indirectly obtained from observations of the discharge of pipes and canals. In obtaining them, however, some assumptions as to the motion of the water must be made, and it will be better therefore to discuss these values in connexion with the cases to which they are related.

Many attempts have been made to express the coefficient of friction in a form applicable to low as well as high velocities. The older hydraulic writers considered the resistance termed fluid friction to be made up of two parts,—a part due directly to the distortion of the mass of water and proportional to the velocity of the water relatively to the solid surface, and another part due to kinetic energy imparted to the water striking the roughnesses of the solid surface and proportional to the square of the velocity. Hence they proposed to take

$$\xi = \alpha + \frac{\beta}{v},$$

in which expression the second term is of greatest importance at very low velocities, and of comparatively little importance at velocities over about ½ foot per second. Values of ξ expressed in this and similar forms will be given in connexion with pipes and canals.

All these expressions must at present be regarded as merely empirical expressions serving practical purposes. The frictional resistance will be seen to vary through wider limits than these expressions allow, and to depend on circumstances of which they do not take account.

65. *Coulomb's Experiments.*—The first direct experiments on fluid friction were made by Coulomb, who employed a circular disk suspended by a thin brass wire and oscillated in its own plane. His experiments were chiefly made at very low velocities. When the disk is rotated to any given angle, it oscillates under the action of its inertia and the torsion of the wire. The oscillations diminish gradually in consequence of the work done in overcoming the friction of the disk. The diminution furnishes a means of determining the friction.

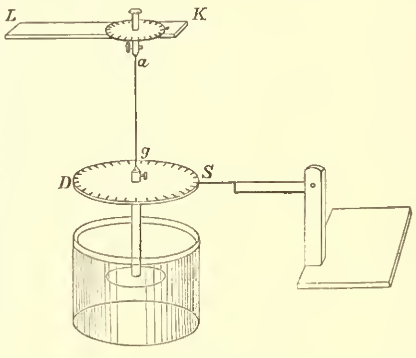

Fig. 78.

Fig. 78 shows Coulomb's apparatus. LK supports the wire and disk; ag is the brass wire, the torsion of which causes the oscillations; DS is a graduated disk serving to measure the angles through which the apparatus oscillates. To this the friction disk is rigidly attached hanging in a vessel of water. The friction disks were from 4·7 to 7·7 inches diameter, and they generally made one oscillation in from 20 to 30 seconds, through angles varying from 360° to 6°. When the velocity of the circumference of the disk was less than 6 inches per second, the resistance was sensibly proportional to the velocity.

Beaufoy's Experiments.—Towards the end of the last century Colonel Beaufoy made an immense mass of experiments on the resistance of bodies moved through water (*Nautical and Hydraulic Experiments*, London, 1834). Of these the only ones directly bearing on surface friction were some made in 1796 and 1798. Smooth painted planks were drawn through water and the resistance measured. For two planks differing in area by 46 square feet, at a velocity of 10 feet per second, the difference of resistance, measured on the difference of area, was 0·339 lb per square foot. Also the resistance varied as the 1·949th power of the velocity.

66. *Mr Froude's Experiments.*—The most important direct experiments on fluid friction at ordinary velocities are those made by Mr Froude at Torquay. The method adopted in these experiments was to tow a board in a still water canal, the velocity and the resistance being registered by very ingenious recording arrangements. The general arrangement of the apparatus is shown in fig. 79. AA is the board the resistance of which is to be determined. B is a cutwater giving a fine entrance to the plane surfaces of the board. CC is a bar to which the board AA is attached, and which is suspended by a parallel motion from a carriage running on rails above the still water canal. G is a link by which the resistance of the board is transmitted to a spiral spring H. A bar I rigidly connects the other end of the spring to the carriage. The dotted lines K, L indicate the position of a couple of levers by which the extension of the spring is caused to move a pen M, which records the extensions on a greatly increased scale, by a line drawn on the paper cylinder N. This cylinder revolves at a speed proportionate to that of the carriage, its motion being obtained from the axle of the carriage wheels. A second pen O, receiving jerks at every second and a quarter from a clock P, records time on the paper cylinder. The scale for the line of resistance is ascertained by stretching the spiral spring by known weights. The boards used for the experiment were $\frac{3}{16}$ inch thick, 19 inches deep, and from 1 to 50 feet in length, cutwater included. A lead keel counteracted the buoyancy of the board. The boards were covered with various substances, such as paint, varnish, Hay's composition, tinfoil, &c., so as to try the effect of different degrees

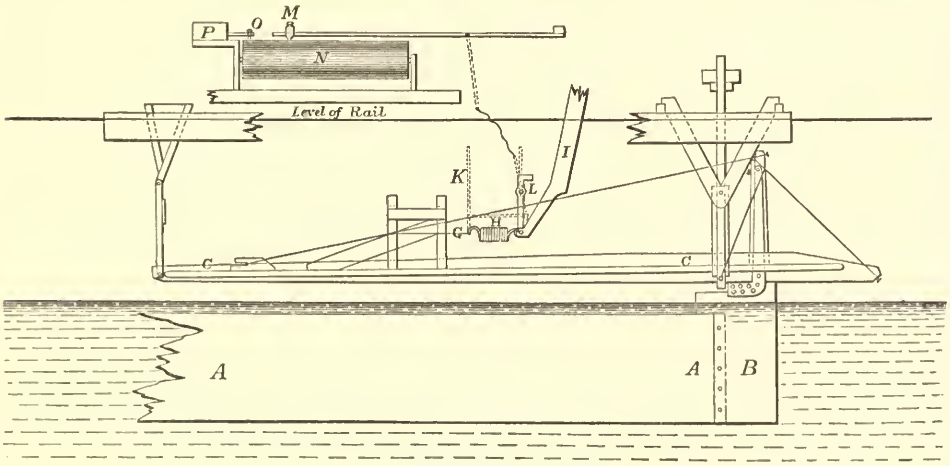

Fig. 79.

of roughness of surface. The results obtained by Mr Froude may be summarized as follows :—

(1) The friction per square foot of surface varies very greatly for different surfaces, being generally greater as the sensible roughness of the surface is greater. Thus, when the surface of the board was covered as mentioned below, the resistance for boards 50 feet long, at 10 feet per second, was—

Tinfoil or varnish	0·25 lb per sq. ft.
Calico	0·47 ,, ,,
Fine sand	0·405 ,, ,,
Coarser sand....................................	0·488 ,, ,,

(2) The power of the velocity to which the friction is proportional varies for different surfaces. Thus, with short boards 2 feet long,

For tinfoil the resistance varied as $v^{2\cdot16}$

For other surfaces ,, ,, $v^{2\cdot00}$

With boards 50 feet long,

For varnish or tinfoil the resistance varied as $v^{1\cdot83}$

For sand ,, ,, ,, $v^{2\cdot00}$

(3) The average resistance per square foot of surface was much greater for short than for long boards; or, what is the same thing, the resistance per square foot at the forward part of the board was greater than the friction per square foot of portions more sternward. Thus,

		Mean Resistance in lb per sq. ft.
Varnished surface...............	2 ft. long	0·41
	50 ,,	0·25
Fine sand surface	2 ,,	0·81
	50 ,,	0·405

This remarkable result is explained thus by Mr Froude :—"The portion of surface that goes first in the line of motion, in experiencing resistance from the water, must in turn communicate motion to the water, in the direction in which it is itself travelling. Consequently the portion of surface which succeeds the first will be rubbing, not against stationary water, but against water partially moving in its own direction, and cannot therefore experience so much resistance from it."

67. The following table gives a general statement of Mr Froude's results. In all the experiments in this table, the boards had a fine cutwater and a fine stern end or run, so that the resistance was entirely due to the surface. The table gives the resistances per square foot in pounds, at the standard speed of 600 feet per minute, and the power of the speed to which the friction is proportional, so that the resistance at other speeds is easily calculated.

	Length of Surface, or distance from Cutwater, in feet.											
	2 feet.			8 feet.			20 feet.			50 feet.		
	A	B	C	A	B	C	A	B	C	A	B	C
Varnish...............	2·00	·41	·390	1·85	·325	·264	1·85	·278	·240	1·83	·250	·226
Paraffin...............	...	·38	·370	1·94	·314	·260	1·93	·271	·237	...	...	...
Tinfoil	2·16	·30	·295	1·99	·278	·263	1·90	·262	·244	1·83	·246	·232
Calico	1·93	·87	·725	1·92	·626	·504	1·89	·531	·447	1·87	·474	·423
Fine sand	2·00	·81	·690	2·00	·583	·450	2·00	·480	·384	2·06	·405	·337
Medium sand	2·00	·90	·730	2·00	·625	·488	2·00	·534	·465	2·00	·488	·456
Coarse sand.........	2·00	1·10	·880	2·00	·714	·520	2·00	·588	·490	...	...	...

Columns A give the power of the speed to which the resistance is approximately proportional.

Columns B give the mean resistance per square foot of the whole surface of a board of the lengths stated in the table.

Columns C give the resistance in pounds of a square foot of surface at the distance sternward from the cutwater stated in the heading.

Although these experiments do not directly deal with surfaces of greater length than 50 feet, they indicate what would be the resistances of longer surfaces. For at 50 feet the decrease of resistance for an increase of length is so small that it will make no very great difference in the estimate of the friction whether we suppose it to continue to diminish at the same rate or not to diminish at all. For a varnished surface the friction at 10 feet per second diminishes from 0·41 to 0·32 lb per square foot when the length is increased from 2 to 8 feet, but it only diminishes from 0·278 to 0·250 lb per square foot for an increase from 20 feet to 50 feet.

If the decrease of friction sternwards is due to the generation of a current accompanying the moving plane, there is not at first sight any reason why the decrease should not be greater than that shown by the experiments. The current accompanying the board might be assumed to gain in volume and velocity sternwards, till the velocity was nearly the same as that of the moving plane and the friction per square foot nearly zero. That this does not happen appears to be due to the mixing up of the current with the still water surrounding it. Part of the water in contact with the board at any point, and receiving energy of motion from it, passes afterwards to distant regions of still water, and portions of still water are fed in towards the board to take its place. In the forward part of the board more kinetic energy is given to the current than is diffused into surrounding space, and the current gains in velocity. At a greater distance back there is an approximate balance between the energy communicated to the water and that diffused. The velocity of the current accompanying the board becomes constant or nearly constant, and the friction per square foot is therefore nearly constant also.

VIII. STEADY FLOW OF WATER IN PIPES OF UNIFORM SECTION.

68. The ordinary theory of the flow of water in pipes, on which all practical formulæ are based, assumes that the variation of velocity at different points of any cross section may be neglected. The water is considered as moving in plane layers, which are driven through the pipe against the frictional resistance, by the difference of pressure at or elevation of the ends of the pipe. If the motion is steady the velocity at each cross section remains the same from moment to moment, and if the cross sectional area is constant the velocity at all sections must be the same. Hence the motion is uniform. The most important resistance to the motion of the water is the surface friction of the pipe, and it is convenient to estimate this independently of some smaller resistances which will be accounted for presently.

In any portion of a uniform pipe, excluding for the present the ends of the pipe, the water enters and leaves at the same velocity. For that portion therefore the work of the external forces and of the surface friction must be equal. Let fig. 80 represent a very short portion of the pipe, of length dl, between cross sections at z and $z+dz$ feet above any horizontal datum line xx, the pressures at the cross sections being p and $p+dp$ ℔ per square foot. Further, let Q be the volume of flow or discharge of the pipe per second, Ω the area of a normal cross section, and χ the perimeter of the pipe. The Q cubic feet, which flow through the space considered per second, weigh GQ ℔, and fall through a height $-dz$ feet. The work done by gravity is then

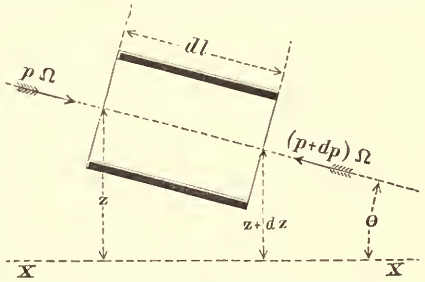

Fig. 80.

$$-\mathrm{GQ}dz\,;$$

a positive quantity if dz is negative, and *vice versa*. The resultant pressure parallel to the axis of the pipe is $p-(p+dp)=-dp$ ℔ per square foot of the cross section. The work of this pressure on the volume Q is

$$-\mathrm{Q}dp\,.$$

The only remaining force doing work on the system is the friction against the surface of the pipe. The area of that surface is $\chi\, dl$.

The work expended in overcoming the frictional resistance per second is (see § 64, eq. 3)

$$-\zeta \mathrm{G}\chi dl\frac{v^3}{2g}\,,$$

or, since $\mathrm{Q}=\Omega v$,

$$-\zeta \mathrm{G}\frac{\chi}{\Omega}\mathrm{Q}\frac{v^2}{2g}dl\,;$$

the negative sign being taken because the work is done against a resistance. Adding all these portions of work, and equating the result to zero, since the motion is uniform,—

$$-\mathrm{GQ}dz-\mathrm{Q}dp-\zeta\mathrm{G}\frac{\chi}{\Omega}\mathrm{Q}\frac{v^2}{2g}dl=0\,.$$

Dividing by GQ,

$$dz+\frac{dp}{\mathrm{G}}+\zeta\frac{\chi}{\Omega}\,\frac{v^2}{2g}dl=0\,.$$

Integrating,

$$z+\frac{p}{\mathrm{G}}+\zeta\frac{\chi}{\Omega}\,\frac{v^2}{2g}l=\text{constant} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

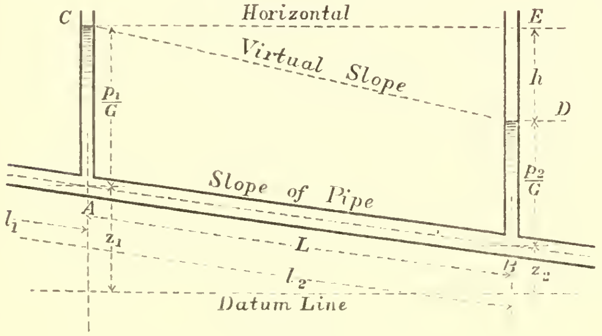

Fig. 81.

69. Let A and B (fig. 81) be any two sections of the pipes for which p, z, l have the values p_1, z_1, l_1, and p_2, z_2, l_2 respectively. Then

$$z_1+\frac{p_1}{\mathrm{G}}+\zeta\frac{\chi}{\Omega}\,\frac{v^2}{2g}l_1=z_2+\frac{p_2}{\mathrm{G}}+\zeta\frac{\chi}{\Omega}\,\frac{v^2}{2g}l_2\,;$$

or, if $l_2-l_1=\mathrm{L}$, rearranging the terms,

$$\zeta\frac{v^2}{2g}=\frac{1}{\mathrm{L}}\left\{\left(z_1+\frac{p_1}{\mathrm{G}}\right)-\left(z_2+\frac{p_2}{\mathrm{G}}\right)\right\}\frac{\Omega}{\chi} \quad . \quad . \quad . \quad (2).$$

Suppose pressure columns introduced at A and B. The water will rise in those columns to the heights $\frac{p_1}{\mathrm{G}}$ and $\frac{p_2}{\mathrm{G}}$ due to the pressures p_1 and p_2 at A and B. Hence $\left(z_1+\frac{p_1}{\mathrm{G}}\right)-\left(z_2+\frac{p_2}{\mathrm{G}}\right)$ is the quantity represented in the figure by DE, the fall of level of the pressure columns, or *virtual fall* of the pipe. If there were no friction in the pipe, then by Bernoulli's equation there would be no fall of level of the pressure columns, the velocity being the same at A and B. Hence DE or h is the head lost in friction in the distance AB. The quantity $\frac{\mathrm{DE}}{\mathrm{AB}}=\frac{h}{\mathrm{L}}$ is termed the virtual slope of the pipe or virtual fall per foot of length. It is sometimes termed very conveniently the relative fall. It will be denoted by the symbol i.

The quantity $\frac{\Omega}{\chi}$ which appears in many hydraulic equations is called the hydraulic mean radius of the pipe. It will be denoted by m.

Introducing these values,

$$\zeta\frac{v^2}{2g}=m\frac{h}{\mathrm{L}}=mi\,. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

For pipes of circular section, and diameter d,

$$m=\frac{\Omega}{\chi}=\frac{\frac{\pi}{4}d^2}{\pi d}=\frac{d}{4}\,.$$

Then

$$\zeta\frac{v^2}{2g}=\frac{d}{4}\cdot\frac{h}{\mathrm{L}}=\frac{di}{4}\,, \quad . \quad . \quad . \quad . \quad . \quad (4);$$

or

$$h=\zeta\,\frac{4\mathrm{L}}{d}\cdot\frac{v^2}{2g}\,, \quad . \quad . \quad . \quad . \quad . \quad . \quad (4a);$$

which shows that the head lost in friction is proportional to the head due to the velocity, and is found by multiplying that head by the coefficient $\zeta\frac{4\mathrm{L}}{d}$.

70. *Hydraulic Gradient or Line of Virtual Slope.*—Join CD. Since the head lost in friction is proportional to L, any intermediate pressure column between A and B will have its free surface on the line CD, and the vertical distance between CD and the pipe at any point measures the pressure, exclusive of atmospheric pressure, in the pipe at that point. If the pipe were laid along the line CD instead of AB, the water would flow at the same velocity by gravity without any change of pressure from section to section. Hence CD is termed the virtual slope or hydraulic gradient of the pipe. It is the line of free surface level for each point of the pipe.

If an ordinary pipe, connecting reservoirs open to the air, rises at any point above the line of virtual slope, the pressure at that point is less than the atmospheric pressure transmitted through the pipe. At such a point there is a liability that air may be disengaged from the water, and the flow stopped or impeded by the accumulation of air. If the pipe rises more than 34 feet above the line of virtual slope, the pressure is negative. But as this is impossible, the continuity of the flow will be broken.

If the pipe is not straight, the line of virtual slope becomes a curved line, but since in actual pipes the vertical alterations of level are generally small, compared with the length of the pipe, distances measured along the pipe are sensibly proportional to distances measured along the horizontal projection of the pipe. Hence the line of hydraulic gradient may be taken to be a straight line without error of practical importance.

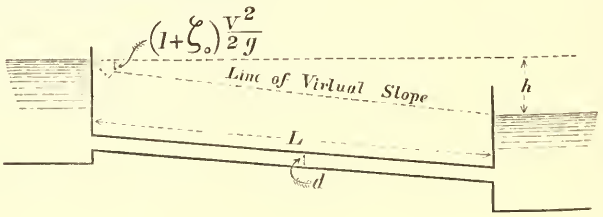

Fig. 82.

71. *Case of a Uniform Pipe connecting two Reservoirs, when all the Resistances are taken into account.*—Let h (fig. 82) be the difference of level of the reservoirs, and v the velocity, in a pipe of length L and diameter d. The whole work done per second is virtually the removal of Q cubic feet of water from the surface of the upper

reservoir to the surface of the lower reservoir, that is GQh foot-pounds. This is expended in three ways. (1) The head $\frac{v^2}{2g}$, corresponding to an expenditure of $GQ\frac{v^2}{2g}$ foot-pounds of work, is employed in giving energy of motion to the water. This is ultimately wasted in eddying motions in the lower reservoir. (2) A portion of head, which experience shows may be expressed in the form $\zeta_0\frac{v^2}{2g}$, corresponding to an expenditure of $GQ\zeta_0\frac{v^2}{2g}$ foot-pounds of work, is employed in overcoming the resistance at the entrance to the pipe. (3) As already shown the head expended in overcoming the surface friction of the pipe is $\zeta\frac{4L}{d}\frac{v^2}{2g}$ corresponding to $GQ\zeta\frac{4L}{d}\cdot\frac{v^2}{2g}$ foot-pounds of work. Hence

$$GQh = GQ\frac{v^2}{2g} + GQ\zeta_0\frac{v^2}{2g} + GQ\zeta\frac{4L}{d}\frac{v^2}{2g};$$

$$\left.\begin{aligned} h &= \left(1+\zeta_0+\zeta\frac{4L}{d}\right)\frac{v^2}{2g}, \\ v &= 8{\cdot}025\sqrt{\frac{hd}{(1+\zeta_0)d+4\zeta L}}. \end{aligned}\right\} \quad . \quad . \quad (5).$$

If the pipe is bellmouthed, ζ_0 is about $= {\cdot}08$. If the entrance to the pipe is cylindrical, $\zeta_0 = 0{\cdot}505$. Hence $1+\zeta_0 = 1{\cdot}08$ to $1{\cdot}505$. In general this is so small compared with $\zeta\frac{4L}{d}$ that, for practical calculations, it may be neglected; that is, the losses of head other than the loss in surface friction are left out of the reckoning. It is only in short pipes and at high velocities that it is necessary to take account of the first two terms in the bracket, as well as the third. For instance, in pipes for the supply of turbines, v is usually limited to 2 feet per second, and the pipe is bellmouthed. Then $1{\cdot}08\frac{v^2}{2g} = 0{\cdot}067$ foot. In pipes for towns' supply v may range from 2 to $4\frac{1}{2}$ feet per second, and then $1{\cdot}5\frac{v^2}{2g} = 0{\cdot}1$ to $0{\cdot}5$ foot. In either case this amount of head is small compared with the whole virtual fall in the cases which most commonly occur.

When d and v or d and h are given, the equations above are solved quite simply. When v and h are given and d is required, it is better to proceed by approximation. Find an approximate value of d by assuming a probable value for ζ as mentioned below. Then from that value of d find a corrected value for ζ and repeat the calculation.

The equation above may be put in the form

$$h = \frac{4\zeta}{d}\left\{\frac{(1+\zeta_0)d}{4\zeta} + L\right\}\frac{v^2}{2g}, \quad . \quad . \quad . \quad . \quad . \quad (6);$$

from which it is clear that the head expended at the mouthpiece is equivalent to that of a length

$$\frac{(1+\zeta_0)d}{4\zeta}$$

of the pipe. Putting $1+\zeta_0 = 1{\cdot}505$ and $\zeta = 0{\cdot}01$, the length of pipe equivalent to the mouthpiece is $37{\cdot}6\,d$ nearly. This may be added to the actual length of the pipe to allow for mouthpiece resistance in approximate calculations.

72. *Coefficient of Friction for Pipes Discharging Water*—From the average of a large number of experiments, the value of ζ for ordinary iron pipes is

$$\zeta = 0{\cdot}007567 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

But practical experience shows that no single value can be taken applicable to very different cases. The earlier hydraulicians occupied themselves chiefly with the dependence of ζ on the velocity. Having regard to the difference of the law of resistance at very low and at ordinary velocities, they assumed that ζ might be expressed in the form

$$\zeta = \alpha + \frac{\beta}{v}.$$

The following are the best numerical values obtained for ζ so expressed:—

	α	β
Prony (from 51 experiments)	0·006836	0·001116
D'Aubuisson	0·00673	0·001211
Eytelwein	0·005493	0·00143

Weisbach proposed the formula

$$\zeta = \alpha + \frac{\beta}{\sqrt{v}} = 0{\cdot}003598 + \frac{0{\cdot}004289}{\sqrt{v}} \quad . \quad . \quad . \quad . \quad (8).$$

The following short table gives Weisbach's values of the coefficient of friction for different velocities in feet per second:—

$v =$	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1	$1\frac{1}{4}$	$1\frac{1}{2}$	2	3	4	6	8	12	20
$\zeta =$	0·0686	0·0527	0·0457	0·0415	0·0387	0·0365	0·0349	0·0336	0·0325	0·0315	0·0297	0·0284	0·0265	0·0243	0·0230	0·0214	0·0205	0·0193	0·0182

73. *Darcy's Experiments.*—All previous experiments on the resistance of pipes have been superseded by the remarkable researches carried out by the late Inspector-General of the Paris Water Works, M. Darcy. His experiments were carried out on a scale, under a variation of conditions, and with a degree of accuracy which leaves little to be desired, and the results obtained are of very great practical importance. These results may be stated thus:—

(1) For new and clean pipes the friction varies considerably with the nature and polish of the surface of the pipe. For clean cast-iron it is about $1\frac{1}{2}$ times as great as for cast-iron covered with pitch.

(2) The nature of the surface has less influence when the pipes are old and incrusted with deposits, due to the action of the water. Thus old and incrusted pipes give twice as great a frictional resistance as new and clean pipes. M. Darcy's coefficients were chiefly determined from experiments on new pipes. He doubles these coefficients for old and incrusted pipes, in accordance with the results of a very limited number of experiments on pipes containing incrustations and deposits.

(3) The coefficient of friction may be expressed in the form $\zeta = \alpha + \frac{\beta}{v}$; but in pipes which have been some time in use it is sufficiently accurate to take $\zeta = \alpha_1$ simply, where α_1 depends on the diameter of the pipe alone, but α and β on the other hand depend both on the diameter of the pipe and the nature of its surface. The following are the values of the constants.

For pipes which have been some time in use, neglecting the term depending on the velocity;

$$\zeta = \alpha\left(1 + \frac{\beta}{d}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

	α	β
For drawn wrought-iron or smooth cast-iron pipes	·004973	·084
For pipes altered by light incrustations	·00996	·084

These coefficients may be put in the following very simple form, without sensibly altering their value:—

$$\left.\begin{aligned} &\text{For clean pipes} \ldots\ldots\ldots\ldots \quad \zeta = {\cdot}005\left(1+\frac{1}{12d}\right) \\ &\text{For slightly incrusted pipes} \ldots\ldots \quad \zeta = {\cdot}01\left(1+\frac{1}{12d}\right) \end{aligned}\right\} (9a).$$

Darcy's Value of the Coefficient of Friction ζ for Velocities not less than 4 inches per second.

Diameter of Pipe in Inches.	ζ New Pipes.	ζ Incrusted Pipes.	Diameter of Pipe in Inches.	ζ New Pipes.	ζ Incrusted Pipes.
2	0·00750	0·01500	18	·00528	·01056
3	·00667	·01333	21	·00524	·01048
4	·00625	·01250	24	·00521	·01042
5	·00600	·01200	27	·00519	·01037
6	·00583	·01167	30	·00517	·01033
7	·00571	·01143	36	·00514	·01028
8	·00563	·01125	42	·00512	·01024
9	·00556	·01111	48	·00510	·01021
12	·00542	·01083	54	·00509	·01019
15	·00533	·01067			

These values of ζ are, however, only applicable when the velocity exceeds 4 inches per second. To embrace all cases Darcy proposes the expression

$$\zeta = \left(\alpha + \frac{\alpha_1}{d}\right) + \frac{\beta + \frac{\beta_1}{d^2}}{v}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (10);$$

which is a modification of Coulomb's, including terms expressing the influence of the diameter and of the velocity. For clean pipes Darcy found these values

$\alpha = {\cdot}001262$
$\alpha_1 = {\cdot}000833$
$\beta = {\cdot}00206$
$\beta_1 = {\cdot}00001042$

74. *Scraping Water Mains.*—The influence of the condition of the surface of a pipe on the friction is shown by various facts known to the engineers of waterworks. Pipes are very often heated and dipped in pitch, which gives them a smooth hard surface and protects them from oxidation. Such pipes are known to give a discharge larger than that calculated by the ordinary formulæ. In pipes which convey certain kinds of water oxidation proceeds rapidly, and the discharge is very perceptibly and sometimes very greatly diminished. In a main laid at Torquay the discharge diminished from this cause more than 50 per cent., and the supply became insufficient for the town. Mr Appold suggested an apparatus for scraping the interior of the pipe, and this was constructed and tried under the direction of Mr Froude. It was found that by scraping the interior of the pipe the discharge was increased 56 per cent. The scraping requires to be repeated at intervals. After each scraping the discharge diminishes rather rapidly by 10 per cent. and afterwards more slowly, the diminution in a year being about 25 per cent.

Fig. 83 shows a scraper for water mains, similar to Mr Appold's but modified in details, as constructed by the Glenfield Company, at Kilmarnock. A is a longitudinal section of the pipe, showing the scraper in place; B is an end view of the plungers, and C, D sections of the boxes placed at intervals on the main for introducing or withdrawing the scraper. The apparatus consists of two plungers, packed with leather so as to fit the main pretty closely. On the spindle of these plungers are fixed eight steel scraping blades, with curved scraping edges fitting the surface of the main. The apparatus is placed in the main by removing the cover from one of the boxes shown at C, D. The cover is then replaced, water pressure is admitted behind the plungers, and the apparatus driven through the main. At Lancaster, after twice scraping the discharge was increased $56\frac{1}{2}$ per cent., at Oswestry $54\frac{1}{2}$ per cent. The increased discharge is due to the diminution of the friction of the pipe by removing the roughnesses due to oxidation.

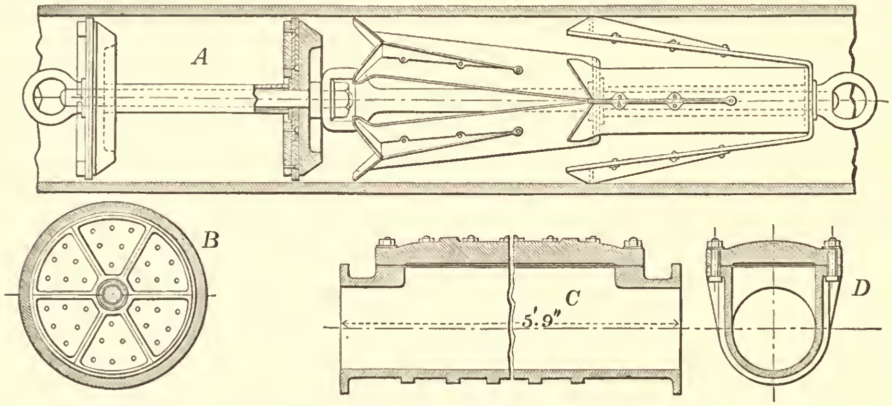

Fig. 83.—Scale $\frac{1}{25}$.

75. *Reduction of a long Pipe of Varying Diameter to an Equivalent Pipe of Uniform Diameter. Dupuit's Equation.*—Water mains for the supply of towns often consist of a series of lengths, the diameter being the same for each length, but differing from length to length. In approximate calculations of the head lost in such mains, it is generally accurate enough to neglect the smaller losses of head and to have regard to the pipe friction only, and then the calculations may be facilitated by reducing the main to a main of uniform diameter, in which there would be the same loss of head. Such a uniform main will be termed an equivalent main.

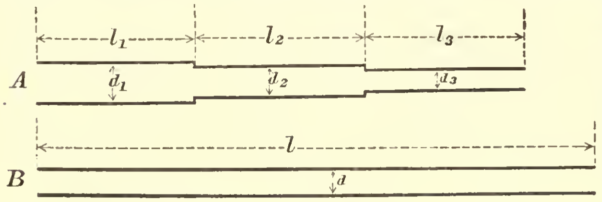

Fig. 84.

In fig. 84, let A be the main of variable diameter, and B the equivalent uniform main. In the given main of variable diameter A, let

$l_1,\ l_2$ . . be the lengths,
$d_1,\ d_2$ . . . . the diameters,
$v_1,\ v_2$ . . . . the velocities,
$i_1,\ i_2$ . . . . the slopes,

for the successive portions, and let l, d, v, and i be corresponding quantities for the equivalent uniform main B. The total loss of head in A due to friction is

$$h = i_1 l_1 + i_2 l_2 + \ldots\ldots\ldots$$
$$= \zeta \frac{v_1^2}{2g}\frac{4l_1}{d_1} + \zeta \frac{v_2^2}{2g}\frac{4l_2}{d_2} + \ldots\ldots ;$$

and in the uniform main

$$il = \zeta \frac{v^2}{2g} \cdot \frac{4l}{d}$$

If the mains are equivalent, as defined above,

$$\zeta \frac{v^2}{2g}\frac{4l}{d} = \zeta \frac{v_1^2}{2g} \cdot \frac{4l_1}{d_1} + \zeta \frac{v_2^2}{2g}\frac{4l_2}{d_2} + \ldots\ldots$$

But, since the discharge is the same for all portions,

$$\frac{\pi}{4} d^2 v = \frac{\pi}{4} d_1^2 v_1 = \frac{\pi}{4} d_2^2 v_2 = \ldots\ldots$$
$$v_1 = v\frac{d^2}{d_1^2}\ ;\ v_2 = v\frac{d^2}{d_2^2} \quad \ldots\ldots$$

Also suppose that ζ may be treated as constant for all the pipes. Then

$$\frac{l}{d} = \frac{d^4}{d_1^4} \cdot \frac{l_1}{d_1} + \frac{d^4}{d_2^4} \cdot \frac{l_2}{d_2} + \ldots\ldots$$
$$l = \frac{d^5}{d_1^5} l_1 + \frac{d^5}{d_2^5} l_2 + \ldots\ldots\ldots$$

which gives the length of the equivalent uniform main which would have the same total loss of head for any given discharge.

76. *Case of a Pipe of Uniform Diameter with Discharge diminishing uniformly along its Length.*—In the case of a branch main the water is delivered at nearly equal distances to service pipes along the route. Such a main approximates to the case of a main of uniform diameter, with a discharge at each point diminished by an amount proportional to the distance from the origin. Let AB (fig. 85) be a main of diameter d and length L; let Q_0 cubic feet per second enter at A, and let q cubic feet be delivered to service pipes per foot of its length. Then at any point C, l feet from A, the discharge is $Q = Q_0 - ql$. Consider a short length dl at c. The loss of head in that length is

$$\zeta \frac{v^2}{2g} \cdot \frac{4dl}{d} = \zeta \frac{Q^2}{\frac{\pi^2}{16} d^4} \cdot \frac{4dl}{d} = 64\,\zeta \frac{Q^2 dl}{\pi^2 d^5} = \frac{64\zeta}{\pi^2 d^5}(Q_0 - ql)^2 dl\,.$$

Hence the whole head lost in the length AB will be

$$h = \frac{64\zeta}{\pi^2 d^5}\int_0^L (Q_0 - ql)^2 dl$$
$$= \frac{64\zeta L}{\pi^2 d^5}\left\{ Q_0^2 - qQ_0 L + \tfrac{1}{3} q^2 L^2 \right\}, \quad \ldots \quad (1);$$

or, putting $P = qL$, the total discharge through the service pipes between A and B,

$$h = \frac{64\zeta L}{\pi^2 d^5}\left\{ Q_0^2 - PQ_0 + \tfrac{1}{3}P^2 \right\}. \quad \ldots \quad (2).$$

The discharge at the end B of the pipe is $Q_1 = Q_0 - P$. If Q' is put for the discharge of the pipe when the flow into the service pipes is stopped, under the same head h, it may be shown that

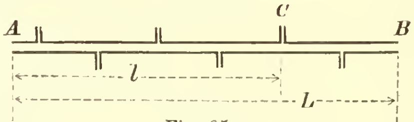

Fig. 85.

$$Q_1 = Q' - 0{\cdot}55P \text{ nearly}$$

If the pipe is so long that

$$Q_1 = Q_0 - P = 0,$$

all the water passing into service pipes *en route*,

$$h = \frac{1}{3}\frac{64\zeta L}{\pi^2 d^5} Q_0^2\,. \quad \ldots\ldots \quad (3).$$

77. *Other Losses of Head in Pipes.*—Most of the losses of head in pipes, other than that due to surface friction against the pipe, are due

to abrupt changes in the velocity of the stream producing eddies. The kinetic energy of these is deducted from the general energy of translation, and practically wasted.

Sudden Enlargement of Section.—Suppose a pipe enlarges in section from an area ω_0 to an area ω_1 (fig. 86); then

$$\frac{v_1}{v_0} = \frac{\omega_0}{\omega_1};$$

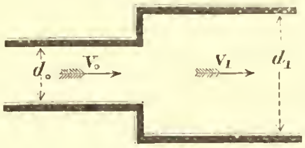

Fig. 86.

or, if the section is circular,

$$\frac{v_1}{v_0} = \left(\frac{d_0}{d_1}\right)^2.$$

The head lost at the abrupt change of velocity has already been shown to be the head due to the relative velocity of the two parts of the stream. Hence head lost

$$\mathfrak{h}_e = \frac{(v_0 - v_1)^2}{2g} = \left(\frac{\omega_1}{\omega_0} - 1\right)^2 \frac{v_1^2}{2g} = \left\{\left(\frac{d_1}{d_0}\right)^2 - 1\right\}^2 \frac{v_1^2}{2g}$$

or

$$\mathfrak{h}_e = \zeta_e \frac{v_1^2}{2g}, \quad \ldots \quad (1),$$

if ζ_e is put for the expression in brackets.

$\frac{\omega_1}{\omega_0} =$	1·1	1·2	1·3	1·4	1·5	1·6	1·7	1·8	1·9	2·0	2·5	3·0	3·5	4·0	5·0	6·0	7·0	8·0
$\frac{d_1}{d_0} =$	1·05	1·10	1·14	1·18	1·22	1·26	1·30	1·34	1·38	1·41	1·58	1·73	1·87	2·00	2·24	2·45	2·65	2·83
$\zeta_e =$	·01	·04	·09	·16	·25	·36	·49	·64	·81	1·00	2·25	4·00	6·25	9·00	16·00	25·00	36·0	49·0

Abrupt Contraction of Section.—When water passes from a larger to a smaller section, as in figs. 87, 88, a contraction is formed, and

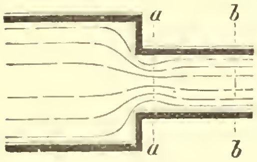

Fig. 87.

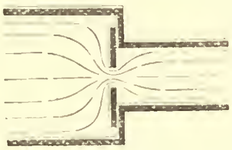

Fig. 88.

the contracted stream abruptly expands to fill the section of the pipe. Let ω be the section and v the velocity of the stream at *bb*. At *aa* the section will be $c_c\omega$, and the velocity $\frac{\omega}{c_c\omega} v = \frac{v}{c_c}$, where c_c is the coefficient of contraction. Then the head lost is

$$\mathfrak{h}_m = \frac{\left(\frac{v}{c_c} - v\right)^2}{2g} = \left(\frac{1}{c_c} - 1\right)^2 \frac{v^2}{2g};$$

and, if c_c is taken 0·64,

$$\mathfrak{h}_m = 0{\cdot}316 \frac{v^2}{2g} \quad \ldots \quad (2).$$

The value of the coefficient of contraction for this case is, however, not well ascertained, and the result is somewhat modified by friction. For water entering a cylindrical, not bellmouthed, pipe from a reservoir of indefinitely large size, experiment gives

$$\mathfrak{h}_a = 0{\cdot}505 \frac{v^2}{2g} \quad \ldots \quad (3).$$

If there is a diaphragm at the mouth of the pipe as in fig. 88, let ω_1 be the area of this orifice. Then the area of the contracted stream is $c_c\omega_1$, and the head lost is

$$\mathfrak{h}_c = \left(\frac{\omega}{c_c\omega_1} - 1\right)^2 \frac{v^2}{2g}$$
$$= \zeta_c \frac{v^2}{2g} \quad \ldots \quad (4)$$

if ζ_c is put for $\left(\frac{\omega}{c_c\omega_1} - 1\right)^2$.

Weisbach has found experimentally the following values of the coefficient, when the stream approaching the orifice was considerably larger than the orifice:—

$\frac{\omega_1}{\omega} =$	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1·0
$c_c =$	·616	·614	·612	·610	·607	·605	·603	·601	·598	·596
$\zeta_c =$	231·7	50·99	19·78	9·612	5·256	3·077	1·876	1·169	0·734	0·480

When a diaphragm was placed in a tube of uniform section (fig. 89),

Fig. 89.

the following values were obtained, ω_1 being the area of the orifice, and ω that of the pipe:—

$\frac{\omega_1}{\omega} =$	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1·0
$c_c =$	·624	·632	·643	·659	·681	712	·755	·813	·892	1·00
$\zeta_c =$	225·9	47·77	30·83	7·801	1·753	1·796	·797	·290	·060	·000

Elbows.—Weisbach considers the loss of head at elbows (fig. 90) to be due to a contraction formed by the stream. From experiments with a pipe $1\frac{1}{4}$ inches diameter, he found the loss of head

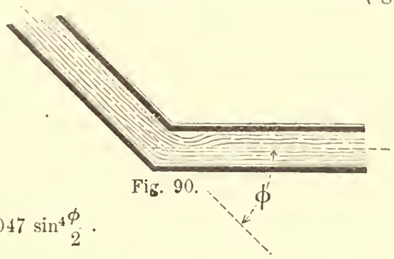

Fig. 90.

$$\mathfrak{h}_e = \zeta_e \frac{v^2}{2g} \quad \ldots \quad (5);$$

$$\zeta_e = 0{\cdot}9457 \sin^2\frac{\phi}{2} + 2{\cdot}047 \sin^4\frac{\phi}{2}.$$

$\phi =$	20°	40°	60°	80°	90°	100°	110°	120°	130°	140°
$\zeta_e =$	0·046	0·139	0·364	0·740	0·984	1·260	1·556	1·861	2·158	2·431

Hence at a right-angled elbow the whole head due to the velocity very nearly is lost.

Bends.—Weisbach traces the loss of head at curved bends to a similar cause to that at elbows, but the coefficients for bends are not very satisfactorily ascertained. Weisbach obtained for the loss of head at a bend in a pipe of circular section

$$\mathfrak{h}_b = \zeta_b \frac{v^2}{2g} \quad \ldots \quad (6);$$

$$\zeta_b = 0{\cdot}131 + 1{\cdot}847 \left(\frac{d}{2\rho}\right)^{\frac{7}{2}},$$

where d is the diameter of the pipe and ρ the radius of curvature of the bend. For bends with rectangular cross sections

$$\zeta_b = 0{\cdot}124 + 3{\cdot}104 \left(\frac{s}{2\rho}\right)^{\frac{7}{2}},$$

where s is the length of the side of the section parallel to the radius of curvature ρ.

$\frac{d}{2\rho} =$	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1·0
$\zeta_b =$	0·131	·138	·158	·206	·294	·440	·661	·977	1·408	1·978

$\frac{s}{2\rho} =$	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1·0
$\zeta_b =$	·124	·135	·180	·250	·398	·643	1·015	1·546	2·271	3·228

Valves, Cocks, and Sluices.—These produce a contraction of the water-stream, similar to that for an abrupt diminution of section already discussed. The loss of head may be taken as before to be

$$\mathfrak{h}_v = \zeta_v \frac{v^2}{2g} \quad \ldots \quad (7);$$

where v is the velocity in the pipe beyond the valve and ζ_v a coefficient determined by experiment. The following are Weisbach's results.

78. *Practical Calculations on the Flow of Water in Pipes.*—In the following explanations it will be assumed that the pipe is of so great a length that only the loss of head in friction against the surface of the pipe needs to be considered. In general it is one of the four quantities d, i, v, or Q which requires to be determined.

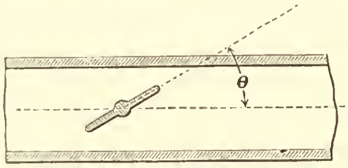

Fig. 94.

For since the loss of head h is given by the relation $h=il$, this need not be separately considered.

There are then three equations (see eq. 4, § 69, and 9*a*, § 73) for the solution of such problems as arise :—

$$\zeta=\alpha\left(1+\frac{1}{12d}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

where $\alpha=0·005$ for new and $=0·01$ for incrusted pipes.

$$\zeta\frac{v^2}{2g}=\frac{di}{4} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

$$Q=\frac{\pi}{4}d^2v \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Problem 1. Given the diameter of the pipe and its virtual slope, to find the discharge and velocity of flow. Here d and i are given, and Q and v are required. Find ζ from (1); then v from (2); lastly Q from (3). This case presents no difficulty.

By combining equations (1) and (2), v is obtained directly :—

$$v=\sqrt{\frac{g}{2\zeta}}\,di=\sqrt{\frac{g}{2\alpha}}\sqrt{\frac{di}{1+\frac{1}{12d}}} \quad . \quad . \quad . \quad . \quad (4).$$

For new pipes $\sqrt{\frac{g}{2\alpha}}=56·72$

For incrusted pipes $=80·24$

For pipes not less than 1, or more than 4 feet in diameter, the mean values of ζ are

For new pipes ....0·00526
For incrusted pipes ....0·01052.

Using these values we get the very simple expressions—

$$\left.\begin{aligned} v&=55·31\sqrt{di} \text{ for new pipes} \\ &=39·11\sqrt{di} \text{ for incrusted pipes} \end{aligned}\right\} \quad . \quad . \quad . \quad (4a).$$

Within the limits stated, these are accurate enough for practical purposes, especially as the precise value of the coefficient ζ cannot be known for each special case.

Problem 2. Given the diameter of a pipe and the velocity of flow, to find the virtual slope and discharge. The discharge is given by (3); the proper value of ζ by (1); and the virtual slope by (2). This also presents no special difficulty.

Problem 3. Given the diameter of the pipe and the discharge, to find the virtual slope and velocity. Find v from (3); ζ from (1); lastly i from (2). If we combine (1) and (2) we get

$$i=\zeta\frac{v^2}{2g}\cdot\frac{4}{d}=2\alpha\left(1+\frac{1}{12d}\right)\frac{v^2}{gd} \quad . \quad . \quad . \quad . \quad (5);$$

and, taking the mean values of ζ for pipes from 1 to 4 feet diameter, given above, the approximate formulæ are

$$\left.\begin{aligned} i&=0·0003268\,\frac{v^2}{d} \text{ for new pipes} \\ &=0·0006536\,\frac{v^2}{d} \text{ for incrusted pipes} \end{aligned}\right\} \quad . \quad . \quad . \quad (5a).$$

Problem 4. Given the virtual slope and the velocity, to find the diameter of the pipe and the discharge. The diameter is obtained from equations (2) and (1), which give the quadratic expression

$$d^2-d\,\frac{2\alpha v^2}{gi}-\frac{\alpha v^2}{6gi}=0\,.$$

$$\therefore\quad d=\frac{\alpha v^2}{gi}+\sqrt{\left\{\frac{\alpha v^2}{gi}\left(\frac{\alpha v^2}{gi}+\frac{1}{6}\right)\right\}} \quad . \quad . \quad . \quad . \quad (6).$$

For practical purposes, the approximate equations

$$d=\frac{2\alpha v^2}{gi}+\frac{1}{12} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6a)$$

$$=0·00031\,\frac{v^2}{i}+·083 \text{ for new pipes}$$

$$=0·00062\,\frac{v^2}{i}+·083 \text{ for incrusted pipes}$$

are sufficiently accurate.

Problem 5. Given the virtual slope and the discharge, to find the diameter of the pipe and velocity of flow. This case, which often occurs in designing, is the one which is least easy of direct solution. From equations (2) and (3) we get—

$$d^5=\frac{32\zeta Q^2}{g\pi^2 i} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

If now the value of ζ in (1) is introduced, the equation becomes very cumbrous. Various approximate methods of meeting the difficulty may be used.

(*a*) Taking the mean values of ζ given above for pipes of 1 to 4 feet diameter we get

$$d=\sqrt[5]{\frac{32\zeta}{g\pi^2}}\sqrt[5]{\frac{Q^2}{i}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

$$=0·2216\sqrt[5]{\frac{Q^2}{i}} \text{ for new pipes}$$

$$=0·2541\sqrt[5]{\frac{Q^2}{i}} \text{ for incrusted pipes ;}$$

equations which are interesting as showing that when the value of ζ is doubled the diameter of pipe for a given discharge is only increased by 13 per cent.

(*b*) A second method is to obtain a rough value of d by assuming $\zeta=\alpha$. This value is

$$d'=\sqrt[5]{\frac{32Q^2}{g\pi^2 i}}\sqrt[5]{\alpha}=0·6319\sqrt[5]{\frac{Q^2}{i}}\sqrt[5]{\alpha}\,.$$

Then a very approximate value of ζ is

$$\zeta'=\alpha\left(1+\frac{1}{12d'}\right);$$

and a revised value of d, not sensibly differing from the exact value, is

$$d''=\sqrt[5]{\frac{32Q^2}{g\pi^2 i}}\sqrt[6]{\zeta'}=0·6319\sqrt[5]{\frac{Q^2}{i}}\sqrt[5]{\zeta'}\,.$$

(*c*) Equation 7 may be put in the form

$$d=\sqrt[5]{\frac{32\alpha Q^2}{g\pi^2 i}}\left(1+\frac{1}{12d}\right)^{\frac{1}{5}} \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Expanding the term in brackets,

$$\left(1+\frac{1}{12d}\right)^{\frac{1}{5}}=1+\frac{1}{60d}-\frac{1}{1800d^2}\ \cdots\cdots$$

Neglecting the terms after the second,

$$d=\sqrt[5]{\frac{32a}{g\pi^2}}\sqrt[5]{\frac{Q^2}{i}}\left(1+\frac{1}{60d}\right)$$

$$=\sqrt[5]{\frac{32a}{g\pi^2}}\sqrt[5]{\frac{Q^2}{i}}+0\cdot01667\quad . \quad . \quad . \quad . \quad (9a);$$

and

$$\sqrt[5]{\frac{32a}{g\pi^2}}=0\cdot219 \text{ for new pipes}$$

$$=0\cdot252 \text{ for incrusted pipes.}$$

79. *Arrangement of a Pipe Network for Town's Supply.*—Excluding the service pipes which directly supply the houses, the smallest branch water mains are made 3 to 4 inches in diameter. For the smallest districts supplied, these are sufficient or more than sufficient to convey the necessary supply, and in that case the only question arising is, to lay them out so that their total length is as small as possible.

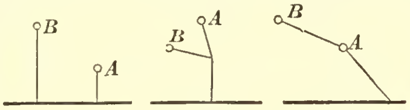

Fig. 95.

Thus if there are two places of consumption A and B there is choice of any of the three arrangements shown in fig 95, the principal main being shown by the dark line, and the branch mains by the thinner ones. If, however, the supply through the branch mains requires pipes of more than the minimum diameter, then the condition to be fulfilled is that the sum of the products of the lengths and diameters should be a minimum, because the cost of the mains when laid in place is very approximately proportional to their length and diameter.

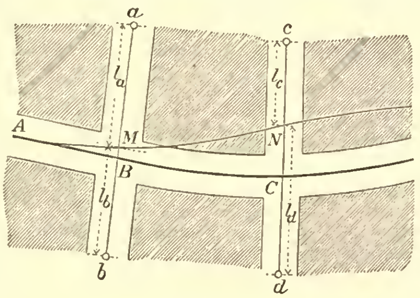

Fig. 96.

For a main delivering water to branch mains on each side, the best position is that which makes the branch mains of equal diameter. Suppose water is to be supplied from an intermediate main along branch mains to a and b (fig. 96). Let Q_a, Q_b be the quantities to be delivered at a and b, and $\mathfrak{h}_a$, $\mathfrak{h}_b$ the virtual fall of the two branch mains. Then, according to Dupuit, the best position for the intersection M is that for which

$$\frac{l_a}{l_b}=\frac{\mathfrak{h}_a Q_b^2}{\mathfrak{h}_b Q_a^2};$$

or, if the consumption of water occurs uniformly throughout the length of the branch mains, then

$$\frac{l_a}{l_b}=\sqrt[3]{\frac{\mathfrak{h}_a}{\mathfrak{h}_b}}.$$

In this way various points MN may be determined giving the position AMN for the main, and afterwards the nearest convenient position ABC may be fixed.

In determining the consumption of water Q for any given locality, the mode of supply must be taken into account. On the intermittent system, water is supplied for a period of t seconds daily. Then the discharge per second is $\frac{NQ_d}{t}$, where N is the number of inhabitants, and Q_d the daily supply to each in cubic feet. With a constant supply the rate of flow is variable at different periods of the day, and the maximum rate of flow may be taken at 2·1 times the mean rate. Hence in this case the discharge to be provided for in the mains is $\frac{2\cdot1NQ_d}{24\times60\times60}$. The daily supply to a district NQ_d is sometimes taken proportional to the area supplied, sometimes to the length of house frontage in the district.

Determination of the Diameters of Different Parts of a Water Main.

When the plan of the arrangement of mains is determined upon, and the supply to each locality and the pressure required is ascertained, it remains to determine the diameters of the pipes. Let fig. 97 show an elevation of a main ABCD . . ., R being the reservoir from which the supply is derived. Let NN be the datum line of the levelling operations, and H_a, H_b . . . the heights of the main above the datum line, H_r being the height of the water surface in the reservoir from the same datum. Set up next heights AA_1, BB_1, . . . representing the minimum pressure height necessary for the adequate supply of each locality. Then $A_1B_1C_1D_1$ . . . is a line which should form a lower limit to the line of virtual slope. Then if heights $\mathfrak{h}_a$, $\mathfrak{h}_b$, $\mathfrak{h}_c$ . . . are taken representing the actual losses of head in each length l_a, l_b, l_c . . . of the main, $A_0B_0C_0$ will be the line of virtual slope, and it will be obvious at what points such as D_0 and E_0, the pressure is deficient, and a different choice of diameter of main is required. For any point z in the length of the main, we have

$$\text{Pressure height}=H_r-H_z-(\mathfrak{h}_a+\mathfrak{h}_b+\ .\ .\ .\ .\ .\ .\ \mathfrak{h}_z).$$

Where no other circumstance limits the loss of head to be assigned to a given length of main, a consideration of the safety of the main from fracture by hydraulic shock leads to a limitation of the velocity of flow. Generally the velocity in water mains lies between $1\frac{1}{2}$ and $4\frac{1}{2}$ feet per second. Occasionally the velocity in pipes reaches 10 feet per second, and in hydraulic machinery working under enormous pressures even 20 feet per second. Usually the velocity diminishes along the main as the discharge diminishes, so as to reduce somewhat the total loss of head which is liable to render the pressure insufficient at the end of the main.

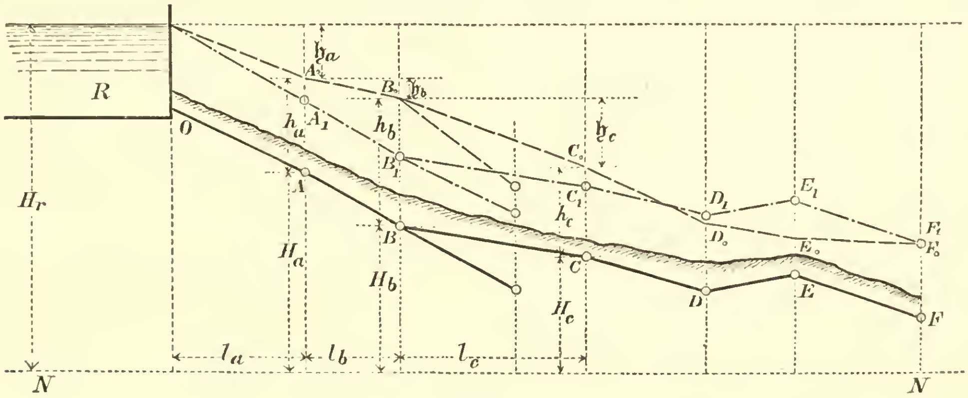

Fig. 97.

Mr Fanning gives the following velocities as suitable in pipes for towns' supply:—

Diameter in inches	4	8	12	18	24	30	36
Velocity in feet per sec. ...	2·5	3·0	3·5	4·5	5·3	6·2	7·0

80. *Branched Pipe connecting Reservoirs at Different Levels.*—Let A, B, C (fig. 98) be three reservoirs connected by the arrangement of pipes shown,—l_1, d_1, Q_1, v_1; l_2, d_2, Q_2, v_2; l_3, d_3, Q_3, v_3 being the length, diameter, discharge, and velocity in the three portions of the main pipe. Suppose the dimensions and positions of the pipes known and the discharges required.

If a pressure column is introduced at X, the water will rise to a height XR, measuring the pressure at X, and aR, Rb, Rc will be the lines of virtual slope. If the free surface level at R is above b, the reservoir A supplies B and C, and if R is below b, A and B supply C. Consequently there are three cases:—

I. R above b; $Q_1=Q_2+Q_3$.
II. R level with b; $Q_1=Q_3$; $Q_2=0$.
III. R below b; $Q_1+Q_2=Q_3$.

To determine which case has to be dealt with in the given conditions, suppose the pipe from X to B closed by a sluice. Then there is a simple main, and the height of free surface h' at X can be determined. For this condition

$$h_a - h' = \zeta \frac{v_1^2}{2g} \cdot \frac{4l_1}{d_1} = \frac{32\zeta Q'^2 l_1}{g\pi^2 d_1^5} ;$$

$$h' - h_c = \zeta \frac{v_3^2}{2g} \cdot \frac{4l_3}{d_3} = \frac{32\zeta Q'^2 l_3}{g\pi^2 d_3^5} ;$$

where Q′ is the common discharge of the two portions of the pipe. Hence

$$\frac{h_a - h'}{h' - h_c} = \frac{l_1 d_3^5}{l_3 d_1^5} ,$$

from which h' is easily obtained. If then h' is greater than hb, opening the sluice between X and B will allow flow towards B, and the case in hand is case I. If h' is less than h_b, opening the sluice will allow flow from B, and the case is case III. If $h' = h_b$, the case is case II., and is already completely solved.

The true value of h must lie between h' and h_b. Choose a new value of h, and recalculate Q_1, Q_2, Q_3. Then if

$$Q_1 > Q_2 + Q_3 \text{ in case I.,}$$

or

$$Q_1 + Q_2 > Q_3 \text{ in case III.,}$$

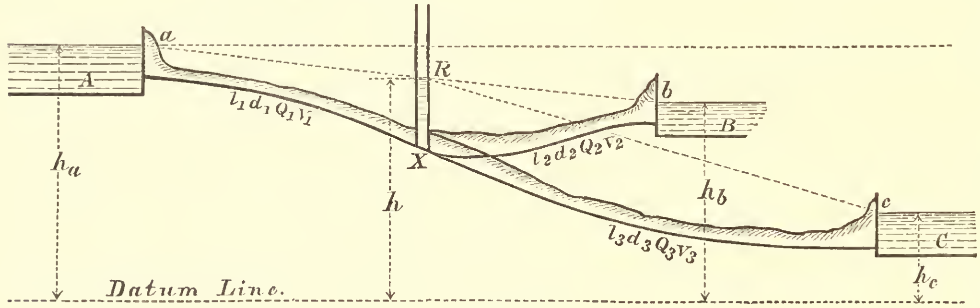

Fig. 98.

the value chosen for h is too small, and a new value must be chosen If

$$Q_1 < Q_2 + Q_3 \text{ in case I.,}$$

or

$$Q_1 + Q_2 < Q_3 \text{ in case III.,}$$

the value of h is too great.

Since the limits between which h can vary are in practical cases not very distant, it is easy to approximate to values sufficiently accurate.

IX. FLOW OF COMPRESSIBLE FLUIDS IN PIPES.

81. *Flow of Air in Long Pipes.*[1]—When air flows through a long pipe, by far the greater part of the work expended is used in overcoming frictional resistances due to the surface of the pipe. The work expended in friction generates heat, which for the most part must be developed in and given back to the air. Some heat may be transmitted through the sides of the pipe to surrounding materials, but in experiments hitherto made the amount so conducted away appears to be very small, and if no heat is transmitted the air in the tube must remain sensibly at the same temperature during expansion. In other words, the expansion may be regarded as isothermal expansion, the heat generated by friction exactly neutralizing the cooling due to the work done. Experiments on the pneumatic tubes used for the transmission of messages, by Messrs Culley & Sabine, show that the change of temperature of the air flowing along the tube is much less than it would be in adiabatic expansion.

82. *Differential Equation of the Steady Motion of Air Flowing in a Long Pipe of Uniform Section.*—When air expands at a constant absolute temperature τ, the relation between the pressure p in pounds per square foot and the density or weight per cubic foot G is given by the equation

$$\frac{p}{G} = c\tau \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where $c = 53{\cdot}15$. Taking $\tau = 521$, corresponding to a temperature of 60° Fahr.,

$$c\tau = 27690 \text{ foot-pounds} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

The equation of continuity, which expresses the condition that in steady motion the same weight of fluid, W, must pass through each cross section of the stream in the unit of time, is

$$G\Omega u = W = \text{constant} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

where Ω is the section of the pipe and u the velocity of the air. Combining (1) and (3),

$$\frac{\Omega u p}{W} = c\tau = \text{constant} \quad . \quad . \quad . \quad . \quad (3a).$$

[1] This investigation was first given in the *Proc Inst. of Civil Engineers*, vol. xliii.

Since the work done by gravity on the air during its flow through a pipe due to variations of its level is generally small compared with the work done by changes of pressure, the former may in many cases be neglected.

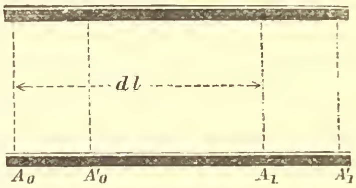

Fig. 99.

Consider a short length dl of the pipe limited by sections A_0, A_1 at a distance dl (fig. 99). Let p, u be the pressure and velocity at A_0, $p + dp$ and $u + du$ those at A_1. Further, suppose that in a very short time dt the mass of air between A_0A_1 comes to $A'_0A'_1$ so that $A_0A'_0 = udt$ and $A_1A'_1 = (u + du)dt$. Let Ω be the section, and m the hydraulic mean radius of the pipe, and W the weight of air flowing through the pipe per second.

From the steadiness of the motion the weight of air between the sections $A_0A'_0$, and $A_1A'_1$ is the same. That is,

$$Wdt = G\Omega u dt = G\Omega(u + du)dt .$$

By analogy with liquids the head lost in friction is, for the length dl (see § 69, eq. 3),

$$\zeta \frac{u^2}{2g} \cdot \frac{dl}{m} .$$

Let $H = \frac{u^2}{2g}$. Then the head lost is

$$\zeta \frac{H}{m} dl ;$$

and, since Wdt pounds of air flow through the pipe in the time considered, the work expended in friction is

$$-\zeta \frac{H}{m} W dl\, dt .$$

The change of kinetic energy in dt seconds is the difference of the kinetic energy of $A_0A'_0$ and $A_1A'_1$, that is,

$$\frac{W}{g} dt \frac{(u + du)^2 - u^2}{2}$$

$$= \frac{W}{g} u du dt = W dH dt .$$

The work of expansion when $\Omega u dt$ cubic feet of air at a pressure p expand to $\Omega(u + du)dt$ cubic feet is

$$\Omega\, p du dt .$$

But from (3a)

$$u = \frac{c\tau W}{\Omega p} ,$$

$$\therefore \quad \frac{du}{dp} = -\frac{c\tau W}{\Omega p^2} .$$

And the work done by expansion is

$$-\frac{c\tau W}{p} dp dt .$$

The work done by gravity on the mass between A_0 and A_1 is zero if the pipe is horizontal, and may in other cases be neglected without great error. The work of the pressures at the sections A_0A_1 is

$$p\Omega u dt - (p + dp)\Omega(u + du)dt$$
$$= -(pdu + udp)\Omega dt .$$

But from (3a)

$$pu = \text{constant} ,$$
$$pdu + udp = 0 ,$$

and the work of the pressures is zero. Adding together the quantities of work, and equating them to the change of kinetic energy,

$$W dH dt = -\frac{c\tau W}{p} dp dt - \zeta \frac{H}{m} W dl dt$$

$$dH + \frac{c\tau}{p} dp + \zeta \frac{H}{m} dl = 0 ,$$

$$\frac{dH}{H} + \frac{c\tau}{Hp} dp + \zeta \frac{dl}{m} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

But

$$u = \frac{c\tau W}{\Omega p} ,$$

and

$$H = \frac{u^2}{2g} = \frac{c^2\tau^2 W^2}{2g\Omega^2 p^2} ,$$

$$\therefore \quad \frac{dH}{H} + \frac{2g\Omega^2 p}{c\tau W^2} dp + \zeta \frac{dl}{m} = 0 \quad . \quad . \quad . \quad . \quad (4a).$$

For tubes of uniform section m is constant; for steady motion W is constant; and for isothermal expansion τ is constant. Integrating,

$$\log \mathrm{H} + \frac{g\Omega^2 p^2}{\mathrm{W}^2 c\tau} + \zeta \frac{l}{m} = \text{constant} \quad . \quad . \quad . \quad . \quad (5);$$

for $\quad l=0$, let $\mathrm{H}=\mathrm{H}_0$, and $p=p_0$;

and for $\quad l=l$, let $\mathrm{H}=\mathrm{H}_1$, and $p=p_1$.

$$\log \frac{\mathrm{H}_1}{\mathrm{H}_0} + \frac{g\Omega^2}{\mathrm{W}^2 c\tau}(p_1^2 - p_0^2) + \zeta \frac{l}{m} = 0 \quad . \quad . \quad . \quad (5a),$$

where p_0 is the greater pressure and p_1 the less, and the flow is from A_0 towards A_1.

By replacing W and H,

$$\log \frac{p_0}{p_1} + \frac{gc\tau}{u_0^2 p_0^2}(p_1^2 - p_0^2) + \zeta \frac{l}{m} = 0 \quad . \quad . \quad . \quad (6).$$

Hence the initial velocity in the pipe is

$$u_0 = \sqrt{\left\{ \frac{gc\tau(p_0^2 - p_1^2)}{p_0^2\left(\zeta \frac{l}{m} + \log \frac{p_0}{p_1}\right)} \right\}} \quad . \quad . \quad . \quad . \quad (7).$$

When l is great, $\log \frac{p_0}{p_1}$ is comparatively small, and then

$$u_0 = \sqrt{\left\{ \frac{gc\tau m}{\zeta l} \frac{p_0^2 - p_1^2}{p_0^2} \right\}} \quad . \quad . \quad . \quad . \quad (7a),$$

a very simple and easily used expression. For pipes of circular section $m = \frac{d}{4}$, where d is the diameter:—

$$u_0 = \sqrt{\left\{ \frac{gc\tau d}{4\zeta l} \frac{p_0^2 - p_1^2}{p_0^2} \right\}} \quad . \quad . \quad . \quad . \quad (7b);$$

or approximately

$$u_0 = \left(1{\cdot}1319 - 0{\cdot}7264 \frac{p_1}{p_0}\right) \sqrt{\frac{gc\tau d}{4\zeta l}} \quad . \quad . \quad . \quad (7c).$$

83. *Coefficient of Friction for Air.*—A discussion by Professor Unwin of the experiments by Messrs Culley & Sabine on the rate of transmission of light carriers through pneumatic tubes, in which there is steady flow of air not sensibly affected by any resistances other than surface friction, furnished the value $\zeta = {\cdot}007$. The pipes were lead pipes, slightly moist, $2\frac{1}{4}$ inches (0·187 ft.) in diameter, and in lengths of 2000 to nearly 6000 feet.

Some experiments on the flow of air through cast-iron pipes have been made by M. Arson. He found the coefficient of friction to vary with the velocity and diameter of the pipe. Putting

$$\zeta = \frac{\alpha}{v} + \beta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

he obtained the following values—

Diameter of Pipe in Feet.	α	β	ζ for 100 feet per second.
1·64	·00129	·00483	·00484
1·07	·00972	·00640	·00650
·83	·01525	·00704	·00719
·338	·03604	·00941	·00977
·266	·03790	·00959	·00997
·164	·04518	·01167	·01212

It is worth while to try if these numbers can be expressed in the form proposed by Darcy for water. For a velocity of 100 feet per second, and without much error for higher velocities, these numbers agree fairly with the formula

$$\zeta = {\cdot}005\left(1 + \frac{3}{10d}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (9),$$

which only differs from Darcy's value for water in that the second term, which is always small except for very small pipes, is larger.

Some more recent experiments on a very large scale, by M. Stockalper at the St Gotthard Tunnel, agree better with the value

$$\zeta = 0{\cdot}0028\left(1 + \frac{3}{10d}\right).$$

These pipes were probably less rough than M. Arson's.

When the variation of pressure is very small, it is no longer safe to neglect the variation of level of the pipe. For that case we may neglect the work done by expansion, and then

$$z_0 - z_1 - \frac{p_0}{\mathrm{G}_0} - \frac{p_1}{\mathrm{G}_1} - \zeta \frac{v^2}{2g} \frac{l}{m} = 0 \quad . \quad . \quad . \quad . \quad (10),$$

precisely equivalent to the equation for the flow of water, z_0 and z_1 being the elevations of the two ends of the pipe above any datum, p_0 and p_1 the pressures, G_0 and G_1 the densities, and v the mean velocity in the pipe. This equation may be used for the flow of coal gas.

84. *Distribution of Pressure in a Pipe in which Air is Flowing.*—From equation (7a) it results that the pressure p, at l feet from that end of the pipe where the pressure is p_0, is

$$p = p_0 \sqrt{\left\{ 1 - \frac{\zeta l u_0^2}{mgc\tau} \right\}} \quad . \quad . \quad . \quad . \quad . \quad (11);$$

which is of the form

$$p = \sqrt{al + b}$$

for any given pipe with given end pressures. The curve of free surface level for the pipe is, therefore, a parabola with horizontal axis. Fig. 100 shows calculated curves of pressure for two of Mr Sabine's

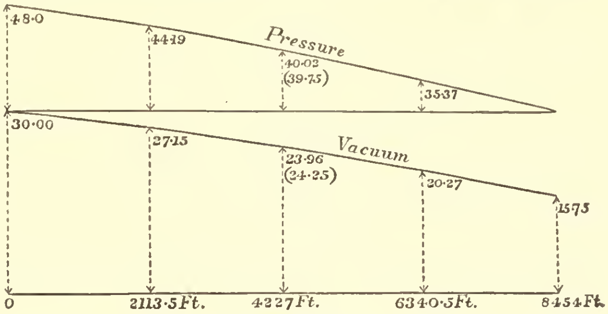

Fig. 100.

experiments, in one of which the pressure was greater than atmospheric pressure, and in the other less than atmospheric pressure. The observed pressures are given in brackets and the calculated pressures without brackets. The pipe was the pneumatic tube between Fenchurch Street and the Central Station, 2818 yards in length. The pressures are given in inches of mercury.

Variation of Velocity in the Pipe.—Let p_0, u_0 be the pressure and velocity at a given section of the pipe; p, u, the pressure and velocity at any other section. From equation (3a)

$$u\,p = \frac{c\tau \mathrm{W}}{\Omega} = \text{constant};$$

so that, for any given uniform pipe,

$$u\,p = u_0 p_0,$$

$$u = u_0 \frac{p_0}{p} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12);$$

which gives the velocity at any section in terms of the pressure, which has already been determined. Fig. 101 gives the velocity

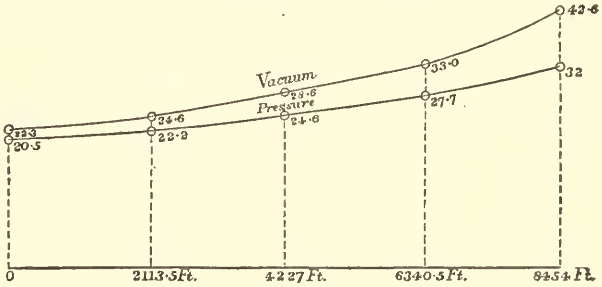

Fig. 101.

curves for the two experiments of Messrs Culley & Sabine, for which the pressure curves have already been drawn. It will be seen that the velocity increases considerably towards that end of the pipe where the pressure is least.

85. *Weight of Air Flowing per Second.*—The weight of air discharged per second is (equation 3a)—

$$\mathrm{W} = \frac{\Omega u_0 p_0}{c\tau}.$$

From equation (7b), for a pipe of circular section and diameter d,

$$\mathrm{W} = \frac{\pi}{4} \sqrt{\left\{ \frac{gd^5}{\zeta l c\tau}(p_0^2 - p_1^2) \right\}},$$

$$= {\cdot}611 \sqrt{\left\{ \frac{d^5}{\zeta l\tau}(p_0^2 - p_1^2) \right\}} \quad . \quad . \quad . \quad . \quad (13).$$

Approximately

$$\mathrm{W} = ({\cdot}6916 p_0 - {\cdot}4438 p_1)\left(\frac{d^5}{\zeta l\tau}\right)^{\frac{1}{2}} \quad . \quad . \quad . \quad . \quad (13a).$$

86. *Application to the Case of Pneumatic Tubes for the Transmission of Messages.*—In Paris, Berlin, London, and other towns, it has been found cheaper to transmit messages in pneumatic tubes than to telegraph by electricity. The tubes are laid underground with easy curves; the messages are made into a roll and placed in

a light felt carrier, the resistance of which in the tubes in London is only ¾ oz. A current of air forced into the tube or drawn through it propels the carrier. In most systems the current of air is steady and continuous, and the carriers are introduced or removed without materially altering the flow of air.

Time of Transit through the Tube.—Putting t for the time of transit from 0 to l,

$$t=\int_0^l \frac{dl}{u},$$

From (4*a*) neglecting $\frac{dH}{H}$, and putting $m=\frac{d}{4}$,

$$dl=\frac{gd\Omega^2 p}{2\zeta W^2 c\tau}dp\,.$$

From (1) and (3)

$$u=\frac{Wc\tau}{p\Omega};$$

$$\frac{dl}{u}=\frac{gd\Omega^3 p^2}{2\zeta W^3 c^2\tau^2}dp;$$

$$t=\int_{p_1}^{p_0}\frac{gd\Omega^3 p^2}{2\zeta W^3 c^2\tau^2}dp,$$

$$=\frac{gd\Omega^3}{6\zeta W^3 c^2\tau^2}(p_0^3-p_1^3) \quad . \quad . \quad . \quad . \quad . \quad (14).$$

But

$$W=\frac{p_0 u_0 \Omega}{c\tau};$$

$$\therefore\ t=\frac{1}{6}\,\frac{gdc\tau}{\zeta p_0^3 u_0^3}(p_0^3-p_1^3),$$

$$=\frac{1}{6}\,\frac{\zeta^{\frac12} l^{\frac32}}{(gc\tau d)^{\frac12}}\,\frac{p_0^3-p_1^3}{(p_0^2-p_1^2)^{\frac32}} \quad . \quad . \quad . \quad . \quad (15).$$

If $\tau=521°$, corresponding to 60° F.,

$$t=\cdot001412\frac{\zeta^{\frac12} l^{\frac32}}{d^{\frac12}}\,\frac{p_0^3-p_1^3}{(p_0^2-p_1^2)^{\frac32}} \quad . \quad . \quad . \quad . \quad (15a);$$

which gives the time of transmission in terms of the initial and final pressures and the dimensions of the tube.

Mean Velocity of Transmission.—The mean velocity is $\frac{l}{t}$; or, for $\tau=521°$,

$$u_{\text{mean}}=0\cdot708\sqrt{\left\{\frac{d}{\zeta l}\,\frac{(p_0^2-p_1^2)^{\frac32}}{p_0^3-p_1^3}\right\}} \quad . \quad . \quad . \quad (16).$$

The following table gives some results:—

Absolute Pressures in lb per sq. inch.		Mean Velocities for Tubes of a length in ft.				
p_0	p_1	1000	2000	3000	4000	5000
		Vacuum Working.				
15	5	99·4	70·3	57·4	49·7	44·5
15	10	67·2	47·5	38·8	34·4	30·1
		Pressure Working.				
20	15	57·2	40·5	33·0	28·6	25·6
25	15	74·6	52·7	43·1	37·3	33·3
30	15	84·7	60·0	49·0	42·4	37·9

Limiting Velocity in the Pipe when the Pressure at one End is diminished indefinitely.—If in the last equation there be put $p_1=0$, then

$$u'_{\text{mean}}=0\cdot708\sqrt{\frac{d}{\zeta l}};$$

where the velocity is independent of the pressure p_0 at the other end, a result which apparently must be absurd. Probably for long pipes, as for orifices, there is a limit to the ratio of the initial and terminal pressures for which the formula is applicable.

X. FLOW IN RIVERS AND CANALS.

87. *Flow of Water in Open Canals and Rivers.*—When water flows in a pipe the section at any point is determined by the form of the boundary. When it flows in an open channel with free upper surface, the section depends on the velocity due to the dynamical conditions.

Suppose water admitted to an unfilled canal. The channel will gradually fill, the section and velocity at each point gradually changing. But if the inflow to the canal at its head is constant, the increase of cross section and diminution of velocity at each point attain after a time a limit. Thenceforward the section and velocity at each point are constant, and the motion is steady, or permanent regime is established.

If when the motion is steady the sections of the stream are all equal, the motion is uniform. By hypothesis, the inflow Ωv is constant for all sections, and Ω is constant; therefore v must be constant also from section to section. The case is then one of uniform steady motion. In most artificial channels the form of section is constant, and the bed has a uniform slope. In that case the motion is uniform, the depth is constant, and the stream surface is parallel to the bed. If when steady motion is established the sections are unequal, the motion is steady motion with varying velocity from section to section. Ordinary rivers are in this condition, especially where the flow is modified by weirs or obstructions. Short unobstructed lengths of a river may be treated as of uniform section without great error, the mean section in the length being put for the actual sections.

In all actual streams the different fluid filaments have different velocities, those near the surface and centre moving faster than those near the bottom and sides. The ordinary formulæ for the flow of streams rest on an hypothesis that this variation of velocity may be neglected, and that all the filaments may be treated as having a common velocity equal to the mean velocity of the stream. On this hypothesis, a plane layer *abab* (fig. 102) between sections normal to the direction of motion is treated as sliding down the channel to *a'a'b'b'* without deformation. The component of the weight parallel to the channel bed balances the friction against the channel, and in estimating the friction the velocity of rubbing is taken to be the mean velocity of the stream. In actual streams, however, the velocity of rubbing on which the friction depends is not the mean velocity of the stream, and is not in any simple relation with it, for channels of different forms. The theory is therefore obviously based on an imperfect hypothesis. However, by taking variable values for the coefficient of friction, the errors of the ordinary formulæ are to a great extent neutralized, and they may be used without leading to practical errors. Formulæ have been obtained based on less restricted hypotheses, but at present they are not practically so reliable, and are more complicated than the formulæ obtained in the manner described above.

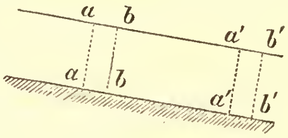

Fig. 102.

88. *Steady Flow of Water with Uniform Velocity in Channels of Constant Section.*—Let *aa'*, *bb'* (fig. 103) be two cross sections normal to the direction of motion at a distance *dl*. Since the mass *aa'bb'* moves uniformly, the external forces acting on it are in equilibrium. Let Ω be the area of the cross sections, χ the wetted perimeter, $pq+qr+rs$, of a section. Then the quantity $m=\frac{\Omega}{\chi}$ is termed the hydraulic mean depth of the section. Let v be the mean velocity of the stream, which is taken as the common velocity of all the particles, i, the slope or fall of the stream in feet, per foot, being the ratio $\frac{bc}{ab}$.

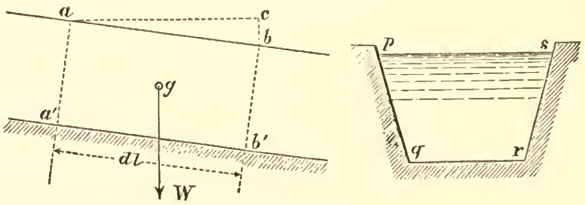

Fig. 103.

The external forces acting on *aa'bb'* parallel to the direction of motion are three:—(*a*) The pressures on *aa'* and *bb'*, which are equal and opposite since the sections are equal and similar, and the mean pressures on each are the same. (*b*) The component of the weight W of the mass in the direction of motion, acting at its centre of gravity *g*. The weight of the mass *aa'bb'* is $G\Omega dl$, and the component of the weight in the direction of motion is $G\Omega dl\times$ the cosine of the angle between W*g* and *ab*, that is, $G\Omega dl \cos abc=G\Omega dl\frac{bc}{ab}=G\Omega i dl$. (*c*) There is the friction of the stream on the sides and bottom of the channel. This is proportional to the area χdl of rubbing surface and to a function of the velocity which may be written $f(v)$; $f(v)$ being the friction per square foot at a velocity v. Hence the friction is $-\chi dl\,f(v)$. Equating the sum of the forces to zero,

$$G\,\Omega\, i\, dl-\chi dl\, f(v)=0\,,$$

$$\frac{f(v)}{G}=\frac{\Omega}{\chi}i=mi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

But it has been already shown (§ 63) that $f(v)=\zeta G\frac{v^2}{2g}$,

$$\therefore\ \zeta\frac{v^2}{2g}=mi\,. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

This may be put in the form

$$v=\sqrt{\frac{2g}{\zeta}}\sqrt{mi}=c\sqrt{mi} \quad . \quad . \quad . \quad . \quad . \quad (2a);$$

where c is a coefficient depending on the roughness and form of the channel.

The coefficient of friction ζ varies greatly with the degree of roughness of the channel sides, and somewhat also with the velocity. It must also be made to depend on the absolute dimensions of the section, to eliminate the error of neglecting the variations of velocity in the cross section. A common mean value assumed for ζ is 0·00757. The range of values will be discussed presently.

It is often convenient to estimate the fall of the stream in feet per mile, instead of in feet per foot. If f is the fall in feet per mile

$$f=5280\ i.$$

Putting this and the above value of ζ in (2a), we get the very simple and long-known approximate formula for the mean velocity of a stream—

$$v=1\tfrac{1}{2}\sqrt{2mf} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The flow down the stream per second, or discharge of the stream, is

$$Q=\Omega v=\Omega c\sqrt{mi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

89. *Coefficient of Friction for Open Channels.*—Various expressions have been proposed for the coefficient of friction for channels as for pipes. Weisbach, giving attention chiefly to the variation of the coefficient of friction with the velocity, proposed an expression of the form

$$\zeta=\alpha\left(1+\frac{\beta}{v}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and from 255 experiments obtained for the constants the values

$$\alpha=0·007409\ ;\ \beta=0·1920.$$

This gives the following values at different velocities:—

$v=$	0·3	0·4	0·5	0·6	0·7	0·8	0·9	1	1½	2	3	5	7	10	15
$\zeta=$	0·01215	0·91907	0·01025	0·00978	0·00944	0·06918	0·00899	0·00883	0·00836	0·00812	0·9C788	0·00769	0·00761	0·00755	0·00750

In using this value of ζ when v is not known, it is best to proceed by approximation. Calculate a rough value of v by taking any mean value of ζ, for instance the one given in the preceding section. Then from this value of v calculate a revised value of ζ, and from this a new value of v.

90. *Darcy & Bazin's Expression for the Coefficient of Friction.*—Darcy & Bazin's researches have shown that ζ varies very greatly for different degrees of roughness of the channel bed, and that it also varies with the dimensions of the channel. They give for ζ an empirical expression (similar to that for pipes) of the form

$$\zeta=\alpha\left(1+\frac{\beta}{m}\right). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6);$$

where m is the hydraulic mean depth. For different kinds of channels they give the following values of the coefficient of friction:—

Kind of Channel.	α	β
I. Very smooth channels, sides of smooth cement or planed timber..................	0·00316	0·1
II. Smooth channels, sides of ashlar, brickwork, planks..................................	0·00401	0·23
III. Rough channels, sides of rubble masonry or pitched with stone	0·00507	0·82
IV. Very rough canals in earth....................	0·00592	4·10
V. Torrential streams encumbered with detritus	0·00846	8·2

The last values (Class V.) are not Darcy & Bazin's, but are taken from experiments by Ganguillet & Kutter on Swiss streams.

The following table very much facilitates the calculation of the mean velocity and discharge of channels, when Darcy & Bazin's value of the coefficient of friction is used. Taking the general formula for the mean velocity already given in equation (2a) above,

$$v=c\sqrt{mi},$$

where $c=\sqrt{\frac{2g}{\zeta}}$, the following table gives values of c for channels of different degrees of roughness, and for such values of the hydraulic mean depths as are likely to occur in practical calculations:—

Values of c *in* $v=c\sqrt{mi}$, *deduced from Darcy & Bazin's Values.*

Hydraulic Mean Depth $=m$.	Very Smooth Channels. Cement.	Smooth Channels. Ashlar or Brickwork.	Rough Channels. Rubble Masonry.	Very Rough Channels. Canals in Earth.	Excessively Rough Channels encumbered with Detritus.	Hydraulic Mean Depth $=m$.	Very Smooth Channels. Cement.	Smooth Channels. Ashlar or Brickwork.	Rough Channels. Rubble Masonry. 91. *Ganguillet & Kutter's modified Darcy Formula.*—Starting from the general expression $v=c\sqrt{mi}$, Messrs Ganguillet & Kutter have examined the variations of c for a wider variety of cases than those discussed by Darcy & Bazin. Darcy & Bazin's experiments are confined to channels of moderate section, and to a limited variation of slope. Ganguillet & Kutter brought into the discussion two very distinct and important additional series of results. The gaugings of the Mississippi by Messrs Humphreys & Abbot afford data of discharge for the case of a stream of exceptionally large section and of very low slope. On the other hand, their own measurements of the flow in the regulated channels of some Swiss torrents gave data for cases in which the inclination and roughness of the channels were exceptionally great. Darcy & Bazin's experiments alone were conclusive as to the dependence of the coefficient c on the dimensions of the channel and on its roughness of surface. Plotting values of c for channels of different inclination indicated to Ganguillet & Kutter that it also depended on the slope of the stream. Taking the Mississippi data only, they found

c = 256 for an inclination of 0·0034 per thousand,
= 154 ,, ,, 0·02 ,,

so that for very low inclinations no constant value of c independent of the slope would furnish good values of the discharge. In small rivers, on the other hand, the values of c vary little with the slope. As regards the influence of roughness of the sides of the channel a different law holds. For very small channels differences of roughness have a great influence on the discharge, but for very large channels different degrees of roughness have but little influence, and for indefinitely large channels the influence of different degrees of roughness must be assumed to vanish. The coefficients given by Darcy & Bazin are different for each of the classes of channels of different roughness, even when the dimensions of the channel are infinite. But, as it is much more probable that the influence of the nature of the sides diminishes indefinitely as the channel is larger, this must be regarded as a defect in their formula.

Comparing their own measurements in torrential streams in Switzerland with those of Darcy & Bazin, Ganguillet & Kutter found that the four classes of coefficients proposed by Darcy & Bazin were insufficient to cover all cases. Some of the Swiss streams gave results which showed that the roughness of the bed was markedly greater than in any of the channels tried by the French engineers. It was necessary therefore in adopting the plan of arranging the different channels in classes of approximately similar roughness to increase the number of classes. Especially an additional class was required for channels obstructed by detritus.

To obtain a new expression for the coefficient in the formula

$$v=\sqrt{\frac{2g}{\zeta}}\sqrt{mi}=c\sqrt{mi},$$

in which Darcy & Bazin take

$$c=\sqrt{\frac{2g}{\alpha\left(1+\frac{\beta}{m}\right)}},$$

Ganguillet & Kutter proceeded in a purely empirical way. They found that an expression of the form

$$c=\frac{a}{1+\frac{\beta}{\sqrt{m}}}$$

could be made to fit the experiments somewhat better than Darcy's expression. Inverting this, we get

$$\frac{1}{c}=\frac{1}{a}+\frac{\beta}{a\sqrt{m}},$$

an equation to a straight line having $\frac{1}{\sqrt{m}}$ for abscissa, $\frac{1}{c}$ for ordinate, and inclined to the axis of abscissæ at an angle the tangent of which is $\frac{\beta}{\alpha}$.

Plotting the experimental values of $\frac{1}{c}$ and $\frac{1}{\sqrt{m}}$, the points so found indicated a curved rather than a straight line, so that β must depend on α. After much comparison the following form was arrived at—

$$c=\frac{\mathrm{A}+\frac{l}{n}}{1+\frac{\mathrm{A}n}{\sqrt{m}}},$$

where n is a coefficient depending only on the roughness of the sides of the channel, and A and l are new coefficients, the value of which remains to be determined. From what has been already stated, the coefficient c depends on the inclination of the stream, decreasing as the slope i increases.

Let $$\mathrm{A}=a+\frac{p}{i}.$$

Then $$c=\frac{a+\frac{l}{n}+\frac{p}{i}}{1+\left(a+\frac{p}{i}\right)\frac{n}{\sqrt{m}}},$$

the form of the expression for c ultimately adopted by Ganguillet & Kutter.

For the constants a, l, p Ganguillet & Kutter obtain the values 23, 1, and 0·00155 for metrical measures, or 41·6, 1·811, and 0·00281 for English feet. The coefficient of roughness n is found to vary from 0·008 to 0·050 for either metrical or English measures.

The most practically useful values of the coefficient of roughness n are given in the following table:—

Nature of Sides of Channel.	Coefficient of Roughness n.
Well-planed timber	0·009
Cement plaster	0·010
Plaster of cement with one-third sand	0·011
Unplaned planks	0·012
Ashlar and brickwork	0·013
Canvass on frames	0·015
Rubble masonry	0·017
Canals in very firm gravel	0·020
Rivers and canals in perfect order, free from stones or weeds	0·025
Rivers and canals in moderately good order, not quite free from stones and weeds	0·030
Rivers and canals in bad order, with weeds and detritus	0·035
Torrential streams encumbered with detritus	0·050

Ganguillet & Kutter's formula is so cumbrous that it is difficult to use without the aid of tables.

Mr Lowis D'A. Jackson has published complete and extensive tables for facilitating the use of the Ganguillet & Kutter formula (*Canal and Culvert Tables*, London, 1878). To lessen calculation he puts the formula in this form:—

$$\mathrm{M}=n\left(41{\cdot}6+\frac{0{\cdot}00281}{i}\right);$$

$$v=\frac{\sqrt{m}}{n}\left(\frac{\mathrm{M}+1{\cdot}811}{\mathrm{M}+\sqrt{m}}\right)\sqrt{mi}.$$

The following table gives a selection of values of M, taken from Mr Jackson's tables:—

	Values of M for n =						
	0·010	0·012	0·015	0·017	0·020	0·025	0·030
·00001	3·2260	3·8712	4·8390	5·4842	6·4520	8·0650	9·6780
·00002	1·8210	2·1852	2·7315	3·0957	3·6120	4·5525	5·4630
·00004	1·1185	1·3422	1·6777	1·9011	2·2370	2·7962	3·3555
·00006	0·8843	1·0612	1·3264	1·5033	1·7686	2·2107	2·6529
·00008	0·7672	0·9206	1·1508	1·3042	1·5344	1·9180	2·3016
·00010	0·6970	0·8364	1·0455	1·1849	1·3940	1·7425	2·0910
·00025	0·5284	0·6341	0·7926	0·8983	1·0568	1·3210	1·5852
·00050	0·4722	0·5666	0·7083	0·8027	0·9444	1·1805	1·4166
·00075	0·4535	0·5442	0·6802	0·7709	0·9070	1·1337	1·3605
·00100	0·4441	0·5329	0·6661	0·7550	0·8882	1·1102	1·3323
·00200	0·4300	0·5160	0·6450	0·7310	0·8600	1·0750	1·2900
·00300	0·4254	0·5105	0·6381	0·7232	0·8508	1·0635	1·2762

One principal difficulty in the use of this formula is the selection of the coefficient of roughness. The difficulty is one which no theory will overcome, because no absolute measure of the roughness of stream beds is possible. For channels lined with timber or masonry the difficulty is not so great. The constants in that case are few and sufficiently defined. But in the case of ordinary canals and rivers the case is different, the coefficients having a much greater range. For artificial canals in rammed earth or gravel n varies from 0·0163 to 0·0301. For natural channels or rivers n varies from 0·020 to 0·035.

In Mr Jackson's opinion even Kutter's numerous classes of channels seem inadequately graduated, and after careful examination he proposes for artificial canals the following classification:—

I.	Canals in very firm gravel, in perfect order	$n=0{\cdot}02$
II.	Canals in earth, above the average in order	$n=0{\cdot}0225$
III.	Canals in earth, in fair order	$n=0{\cdot}025$
IV.	Canals in earth, below the average in order	$n=0{\cdot}0275$
V.	Canals in earth, in rather bad order, partially overgrown with weeds and obstructed by detritus	$n=0{\cdot}03$

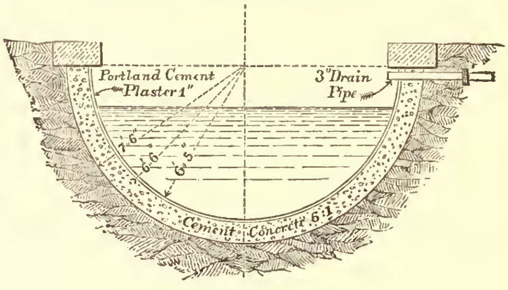

Fig 104.

92. *Forms of Section of Channels.*—The simplest form of section for channels is the semicircular or nearly semicircular channel (fig. 104), a form now often adopted from the facility with which it can be

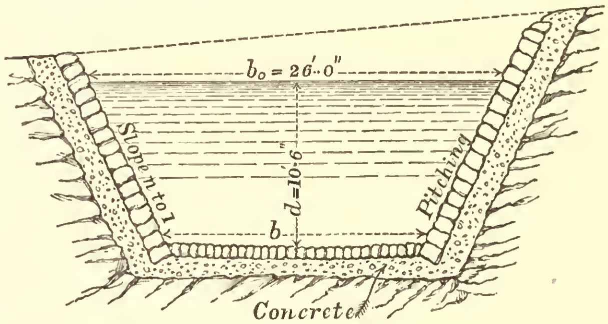

Fig. 105.

executed in concrete. It has the advantage that the rubbing surface is less in proportion to the area than in any other form.

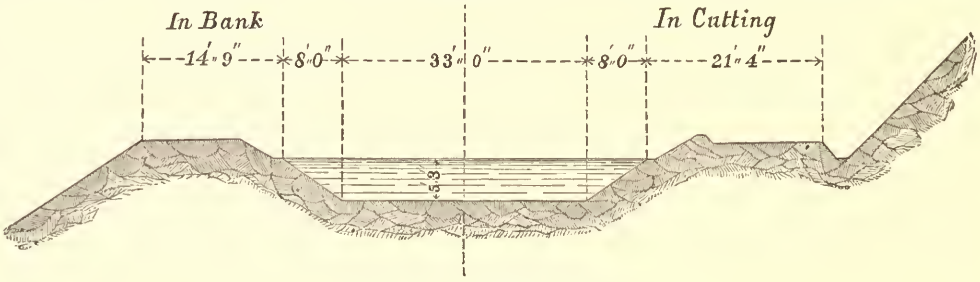

Fig. 106.—Scale 20 feet = 1 inch.

Wooden channels or flumes, of which there are examples on a large scale in America, are rectangular in section, and the same form is adopted for wrought and cast-iron aqueducts. Channels built with brickwork or masonry may be also rectangular, but they are often trapezoidal, and are always so if the sides are pitched with masonry laid dry. In a trapezoidal channel, let b (fig. 105) be the bottom breadth, b_0 the top breadth, d the depth, and let the slope of the sides be n horizontal to 1 vertical. Then the area of section is $\Omega=(b+nd)d=(b_0-nd)d$, and the wetted perimeter $\chi=b+2d\sqrt{n^2+1}$.

When a channel is simply excavated in earth it is always originally trapezoidal, though it becomes more or less rounded in course of time. The slope of the sides then depends on the stability of the earth, a slope of 2 to 1 being the one most commonly adopted.

Figs. 106, 107 show the form of canals excavated in earth, the former being the section of a Navigation Canal and the latter the section of an Irrigation Canal.

93. *Channels of Circular Section.*—The following short table facilitates calculations of the discharge with different depths of water in the channel. Let r be the radius of the channel section; then for a depth of water $=\kappa r$, the hydraulic mean radius is μr and the area of section of the waterway νr^2, where κ, μ, and ν have the following values:—

Depth of water in terms of radius	$\kappa=$	·01	·05	·10	·15	·20	·25	·30	·35	·40	·45	·50	·55	·60	·65	·70	·75	·8	·85	·9	·95	1·0
Hydraulic mean depth in terms of radius ...	$\mu=$	·00668	·0321	·0523	·0963	·1278	·1574	·1852	·2142	242	·269	·293	·320	·343	·365	·387	·408	·429	·449	·466	·484	·500
Waterway in terms of square of radius......	$\nu=$	00189	·0211	·0598	·1067	·1651	·228	·294	·370	·450	·532	614	·709	·795	885	·979	1·075	1·175	1·276	1·371	1·470	1·571

94. *Egg-Shaped Channels or Sewers.*—In sewers for discharging storm water and house drainage the volume of flow is extremely variable; and there is a great liability for deposits to be left when the flow is small, which are not removed during the short periods when the flow is large. The sewer in consequence becomes choked. To

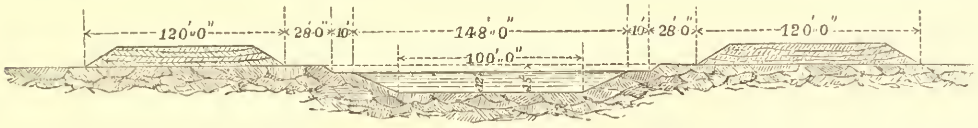

FIG. 107.—Scale 80 feet = 1 inch.

obtain uniform scouring action, the velocity of flow should be constant or nearly so; a complete uniformity of velocity cannot be obtained with any form of section suitable for sewers, but an approximation to uniform velocity is obtained by making the sewers of oval section. Various forms of oval have been suggested, the simplest being one in which the radius of the crown is double the radius of the invert, and the greatest width is two-thirds the height. The section of such a sewer is shown in fig. 108, the numbers marked on the figure being proportional numbers.

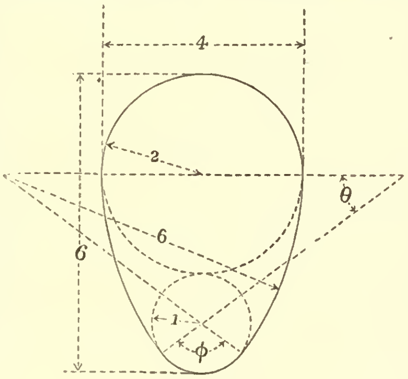

Fig. 108.

95. *Problems on Channels in which the Flow is Steady and at Uniform Velocity.*—The general equations given in §§ 88, 90 are

$$\zeta = \alpha\left(1 + \frac{\beta}{m}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

$$\zeta \frac{v^2}{2g} = mi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2);$$

$$Q = \Omega v \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Problem I. Given the transverse section of stream and discharge, to find the slope. From the dimensions of the section find Ω and m; from (1) find ζ, from (3) find v, and lastly from (2) find i.

Problem II. Given the transverse section and slope, to find the discharge. Find v from (2), then Q from (3).

Problem III. Given the discharge and slope, and either the breadth, depth, or general form of the section of the channel, to determine its remaining dimensions. This must generally be solved by approximations. A breadth or depth or both are chosen, and the discharge calculated. If this is greater than the given discharge, the dimensions are reduced and the discharge recalculated.

Since m lies generally between the limits $m=d$ and $m=\frac{1}{2}d$, where d is the depth of the stream, and since, moreover, the velocity varies as $\sqrt{m}$ so that an error in the value of m leads only to a much less error in the value of the velocity calculated from it, we may proceed thus. Assume a value for m, and calculate v from it. Let v_1 be this first approximation to v. Then $\frac{Q}{v_1}$ is a first approximation to Ω, say Ω_1. With this value of Ω design the section of the channel; calculate a second value for m; calculate from it a second value of v, and from that a second value for Ω. Repeat the process till the successive values of m approximately coincide.

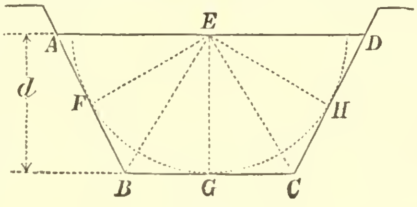

Fig. 109.

96. *Problem* IV. *Most Economical Form of Channel for given Side Slopes.*—Suppose the channel is to be trapezoidal in section (fig. 109), and that the sides are to have a given slope. Let the longitudinal slope of the stream be given, and also the mean velocity. An infinite number of channels could be found satisfying the foregoing conditions. To render the problem determinate, let it be remembered that, since for a given discharge $\Omega \propto \sqrt[3]{\chi}$, other things being the same, the amount of excavation will be least for that channel which has the least wetted perimeter. Let d be the depth and b the bottom width of the channel, and let the sides slope n horizontal to 1 vertical (fig. 110), then

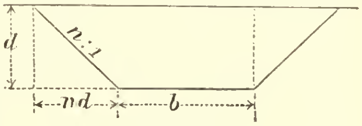

Fig. 110.

$$\Omega = (b + nd)d\;;$$
$$\chi = b + 2d\sqrt{n^2+1}\,.$$

Both Ω and χ are to be minima. Differentiating, and equating to zero,

$$\left(\frac{db}{dd} + n\right)d + b + nd = 0\,,$$

$$\frac{db}{dd} + 2\sqrt{n^2+1} = 0\;;$$

eliminating $\frac{db}{dd}$,

$$(n - 2\sqrt{n^2+1})d + b + nd = 0\,,$$

$$b = 2(\sqrt{n^2+1} - n)d\,.$$

But

$$\frac{\Omega}{\chi} = \frac{(b+nd)d}{b+2d\sqrt{n^2+1}}\,.$$

Inserting the value of b,

$$m = \frac{\Omega}{\chi} = \frac{2d\sqrt{n^2+1} - nd}{4d\sqrt{n^2+1} - 2nd} = \frac{d}{2}\,.$$

That is, with given slide slopes, the section is least for a given discharge when the hydraulic mean depth is half the actual depth.

A simple construction gives the form of the channel which fulfils this condition, for it can be shown that when $m = \frac{d}{2}$ the sides of the channel are tangential to a semi-circle drawn on the water line.

Since

$$\frac{\Omega}{\chi} = \frac{d}{2}\,,$$

therefore

$$\Omega = \tfrac{1}{2}\chi d \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Let ABCD be the channel (fig. 109); from E the centre of AD drop perpendiculars EF, EG, EH on the sides.

Let

$$AB = CD = a\;;\;\; BC = b\;;\;\; EF = EH = c\;;\; \text{and } EG = d.$$

$$\Omega = \text{area } AEB + BEC + CED\,,$$
$$= ac + \tfrac{1}{2}bd\,.$$
$$\chi = 2a + b\,.$$

Putting these values in (1),

$$ac + \tfrac{1}{2}bd = (a + \tfrac{1}{2}b)d\;;\;\text{and hence } c = d.$$

That is, EF, EG, EH are all equal, hence a semicircle struck from E with radius equal to the depth of the stream will pass through F and H and be tangential to the sides of the channel.

To draw the channel, describe a semicircle on a horizontal line with radius = depth of channel. The bottom will be a horizontal tangent of that semicircle, and the sides tangents drawn at the required side slopes.

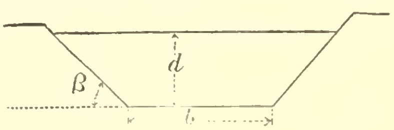

Fig. 111.

The above result may be obtained thus (fig. 111):—

$$\chi = b + \frac{2d}{\sin\beta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

$$\Omega = d(b + d\cot\beta)\ ;$$

$$\frac{\Omega}{d} = b + d\cot\beta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)\ ;$$

$$\frac{\Omega}{d^2} = \frac{b}{d} + \cot\beta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

From (1) and (2),

$$\chi = \frac{\Omega}{d} - d\cot\beta + \frac{2d}{\sin\beta}\,.$$

This will be a minimum for

$$\frac{d\chi}{dd} = \frac{\Omega}{d^2} + \cot\beta - \frac{2}{\sin\beta} = 0\,,$$

or

$$\frac{\Omega}{d^2} = 2\ \text{cosec.}\ \beta - \cot\beta \quad . \quad . \quad . \quad . \quad . \quad (4).$$

or

$$d = \sqrt{\frac{\Omega\sin\beta}{2 - \cos\beta}}\,.$$

From (3) and (4),

$$\frac{b}{d} = \frac{2(1-\cos\beta)}{\sin\beta} = 2\tan\tfrac{1}{2}\beta\,.$$

Proportions of Channels of Maximum Discharge for given Area and Side Slopes. Depth of channel $=d$; *Hydraulic mean depth* $=\frac{1}{2}d$; *Area of section* $=\Omega$.

	Inclination of Sides to Horizon.	Ratio of Side Slopes.	Area of Section Ω.	Bottom Width.	Top width = twice length of each Side Slope.
Semicircle	...	...	$1\cdot571d^2$	0	$2d$
Semi-hexagon...	60° 0′	3 : 5	$1\cdot732d^2$	$1\cdot155d$	$2\cdot310d$
Semi-square	90° 0′	0 : 1	$2d^2$	$2d$	$2d$

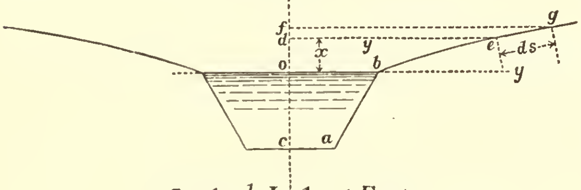
	21° 48′	2½ : 1	$2\cdot885d^2$	$0\cdot385d$	$5\cdot385d$
	19° 58′	2¾ : 1	$3\cdot104d^2$	$0\cdot354d$	$5\cdot854d$
	18° 26′	3 : 1	$3\cdot325d^2$	$0\cdot325d$	$6\cdot325d$

Half the top width is the length of each side slope. The wetted perimeter is the sum of the top and bottom widths.

97. *Form of Cross Section of Channel in which the Mean Velocity is Constant with Varying Discharge.*

In designing waste channels from canals, and in some other cases, it is desirable that the mean velocity should be restricted within narrow limits with very different volumes of discharge. In channels of trapezoidal form the velocity increases and diminishes with the discharge. Hence when the discharge is large there is danger of erosion, and when it is small of silting or obstruction by weeds. A theoretical form of section for which the mean velocity would be constant can be found, and, although this is not very suitable for practical purposes, it can be more or less approximated to in actual channels.

Let fig. 112 represent the cross section of the channel. From the symmetry of the section, only half the channel need be considered.



Scale $\frac{1}{10}$ *Inch = 1 Foot.*

Fig. 112.

Let $obac$ be any section suitable for the minimum flow, and let it be required to find the curve beg for the upper part of the channel so that the mean velocity shall be constant. Take o as origin of coordinates, and let de, fg be two levels of the water above ob.

Let $ob = \frac{b}{2}$; $de = y$, $fg = y + dy$, $od = x$, $of = x + dx$; $eg = ds$.

The condition to be satisfied is that

$$v = c\sqrt{mi}$$

should be constant, whether the water level is at ob, de, or fg. Consequently

$$m = \text{constant} = k$$

for all three sections, and can be found from the section $obac$. Hence also

$$\frac{\text{Increment of section}}{\text{Increment of perimeter}} = \frac{ydx}{ds} = k\,.$$

$$y^2dx^2 = k^2ds^2 = k^2(dx^2 + dy^2)\ ; \text{and}\ dx = \frac{kdy}{\sqrt{y^2 - k^2}}\,.$$

Integrating,

$$x = k\log_\epsilon\left(y + \sqrt{y^2 - k^2}\right) + \text{constant}\ ;$$

and, since $y = \frac{b}{2}$ when $x = 0$,

$$x = k\left\{\log_\epsilon \frac{y + \sqrt{y^2 - k^2}}{\frac{b}{2} + \sqrt{\frac{b^2}{4} - k^2}}\right\}.$$

Assuming values for y, the values of x can be found and the curve drawn.

The figure has been drawn for a channel the minimum section of which is a half hexagon of 4 feet depth. Hence $k = 2$; $b = 9\cdot2$; the rapid flattening of the side slopes is remarkable.

98. *Variation of Velocity in Different Parts of the Cross Section of a Uniform Stream.*

Vertical Velocity Curve in a Stream.—If it is assumed that the resistance to the relative sliding of the layers of water in a stream is of the nature of a viscous resistance, then the law of the distribution of velocity in a vertical longitudinal section of the stream can be determined theoretically. For simplicity, suppose the stream of uniform depth and indefinite width. Let fig. 113 show a portion of a vertical longitudinal section of the stream, and let OA, O′A′ be the intersections with this of two transverse sections at a distance apart l. Let ab, cd be the traces of two planes parallel to the free surface or to the bed, and let us consider the equilibrium of a layer $abcd$ of width unity. Let $Oa = y$, $ac = dy$, and let v be the velocity of the particles comprised in $abcd$, v being a function of y which is to be determined.

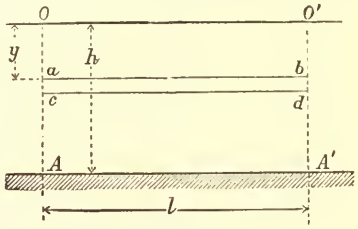


Fig. 113.

Taking the components of the forces acting on $abcd$, parallel to OO, the pressures on ac, bd, being proportional to the depth from the free surface, are equal and opposite; also, the frictions or viscous resistances on the lateral faces of the prism are zero, since in a wide stream there is no relative sliding between $abcd$ and the layers on each side. There remain only the resistances on the upper and lower surface, and the component of the weight.

The weight of the layer is $Gl\,dy$, and if i is the slope of the stream the component of the weight parallel to OO is $Gli\,dy$. The friction or viscous resistance on the face ab is proportional to its area and to the differential coefficient $\frac{dv}{dy}$ (§ 3). The resistance is, therefore, $-kl\frac{dv}{dy}$, the negative sign being used because, if v increases with y, $\frac{dv}{dy}$ is positive, while the action of the layers above ab is a retarding action. The resistance on the face cd is similarly $kl\frac{dv}{dy} + kld\frac{dv}{dy}$. The resultant of the action of the layers above and below is, therefore, $kld\frac{dv}{dy}$.

When the motion is uniform,

$$Glidy + kld\frac{dv}{dy} = 0\ ;$$

$$\frac{d^2v}{dy^2} = -\frac{Gi}{k}\ ;$$

integrating,

$$\frac{dv}{dy} = -\frac{Gi}{k}y + C\ ;$$

$$v = -\frac{1}{2}\frac{Gi}{k}y^2 + Cy + v_0 \quad . \quad . \quad (1)\ ;$$

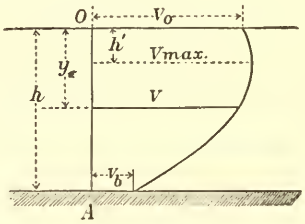

Fig. 114.

an equation which gives the velocity v at any depth y. If on a vertical line OA (fig. 114), representing the depth of the stream, the values of v are set off horizontally, a parabolic curve is obtained, termed the vertical velocity curve for the section considered. The constant v_0 is evidently the surface velocity, being the value of v for $y = 0$. The parabola has a horizontal axis corresponding to the position of the filament of maximum velocity. If there is no resistance at the surface of the stream like that at the bottom and sides, the maximum velocity should be at the surface, and then $c=0$, and the equation becomes

$$v=v_0-\frac{1}{2}\frac{Gi}{k}y^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Assuming this for the present, the mean velocity is

$$v_m=\frac{\int_0^h vdy}{h}=v_0-\frac{1}{6}\frac{Gi}{k}h^2 \quad . \quad . \quad . \quad . \quad (3).$$

The bottom velocity is, putting the depth h for y in (2);

$$v_b=v_0-\frac{1}{2}\frac{Gi}{k}h^2 ;$$

and therefore

$$v_m=\tfrac{1}{3}(2v_0+v_b) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

It is now understood that the motion in a stream is much more complete than the viscous theory just stated assumes. The retardation of the stream is much greater than it would be in simple motion of that kind. This has already been partly explained in the introduction to the present article. Nevertheless the viscous theory may probably be so modified as to furnish ultimately a true theory of streams.

99. *Experimental Observations on the Vertical Velocity Curve.*—In obtaining the vertical velocity curve from direct observations in streams, a preliminary difficulty arises from the fact that the velocity at any given depth is not constant, and hence the motion in the strict sense is not steady. The velocities taken on a given vertical section at any given moment do not form when plotted any regular curve. But if a series of observations are taken at each depth and the results averaged, the mean velocities at each depth when plotted give a regular curve, agreeing very fairly with the parabola, which might be expected from the theory above. Hence it may be inferred that the velocity at any given point fluctuates about a mean value, the fluctuations being due to irregular eddying motions superposed on the general steady motion of the stream, and having an effect which disappears in the mean of a series of observations. For certain purposes these irregular motions may be ignored, and the constant mean velocity substituted for the actual varying velocities at each point. In the next place, all the best observations show that the maximum velocity is to be found, not at the free surface of the stream, but at some distance below it.[1]

Influence of the Wind.—In the experiments on the Mississippi the vertical velocity curve in calm weather was found to agree fairly with a parabola, the greatest velocity being at $\frac{3}{10}$ths of the depth of the stream from the surface. With a wind blowing down stream the surface velocity is increased, and the axis of the parabola approaches the surface. On the contrary, with a wind blowing up stream the surface velocity is diminished, and the axis of the parabola is lowered, sometimes to half the depth of the stream. The American observers drew from their observations the conclusion that there was an energetic retarding action at the surface of a stream like that due to the bottom and sides. If there were such a retarding action the position of the filament of maximum velocity below the surface would be explained.

It is not difficult to understand that a wind acting on surface ripples should accelerate or retard the surface motion of the stream, and the Mississippi results may be accepted so far as showing that the surface velocity of a stream is variable when the mean velocity of the stream is constant. Hence observations of surface velocity by floats or otherwise should only be made in very calm weather. But it is very difficult to suppose that, in still air, there is a resistance at the free surface of the stream at all analogous to that at the sides and bottom. Further, in very careful experiments, Boileau found the maximum velocity, though raised a little above its position for calm weather, still at a considerable distance below the surface, even when the wind was blowing down stream with a velocity greater than that of the stream, and when the action of the air must have been an accelerating and not a retarding action. Professor James Thomson has given a much more probable explanation of the diminution of the velocity at and near the free surface. He points out that portions of water, with a diminished velocity from retardation by the sides or bottom, are thrown off in eddying masses and mingle with the rest of the stream. These eddying masses modify the velocity in all parts of the stream, but have their greatest influence at the free surface. Reaching the free surface they spread out and remain there, mingling with the water at that level and diminishing the velocity which would otherwise be found there.

100. *Influence of the Wind on the Depth at which the Maximum Velocity is found.*—In the gaugings of the Mississippi the vertical velocity curve was found to agree well with a parabola having a horizontal axis at some distance below the water surface, the ordinate of the parabola at the axis being the maximum velocity of the section. During the gaugings the force of the wind was registered on a scale ranging from 0 for a calm to 10 for a hurricane. Arranging the velocity curves in three sets—(1) with the wind blowing up stream, (2) with the wind blowing down stream, (3) calm or wind blowing across stream—it was found that an up stream wind lowered, and a down stream wind raised, the axis of the parabolic velocity curve. In calm weather the axis was at $\frac{3}{10}$ths of the total depth from the surface for all conditions of the stream.

Let h' be the depth of the axis of the parabola, m the hydraulic mean depth, f the number expressing the force of the wind, which may range from $+10$ to -10, positive if the wind is up stream, negative if it is down stream. Then Messrs Humphreys and Abbot find their results agree with the expression

$$\frac{h'}{m}=0{\cdot}317\pm0{\cdot}06f .$$

Fig. 115 shows the parabolic velocity curves according to the American observers for calm weather, and for an up or down stream wind of a force represented by 4.

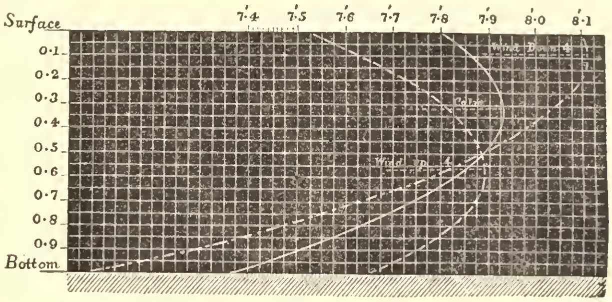

Fig. 115.

101. *Bazin's Formulæ for the Variation of Velocity in a Vertical Longitudinal Section of a Stream.*—M. Bazin assumes that the vertical velocity curve is a parabola, and has investigated numerical values for the constants from his own and other experiments. Assuming the general equation already found, § 98,

$$v=v_0+cy-\frac{1}{2}\frac{Gi}{k}y^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

v will have the maximum value V, for a value of h' of y which makes $\frac{dv}{dy}$ zero. That is,

$$h'=\frac{ck}{Gi}, \quad \text{or} \quad c=\frac{Gi}{k}h' ;$$

and the maximum velocity is

$$V=v_0+\frac{1}{2}\frac{Gi}{k}h'^2 ;$$

$$\therefore \quad v_0=V-\frac{1}{2}\frac{Gi}{k}h'^2 .$$

Inserting these values of v_0 and c in (1),

$$v=V-\frac{Gi}{2k}(y-h')^2 ;$$

or putting $M=\frac{Gih^2}{2k}$, where h is the whole depth of the section,

$$v=V-M\left(\frac{y-h'}{h}\right)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

where M is constant for any given stream. Let $\frac{y}{h}=x$ and $\frac{h'}{h}=\alpha$,

$$v=V-M(x-\alpha)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2a).$$

Then the mean velocity on the vertical is

$$v_m=\int_0^h\left\{V-M(x-\alpha)^2\right\}dx=V-M(\tfrac{1}{3}-\alpha+\alpha^2) .$$

Let v_n be the velocity at nh feet from the surface, v_{1-n} the velocity at an equal depth from the bottom,

$$\tfrac{1}{2}(v_n+v_{1-n})=V-M(n^2-n+\alpha^2-\alpha+\tfrac{1}{2}) ,$$

$$=v_m-M(n^2-n+\tfrac{1}{6}) ,$$

Let $n=\frac{1}{2}$, and put $v_{\frac{1}{2}}$ for the velocity at mid depth, then

$$v_{\frac{1}{2}}=v_m+\tfrac{1}{12}M \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3) ;$$

so that the mid depth velocity differs from the mean velocity by the small quantity $\frac{1}{12}$ M only, whatever be the position of the axis of the parabola. Messrs Humphreys and Abbot have based on this property a method of rapidly gauging rivers which will be described hereafter.

[1] Pitot first showed, in 1732, that the velocity in a stream diminishes from the surface downwards; about sixty years after, Woltmann concluded that the vertical velocity curve was a parabola.

From a discussion of experiments in which the maximum velocity was at the surface, Bazin was led to take

$$M = 36{\cdot}3\sqrt{hi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4);$$

and for that case the equation to the vertical velocity curve is ($\alpha = 0$)

$$v = V - 36{\cdot}3\sqrt{hi}x^2.$$

In the cases in which the maximum velocity was below the surface, Bazin found that the difference between the maximum velocity V and the bottom velocity v_b remained constant.

But, putting $x = \frac{h}{h} = 1$ in the equation ($2a$), and v_b for the bottom velocity,

$$v_b = V - M(1-\alpha)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5);$$

$$V - v_b = M(1-\alpha)^2 = \text{constant},$$

for different positions of the axis of the parabola.
Let

$$M = \frac{N}{(1-\alpha)^2},$$

where N is a constant; then

$$v = V - N\left(\frac{x-\alpha}{1-\alpha}\right)^2$$

for any position of the axis of the parabola. But this must agree with the equation (4) above, for $\alpha = 0$; hence,

$$N = 36{\cdot}3\sqrt{hi};$$

and the general equation for all cases becomes

$$v = V - 36{\cdot}3\sqrt{hi}\left(\frac{x-\alpha}{1-\alpha}\right)^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Bazin has shown that this equation agrees well with experiments on artificial channels by himself, and on the Saone, Seine, Garonne, and Rhine. In all these the ratio $\frac{V}{v_m}$ ranged from 1·10 to 1·13, except in the case of the Rhine at Basel, for which the ratio was 1·17. The parameter $\frac{36{\cdot}3\sqrt{hi}}{(1-\alpha)^2}$ lies between 13 and 20, and the ratio of the depth at which the maximum velocity is found to the whole depth, $=\alpha$, ranges from zero to 0·2, except in some of the artificial channels, where it reached 0·35. The Mississippi experiments give different results, and Bazin inclines to believe that the method of experimenting was untrustworthy.

The extreme difference $V - v_b$ between the maximum and bottom velocity is found by Bazin to range from $\frac{1}{4}$ V to $\frac{1}{2}$ V in artificial channels, being greater the greater the roughness of the sides. In natural streams it is more generally $\frac{1}{3}$ V, but in the Rhine at Basel it reached $\frac{1}{2}$V, the bed being covered with boulders.

Boileau's Formulæ.—Boileau also assumes the vertical velocity curve to be a parabola; below the filament of greatest velocity the curve is expressed by the relation

$$v = A - By^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

That is, the velocity curve is a parabola having its axis at the free surface of the stream. Above the filament of greatest velocity this law fails, and the velocities diminish instead of increasing. The vertical velocity curve is therefore such a curve as M′MM″ (fig. 116), where the part MM″ is a parabola having its vertex at S, and DM is the maximum velocity. The part M′M does not follow the parabolic law. Let V be the maximum velocity DM, CM its depth $=\theta$. Draw at M the tangent and normal to the parabola. Then PC is the half parameter $\frac{1}{2B}$. Let OS $= V + c$, then CT $= 2$CS $= 2c$.

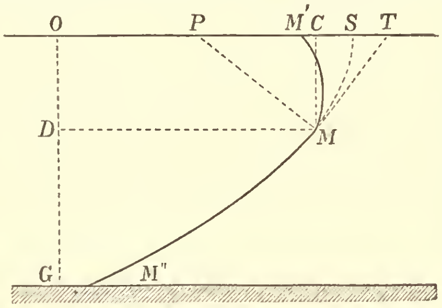

Fig. 116.

$$B = \frac{1}{2}\,\frac{1}{PC}, \text{ and } CM^2 = PC \cdot CT;$$

$$\therefore \quad B = \frac{1}{2}\,\frac{CT}{CM^2} = \frac{c}{\theta^2}.$$

Boileau finds $c = B\theta^2$ to be nearly constant for very different streams. Thus from two experiments of his own on streams 0·2 and 0·3 metres deep, $c = 0{\cdot}01070$ and $0{\cdot}01072$. In Hennocque's experiments on the Rhine, 2·45 metres deep, $c = 0{\cdot}0107$; and in the Mississippi experiments with a depth of 32 metres, $c = 0{\cdot}0093$ to $0{\cdot}0113$. Replacing A and B in (1) by the values now given

$$v = V - c\frac{y^2}{\theta^2} + c \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

an equation which gives the velocity v at any depth y from the surface in the region below the filament of maximum velocity. For the region above the filament of maximum velocity Boileau assumes

$$v_s = V' - c\frac{y^2}{\theta^2} + (V - V' + c)\frac{z}{\theta} \quad . \quad . \quad . \quad . \quad (3),$$

where v is the velocity at the depth y and V′ is the surface velocity.

102. *Ratio of Mean to Greatest Surface Velocity, for the whole Cross Section in Trapezoidal Channels.*—It is often very important to be able to deduce the mean velocity, and thence the discharge, from observation of the greatest surface velocity. The simplest method of gauging small streams and channels is to observe the greatest surface velocity by floats, and thence to deduce the mean velocity. Now, for channels not widely differing from those experimented on by Bazin, the expression obtained by him for the ratio of surface to mean velocity may be relied on as at least a good approximation to the truth. Let v_0 be the greatest surface velocity, v_m the mean velocity of the stream. Then, according to Bazin,

$$v_m = v_0 - 25{\cdot}4\sqrt{mi}.$$

But

$$v_m = c\sqrt{mi},$$

where c is a coefficient, the values of which have been already given in the table in § 90. Hence

$$v_m = \frac{c}{c + 25{\cdot}4}v_0.$$

Values of Coefficient $\frac{c}{c+25{\cdot}4}$ *in the Formula* $v_m = \frac{c}{c+25{\cdot}4}v_0$.

103. *River Bends.*—In rivers flowing in alluvial plains, the windings which already exist tend to increase in curvature by the scouring away of material from the outer bank and the deposition of detritus along the inner bank. The sinuosities sometimes increase till a loop is formed with only a narrow strip of land between the two encroaching branches of the river. Finally a "cut off" may occur, a waterway being opened through the strip of land and the loop left separated from the stream, forming a horse-shoe shaped lagoon or marsh. Professor James Thomson has pointed out (*Proc. Royal Soc.* 1877, p. 356; *Proc. Inst. of Mech. Engineers*, 1879, p. 456) that the usual supposition is that the water tending to go forwards in a straight line, rushes against the outer bank and scours it, at the same time creating deposits at the inner bank. That view is very far from a complete account of the matter, and Professor Thomson has given a much more ingenious account of the action at the bend, which he has completely confirmed by experiment.

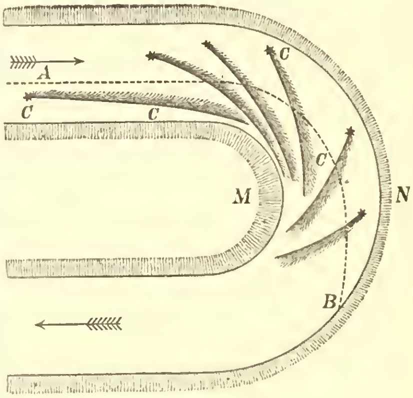

Fig. 117.

When water moves round a circular curve under the action of gravity only, it takes a motion like that in a free vortex. Its velocity is greater parallel to the axis of the stream at the inner than at the outer side of the bend. Hence the scouring at the outer side and the deposit at the inner side of the bend are not due to mere difference of velocity of flow in the general direction of the stream; but, in virtue of the centrifugal force, the water passing round the bend presses outwards, and the free surface in a radial cross section has a slope from the inner side upwards to the outer side (fig. 118). For the greater part of the water flowing in curved paths, this difference of pressure produces no tendency to transverse motion. But the water immediately in contact with the rough bottom and sides of the channel is retarded, and its centrifugal force is insufficient to balance the pressure due to the greater depth at the outside of the bend. It therefore flows inwards towards the inner side of the bend, carrying with it detritus which is deposited at the inner bank. Conjointly with this flow inwards along the bottom and sides, the general mass of water must flow outwards to take its place. Fig. 117 shows the directions of flow as observed in a small artificial stream, by means of light seeds and specks of aniline dye. The lines CC show the directions of flow immediately in contact with the sides and bottom. The dotted line AB shows the direction of motion of floating particles on the surface of the stream.

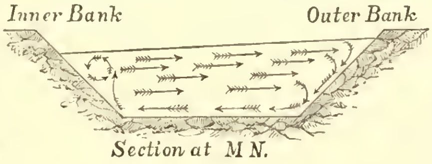

Fig. 118.

Steady Motion of Water in Open Channels of Varying Cross Section and Slope.

104. In every stream the discharge of which is constant, or may be regarded as constant for the time considered, the velocity at different places depends on the slope of the bed. Except at certain exceptional points the velocity will be greater as the slope of the bed is greater, and, as the velocity and cross section of the stream vary inversely, the section of the stream will be least where the velocity and slope are greatest. If in a stream of tolerably uniform slope an obstruction such as a weir is built, that will cause an alteration of flow similar to that of an alteration of the slope of the bed for a greater or less distance above the weir, and the originally uniform cross section of the stream will become a varied one. In such cases it is often of much practical importance to determine the longitudinal section of the stream.

The cases now considered will be those in which the changes of velocity and cross section are gradual and not abrupt, and in which the only internal work which needs to be taken into account is that due to the friction of the stream bed, as in cases of uniform motion. Further, the motion will be supposed to be steady, the mean velocity at each given cross section remaining constant, though it varies from section to section along the course of the stream.

Let fig. 119 represent a longitudinal section of the stream, A_0A_1 being the water surface, B_0B_1 the stream bed. Let A_0B_0, A_1B_1 be

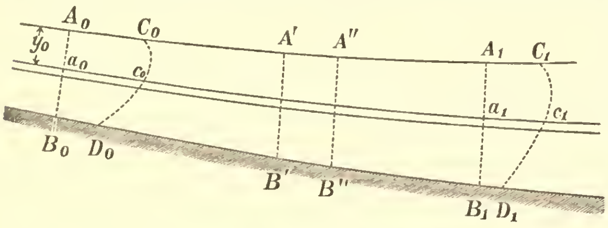

Fig. 119.

cross sections normal to e direction of flow. Suppose the mass of water $A_0B_0A_1B_1$ comes in a short time θ to $C_0D_0C_1D_1$, and let the work done on the mass be equated to its change of kinetic energy during that period. Let l be the length A_0A_1 of the portion of the stream considered, and z the fall of surface level in that distance. Let Q be the discharge of the stream per second.

Change of Kinetic Energy.—At the end of the time θ there are as many particles possessing the same velocities in the space $C_0D_0A_1B_1$ as at the beginning. The change of kinetic energy is therefore the difference of the kinetic energies of $A_0B_0C_0D_0$ and $A_1B_1C_1D_1$.

Let fig. 120 represent the cross section A_0B_0, and let ω be a small element of its area at a point where the velocity is v. Let Ω_0 be the whole area of the cross section and u_0 the mean velocity for the whole cross section. From the definition of mean velocity we have

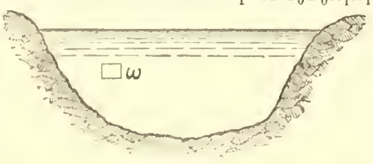

Fig. 120.

$$u_0 = \frac{\Sigma\omega v}{\Omega_0}.$$

Let $v = u_0 + w$, where w is the difference between the velocity at the small element ω and the mean velocity. For the whole cross section, $\Sigma\omega w = 0$.

The mass of fluid passing through the element of section ω, in θ seconds, is $\frac{G}{g}\omega v\theta$, and its kinetic energy is $\frac{G}{2g}\omega v^3\theta$. For the whole section, the kinetic energy of the mass $A_0B_0C_0D_0$ passing in θ seconds is

$$\frac{G\theta}{2g}\Sigma\omega v^3,$$

$$= \frac{G\theta}{2g}\Sigma\omega(u_0^3 + 3u_0^2 w + 3u_0 w^2 + w^3),$$

$$= \frac{G\theta}{2g}\left\{u_0^3\Omega + \Sigma\omega w^2(3u_0 + w)\right\}.$$

The factor $3u_0 + w$ is equal to $2u_0 + v$, a quantity necessarily positive. Consequently $\Sigma\omega v^3 > \Omega_0 u_0^3$, and consequently the kinetic energy of $A_0B_0C_0D_0$ is greater than

$$\frac{G\theta}{2g}\Omega_0 u_0^3 \text{ or } \frac{G\theta}{2g}Qu_0^2,$$

which would be its value if all the particles passing the section had the same velocity u_0. Let the kinetic energy be taken at

$$\alpha\frac{G\theta}{2g}\Omega_0 u_0^3 = \alpha\frac{G\theta}{2g}Qu_0^2,$$

where α is a corrective factor, the value of which has been estimated by Belanger at 1·1.[1] Its precise value is not of great importance.

In a similar way we should obtain for the kinetic energy of $A_1B_1C_1D_1$ the expression

$$\alpha\frac{G\theta}{2g}\Omega_1 u_1^3 = \alpha\frac{G\theta}{2g}Qu_1^2,$$

where Ω_1, u_1 are the section and mean velocity at A_1B_1, and where α may be taken to have the same value as before without any important error.

Hence the change of kinetic energy in the whole mass $A_0B_0A_1B_1$ in θ seconds is

$$\alpha\frac{G\theta}{2g}Q(u_1^2 - u_0^2) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Motive Work of the Weight and Pressures.—Consider a small filament a_0a_1 which comes in θ seconds to c_0c_1. The work done by gravity during that movement is the same as if the portion a_0c_0 were carried to a_1c_1. Let $dQ\theta$ be the volume of a_0c_0 or a_1c_1, and y_0, y_1 the depths of a_0, a_1 from the surface of the stream. Then the volume $dQ\theta$ or $GdQ\theta$ pounds falls through a vertical height $z + y_1 - y_0$, and the work done by gravity is

$$G\, dQ\, \theta(z + y_1 - y_0).$$

Putting p_a for atmospheric pressure, the whole pressure per unit of area at a_0 is $Gy_0 + p_a$, and that at a_1 is $-(Gy_1 + p_a)$. The work of these pressures is

$$G\left(y_0 + \frac{p_a}{G} - y_1 - \frac{p_a}{G}\right)dQ\,\theta,$$

$$= G(y_0 - y_1)\,dQ\,\theta.$$

Adding this to the work of gravity, the whole work is $GzdQ\theta$; or, for the whole cross section,

$$GzQ\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Work expended in Overcoming the Friction of the Stream Bed.—Let A′B′, A″B″ be two cross sections at distances s and $s + ds$ from A_0B_0. Between these sections the velocity may be treated as uniform, because by hypothesis the changes of velocity from section to section are gradual. Hence, to this short length of stream the equation for uniform motion is applicable. But in that case the work in overcoming the friction of the stream bed between A′B′ and A″B″ is

$$GQ\theta\zeta\frac{u^2}{2g}\frac{\chi}{\Omega}ds,$$

where u, χ, Ω are the mean velocity, wetted perimeter, and section at A′B′. Hence the whole work lost in friction from A_0B_0 to A_1B_1 will be

$$GQ\theta\int_0^l \zeta\frac{u^2}{2g}\frac{\chi}{\Omega}ds \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Equating the work given in (2) and (3) to the change of kinetic energy given in (1),

$$\alpha\frac{GQ\theta}{2g}(u_1^2 - u_0^2) = GQz\theta - GQ\theta\int_0^l \zeta\frac{u^2}{2g}\frac{\chi}{\Omega}ds;$$

$$\therefore \quad z = \alpha\frac{(u_1^2 - u_0^2)}{2g} + \int_0^l \zeta\frac{u^2}{2g}\frac{\chi}{\Omega}ds.$$

[1] Boussinesq has shown that this mode of determining the corrective factor α is not satisfactory.

105. *Fundamental Differential Equation of Steady Varied Motion.*—Suppose the equation just found to be applied to an indefinitely short length ds of the stream, limited by the end sections ab, a_1b_1, taken for simplicity normal to the stream bed (fig. 121). For that

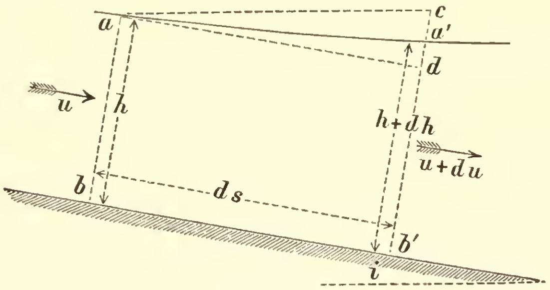

Fig. 121.

short length of stream the fall of surface level, or difference of level of a and a_1, may be written dz. Also, if we write u for u_0, and $u+du$ for u_1, the term $\frac{u_0^2-u_1^2}{2g}$ becomes $\frac{udu}{g}$. Hence the equation applicable to an indefinitely short length of the stream is

$$dz=\frac{udu}{g}+\frac{\chi}{\Omega}\zeta\frac{u^2}{2g}ds \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

From this equation some general conclusions may be arrived at as to the form of the longitudinal section of the stream, but, as the investigation is somewhat complicated, it is convenient to simplify it by restricting the conditions of the problem.

Modification of the Formula for the Restricted Case of a Stream flowing in a Prismatic Stream Bed of Constant Slope.—Let i be the constant slope of the bed. Draw ad parallel to the bed, and ac horizontal. Then dz is sensibly equal to $a'c$. The depths of the stream, h and $h+dh$, are sensibly equal to ab and $a'b'$, and therefore $dh=a'd$. Also cd is the fall of the bed in the distance ds, and is equal to ids. Hence

$$dz=a'd=cd-a'c=ids-dh \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Since the motion is steady—

$$Q=\Omega u=\text{constant}.$$

Differentiating,

$$\Omega du+ud\Omega=0\,;$$

$$\therefore \quad du=-\frac{ud\Omega}{\Omega}.$$

Let x be the width of the stream, then $d\Omega=xdh$ very nearly. Inserting this value,

$$du=-\frac{ux}{\Omega}dh \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Putting the values of du and dz found in (2) and (3) in equation (1),

$$ids-dh=\frac{u^2x}{g\Omega}dh+\frac{\chi}{\Omega}\zeta\frac{u^2}{2g}ds.$$

$$\frac{dh}{ds}=\frac{i-\frac{\chi}{\Omega}\zeta\frac{u^2}{2g}}{1-\frac{u^2}{g}\frac{x}{\Omega}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Further Restriction to the Case of a Stream of Rectangular Section and of Indefinite Width.—The equation might be discussed in the form just given, but it becomes a little simpler if restricted in the way just stated. For, if the stream is rectangular, $xh=\Omega$, and if x is large compared with h, $\frac{\Omega}{\chi}=\frac{xh}{x}=h$ nearly. Then equation (4) becomes

$$\frac{dh}{ds}=i\frac{1-\zeta\frac{u^2}{2gih}}{1-\frac{u^2}{gh}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

106. *General Indications as to the Form of Water Surface furnished by Equation* (5).—Let A_0A_1 (fig. 122) be the water surface, B_0B_1 the bed in a longitudinal section of the stream, and ab any section at a distance s from B_0, the depth ab being h. Suppose B_0B_1, B_0A_0 taken as rectangular coordinate axes, then $\frac{dh}{ds}$ is the trigonometric tangent of the angle which the surface of the stream at a makes with the axis B_0B_1. This tangent $\frac{dh}{ds}$ will be positive, if the stream is increasing in depth in the direction B_0B_1; negative, if the stream is diminishing in depth from B_0 towards B_1. If $\frac{dh}{ds}=0$, the surface of the stream is parallel to the bed, as in cases of uniform motion. But from equation (4)

$$\frac{dh}{ds}=0, \text{ if } \quad i-\frac{\chi}{\Omega}\zeta\frac{u^2}{2g}=0\,;$$

$$\therefore \quad \zeta\frac{u^2}{2g}=\frac{\Omega}{\chi}i=mi\,,$$

which is the well-known general equation for uniform motion, based on the same assumptions as the equation for varied steady motion now being considered. The case of uniform motion is therefore a limiting case between two different kinds of varied motion.

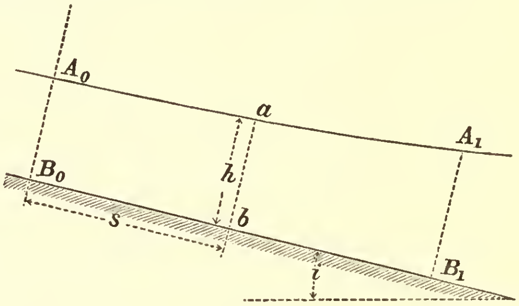

Fig. 122.

Consider the possible changes of value of the fraction

$$\frac{1-\zeta\frac{u^2}{2gih}}{1-\frac{u^2}{gh}}.$$

As h tends towards the limit 0, and consequently u is large, the numerator tends to the limit $-\infty$. On the other hand if $h=\infty$, in which case u is small, the numerator becomes equal to 1. For a value H of h given by the equation

$$1-\zeta\frac{u^2}{2gi\mathrm{H}}=0\,,$$

$$\mathrm{H}=\zeta\frac{u^2}{2gi}\,,$$

we fall upon the case of uniform motion. The results just stated may be tabulated thus:—

For	$h=0$	H	$>$H	∞
the numerator has the value	$-\infty$	0	>0	1.

Next consider the denominator. If h becomes very small, in which case u must be very large, the denominator tends to the limit $-\infty$. As h becomes very large and u consequently very small, the denominator tends to the limit 1. For $h=\frac{u^2}{g}$, or $u=\sqrt{gh}$, the denominator becomes zero. Hence, tabulating these results as before:—

For	$h=0$	$\frac{u^2}{g}$	$>\frac{u^2}{g}$	∞
the denominator becomes	$-\infty$	0	>0	1.

107. *Case* 1.—Suppose $h>\frac{u^2}{g}$, and also $h>$H, or the depth greater than that corresponding to uniform motion. In this case $\frac{dh}{ds}$ is positive, and the stream increases in depth in the direction of flow. In fig. 123 let B_0B_1 be the bed, C_0C_1 a line parallel to the bed and

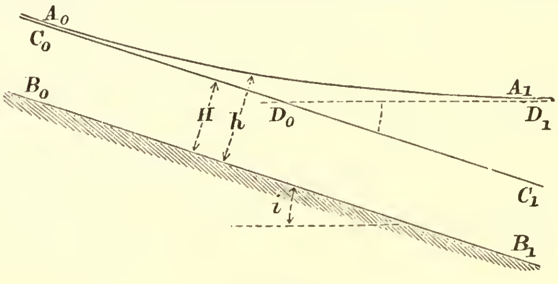

Fig. 123.

at a height above it equal to H. By hypothesis, the surface A_0A_1 of the stream is above C_0C_1, and it has just been shown that the depth of the stream increases from B_0 towards B_1. But going up stream h approaches more and more nearly the value H, and therefore $\frac{dh}{ds}$

approaches the limit 0, or the surface of the stream is asymptotic to C_0C_1. Going down stream h increases and u diminishes, the numerator and denominator of the fraction $\dfrac{1-\zeta\dfrac{2gih}{u^2}}{1-\dfrac{u^2}{gh}}$ both tend towards the limit 1, and $\dfrac{dh}{ds}$ to the limit i. That is, the surface of the stream tends to become asymptotic to a horizontal line D_0D_1.

The form of water surface here discussed is produced when the flow of a stream originally uniform is altered by the construction of a weir. The raising of the water surface above the level C_0C_1 is termed the backwater due to the weir.

108. *Case* 2.—Suppose $h>\dfrac{u^2}{g}$, and also $h<$H. Then $\dfrac{dh}{ds}$ is negative, and the stream is diminishing in depth in the direction of flow. In fig. 124 let B_0B_1 be the stream bed as before; C_0C_1 a line drawn parallel to B_0B_1 at a height above it equal to H. By hypothesis the surface A_0A_1 of the stream is below C_0C_1, and the depth has just been shown to diminish from B_0 towards B_1.

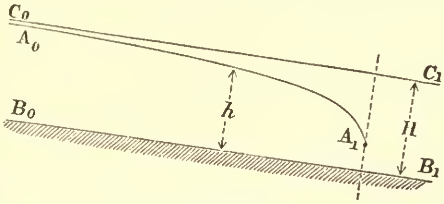

Fig. 124.

Going up stream h approaches the limit H, and $\dfrac{dh}{ds}$ tends to the limit zero. That is, up stream A_0A_1 is asymptotic to C_0C_1. Going down stream h diminishes and u increases; the inequality $h>\dfrac{u^2}{g}$ diminishes; the denominator of the fraction $\dfrac{1-\zeta\dfrac{u^2}{2gih}}{1-\dfrac{u^2}{gh}}$ tends to the limit zero, and consequently $\dfrac{dh}{ds}$ tends to ∞. That is, down stream A_0A_1 tends to a direction perpendicular to the bed. Before, however, this limit was reached the assumptions on which the general equation is based would cease to be even approximately true, and the equation would cease to be applicable. The filaments would have a relative motion, which would make the influence of internal friction in the fluid too important to be neglected. A stream surface of this form may be produced if there is an abrupt fall in the bed of the stream (fig. 125).

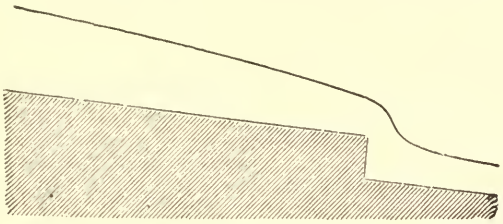

Fig. 125.

On the Ganges canal, as originally constructed, there were abrupt falls precisely of this kind, and it appears that the lowering of the water surface and increase of velocity which such falls occasion, for a distance of some miles up stream, was not foreseen. The result was that, the velocity above the falls being greater than was intended, the bed was scoured and considerable damage was done to the works. "When the canal was first opened the water was allowed to pass freely over the crests of the overfalls, which were laid on the level of the bed of the earthen channel; erosion of bed and sides for some miles up rapidly followed, and it soon became apparent that means must be adopted for raising the surface of the stream at those points (that is, the crests of the falls). Planks were accordingly fixed in the grooves above the bridge arches, or temporary weirs were formed over which the water was allowed to fall; in some cases the surface of the water was thus raised above its normal height, causing a backwater in the channel above" (Crofton's *Report on the Ganges Canal*, p. 14). Fig. 126 represents in an exaggerated form what probably occurred, the diagram being intended to represent some miles' length of the canal bed above the fall. AA parallel to the canal bed is the level corresponding to uniform motion with the intended velocity of the canal. In consequence of the presence of the ogee fall, however, the water surface would take some such form as BB, corresponding to Case 2 above, and the velocity would be greater than the intended velocity, nearly in the inverse ratio of the actual to the intended depth. By constructing a weir on the crest of the fall, as shown by dotted lines, a new water surface CC corresponding to Case 1 would be produced, and by suitably choosing the height of the weir this might be made to agree approximately with the intended level AA.

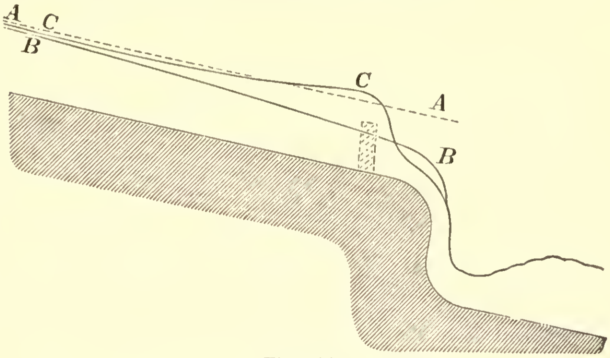

Fig. 126.

109. Case 3.—Suppose a stream flowing uniformly with a depth $H<\dfrac{u^2}{g}$. For a stream in uniform motion $\zeta\dfrac{u^2}{2g}=mi$, or if the stream is of indefinitely great width, so that $m=$H, then $\zeta\dfrac{u^2}{2g}=i$H, and $H=\zeta\dfrac{u^2}{2gi}$. Consequently the condition stated above involves that

$$\zeta\frac{u^2}{2gi}<\frac{u^2}{g}\text{, or that } i>\frac{\zeta}{2}\,.$$

If such a stream is interfered with by the construction of a weir which raises its level, so that its depth at the weir becomes $h_1>\dfrac{u^2}{g}$, then for a portion of the stream the depth h will satisfy the conditions $h<\dfrac{u^2}{g}$ and $h>$H, which are not the same as those assumed in the two previous cases. At some point of the stream above the weir the depth h becomes equal to $\dfrac{u^2}{g}$, and at that point $\dfrac{dh}{ds}$ becomes infinite, or the surface of the stream is normal to the bed. It is obvious that at that point the influence of internal friction will be too great to be neglected, and the general equation will cease to represent the true conditions of the motion of the water. It is known that, in cases such as this, there occurs an abrupt rise of the free surface of the stream, or a standing wave is formed, the conditions of motion in which will be examined presently.

It appears that the condition necessary to give rise to a standing wave is that $i>\dfrac{\zeta}{2}$. Now ζ depends for different channels on the roughness of the channel and its hydraulic mean depth. M. Bazin has calculated the values of ζ for channels of different degrees of roughness and different depths given in the following table, and the corresponding minimum values of i for which the exceptional case of the production of a standing wave may occur.

Nature of Bed of Stream.	Slope below which a Standing Wave is impossible in feet per foot.	Standing Wave Formed.	
		Slope in feet per foot.	Least Depth in feet.
Very smooth cemented surface	0·00147	0·002	0·262
		0·003	·098
		0·004	·065
Ashlar or brickwork	0·00186	0·003	·394
		0·004	·197
		0·006	·098
Rubble masonry	0·00235	0·004	1·181
		0·006	·525
		0·010	·262
Earth	0·00275	0·006	3·478
		0 010	1·542
		0·015	·919

Standing Waves.

110. The formation of a standing wave was first observed by Bidone. Into a small rectangular masonry channel, having a slope of 0·023 feet per foot, he admitted water till it flowed uniformly with a depth of 0·2 feet. He then placed a plank across the stream which raised the level just above the obstruction to 0·95 feet. He found that the stream above the obstruction was sensibly unaffected up to a point 15 feet from it. At that point the depth suddenly increased from 0·2 feet to 0·56 feet. The velocity of the stream in

the part unaffected by the obstruction was 5·54 feet per second. Above the point where the abrupt change of depth occurred $u^2 = 5·51^2 = 30·7$, and $gh = 32·2 \times 0·2 = 6·44$; hence u^2 was $> gh$. Just below the abrupt change of depth $u = 5·54 \times \frac{0·2}{0·56} = 1·97$; $u^2 = 3·88$; and $gh = 32·2 \times 0·56 = 18·03$; hence at this point $u^2 < gh$. Between these two points, therefore, $u = gh$; and the condition for the production of a standing wave occurred.

The change of level at a standing wave may be found thus. Let fig. 127 represent the longitudinal section of a stream and

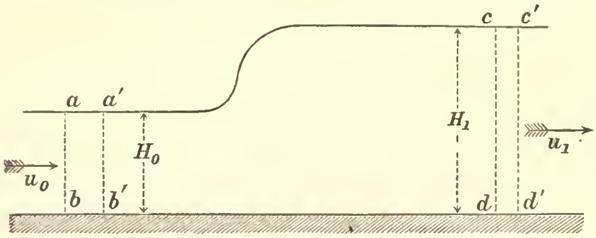

Fig. 127.

ab, *cd* cross sections normal to the bed, which for the short distance considered may be assumed horizontal. Suppose the mass of water *abcd* to come to *a′b′c′d′* in a short time t; and let u_0, u_1 be the velocities at *ab* and *cd*, Ω_0, Ω_1 the areas of the cross sections. The force causing change of momentum in the mass *abcd* estimated horizontally is simply the difference of the pressures on *ab* and *cd*. Putting h_0, h_1 for the depths of the centres of gravity of *ab* and *cd* measured down from the free water surface, the force is $G(h_0\Omega_0 - h_1\Omega_1)$ pounds, and the impulse in t seconds is $G\ (h_0\Omega_0 - h_1\Omega_1)\ t$ second pounds. The horizontal change of momentum is the difference of the momenta of *cdc′d′* and *aba′b′*; that is,

$$\frac{G}{g}(\Omega_1 u_1^2 - \Omega_0 u_0^2)t\,.$$

Hence, equating impulse and change of momentum,

$$G(h_0\Omega_0 - h_1\Omega_1)t = \frac{G}{g}(\Omega_1 u_1^2 - \Omega_0 u_0^2)t\,;$$

$$\therefore\ h_0\Omega_0 - h_1\Omega_1 = \frac{\Omega_1 u_1^2 - \Omega_0 u_0^2}{g} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

For simplicity let the section be rectangular, of breadth B and depths H_0 and H_1, at the two cross sections considered; then $h_0 = \frac{1}{2}H_0$, and $h_1 = \frac{1}{2}H_1$. Hence

$$H_0^2 - H_1^2 = \frac{2}{g}(H_1 u_1^2 - H_0 u_0^2)\,.$$

But, since $\Omega_0 u_0 = \Omega_1 u_1$, we have

$$u_1^2 = u_0^2 \frac{H_0^2}{H_1^2}\,,$$

$$H_0^2 - H_1^2 = \frac{2u_0^2}{g}\left(\frac{H_0^2}{H_1} - H_0\right) \quad . \quad . \quad . \quad . \quad (2).$$

This equation is satisfied if $H_0 = H_1$, which corresponds to the case of uniform motion. Dividing by $H_0 - H_1$, the equation becomes

$$\frac{H_1}{H_0}(H_0 + H_1) = \frac{2u_0^2}{g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)\,;$$

$$\therefore\ H_1 = \sqrt{\left\{\frac{2u_0^2}{g}H_0 + \frac{1}{4}H_0^2\right\}} - \frac{1}{2}H_0\,. \quad . \quad . \quad (4).$$

In Bidone's experiment $u_0 = 5·54$, and $H = 0·2$. Hence $H_1 = 0·52$, which agrees very well with the observed height.

Fig. 128.

111. A standing wave is frequently produced at the foot of a weir. Thus in the ogee falls originally constructed on the Ganges canal a standing wave was observed as shown in fig. 128. The water falling over the weir crest A acquired a very high velocity on the steep slope AB, and the section of the stream at B became very small. It easily happened, therefore, that at B the depth $h < \frac{u^2}{g}$. In flowing along the rough apron of the weir the velocity u diminished and the depth h increased. At a point C, where h became equal to $\frac{u^2}{g}$, the conditions for producing the standing wave occurred. Beyond C the free surface abruptly rose to the level corresponding to uniform motion with the assigned slope of the lower reach of the canal.

A standing wave is sometimes formed on the down stream side of bridges the piers of which obstruct the flow of the water. Some interesting cases of this kind are described in a paper on the "Floods in the Nerbudda Valley" in the *Proc. Inst. of Civil Engineers*, vol. xxvii. p. 222, by Mr A. C. Howden. Fig. 129 is compiled from the data given in that paper. It represents the section of the stream at pier 8 of the Towah Viaduct, during the flood of 1865. The ground level is not exactly given by Mr Howden, but has been inferred from data given on another drawing. The velocity of the stream was not observed, but the author states it was probably the same as at the Gunjal river during a similar flood, that is 16·58 feet per second. Now, taking the depth on the down stream face of the pier at 26 feet, the velocity necessary for the production of a standing wave would be $u = \sqrt{gh} = \sqrt{(32·2 \times 26)} = 29$ feet per second nearly. But the velocity at this point was probably from Mr Howden's statements $16·58 \times \frac{40}{26} = 25·5$ feet, an agreement as close as the approximate character of the data would lead us to expect.

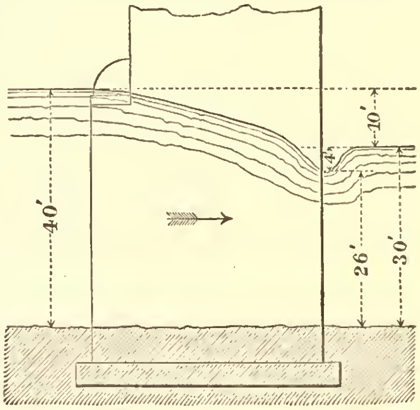

Fig. 129.

XI. ON STREAMS AND RIVERS.

112. *Catchment Basin.*—A stream or river is the channel for the discharge of the available rainfall of a district, termed its catchment basin. The catchment basin is surrounded by a ridge or watershed line, continuous except at the point where the river finds an outlet. The area of the catchment basin may be determined from a suitable contoured map on a scale of at least 1 in 100,000. Of the whole rainfall on the catchment basin, a part only finds its way to the stream. Part is directly re-evaporated, part is absorbed by vegetation, part may escape by percolation into neighbouring districts. The following table gives the relation of the average stream discharge to the average rainfall on the catchment basin (Tiefenbacher).

	Ratio of average Discharge to average Rainfall.	Loss by Evaporation, &c., in per cent. of total Rainfall.
Cultivated land and spring-forming declivities	·3 to ·33	67 to 70
Wooded hilly slopes	·35 to ·45	55 to 65
Naked unfissured mountains ...	·55 to ·60	40 to 45

113. *Flood Discharge.*—The flood discharge can generally only be determined by examining the greatest height to which floods have been known to rise. To produce a flood the rainfall must be heavy and widely distributed, and to produce a flood of exceptional height the duration of the rainfall must be so great that the flood waters of the most distant affluents reach the point considered, simultaneously with those from nearer points. The larger the catchment basin the less probable is it that all the conditions tending to produce a maximum discharge should simultaneously occur. Further, lakes and the river bed itself act as storage reservoirs during the rise of water level and diminish the rate of discharge, or serve as flood moderators. The influence of these is often important, because very heavy rain storms are in most countries of comparatively short duration. Tiefenbacher gives the following estimate of the flood discharge of streams in Europe:—

	Flood discharge of Streams per Second per Square Mile of Catchment Basin.
In flat country	8·7 to 12·5 cub. ft.
In hilly districts	17·5 to 22·5 ,,
In moderately mountainous districts	36·2 to 45·0 ,,
In very mountainous districts	50·0 to 75·0 ,,

It has been attempted to express the decrease of the rate of flood discharge with the increase of extent of the catchment basin by empirical formulae. Thus Colonel O'Connell proposes the formula $y = \mathrm{M}\sqrt{x}$, where M is a constant called the modulus of the river, the value of which depends on the amount of rainfall, the physical characters of the basin, and the extent to which the floods are moderated by storage of the water. If M is small for any given river, it shows that the rainfall is small, or that the permeability or slope of the sides of the valley is such that the water does not drain rapidly to the river, or that lakes and river bed moderate the rise of the floods. If values of M are known for a number of rivers, they may be used in inferring the probable discharge of other similar rivers. For British rivers M varies from 0·43 for a small stream draining meadow land to 37 for the Tyne. Generally it is about 15 or 20. For large European rivers M varies from 16 for the Seine to 67·5 for the Danube. For the Nile M = 11, a low value which results from the immense length of the Nile throughout which it receives no affluent, and probably also from the influence of lakes. For different tributaries of the Mississippi M varies from 13 to 56. For various Indian rivers it varies from 40 to 303, this variation being due to the great variations of rainfall, slope, and character of Indian rivers.

In some of the tank projects in India, the flood discharge has been calculated from the formula $\mathrm{D} = \mathrm{C}\sqrt[3]{n^2}$, where D is the discharge in cubic yards per hour from n square miles of basin. The constant C was taken = 61,523 in the designs for the Ekrooka tank, = 75,000 on Ganges and Godavery works, and = 10,000 on Madras works.

114. *Action of a Stream on its Bed.*—If the velocity of a stream exceeds a certain limit, depending on its size, and on the size, heaviness, form, and coherence of the material of which its bed is composed, it scours its bed and carries forward the materials. The quantity of material which a given stream can carry in suspension depends on the size and density of the particles in suspension, and is greater as the velocity of the stream is greater. If in one part of its course the velocity of a stream is great enough to scour the bed and the water becomes loaded with silt, and in a subsequent part of the river's course the velocity is diminished, then part of the transported material must be deposited. Probably deposit and scour go on simultaneously over the whole river bed, but in some parts the rate of scour is in excess of the rate of deposit, and in other parts the rate of deposit is in excess of the rate of scour. Deep streams appear to have the greatest scouring power at any given velocity. It is possible that the difference is strictly a difference of transporting, not of scouring action. Let fig. 130 represent a section of a stream. The material lifted at a will be diffused through the mass of the stream and deposited at different distances down stream. The average path of a particle lifted at a will be some such curve as abc, and the average distance of transport each time a particle is lifted will be represented by ac. In a deeper stream such as that in fig. 131, the average height to which particles are lifted, and, since the rate of vertical fall through the water may be assumed the same as before, the average distance $a'c'$ of transport, will be greater. Consequently, although the scouring action may be identical in the two streams, the velocity of transport of material down stream is greater as the depth of the stream is greater. The effect is that the deep stream excavates its bed more rapidly than the shallow stream.

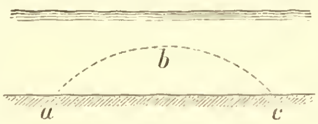

Fig. 130.

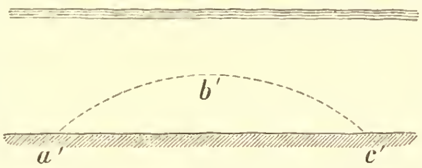

Fig. 131.

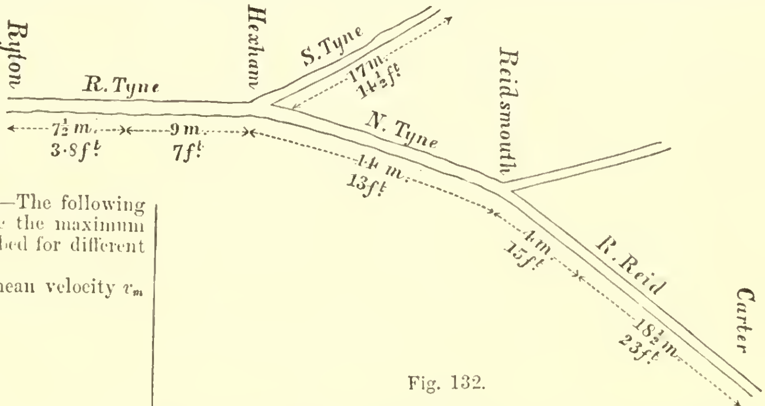

Fig. 132.

115. *Bottom Velocity at which Scour commences.*—The following bottom velocities were determined by Dubuat to be the maximum velocities consistent with stability of the stream bed for different materials.

Darcy and Bazin give, for the relation of the mean velocity v_m and bottom velocity v_b,

$$v_m = v_b + 10{\cdot}87\sqrt{mi}\,.$$

But

$$\sqrt{mi} = v_m\sqrt{\frac{\zeta}{2g}}\,;$$

$$\therefore\quad v_m = v_b \div \left(1 - 10{\cdot}87\sqrt{\frac{\zeta}{2g}}\right).$$

Taking a mean value for ζ, we get

$$v_m = 1{\cdot}312 v_b\,,$$

and from this the following values of the mean velocity are obtained :—

	Bottom Velocity $= v_b$.	Mean Velocity $= v_m$.
1. Soft earth	0·25	·33
2. Loam	0·50	·65
3. Sand	1·00	1·30
4. Gravel	2·00	2·62
5. Pebbles	3·40	4·46
6. Broken stone, flint	4·00	5·25
7. Chalk, soft shale	5·00	6·56
8. Rock in beds	6·00	7·87
9. Hard rock	10·00	13·12

The following table of velocities which should not be exceeded in channels is given in the *Ingenieurs Taschenbuch* of the Verein "Hütte":—

	Surface Velocity.	Mean Velocity.	Bottom Velocity.
Slimy earth or brown clay	·49	·36	·26
Clay	·98	·75	·52
Firm sand	1·97	1·51	1·02
Pebbly bed	4·00	3·15	2·30
Boulder bed	5·00	4·03	3·08
Conglomerate of slaty fragments	7·28	6·10	4·90
Stratified rocks	8·00	7·45	6·00
Hard rocks	14·00	12·15	10·36

116. *Regime of a River Channel.*—A river channel is said to be in a state of regime, or stability, when it changes little in draught or form in a series of years. In some rivers the deepest part of the channel changes its position perpetually, and is seldom found in the same place in two successive years. The sinuousness of the river also changes by the erosion of the banks, so that in time the position of the river is completely altered. In other rivers the change from year to year is very small, but probably the regime is never perfectly stable except where the rivers flow over a rocky bed.

If a river had a constant discharge it would gradually modify its bed till a permanent regime was established. But as the volume discharged is constantly changing, and therefore the velocity, silt is deposited when the velocity decreases, and scour goes on when the velocity increases in the same place. When the scouring and silting are considerable, a perfect balance between the two is rarely established, and hence continual variations occur in the form of the river and the direction of its currents. In other cases, where the action is less violent, a tolerable balance may be established, and the deepening of the bed by scour at one time is compensated by the silting at another. In that case the general regime is permanent, though alteration is constantly going on. This is more likely to happen if by artificial means the erosion of the banks is prevented. If a river flows in soil incapable of resisting its tendency to scour it is necessarily sinuous (§ 103), for the slightest deflexion of the current to either side begins an erosion which increases progressively till a considerable bend is formed. If such a river is straightened it becomes sinuous again unless its banks are protected from scour.

117. *Longitudinal Section of River Bed.*—The declivity of rivers decreases from source to mouth. In their higher parts rapid and torrential, flowing over beds of gravel or boulders, they enlarge in volume by receiving affluent streams, their slope diminishes, their bed consists of smaller materials, and finally they reach the sea. Fig. 132 shows the length in miles, and the surface fall in feet per mile, of the Tyne and its tributaries.

The decrease of the slope is due to two causes. (1) The action of the transporting power of the water, carrying the smallest debris the greatest distance, causes the bed to be less stable near the mouth than in the higher parts of the river; and, as the river adjusts its slope to the stability of the bed by scouring or increasing its sinousness when the slope is too great, and by silting or straightening its course if the slope is too small, the decreasing stability of the bed would coincide with a decreasing slope. (2) The increase of volume and section of the river leads to a decrease of slope; for the larger the section the less slope is necessary to ensure a given velocity.

The following investigation, though it relates to a purely arbitrary case, is not without interest. Let it be assumed, to make the conditions definite—(1) that a river flows over a bed of uniform resistance to scour, and let it be further assumed that to maintain stability the velocity of the river in these circumstances is constant from source to mouth · (2) suppose the sections of the river at all points are similar, so that, b being the breadth of the river at any point, its hydraulic mean depth is ab and its section is cb^2, where a and c are constants applicable to all parts of the river; (3) let us further assume that the discharge increases uniformly in consequence of the supply from affluents, so that, if l is the length of the river from its source to any given point, the discharge there will be kl, where k is another constant applicable to all points in the course of the river.

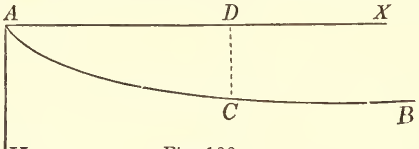

Fig. 133.

Let AB (fig. 133) be the longitudinal section of the river, whose source is at A; and take A for the origin of vertical and horizontal coordinates. Let C be a point whose ordinates are x and y, and let the river at C have the breadth b, the slope i, and the velocity v.

Since velocity × area of section = discharge, $vcb^2=kl$, or $b=\sqrt{\frac{kl}{cv}}$.

Hydraulic mean depth $=ab=a\sqrt{\frac{kl}{cv}}$.

But, by the ordinary formula for the flow of rivers, $mi=\zeta v^2$;

$$\therefore \quad i=\frac{\zeta v^2}{m}=\frac{\zeta v^{\frac{3}{2}}}{a}\sqrt{\frac{c}{kl}}\,.$$

But i is the tangent of the angle which the curve at C makes with the axis of X, and is therefore $=\frac{dy}{dx}$. Also, as the slope is small, $l=\text{AC}=\text{AD}=x$ nearly.

$$\therefore \quad \frac{dy}{dx}=\frac{\zeta v^{\frac{3}{2}}}{a}\sqrt{\frac{c}{kx}}\,;$$

and, remembering that v is constant,

$$y=\frac{2\zeta v^{\frac{3}{2}}}{a}\sqrt{\frac{cx}{k}}\,;$$

or

$$y^2=\text{constant}\times x\,;$$

so that the curve is a common parabola, of which the axis is horizontal and the vertex at the source. This may be considered an ideal longitudinal section, to which actual rivers approximate more or less, with exceptions due to the varying hardness of their beds, and the irregular manner in which their volume increases.

118. *Surface Level of River.*—The surface level of a river is a plane changing constantly in position from changes in the volume of water discharged, and more slowly from changes in the river bed, and the circumstances affecting the drainage into the river.

For the purposes of the engineer, it is important to determine (1) the extreme low water level, (2) the extreme high water or flood level, and (3) the highest navigable level.

(1) *Low Water Level* cannot be absolutely known, because a river reaches its lowest level only at rare intervals, and because alterations in the cultivation of the land, the drainage, the removal of forests, the removal or erection of obstructions in the river bed, &c., gradually alter the conditions of discharge. The lowest level of which records can be found is taken as the conventional or approximate low water level, and allowance is made for possible changes.

(2) *High Water or Flood Level.*—The engineer assumes as the highest flood level the highest level of which records can be obtained. In forming a judgment of the data available, it must be remembered that the highest level at one point of a river is not always simultaneous with the attainment of the highest level at other points, and that the rise of a river in flood is very different in different parts of its course. In temperate regions, the floods of rivers seldom rise more than 20 feet above low water level, but in the tropics the rise of floods is greater.

(3) *Highest Navigable Level.*—When the river rises above a certain level, navigation becomes difficult from the increase of the velocity of the current, or from submersion of the tow paths, or from the headway under bridges becoming insufficient. Ordinarily the highest navigable level may be taken to be that at which the river begins to overflow its banks.

119. *Relative Value of Different Materials for Submerged Works.*—That the power of water to remove and transport different materials depends on their density has an important bearing on the selection of materials for submerged works. In many cases, as in the aprons or floorings beneath bridges, or in front of locks or falls, and in the formation of training walls and breakwaters by *pierres perdus*, which have to resist a violent current, the materials of which the structures are composed should be of such a size and weight as to be able individually to resist the scouring action of the water. The heaviest materials will therefore be the best; and the different value of materials in this respect will appear much more striking, if it is remembered that all materials lose part of their weight in water. A block whose volume is V cubic feet, and whose density in air is w lb per cubic foot, weighs in air wV lb, but in water only $(w-62{\cdot}4)$ V lb.

	Weight of a Cubic Foot in lb.	
	In Air.	In Water.
Basalt	187·3	124·9
Brick	130·0	67·6
Brickwork	112·0	49·6
Granite and limestone	170·0	107·6
Sandstone	144·0	81·6
Masonry	116–144	53·6–81·6

120. *Inundation Deposits from a River.*—When a river carrying silt periodically overflows its banks, it deposits silt over the area flooded, and gradually raises the surface of the country. The silt is deposited in greatest abundance where the water first leaves the river. It hence results that the section of the country assumes a peculiar form, the river flowing in a trough along the crest of a ridge, from which the land slopes downwards on both sides. The silt deposited from the water forms two wedges, having their thick ends towards the river (fig. 134).

Fig. 134.

This is strikingly the case with the Mississippi, and that river is now kept from flooding immense areas by artificial embankments or levees. In India, the term *deltaic segment* is sometimes applied to that portion of a river running through deposits formed by inundation, and having this characteristic section. The irrigation of the country in this case is very easy, a comparatively slight raising of the river surface by a weir or annicut gives a command of level which permits the water to be conveyed to any part of the district.

121. *Deltas.*—The name delta was originally given to the Δ-shaped portion of Lower Egypt, included between seven branches of the Nile. It is now given to the whole of the alluvial tracts round river mouths formed by deposition of sediment from the river, where its velocity is checked on its entrance to the sea. The characteristic feature of these alluvial deltas is that the river traverses them, not in a single channel, but in two or many bifurcating branches. Each branch

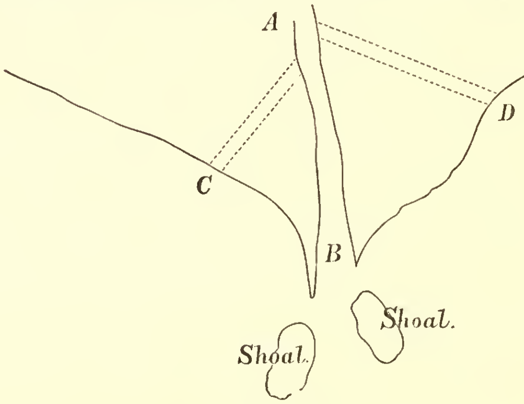

Fig. 135.

has a tract of the delta under its influence, and gradually raises the surface of that tract, and extends it seaward. As the delta extends itself seaward, the conditions of discharge through the different branches change. The water finds the passage through one of the branches less obstructed than through the others; the velocity and scouring action in that branch are increased; in the others they diminish. The one channel gradually absorbs the whole of the water supply, while the other branches silt up. But as the mouth of the new main channel extends seaward the resistance increases both from the greater length of the channel and the formation of shoals at its mouth, and the river tends to form new bifurcations AC or AD (fig. 135), and one of these may in time become the main channel of the river.

122. *Field Operations preliminary to a Study of River Improvement.*—There are required (1) a plan of the river, on which the positions of lines of levelling and cross sections are marked ; (2) a longitudinal section and numerous cross sections of the river ; (3) a series of gaugings of the discharge at different points and in different conditions of the river.

Longitudinal Section.—This requires to be carried out with great accuracy. A line of stakes is planted, following the sinuosities of the river and chained and levelled. The cross sections are referred to the line of stakes, both as to position and direction. To determine the slope of the water surface great care is necessary.

123. *Cross Sections.*—A stake is planted flush with the water, and its level relatively to some point on the line of levels is determined. Then the depth of the water is determined at a series of points (if possible at uniform distances) in a line starting from the stake and perpendicular to the thread of the stream. To obtain these, a wire may be stretched across with equal distances marked on it by hanging tags. The depth at each of these tags may be obtained by a light woollen staff, with a disk-shaped shoe 4 to 6 inches in diameter. If the depth is great, soundings may be taken by a chain and weight. To ensure the wire being perpendicular to the thread of the stream, it is desirable to stretch two other wires similarly graduated, one above and the other below, at a distance of 20 to 40 yards. A number of floats being then thrown in, it is observed whether they pass the same graduation on each wire.

For large and rapid rivers the cross section is obtained by sounding in the following way. Let AC (fig. 136) be the line on which soundings are required. A base line AB is measured out at right angles to AC, and ranging staves are set up at AB and at D in line with AC. A boat is allowed to drop down stream, and, at the moment it comes in line with AD, the lead is dropped and an observer in the boat takes, with a box sextant, the angle AEB subtended by AB. The sounding line may have a weight of 14 lb of lead, and, if the boat drops down stream slowly, it may hang near the bottom, so that the observation is made instantly. In extensive surveys of the Mississippi observers with theodolites were stationed at A and B. The theodolite at A was directed towards C, that at B was kept on the boat. When the boat came on the line AC, the observer at A signalled, the sounding line was dropped, and the observer at B read off the angle ABE. By repeating observations a number of soundings are obtained, which can be plotted in their proper position, and the form of the river bed drawn by connecting the extremities of the lines. From the section can be measured the sectional area of the stream Ω and its wetted perimeter χ ; and from these the hydraulic mean depth m can be calculated.

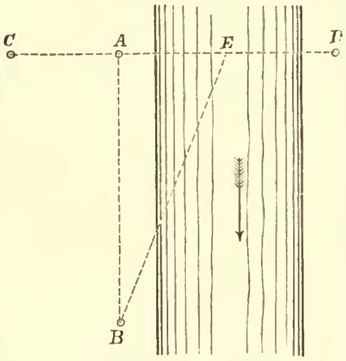

Fig. 136.

124. *Measurement of the Discharge of Rivers.*—The area of cross section multiplied by the mean velocity gives the discharge of the stream. The height of the river with reference to some fixed mark should be noted whenever the velocity is observed, as the velocity and area of cross section are different in different states of the river. To determine the mean velocity various methods may be adopted ; and, since no method is free from liability to error, either from the difficulty of the observations or from uncertainty as to the ratio of the mean velocity to the velocity observed, it is desirable that more than one method should be used.

Instruments for Measuring the Velocity of Water.

125. *Surface Floats* are convenient for determining the surface velocities of a stream, though their use is difficult near the banks. The floats may be small balls of wood, of wax, or of hollow metal, so loaded as to float nearly flush with the water surface. To render them visible they may have a vertical painted stem. In experiments on the Seine, cork balls $1\frac{3}{4}$ inches diameter were used, loaded to float flush with the water, and provided with a stem. In Captain Cunningham's observations at Roorkee, the floats were thin circular disks of English deal, 3 inches diameter and $\frac{1}{4}$ inch thick. For observations near the banks, floats 1 inch diameter and $\frac{1}{8}$ inch thick were used. To render them visible a tuft of cotton wool was used loosely fixed in a hole at the centre.

The velocity is obtained by allowing the float to be carried down, and noting the time of passage over a measured length of the stream. If v is the velocity of any float, t the time of passing over a length l, then $v=\frac{l}{t}$. To mark out distinctly the length of stream over which the floats pass, two ropes may be stretched across the stream at a distance apart, which varies usually from 50 to 250 feet, according to the size and rapidity of the river. In the Roorkee experiments a length of run of 50 feet was found best for the central two-fifths of the width, and 25 feet for the remainder, except very close to the banks, where the run was made $12\frac{1}{2}$ feet only. The longer the run the less is the proportionate error of the time observations, but on the other hand the greater the deviation of the floats from a straight course parallel to the axis of the stream. To mark the precise position at which the floats cross the ropes, Captain Cunningham used short white rope pendants, hanging so as nearly to touch the surface of the water. In this case the streams were 80 to 180 feet in width. In wider streams the use of ropes to mark the length of run is impossible, and recourse must be had to box sextants or theodolites to mark the path of the floats.

Let AB (fig. 137) be a measured base line strictly parallel to the thread of the stream, and AA_1, BB_1 lines at right angles to AB marked out by ranging rods at A_1 and B_1. Suppose observers stationed at A and B with sextants or theodolites, and let CD be the path of any float down stream. As the float approaches AA_1, the observer at B keeps it on the cross wire of his instrument. The observer at A observes the instant of the float reaching the line AA_1, and signals to B who then reads off the angle ABC. Similarly, as the float approaches BB_1, the observer at A keeps it in sight, and when signalled to by B reads the angle BAD. The data so obtained are sufficient for plotting the path of the float and determining the distances AC, BD.

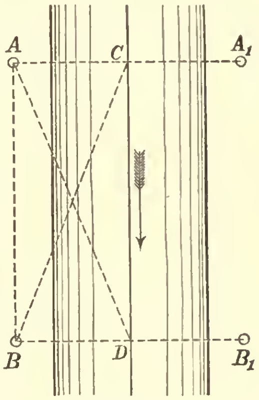

Fig. 137.

The time taken by the float in passing over the measured distance may be observed by a chronograph. started as the float passes the upper rope or line, and stopped when it passes the lower. In Captain Cunningham's observations two chronometers were sometimes used, the time of passing one end of the run being noted on one, and that of passing the other end of the run being noted on the other. The chronometers were compared immediately before the observations. In other cases a single chronometer was used placed midway of the run. The moment of the floats passing the ends of the run was signalled to a timekeeper at the chronometer by shouting. It was found quite possible to count the chronometer beats to the nearest half second, and in some cases to the nearest quarter second.

126. *Sub-surface Floats.*—The velocity at different depths below the surface of a stream may be obtained by sub-surface floats, used precisely in the same way as surface floats. The most usual arrangement is to have a large float, of slightly greater density than water, connected with a small and very light surface float. The motion of the combined arrangement is not sensibly different from that of the large float, and the small surface float enables an observer to note the path and velocity of the sub-surface float. The instrument is, however, not free from objection. If the large submerged float is made of very nearly the same density as water, then it is liable to be thrown upwards by very slight eddies in the water, and it does not maintain its position at the depth at which it is intended to float. On the other hand, if the large float is made sensibly heavier than water, the indicating or surface float must be made rather large, and then it to some extent influences the motion of the submerged float. Fig. 138 shows one form of sub-surface float. It consists of a couple of tin plates bent at a right angle and soldered together at the angle. This is connected with a wooden ball at the surface by a very thin wire or cord. As the tin alone makes a heavy submerged float, it is better to attach to the tin float some pieces of wood to diminish its weight in water. Fig. 139 shows the form of submerged float used by Captain Cunningham. It consists of a hollow metal ball connected to a slice of cork, which serves as the surface float.

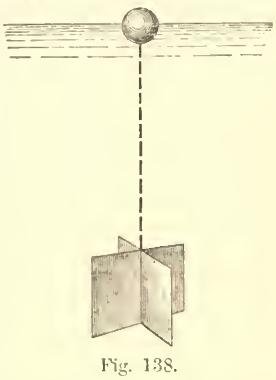

Fig. 138.

127. *Twin Floats.*—Suppose two equal and similar floats (fig. 140) connected by a wire. Let one float be a little lighter and the other a little heavier than water. Then the velocity of the combined floats will be the mean of the surface velocity and the velocity at the

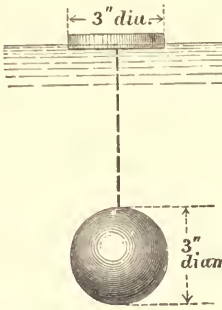

Fig. 139.

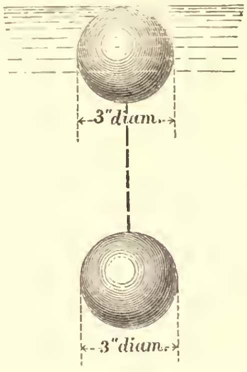

Fig. 140.

depth at which the heavier float swims, which is determined by the length of the connecting wire. Thus if v_s is the surface velocity and v_d the velocity at the depth to which the lower float is sunk, the velocity of the combined floats will be

$$v = \frac{v_s + v_d}{2} .$$

Consequently, if v is observed, and v_s determined by an experiment with a single float,

$$v_d = 2v - v_s .$$

According to Captain Cunningham, the twin float gives better results than the sub-surface float.

128. *Velocity Rods.*—Another form of float is shown in fig. 141. This consists of a cylindrical rod loaded at the lower end so as to float nearly vertical in water. A wooden rod, with a metal cap at the bottom in which shot can be placed, answers better than anything else, and sometimes the wooden rod is made in lengths which can be screwed together so as to suit streams of different depths. A tuft of cotton wool at the top serves to make the float more easily visible. Such a rod, so adjusted in length that it sinks nearly to the bed of the stream, gives directly the mean velocity of the whole vertical section in which it floats.

Fig. 141.

129. *Revy's Current Meter.*—No instrument has been so much used in directly determining the velocity of a stream at a given point as the screw current meter. Of this there are a dozen varieties at least. As an example of the instrument in its simplest form, Mr Revy's meter may be selected. This is an ordinary screw meter of a larger size than usual, more carefully made, and with its details carefully studied (figs. 142, 143). It was designed after experience in gauging the great South American rivers. The screw, which is actuated by the water, is 6 inches in diameter, and is of the type of the Griffiths screw used in ships. The hollow spherical boss serves to make the weight of the screw sensibly equal to its displacement, so that friction is much reduced. On the axis *aa* of the screw is a worm which drives the counter. This consists of two worm wheels *g* and *h* fixed on a common axis. The worm wheels are carried on a frame attached to the pin *l*. By means of a string attached to *l* they can be pulled into gear with the worm, or dropped out of gear and stopped at any instant. A nut *m* can be screwed up, if necessary, to keep the counter permanently in gear. The worm is two-threaded, and the worm wheel *g* has 200 teeth. Consequently it makes one rotation for 100 rotations of the screw, and the number of rotations up to 100 is marked by the passage of the graduations on its edge in front of a fixed index. The second worm wheel has 196 teeth, and its edge is divided into 49 divisions. Hence it falls behind the first wheel one division for a complete rotation of the latter. The number of hundreds of rotations of the screw are therefore shown by the number of divisions on *h* passed over by an index fixed to *g*. One difficulty in the use of the ordinary screw meter is that particles of grit, getting into the working parts, very sensibly alter the friction, and therefore the speed of the meter. Mr Revy obviates this by enclosing the counter in a brass box with a glass face. This box is filled with pure water, which ensures a constant coefficient of friction for the rubbing parts, and prevents any mud or grit finding its way in. In order

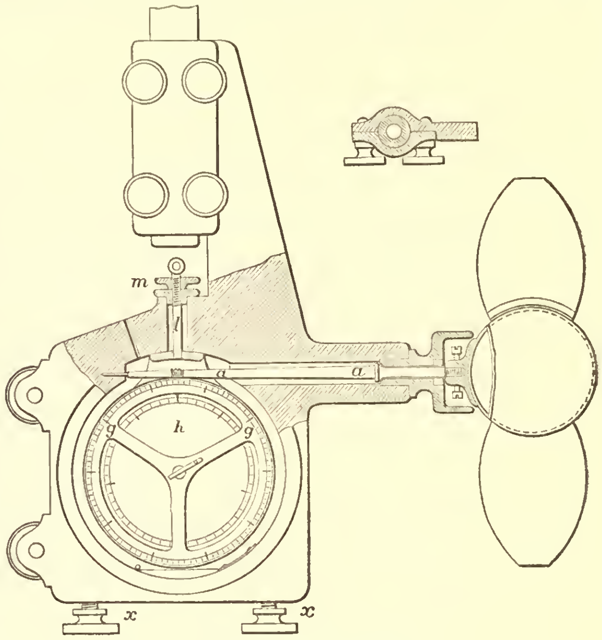

Fig. 142.—Scale ½ full size.

that the meter may place itself with the axis parallel to the current, it is pivoted on a vertical axis and directed by a large vane shown in fig. 143. To give the vane more directing power the vertical axis is nearer the screw than in ordinary meters, and the vane is larger. A second horizontal vane is attached by the screws *x*,*x*, the object of which is to allow the meter to rest on the ground without the motion of the screw being interfered with. The string or wire for starting and stopping the meter is carried through the centre of the vertical axis, so that the strain on it may not tend to pull the meter oblique to the current. The pitch of the screw is about 9 inches. The screws at *x* serve for filling the meter with water. The whole apparatus is fixed to a rod (fig. 143), of a length proportionate to the depth, or for very great depths it is fixed to a weighted bar lowered by ropes, a plan invented by Mr Revy. The instrument is generally used thus. The reading of the counter is noted, and it is put out of gear. The meter is then lowered into the water to the required position from a platform between two boats, or better from a temporary bridge. Then the counter is put into gear for one, two, or five minutes. Lastly, the instrument is raised and the counter again read. The velocity is deduced from the number of rotations in unit time by the formulæ given below. For surface velocities the counter may be kept permanently in gear, the screw being started and stopped by hand.

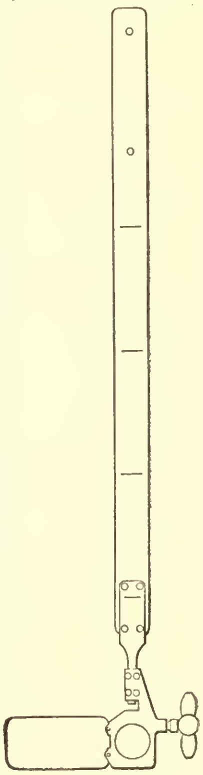

Fig. 143.

130. *The Harlacher Current Meter.*—A very interesting modification of the current meter is that made by Amsler Laffon of Schaffhausen, which is described in Heusinger von Waldegg (*Handb. der Ingenieurwissenschaften*, iii. p. 284). In this the ordinary counting apparatus is abandoned. A worm drives a worm wheel, which makes an electrical contact once for each 100 rotations of the worm. This contact gives a signal above water. With this arrangement, a series of velocity observations can be made, without removing the instrument from the water, and a number of practical difficulties attending the accurate starting and stopping of the ordinary counter are entirely got rid of. Fig 144 shows the meter. The worm wheel *z* makes one rotation for 100 of the screw. A pin moving the lever *x* makes the electrical contact. The wires *b*, *c* are led through a gas pipe B; this also serves to adjust the meter to any required position on the wooden rod *dd*. The rudder or

vane is shown at WH. The galvanic current acts on the electro-magnet m, which is fixed in a small metal box containing also the battery. The magnet exposes and withdraws a coloured disk at an opening in the cover of the box.

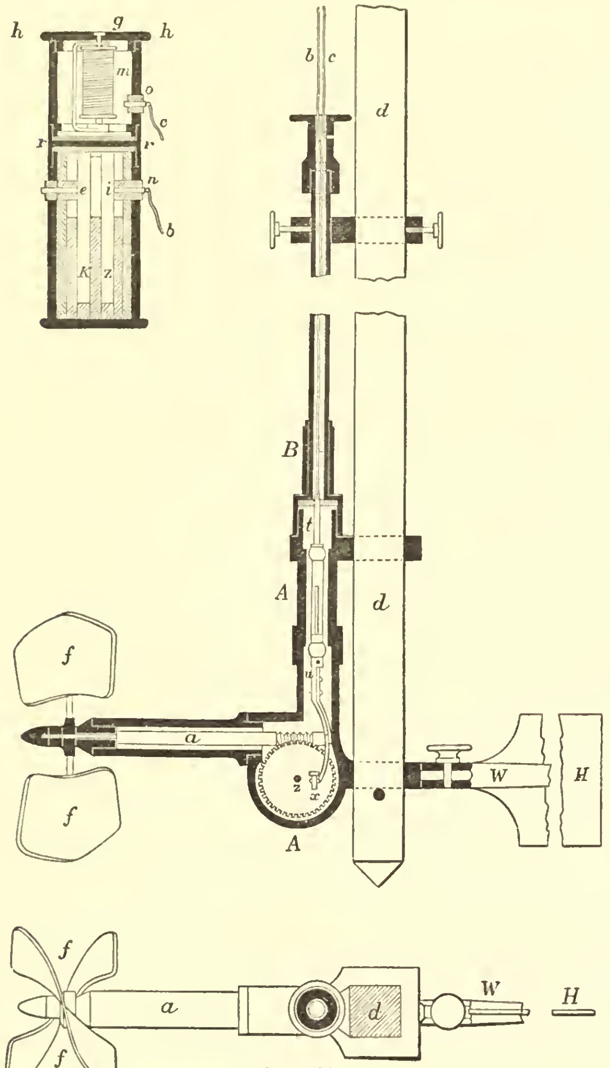

Fig. 144.

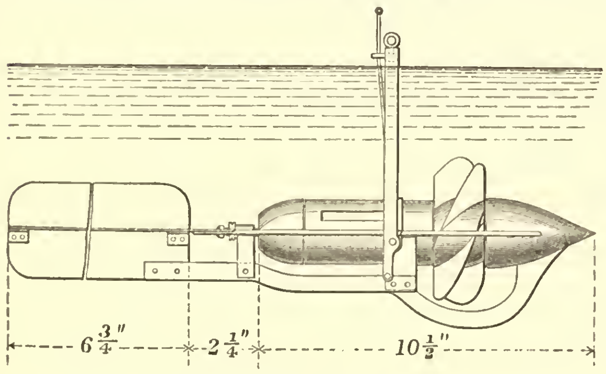
Moore's Current Meter.—The difficulties in using the ordinary current meter have been overcome to a great extent by an arrangement of another kind, invented by Mr B. T. Moore (*Proc. Inst.*



Scale $\frac{1}{6}$ *Full Size.*

Fig. 145.

Civil Eng., xlv. 220). This instrument (fig. 145) can be lowered into the water to any required depth by a light cord or chain. The counting arrangement inside the meter can be started or stopped at any instant. The instrument consists of a light brass frame carrying an ogival head, and long rudder, cross-shaped in section. The frame is suspended in a stirrup, and if necessary a lead weight can be suspended below the meter. A rotating cylinder with screw blades is placed behind the ogival head. The centre of gravity of the instrument is accurately in the intersection of the axis of the stirrup-bearings and the longitudinal axis of the instrument. The rotating cylinder is started by releasing a spring by a cord. The recording mechanism is inside the rotating cylinder. The instrument is put in motion by a very small force. Some experiments made by towing it in still water gave the following equations:—

For speeds giving more than sixty rotations per minute,

$$v = 1{\cdot}2\mathrm{R},$$

where v is the velocity of the water relatively to the instrument in feet per minute, and R the number of rotations per minute. For lower speeds,

$$v = \mathrm{R} + 12.$$

It would appear therefore that the instrument will record velocities down to 12 feet per minute. Mr Moore states that a velocity at any depth down to 20 feet can be taken in five minutes, the meter being raised and lowered much more easily than when it is attached to a rod.

Determination of the Coefficients of the Current Meter.—Suppose a series of observations have been made, by towing the meter in still water, at different speeds, and it is required from these to ascertain the coefficients of the meter. A formula must be assumed to connect the observed velocities v with the number of rotations per second n. Then, in determining the coefficients of the formula from the given observations, the condition to be fulfilled is that the sum of the squares of the differences between the observed results and those given by the formula should be a minimum.

Let the formula assumed be of the form

$$v = \alpha n + \beta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Then the difference in any case between the observed and calculated quantity is $v - \alpha n - \beta$; and therefore $\Sigma(v - \alpha n - \beta)^2$ is to be a minimum.

The coefficients being independent, we must equate separately to zero the differential coefficients of the expression with respect to the two coefficients.

$$\Sigma\Big[\,(v - \alpha n - \beta)n\,\Big] = 0\,;$$

$$\Sigma\Big[\,(v - \alpha n - \beta)\,\Big] = 0\,;$$

whence

$$\Sigma\,(n^2)\,\alpha + \Sigma(n)\beta = \Sigma(vn)\,;$$
$$\Sigma(n)\alpha + \Sigma(n)\beta = \Sigma(v)\,;$$

from which α and β are easily determined.

Exner has shown (*Zeitschrift für Bauwesen*, 1875) that the relation between the velocity of the water and the number of rotations of the meter is better expressed by the formula

$$v = \sqrt{(a^2 r^2 + v_0{}^2)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

than by that generally used. v_0 is sensibly equal to the velocity at which the meter just ceases to revolve; and a is a constant determined by experiments at different speeds. Other expressions have been given, but they are more complicated and not more accurate than (1) and (2).

131. *Darcy Gauge or Modified Pitot Tube.*—A very old instrument for measuring velocities, invented or used by Pitot, consisted simply of a vertical glass tube with a right-angled bend, placed so that its mouth was normal to the direction of flow (fig. 146).

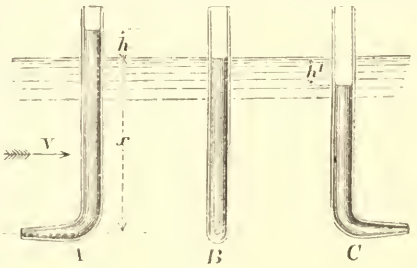


Fig. 146.

The impact of the stream on the mouth of the tube balances a column in the tube, the height of which is approximately $h = \frac{v^2}{2g}$, where v is the velocity at the depth x. Placed with its mouth parallel to the stream the water inside the tube is nearly at the same level as the surface of the stream, and turned with the mouth down stream, the fluid sinks a depth $h' = \frac{v^2}{2g}$ nearly, though the tube in that case interferes with the free flow of the liquid and somewhat modifies the result. Pitot expanded the mouth of the tube so as to form a funnel or bell mouth. In that case he found by experiment

$$h = 1{\cdot}5\,\frac{v^2}{2g}\,.$$

The objection to this is that the motion of the stream is interfered with, and it is no longer certain that the velocity in front of the orifice is exactly the velocity of the unobstructed stream. Darcy preferred to make the mouth of the tube very small, partly to avoid interference with the stream, partly to check oscillations of the column. In that case he found the difference of level of two tubes, such as A and B, to be almost exactly

$$h=\frac{v^2}{2g}.$$

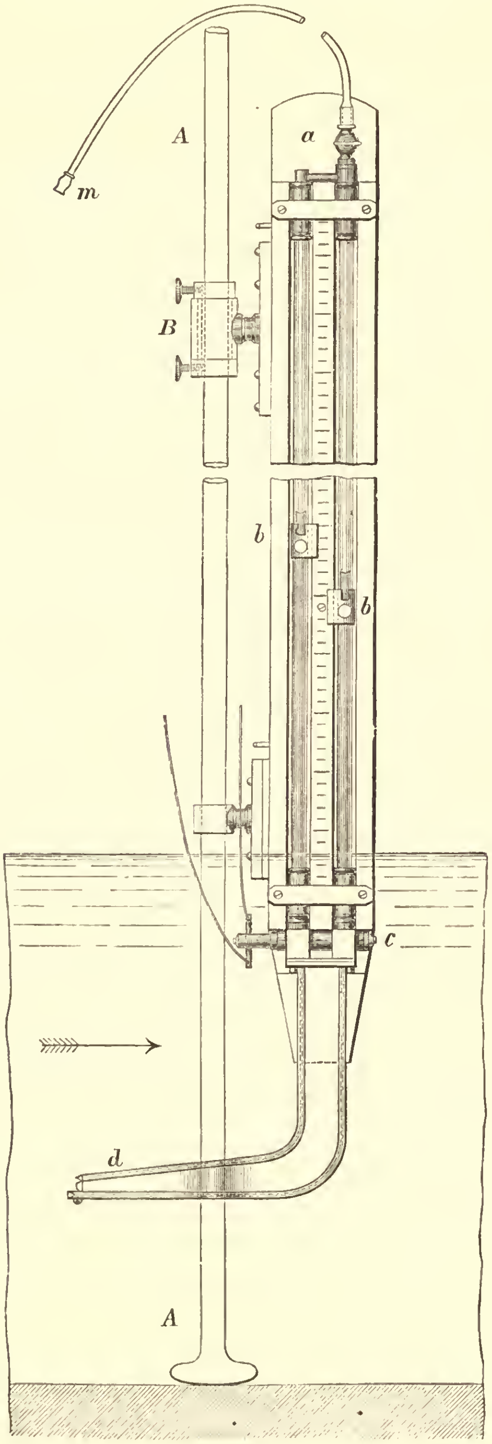

Fig. 147.

One objection to the Pitot tube in its original form was the great difficulty and inconvenience of reading the height h in the immediate neighbourhood of the stream surface. This is obviated in the Darcy gauge, which can be removed from the stream to be read.

Fig. 147 shows a Darcy gauge. It consists of two Pitot tubes having their mouths at right angles. In the instrument shown, the two tubes, formed of copper in the lower part, are united into one for strength, and the mouths of the tubes open vertically and horizontally. The upper part of the tubes is of glass, and they are provided with a brass scale and two verniers b, b. The whole instrument is supported on a vertical rod or small pile AA, the fixing at B permitting the instrument to be adjusted to any height on the rod, and at the same time allowing free rotation, so that it can be held parallel to the current. At c is a two-way cock, which can be opened or closed by cords. If this is shut, the instrument can be lifted out of the stream for reading. The glass tubes are connected at top by a brass fixing, with a stop cock a, and a flexible tube and mouthpiece m. The use of this is as follows. If the velocity is required at a point near the surface of the stream, one at least of the water columns would be below the level at which it could be read. It would be in the copper part of the instrument. Suppose then a little air is sucked out by the tube m, and the cock a closed, the two columns will be forced up an amount corresponding to the difference between atmospheric pressure and that in the tubes. But the difference of level will remain unaltered.

When the velocities to be measured are not very small, this instrument is an admirable one. It requires observation only of a single linear quantity, and does not require any time observation. The law connecting the velocity and the observed height is a rational one, and it is not absolutely necessary to make any experiments on the coefficient of the instrument. If we take

$$v=k\sqrt{2gh},$$

then it appears from Darcy's experiments that for a well-formed instrument k does not sensibly differ from unity. It gives the velocity at a definite point in the stream. The chief difficulty arises from the fact that at any given point in a stream the velocity is not absolutely constant, but varies a little from moment to moment. Darcy in some of his experiments took several readings, and deduced the velocity from the mean of the highest and lowest.

132. *Hydrodynamometer of M. Perrodil.*—This consists of a frame *abcd* (fig. 148) placed vertically in the stream, and of a height not less than the stream's depth. The two vertical members of this frame are connected by cross bars, and united above water by a circular bar, situated in the vertical plane and carrying a horizontal graduated circle *ef*. This whole system is movable round its axis, being suspended on a pivot at g connected with the fixed support *mn*. Other horizontal arms serve as guides. The central vertical rod *gr* forms a torsion rod, being fixed at r to the frame *abcd*, and, passing freely upwards through the guides, it carries a horizontal needle moving over the graduated circle *ef*. The support g, which carries the apparatus, also receives in a tubular guide the end of the torsion rod *gr* and a set screw for fixing the upper end of the torsion rod when necessary. The impulse of the stream of water is received on a circular disk x, in the plane of the torsion rod and the frame *abcd*. To raise and lower the apparatus easily, it is not fixed directly to the rod *mn*, but to a tube *kl* sliding on *mn*.

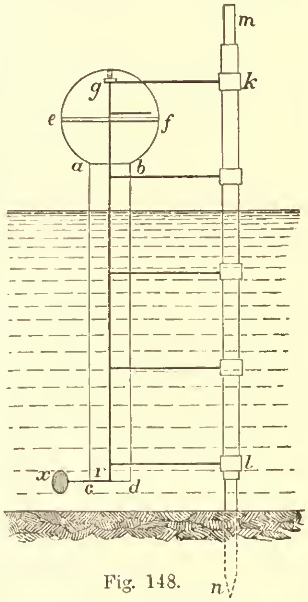

Fig. 148.

Suppose the apparatus arranged so that the disk x is at that level in the stream where the velocity is to be determined. The plane *abcd* is placed parallel to the direction of motion of the water. Then the disk x (acting as a rudder) will place itself parallel to the stream on the down stream side of the frame. The torsion rod will be unstrained, and the needle will be at zero on the graduated circle. If then the instrument is turned by pressing the needle, till the plane *abcd* of the disk and the zero of the graduated circle is at right angles to the stream, the torsion rod will be twisted through an angle which measures the normal impulse of the stream on the disk x. That angle will be given by the distance of the needle from zero. Observation shows that the velocity of the water at a given point is not constant. It varies between limits more or less wide. When the apparatus is nearly in its right position, the set screw at g is made to clamp the torsion spring. Then the needle is fixed, and the apparatus carrying the graduated circle oscillates. It is not then difficult to note the mean angle marked by the needle.

Let r be the radius of the torsion rod, l its length from the needle over *ef* to r, and α the observed torsion angle. Then the moment of the couple due to the molecular forces in the torsion rod is

$$M = E_t I \frac{a}{l};$$

where E_t is the modulus of elasticity for torsion, and I the polar moment of inertia of the section of the rod. If the rod is of circular section, $I = \frac{1}{2}\pi r^4$. Let R be the radius of the disk, and b its leverage, or the distance of its centre from the axis of the torsion rod. The moment of the pressure of the water on the disk is

$$Fb = kb\frac{G}{2g}\pi R^2 v^2,$$

where G is the heaviness of water and k an experimental coefficient. Then

$$E_t I \frac{a}{l} = kb\frac{G}{2g}\pi R^2 v^2.$$

For any given instrument,

$$v = c\sqrt{a};$$

where c is a constant coefficient for the instrument.

The instrument as constructed had three disks which could be used at will. Their radii and leverages were in feet

	R=	b=
1st disk	0·052	0·16
2d ,,	0·105	0·32
3d ,,	0·210	0·66

For a thin circular plate, the coefficient $k = 1·12$. In the actual instrument the torsion rod was a brass wire 0·06 inch diameter and $6\frac{1}{2}$ feet long. Supposing a measured in degrees, we get by calculation

$$v = 0·335\sqrt{a}\ ;\ 0·115\sqrt{a}\ ;\ 0·042\sqrt{a}$$

for the three disks.

Very careful experiments were made with the instrument. It was fixed to a wooden turning bridge, revolving over a circular channel of 2 feet width, and about 76 feet circumferential length. An allowance was made for the slight current produced in the channel. These experiments gave for the coefficient c, in the formula $v = c\sqrt{a}$,

1st disk,	$c = 0·3126$	for velocities of	3 to 16 feet
2d ,,	0·1177	,, ,,	$1\frac{1}{4}$ to $3\frac{1}{4}$,,
3d ,,	0·0349	,, ,,	less than $1\frac{1}{4}$,,

or values little different from the values calculated from the torsion.

The instrument is preferable to the current meter in giving the velocity in terms of a single observed quantity, the angle of torsion, while the current meter involves the observation of two quantities, the number of rotations and the time. The current meter, except in some improved forms, must be withdrawn from the water to read the result of each experiment, and the law connecting the velocity and number of rotations of a current meter is less well-determined than that connecting the pressure on a disk and the torsion of the wire of a hydrodynamometer. At very low velocities the current meter fails altogether.

The Pitot tube, like the hydrodynamometer, does not require a time observation. But, where the velocity is a varying one, and consequently the columns of water in the Pitot tube are oscillating, there is room for doubt as to whether, at any given moment of closing the cock, the difference of level exactly measures the impulse of the stream at the moment. The Pitot tube also fails to give measurable indications of very low velocities.

Processes for Gauging Streams.

133. *Gauging by Observation of the Maximum Surface Velocity.*—The method of gauging which involves the least trouble is to determine the surface velocity at the thread of the stream, and to deduce from it the mean velocity of the whole cross section. The maximum surface velocity may be determined by floats or by a current meter. Unfortunately, however, the ratio of the maximum surface to the mean velocity is extremely variable. Thus putting v_0 for the surface velocity at the thread of the stream, and v_m for the mean velocity of the whole cross section, $\frac{v_m}{v_0}$ has been found to have the following values:—

	$\frac{v_m}{v_0}$
De Prony, experiments on small wooden channels,	0·8164
Experiments on the Seine, ...	0·62
Destrem and De Prony, experiments on the Neva,	0·78
Boileau, experiments on canals, ...	0·82
Baumgartner, experiments on the Garonne, ...	0·80
Brünings (mean), ...	0·85
Cunningham, Solani aqueduct, ...	0·823

Various formulæ, either empirical or based on some theory of the vertical and horizontal velocity curves, have been proposed for determining the ratio $\frac{v_m}{v_0}$. Bazin found from his experiments the empirical expression

$$v_m = v_0 - 25·4\sqrt{mi};$$

where m is the hydraulic mean depth and i the slope of the stream. In article 101, it has already been shown how from this formula the ratio $\frac{v_m}{v_0}$ can be obtained for different kinds of channels.

In the case of irrigation canals and rivers, it is often important to determine the discharge either daily or at other intervals of time, while the depth and consequently the mean velocity is varying. Captain Cunningham, R.E. (*Roorkee Prof. Papers*, vol. iv. p. 47), has shown that, for a given part of such a stream, where the bed is regular and of permanent section, a simple formula may be found for the variation of the central surface velocity with the depth. When once the constants of this formula have been determined by measuring the central surface velocity and depth, in different conditions of the stream, the surface velocity can be obtained by simply observing the depth of the stream, and from this the mean velocity and discharge can be calculated. Let z be the depth of the stream, and v_0 the surface velocity, both measured at the thread of the stream. Then

$$v_0^2 = cz;$$

where c is a constant which for the Solani aqueduct had the values 1·9 to 2, the depths being 6 to 10 feet, and the velocities $3\frac{1}{2}$ to $4\frac{1}{2}$ feet. Without any assumption of a formula, however, the surface velocities, or still better the mean velocities, for different conditions of the stream may be plotted on a diagram in which the abscissæ are depths and the ordinates velocities. The continuous curve through points so found would then always give the velocity for any observed depth of the stream, without the need of making any new float or current meter observations.

134. *Mean Velocity determined by observing a Series of Surface Velocities.*—The ratio of the mean velocity to the surface velocity in one longitudinal section is better ascertained than the ratio of the central surface velocity to the mean velocity of the whole cross section. Suppose the river divided into a number of compartments by equidistant longitudinal planes, and the surface velocity observed in each compartment. From this the mean velocity in each compartment and the discharge can be calculated. The sum of the partial discharges will be the total discharge of the stream. When wires or ropes can be stretched across the stream, the compartments can be marked out by tags attached to them. Suppose two such ropes stretched across the stream, and floats dropped in above the upper rope. By observing within which compartment the path of the float lies, and noting the time of transit between the ropes, the surface velocity in each compartment can be ascertained. The mean velocity in each compartment is 0·85 to 0·91 of the surface velocity in that compartment. Putting k for this ratio, and $v_1, v_2 \ldots$ for the observed velocities, in compartments of area $\Omega_1, \Omega_2 \ldots$ then the total discharge is

$$Q = k(\Omega_1 v_1 + \Omega_2 v_2 + \ldots).$$

If several floats are allowed to pass over each compartment, the mean of all those corresponding to one compartment is to be taken as the surface velocity of that compartment.

This method is very applicable in the case of large streams or rivers too wide to stretch a rope across. The paths of the floats are then ascertained in this way. Let fig. 149 represent a portion of the river, which should be straight and free from obstructions. Suppose a base line AB measured parallel to the thread of the stream, and let the mean cross section of the stream be ascertained either by sounding the terminal cross sections AE, BF, or by sounding a series of equidistant cross sections. The cross sections are taken at right angles to the base line. Observers are placed at A and B with theodolites or box sextants. The floats are dropped in from a boat above AE, and picked up by another boat below BF. An observer with a chronograph or watch notes the time in which each float passes from AE to BF. The method of proceeding is this. The observer A sets his theodolite in the direction AE, and gives a signal to drop a float. B keeps his instrument on the float as it comes down. At the moment the float arrives at C in the line AE, the observer at A calls out. B clamps his instrument and reads off the angle ABC, and the time observer begins to note the time of transit. B now points his instrument in the direction BF, and A keeps the float on the cross wire of his instrument. At the moment the float arrives at D in the line BF, the observer B calls out, A clamps his instrument and reads off the angle BAD, and the time observer notes the time of transit from C to D. Thus all

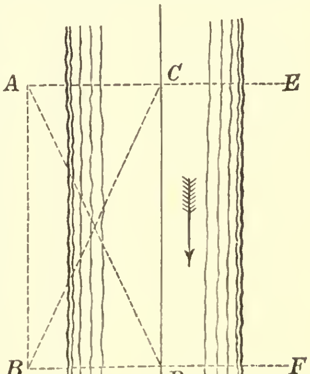

Fig. 149.

the data are determined for plotting the path CΓ of the float and determining its velocity. By dropping in a series of floats, a number of surface velocities can be determined. When all these have been plotted, the river can be divided into convenient compartments. The observations belonging to each compartment are then averaged, and the mean velocity and discharge calculated. It is obvious that, as the surface velocity is greatly altered by wind, experiments of this kind should be made in very calm weather.

The ratio of the surface velocity to the mean velocity in the same vertical can be ascertained from the formulæ for the vertical velocity curve already given (§ 101). Exner, in *Erbkam's Zeitschrift* for 1875, has given the following convenient formula. Let v be the mean and V the surface velocity in any given vertical longitudinal section, the depth of which is h

$$\frac{v}{V}=\frac{1+0{\cdot}1478\sqrt{h}}{1+0{\cdot}2216\sqrt{h}}$$

If vertical velocity rods are used instead of common floats, the mean velocity is directly determined for the vertical section in which the rod floats. No formula of reduction is then necessary. The observed velocity has simply to be multiplied by the area of the compartment to which it belongs.

135. *Mean Velocity of the Stream from a Series of Mid Depth Velocities.*—In the gaugings of the Mississippi it was found that the mid depth velocity differed by only a very small quantity from the mean velocity in the vertical section, and it was uninfluenced by wind. If therefore a series of mid depth velocities are determined by double floats or by a current meter, they may be taken to be the mean velocities of the compartments in which they occur, and no formula of reduction is necessary. If floats are used, the method is precisely the same as that described in the last paragraph for surface floats. The paths of the double floats are observed and plotted, and the mean taken of those corresponding to each of the compartments into which the river is divided. The discharge is the sum of the products of the observed mean mid depth velocities and the areas of the compartments.

136. *Boileau's Process for Gauging Streams.*—Let U be the mean velocity at a given section of a stream, V the maximum velocity, or that of the principal filament, which is generally a little below the surface, W and w the greatest and least velocities at the surface. The distance of the principal filament from the surface is generally less than one-fourth of the depth of the stream; W is a little less than V; and U lies between W and w. As the surface velocities change continuously from the centre towards the sides, there are at the surface two filaments having a velocity equal to U. The determination of the position of these filaments, which Boileau terms the gauging filaments, cannot be effected entirely by theory. But, for sections of a stream in which there are no abrupt changes of depth, their position can be very approximately assigned. Let Δ and l be the horizontal distances of the surface filament, having the velocity W, from the gauging filament, which has the velocity U, and from the bank on one side. Then

$$\frac{\Delta}{l}=c\sqrt[4]{\frac{W+2w}{7(W-w)}},$$

c being a numerical constant. From gaugings by Humphreys and Abbot, Bazin, and Baumgarten, the values $c=0{\cdot}919$, $0{\cdot}922$, and $0{\cdot}925$ are obtained. Boileau adopts as a mean value $0{\cdot}922$. Hence, if W and w are determined by float gauging or otherwise, Δ can be found, and then a single velocity observation at Δ feet from the filament of maximum velocity gives, without need of any reduction, the mean velocity of the stream. More conveniently W, w, and U can be measured from a horizontal surface velocity curve, obtained from a series of float observations.

137. *Direct Determination of the Mean Velocity by a Current Meter or Darcy Gauge.*—The only method of determining the mean velocity at a cross section of a stream which involves no assumption of the ratio of the mean velocity to other quantities is this—a plank bridge is fixed across the stream near its surface. From this, velocities are observed at a sufficient number of points in the cross section of the stream, evenly distributed over its area. The mean of these is the true mean velocity of the stream. In Darcy and Bazin's experiments on small streams, the velocity was thus observed at 36 points in the cross section.

When the stream is too large to fix a bridge across it, the observations may be taken from a boat, or from a couple of boats with a gangway between them, anchored successively at a series of points across the width of the stream. The position of the boat for each series of observations is fixed by angular observations to a base line on shore.

138. *Harlacher's Graphic Method of determining the Discharge from a Series of Current Meter Observations.*—Let ABC (fig. 150) be the cross section of a river at which a complete series of current meter observations have been taken. Let I., II., III. . . . be the verticals at different points of which the velocities were measured. Suppose the depths at I., II., III., . . . (fig. 150), set off as vertical ordinates in fig. 151, and on these vertical ordinates suppose the velocities set off horizontally at their proper depths. Thus, if v is the measured velocity at the depth h from the surface in fig. 150, on vertical marked III., then at III. in fig. 151 take $cd=h$ and $ac=v$.

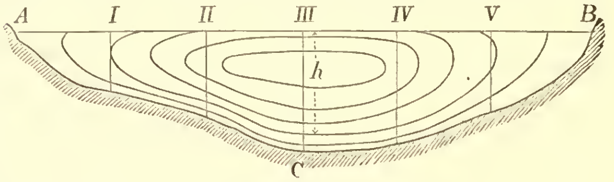

Fig. 150.

Then d is a point in the vertical velocity curve for the vertical III., and, all the velocities for that ordinate being similarly set off, the curve can be drawn. Suppose all the vertical velocity curves I. . . . V. (fig. 151), thus drawn. On each of these figures draw verticals corresponding to velocities of x, $2x$, $3x$ . . . feet per second. Then for instance cd at III. (fig. 151) is the depth at which a velocity of $2x$ feet per second existed on the vertical III. in fig. 150, and if cd is set off at III. in fig. 150 it gives a point in a curve passing through points of the section where the velocity was $2x$ feet per second. Set off on each of the verticals in fig. 150 all the depths thus found in the corresponding diagram in fig. 151. Curves drawn through the corresponding points on the verticals are curves of equal velocity.

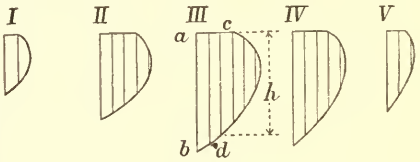

Fig. 151.

The discharge of the stream per second may be regarded as a solid having the cross section of the river (fig. 150), as a base, and cross sections normal to the plane of fig. 150 given by the diagrams in fig. 151. The curves of equal velocity may therefore be considered as contour lines of the solid whose volume is the discharge of the stream per second. Let Ω_0 be the area of the cross section of the river, Ω_1, Ω_2 . . . . the areas contained by the successive curves of equal velocity, or, if these cut the surface of the stream, by the curves and that surface. Let x be the difference of velocity for which the successive curves are drawn, assumed above for simplicity at 1 foot per second. Then the volume of the successive layers of the solid body whose volume represents the discharge, limited by successive planes passing through the contour curves, will be

$$\tfrac{1}{2}x(\Omega_0+\Omega_1),\qquad \tfrac{1}{2}x(\Omega_1+\Omega_2),\qquad \text{and so on.}$$

Consequently the discharge is

$$Q=x\left\{\frac{\Omega_0+\Omega_n}{2}+\Omega_1+\Omega_2+\ .\ .\ .\ +\Omega_{n-1}\right\}.$$

The areas Ω_0, Ω_1 . . . . are easily ascertained by means of the polar planimeter. A slight difficulty arises in the part of the solid lying above the last contour curve. This will have generally a height which is not exactly x, and a form more rounded than the other layers and less like a conical frustum. The volume of this may be estimated separately, and taken to be the area of its base (the area Ω_n) multiplied by $\frac{1}{3}$ to $\frac{1}{2}$ its height.

Fig. 152 shows the results of one of Professor Harlacher's gaugings worked out in this way. The upper figure shows the section of the river and the positions of the verticals at which the soundings and gaugings were taken. The lower gives the curves of equal velocity, worked out from the current meter observations, by the aid of vertical velocity curves. The vertical scale in this figure is ten times as great as in the other. The discharge calculated from the contour curves is 14·1087 cubic metres per second. In the lower figure some other interesting curves are drawn. Thus, the uppermost dotted curve is the curve through points at which the maximum velocity was found; it shows that the maximum velocity was always a little below the surface, and at a greater depth at the centre than at the sides. The next curve shows the depth at which the mean velocity for each vertical was found. The next is the curve of equal velocity corresponding to the mean velocity of the stream; that is, it passes through points in the cross section where the velocity was identical with the mean velocity of the stream.

XII. IMPACT AND REACTION OF WATER.

When a stream of fluid impinges on a solid surface, it presses on the surface with a force equal and opposite to that by which the velocity and direction of motion of the fluid are changed. Generally, in problems on the impact of fluids, it is necessary to neglect the effect of friction between the fluid and the surface on which it moves.

139. *During Impact the Velocity of the Fluid relatively to the Surface on which it impinges remains unchanged in Magnitude.*—Con-

sider a mass of fluid flowing in contact with a solid surface also in motion, the motion of both fluid and solid being estimated relatively to the earth. Then the motion of the fluid may be resolved into two parts, one a motion equal to that of the solid, and in the same direction, the other a motion relatively to the solid. The motion which the fluid has in common with the solid cannot at all be influenced by the contact. The relative component of the motion of the fluid can only be altered in direction, but not in magnitude. The fluid moving in contact with the surface can only have a relative motion parallel to the surface, while the pressure between the fluid and

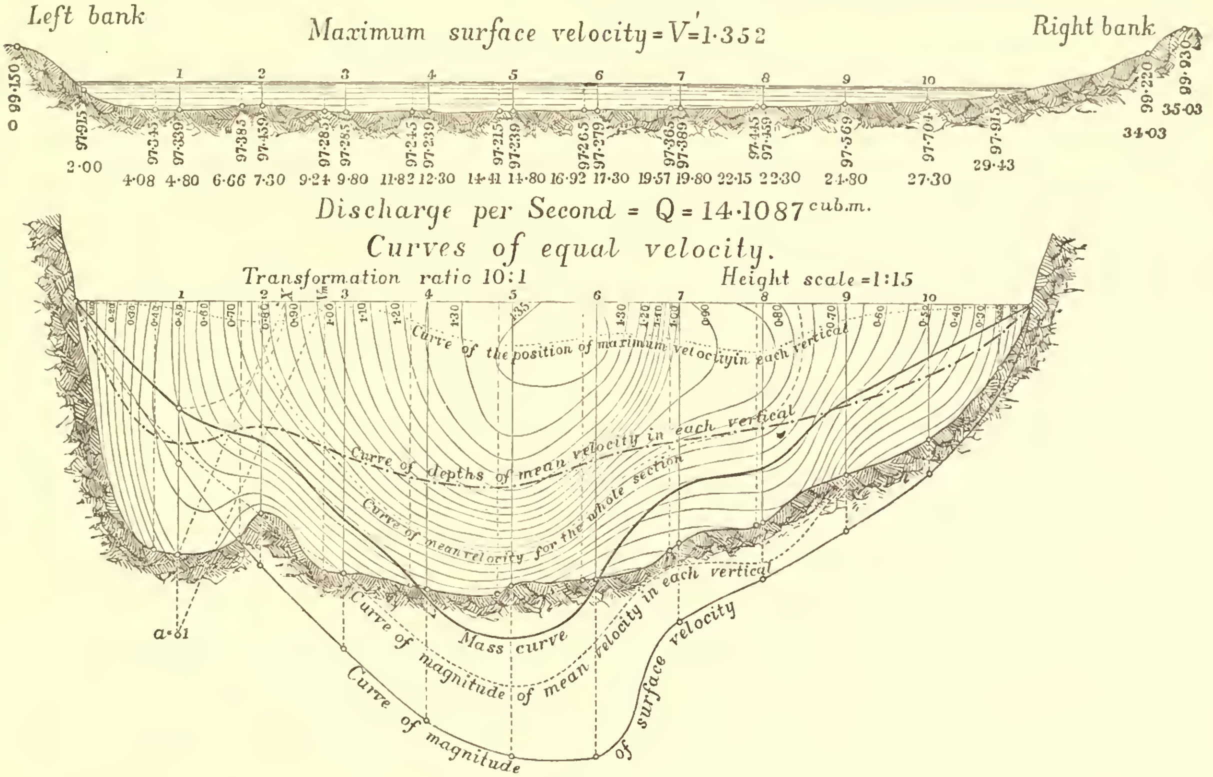

Fig. 152.

solid, if friction is neglected, is normal to the surface. The pressure therefore can only deviate the fluid, without altering the magnitude of the relative velocity. The unchanged common component and, combined with it, the deviated relative component give the resultant final velocity, which may differ greatly in magnitude and direction from the initial velocity.

From the principle of momentum the impulse of any mass of fluid reaching the surface in any given time is equal to the change of momentum estimated in the same direction. The pressure between the fluid and surface, in any direction, is equal to the change of momentum in that direction of so much fluid as reaches the surface in one second. If P_a is the pressure in any direction, m the mass of fluid impinging per second, v_a the change of velocity in the direction of P_a due to impact, then

$$P_a = mv_a .$$

If v_1 (fig. 153) is the velocity and direction of motion before impact, v_2 that after impact, then v is the total change of motion due to impact. The resultant pressure of the fluid on the surface is in the direction of v, and is equal to v multiplied by the mass impinging per second. That is, putting P for the resultant pressure,

$$P = mv .$$

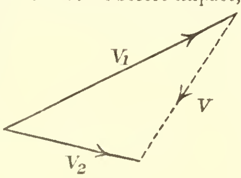

Fig. 153.

Let P be resolved into two components, N and T, normal and tangential to the direction of motion of the solid on which the fluid impinges. Then N is a lateral force producing a pressure on the supports of the solid, T is an effort which does work on the solid. If u is the velocity of the solid, Tu is the work done per second by the fluid in moving the solid surface.

Let Q be the volume, and GQ the weight of the fluid impinging per second, and let v_1 be the initial velocity of the fluid before striking the surface. Then $\frac{1}{2}\frac{G}{g}Qv_1^2$ is the original kinetic energy of Q cubic feet of fluid, and the efficiency of the stream considered as an arrangement for moving the solid surface is

$$\eta = \frac{Tu}{\frac{1}{2}\frac{G}{g}Qv_1^2} .$$

140. *Jet deviated entirely in one Direction—Geometrical Solution* (fig. 154).—Suppose a jet of water impinges on a surface ac with a velocity ab, and let it be wholly deviated in planes parallel to the

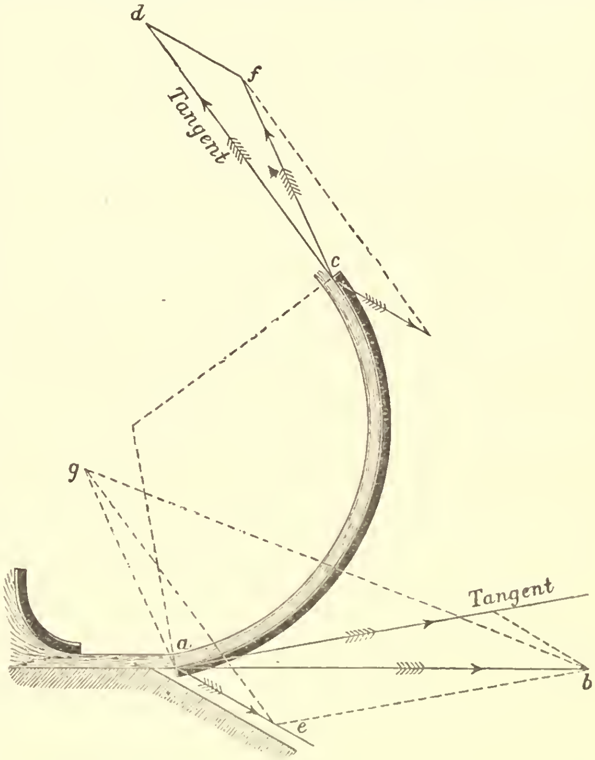

Fig. 154.

figure. Also let ac be the velocity and direction of motion of the surface. Join eb; then the water moves with respect to the surface in the direction and with the velocity eb. As this relative velocity is unaltered by contact with the surface, take $cd=eb$, then cd is the relative motion of the water with respect to the surface at c. Take df equal and parallel to ac. Then fc (obtained by compounding the relative motion of water to surface and common velocity of water and surface) is the absolute velocity and direction of the water leaving the surface. Take ag equal and parallel to fc. Then, since ab is the initial and ag the final velocity and direction of motion, gb is the total change of motion of the water. The resultant pressure on the plane is in the direction gb. Join eg. In the triangle gae, ae is equal and parallel to df, and ag to fc. Hence eg is equal and parallel to cd. But $cd=eb$ = relative motion of water and surface. Hence the change of motion of the water is represented in magnitude and direction by the third side of an isosceles triangle, of which the other sides are equal to the relative velocity of the water and surface, and parallel to the initial and final directions of relative motion.

Special Cases.

141. (1) *A Jet impinges on a plane surface at rest, in a direction normal to the plane* (fig. 155).—Let a jet whose section is ω impinge with a velocity v on a plane surface at rest, in a direction normal to the plane. The particles approach the plane, are gradually deviated, and finally flow away parallel to the plane, having then no velocity in the original direction of the jet. The quantity of water impinging per second is ωv. The pressure on the plane, which is equal to the change of momentum per second, is $\frac{G}{g}\omega v^2$.

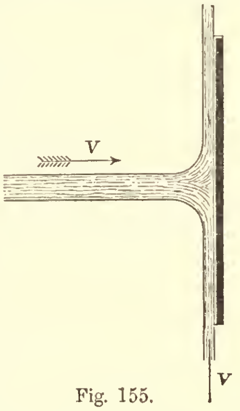

Fig. 155.

(2) *If the plane is moving in the direction of the jet with the velocity* $\pm u$, the quantity impinging per second is $\omega(v\mp u)$. The momentum of this quantity before impact is $\frac{G}{g}\omega(v\mp u)v$. After impact, the water still possesses the velocity $\pm u$ in the direction of the jet; and the momentum, in that direction, of so much water as impinges in one second, after impact, is $\pm\frac{G}{g}\omega(v\mp u)u$. The pressure on the plane, which is the change of momentum per second, is the difference of these quantities or $\frac{G}{g}\omega(v\mp u)^2$. This differs from the expression obtained in the previous case, in that the relative velocity of the water and plane $v\mp u$ is substituted for v. The expression may be written $P=2\times G\times\omega\left(\frac{v\mp u}{2g}\right)^2$, where the last term is the volume of a prism of water whose section is the area of the jet and whose length is the head due to the relative velocity. The pressure on the plane is twice the weight of that prism of water. The work done on the plane in this case is $Pu=\frac{G}{g}\omega(v\mp u)^2$ foot-pounds per second. There issue from the jet ωv cubic feet per second, and the energy of this quantity before impact is $\frac{G}{2g}\omega v^3$. The efficiency of the jet is therefore $\eta=2\frac{(v\mp u)^2}{v^3}u$. The value of u which makes this a maximum is found by differentiating and equating the differential coefficient to zero:—

$$\frac{d\eta}{du}=2\left(\frac{v^2\mp 4vu+3u^2}{v^3}\right)=0\,;$$

$$\therefore\quad u=v \text{ or } \tfrac{1}{3}v.$$

The former gives a minimum, the latter a maximum efficiency.

Putting $u=\frac{1}{3}v$ in the expression above,

$$\eta \text{ max.} = \tfrac{8}{27}\,.$$

(3) If, instead of one plane moving before the jet, a series of planes are introduced at short intervals at the same point, the quantity of water impinging on the series will be ωv instead of $\omega(v-u)$, and the whole pressure $=\frac{G}{g}\omega v(v-u)$. The work done is $\frac{G}{g}\omega vu(v-u)$. The efficiency $\eta=\frac{G}{g}\omega vu(v-u)\div\frac{G}{2g}\omega v^3=2u\left(\frac{v-u}{v^2}\right)$. This becomes a maximum for $\frac{d\eta}{du}=2(v-2u)=0$, or $u=\frac{1}{2}v$. This result is often used as an approximate expression for the velocity of greatest efficiency when a jet of water strikes the floats of a water wheel. The work wasted in this case is half the whole energy of the jet when the floats run at the best speed.

142. (4) *Case of a Concave Cup Vane*, velocity of water v, velocity of vane in the same direction u (fig. 156).

If the cup is hemispherical, the water leaves the cup in a direction parallel to the jet. Its relative velocity is $v-u$ when approaching the cup, and $-(v-u)$ when leaving it. Hence its absolute velocity when leaving the cup is $u-(v-u)=2u-v$. The change of momentum per second $=\frac{G}{g}\omega(v-u)v-\frac{G}{g}\omega(v-u)(2u-v)=2\frac{G}{g}\omega(v-u)^2$.

Comparing this with case 2, it is seen that the pressure on a hemispherical cup is double that on a flat plane. The work done on the cup $=2\frac{G}{g}\omega(v-u)^2u$ foot-pounds per second. The efficiency of the jet is greatest when $v=2u$; in that case the efficiency $=\frac{1}{2}$.

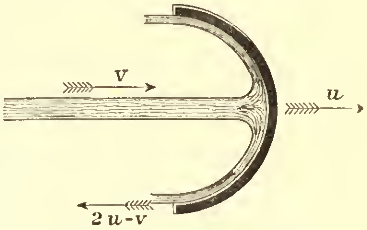

Fig. 156.

If a series of cup vanes are introduced in front of the jet, so that the quantity of water acted upon is ωv instead of $\omega(v-u)$, then the whole pressure on the chain of cups is $\frac{G}{g}\omega v^2-\frac{G}{g}\omega v(2u-v)=2\frac{G}{g}\omega v(v-u)$. In this case the efficiency is greatest when $v=2u$, and the maximum efficiency is unity, or all the energy of the water is expended on the cups.

143. (5) *Case of a Flat Vane oblique to the Jet* (fig. 157).—This case presents some difficulty. The water spreading on the plane in all directions from the point of impact, different particles leave the plane with different absolute velocities. Let $AB=v=$ velocity of water, $AC=u=$ velocity of plane. Then, completing the parallelogram, AD represents in magnitude and direction the relative velocity of water and plane. Draw AE normal to the plane and DE parallel to

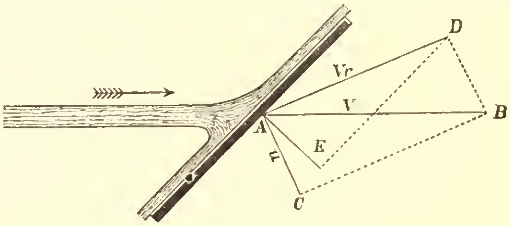

Fig. 157.

the plane. Then the relative velocity AD may be regarded as consisting of two components, one AE normal, the other DE parallel to the plane. On the assumption that friction is insensible, DE is unaffected by impact, but AE is destroyed. Hence AE represents the entire change of velocity due to impact and the direction of that change. The pressure on the plane is in the direction AE, and its amount is = mass of water impinging per second × AE.

Let $DAE=\theta$, and let $AD=v_r$. Then $AE=v_r\cos\theta$; $DE=v_r\sin\theta$. If Q is the volume of water impinging on the plane per second, the change of momentum is $\frac{G}{g}Qv_r\cos\theta$. Let $AC=u=$ velocity of the plane, and let AC make the angle $CAE=\delta$ with the normal to the plane. The velocity of the plane in the direction $AE=u\cos\delta$. The work of the jet on the plane $=\frac{G}{g}Qv_r\cos\theta\, u\cos\delta$. The same problem may be thus treated algebraically (fig. 158). Let $BAF=\alpha$, and $CAF=\delta$. The velocity v of the water may be decom-

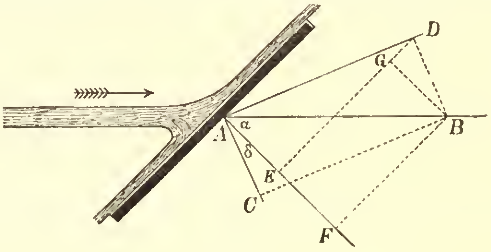

Fig 158.

posed into $AF=v\cos\alpha$ normal to the plane, and $FB=v\sin\alpha$ parallel to the plane. Similarly the velocity of the plane $=u=AC=BD$ can be decomposed into $BG=FE=u\cos\delta$ normal to the plane, and $DG=u\sin\delta$ parallel to the plane. As friction is neglected, the velocity of the water parallel to the plane is unaffected by the impact, but its component $v\cos\alpha$ normal to the plane becomes after impact the same as that of the plane, that is, $u\cos\delta$. Hence the change of velocity during impact $=AE=v\cos\alpha-u\cos\delta$. The change of momentum per second, and consequently the normal pressure on the plane is $N=\frac{G}{g}Q(v\cos\alpha-u\cos\delta)$. The pressure in the direction in which the plane is moving is $P = N\cos\delta = \frac{G}{g}Q(v\cos\alpha - u\cos\delta)\cos\delta$, and the work done on the plane is

$Pu = \frac{G}{g}Q(v\cos\alpha - u\cos\delta)$ $u\cos\delta$, which is the same expression as before, since $AE = v_r\cos\theta = v\cos\alpha - u\cos\delta$.

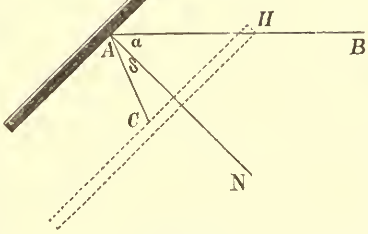

Fig. 159.

In one second the plane moves so that the point A (fig. 159) comes to C, or from the position shown in full lines to the position shown in dotted lines. If the plane remained stationary, a length $AB = v$ of the jet would impinge on the plane, but, since the plane moves in the same direction as the jet, only the length $HB = AB - AH$ impinges on the plane.

But $AH = AC\frac{\cos\delta}{\cos\alpha} = u\frac{\cos\delta}{\cos\alpha}$, and therefore $HB = v - u\frac{\cos\delta}{\cos\alpha}$. Let ω = sectional area of jet; volume impinging on plane per second $= Q = \omega\left(v - u\frac{\cos\delta}{\cos\alpha}\right) = \omega\frac{v\cos\alpha - u\cos\delta}{\cos\alpha}$. Inserting this in the formulæ above, we get

$$N = \frac{G}{g}\frac{\omega}{\cos\alpha}(v\cos\alpha - u\cos\delta)^2 \quad \ldots \quad (1);$$

$$P = \frac{G}{g}\frac{\omega\cos\delta}{\cos\alpha}(v\cos\alpha - u\cos\delta)^2 \quad \ldots \quad (2);$$

$$Pu = \frac{G}{g}\omega u\frac{\cos\delta}{\cos\alpha}(v\cos\alpha - u\cos\delta)^2 \quad \ldots \quad (3).$$

Three cases may be distinguished:—

(*a*) The plane is at rest. Then $u = 0$, $N = \frac{G}{g}\omega v^2\cos\alpha$; and the work done on the plane and the efficiency of the jet are zero.

(*b*) The plane moves parallel to the jet. Then $\delta = \alpha$, and $Pu = \frac{G}{g}\omega u\cos^2\alpha\,(v-u)^2$, which is a maximum when $u = \frac{1}{3}v$.

When $u = \frac{1}{3}v$ then Pu max. $= \frac{4}{27}\frac{G}{g}\omega v^3\cos^2\alpha$, and the efficiency $= \eta = \frac{4}{9}\cos^2\alpha$.

(*c*) The plane moves perpendicularly to the jet. Then $\delta = 90° - \alpha$; $\cos\delta = \sin\alpha$; and $Pu = \frac{G}{g}\omega u\frac{\sin\alpha}{\cos\alpha}(v\cos\alpha - u\sin\alpha)^2$. This is a maximum when $u = \frac{1}{3}v\cos\alpha$.

When $u = \frac{1}{3}v\cos\alpha$, the maximum work and the efficiency are the same as in the last case.

144. *Best Form of Vane to receive Water.*—When water impinges normally or obliquely on a plane, it is scattered in all directions after impact, and the work carried away by the water is then generally lost, from the impossibility of dealing afterwards with streams of water deviated in so many directions. By suitably forming the vane, however, the water may be entirely deviated in one direction, and the loss of energy from agitation of the water is entirely avoided.

Let AB (fig. 160) be a vane, on which a jet of water impinges at the point A and in the direction AC. Take $AC = v$ = velocity of water, and let AD represent in magnitude and direction the velocity of the vane. Completing the parallelogram, DC or AE repre-

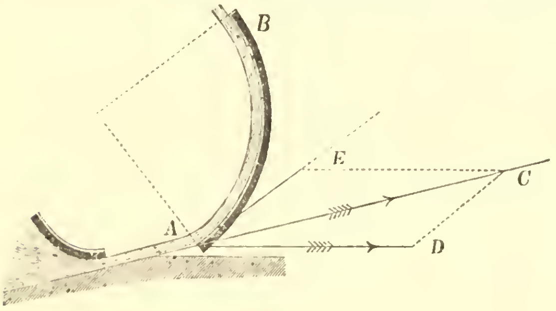

Fig. 160.

sents the direction in which the water is moving relatively to the vane. If the lip of the vane at A is tangential to AE, the water will not have its direction suddenly changed when it impinges on the vane, and will therefore have no tendency to spread laterally. On the contrary it will be so gradually deviated that it will *glide* up the vane in the direction AB. This is sometimes expressed by saying that the vane *receives the water without shock.*

145. *Floats of Poncelet Water Wheels.*—Let AC (fig. 161) represent the direction of a thin horizontal stream of water having the

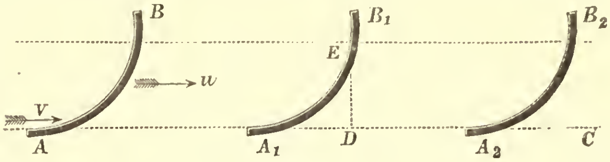

Fig. 161.

velocity v. Let AB be a curved float moving horizontally with velocity u. The relative motion of water and float is then initially horizontal, and equal to $v - u$.

In order that the float may receive the water without shock, it is necessary and sufficient that the lip of the float at A should be tangential to the direction AC of relative motion. At the end of $\frac{v-u}{g}$ seconds the float moving with the velocity u comes to the position A_1B_1, and during this time a particle of water received at A and gliding up the float with the relative velocity $v - u$, attains a height $DE = \frac{(v-u)^2}{2g}$. At E the water comes to relative rest. It then descends along the float, and when after $\frac{2(v-u)}{g}$ seconds the float has come to A_2B_2 the water will again have reached the lip at A_2 and will quit it tangentially, that is, in the direction CA_2, with a relative velocity $-(v-u) = -\sqrt{2gDE}$ acquired under the influence of gravity. The absolute velocity of the water leaving the float is therefore $u - (v - u) = 2u - v$. If $u = \frac{1}{2}v$, the water will drop off the bucket deprived of all energy of motion. The whole of the work of the jet must therefore have been expended in driving the float. The water will have been received without shock and discharged without velocity. This is the principle of the Poncelet wheel, but in that case the floats move over an arc of a large circle; the stream of water has considerable thickness (about 8 inches); in order to get the water into and out of the wheel, it is then necessary that the lip of the float should make a small angle (about 15°) with the direction of its motion. The water quits the wheel with a little of its energy of motion remaining.

146. *Pressure on a Curved Surface when the Water is deviated wholly in one Direction.*—When a jet of water impinges on a curved surface in such a direction that it is received without shock, the pressure on the surface is due to its gradual deviation from its first direction. On any portion of the area the pressure is equal and opposite to the force required to cause the deviation of so much water as rests on that surface. In common language, it is equal to the centrifugal force of that quantity of water.

Case 1. *Surface Cylindrical and Stationary.*—Let AB (fig. 162) be the surface, having its axis at O and its radius $= r$. Let the water impinge at A tangentially, and quit the surface tangentially at B. Since the surface is at rest, v is both the absolute velocity of the water and the velocity relatively to the surface, and this remains unchanged during contact with the surface, because the deviating force is at each point perpendicular to the direction of motion. The water is deviated through an angle $BCD = AOB = \phi$. Each particle of water of weight p exerts radially a centrifugal force $\frac{pv^2}{rg}$. Let the thickness of

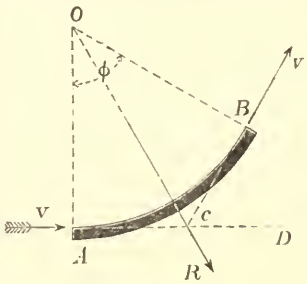

Fig. 162.

the stream $= t$ feet. Then the weight of water resting on unit of surface $= Gt$ lb; and the normal pressure per unit of surface $= n = \frac{Gt}{g}\cdot\frac{v^2}{r}$. The resultant of the radial pressures uniformly distributed from A to B will be a force acting in the direction OC bisecting AOB, and its magnitude will equal that of a force of intensity $= n$, acting on the projection of AB on a plane perpendicular to the direction OC. The length of the chord $AB = 2r\sin\frac{\phi}{2}$; let b = breadth of the surface perpendicular to the plane of the figure. The resultant pressure on surface

$$= R = 2rb\sin\frac{\phi}{2}\times\frac{Gt}{g}\cdot\frac{v^2}{r} = 2\frac{G}{g}btv^2\sin\frac{\phi}{2},$$

which is independent of the radius of curvature. It may be inferred that the resultant pressure is the same for any curved surface of the same projected area, which deviates the water through the same angle.

Case 2. Cylindrical Surface moving in the Direction AC *with Velocity* u.—The relative velocity $=v-u$. The final velocity BF (fig. 163) is found by combining the relative velocity $BD=v-u$

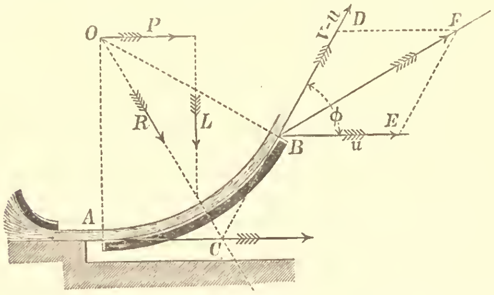

Fig. 163.

tangential to the surface with the velocity $BE=u$ of the surface. The intensity of normal pressure, as in the last case, is $\frac{Gt}{g}\frac{(v-u)^2}{r}$.

The resultant normal pressure $R=2\frac{G}{g}bt\,(v-u)^2\sin\frac{\phi}{2}$. This resultant pressure may be resolved into two components P and L, one parallel and the other perpendicular to the direction of the vane's motion. The former is an effort doing work on the vane. The latter is a lateral force which does no work.

$$P=R\sin\frac{\phi}{2}=\frac{G}{g}\,bt(v-u)^2\,(1-\cos\phi)\;;$$

$$L=R\cos\frac{\phi}{2}=\frac{G}{g}\,bt(v-u)^2\sin\phi.$$

The work done by the jet on the vane is $Pu=\frac{G}{g}btu(v-u)^2(1-\cos\phi)$, which is a maximum when $u=\frac{1}{3}v$. This result can also be obtained by considering that the work done on the plane must be equal to the energy lost by the water, when friction is neglected.

If $\phi=180°$, $\cos\phi=-1$, $1-\cos\phi=2$; then $P=2\frac{G}{g}bt(v-u)^2$, the same result as for a concave cup.

147. *Position which a Movable Plane takes in Flowing Water.*—When a rectangular plane, movable about an axis parallel to one of its sides, is placed in an indefinite current of fluid, it takes a position such that the resultant of the normal pressures on the two sides of the axis passes through the axis. If, therefore, planes pivoted so that the ratio $\frac{a}{b}$ (fig. 164) is varied are placed in water, and the angle they make with the direction of the stream is observed, the position of the resultant of the pressures on the plane is determined for different angular positions. Experiments of this kind have been made by Herr Hagen. Some of his results are given in the following table:—

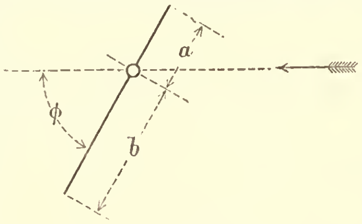

Fig. 164.

	Larger Plane.	Smaller Plane.
$\frac{a}{b}=1{\cdot}0$	$\phi=\ldots$	$\phi=90°$
0·9	75°	$72\frac{1}{2}°$
0·8	60°	57°
0·7	48°	43°
0·6	25°	29°
0·5	13°	13°
0·4	8°	$6\frac{1}{2}°$
0·3	$6\frac{1}{2}°$	...
0·2	4°	...

148. *Effect of Friction during Impulse.*—Thus far the effect of the friction between the water and the surface which deviates it has been neglected. Nothing precise is known of its mode of action, and the following investigation is in part conjectural (Rankine, *Steam Engine*, p. 171, § 146).

Let it be assumed that the friction causes a loss of energy per second proportional to the height due to the velocity of the water relatively to the surface; that is, the head due to the relative velocity being $\frac{v^2}{2g}$, the loss of head due to friction will be $f\frac{v^2}{2g}$; the whole energy due to the relative head being $GQ\frac{v^2}{2g}$, the loss of energy due to friction will be $GQf\frac{v^2}{2g}$.

Cylindrical Surface with Water deviated wholly in one Direction, Friction taken into account.—In Case 2, discussed in § 146, the velocity of the water relatively to the surface is $v-u$. The quantity of water impinging per second is $bt(v-u)$. The loss of head due to friction is $f\frac{(v-u)^2}{2g}$. The loss of energy due to friction is $Gbtf\frac{(v-u)^3}{2g}$. The energy exerted on the surface, after deducting the loss due to friction, is

$$Pu=\frac{G}{g}\,bt(v-u)^2u(1-\cos\phi)-Gbtf\frac{(v-u)^3}{2g}$$
$$=\frac{G}{g}\,bt(v-u)^2\left\{u(1-\cos\phi)-f\frac{v-u}{2}\right\}.$$

The efficiency when friction is taken into account becomes

$$\eta=\frac{Pu}{Gbt(v-u)\frac{v^2}{2g}}=\frac{(v-u)\left\{2u(1-\cos\phi)-f(v-u)\right\}}{v^2}\;;$$

and this becomes a maximum if

$$u=\frac{1-\cos\phi+f}{2-2\cos\phi+f}v,$$

being greater than the speed when friction is neglected in the ratio

$$2(1-\cos\phi)+f:\;3(1-\cos\phi+f).$$

Suppose that the speed of greatest efficiency u has been found by experiment;

$$f=\frac{(2u-v)(1-\cos\phi)}{v-u}.$$

149. *Direct Action distinguished from Reaction* (Rankine, *Steam Engine*, § 147).

The pressure which a jet exerts on a vane can be distinguished into two parts, viz:—

(1) The pressure arising from changing the direct component of the velocity of the water into the velocity of the vane. In fig. 154, § 140, $ab\cos bac$ is the direct component of the water's velocity, or component in the direction of motion of vane. This is changed into the velocity ae of the vane. The pressure due to direct impulse is then

$$P_1=GQ\,\frac{ab\cos bac-ae}{g}.$$

For a flat vane moving normally, this direct action is the only action producing pressure on the vane.

(2) The term reaction is applied to the additional action due to the direction and velocity with which the water glances off the vane. It is this which is diminished by the friction between the water and the vane. In Case 2, § 146, the direct pressure is

$$P_1=Gbt\,\frac{(v-u)^2}{g}.$$

That due to reaction is

$$P_2=-Gbt\,\frac{(v-u)^2}{g}\cos\phi.$$

If $\phi<90°$, the direct component of the water's motion is not wholly converted into the velocity of the vane, and the whole pressure due to direct impulse is not obtained. If $\phi>90°$, $\cos\phi$ is negative and an additional pressure due to reaction is obtained.

150. *Reaction of a Jet issuing from a Vessel.*—Suppose a vessel filled with water (fig. 165), having an orifice of area ω, from which water issues horizontally with a velocity $v=\sqrt{2gh}$. The volume discharged per second, neglecting contraction, $=\omega v$. The momentum generated per second in a horizontal direction $=\frac{G}{g}\omega v^2$; and this is equal to the force producing the change of momentum.

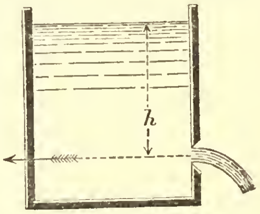

Fig. 165.

Hence the horizontal force or reaction R, acting on the side of the vessel, opposite to the orifice, and equal and opposite to the force producing the momentum, is

$$R=\frac{G}{g}\,\omega v^2=2G\omega h\;;$$

this is the weight of a column of water the section of which is the area of the orifice, and the height is twice the head.

If the vessel moves in a direction opposite to that of the jet, with the velocity u, the absolute velocity of the water leaving the vessel is $v-u$. The momentum generated per second is $\frac{G}{g}\,\omega v(v-u)=R$.

Jet Propeller.—In the case of vessels propelled by a jet of water (fig. 166), driven sternwards from orifices at the side of the vessel, the water, originally at rest outside the vessel, is drawn into the ship and caused to move with the forward velocity V of the ship. Afterwards it is projected sternwards from the jets with a velocity v relatively to the ship, or $v - \mathrm{V}$ relatively to the earth. If Ω is the total sectional area of the jets, Ωv is the quantity of water discharged per second. The momentum generated per second in a sternward direction is $\frac{\mathrm{G}}{g}\,\Omega v(v-\mathrm{V})$, and this is equal to the forward acting reaction P which propels the ship.

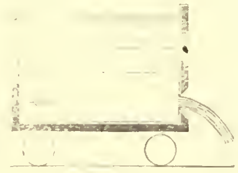

Fig. 166.

The energy carried away by the water

$$=\tfrac{1}{2}\frac{\mathrm{G}}{g}\,.\,\Omega v(v-\mathrm{V})^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

The useful work done on the ship

$$\mathrm{PV}=\frac{\mathrm{G}}{g}\,\Omega v(v-\mathrm{V})\mathrm{V} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Adding (1) and (2), we get the whole work expended on the water, neglecting friction:—

$$\mathrm{W}=\frac{\mathrm{G}}{g}\,\Omega v\,\frac{v^2-\mathrm{V}^2}{2}\,.$$

Hence the efficiency of the jet propeller is

$$\frac{\mathrm{PV}}{\mathrm{W}}=\frac{2\mathrm{V}}{v+\mathrm{V}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

This increases towards unity as v approaches V. In other words, the less the velocity of the jets exceeds that of the ship, and therefore the greater the area of the orifice of discharge, the greater is the efficiency of the propeller.

In the "Waterwitch" v was about twice V. Hence in this case the theoretical efficiency of the propeller, friction neglected, was about $\frac{2}{3}$.

151. *Pressure of a Steady Stream in a Uniform Pipe on a Plane normal to the Direction of Motion.*—Let CD (fig. 167) be a plane

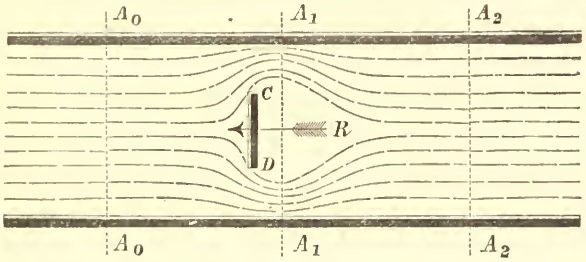

Fig. 167.

placed normally to the stream which, for simplicity, may be supposed to flow horizontally. The fluid filaments are deviated in front of the plane, form a contraction at $\mathrm{A}_1\mathrm{A}_1$, and converge again, leaving a mass of eddying water behind the plane. Suppose the section $\mathrm{A}_0\mathrm{A}_0$ taken at a point where the parallel motion has not begun to be disturbed, and $\mathrm{A}_2\mathrm{A}_2$ where the parallel motion is re-established. Then, since the same quantity of water with the same velocity passes $\mathrm{A}_0\mathrm{A}_0$, $\mathrm{A}_2\mathrm{A}_2$ in any given time, the external forces produce no change of momentum on the mass $\mathrm{A}_0\mathrm{A}_0\mathrm{A}_2\mathrm{A}_2$, and must therefore be in equilibrium. If Ω is the section of the stream at $\mathrm{A}_0\mathrm{A}_0$ or $\mathrm{A}_2\mathrm{A}_2$, and ω the area of the plate CD, the area of the contracted section of the stream at $\mathrm{A}_1\mathrm{A}_1$ will be $c_c\,(\Omega-\omega)$, where c_c is the coefficient of contraction. Hence, if v is the velocity at $\mathrm{A}_0\mathrm{A}_0$ or $\mathrm{A}_2\mathrm{A}_2$, and v_1 the velocity at $\mathrm{A}_1\mathrm{A}_1$,

$$v\Omega=c_c v_1(\Omega-\omega)\,;$$

$$\therefore\quad v_1=v\frac{\Omega}{c_c(\Omega-\omega)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Let p_0, p_1, p_2 be the pressures at the three sections. Applying Bernoulli's theorem to the sections $\mathrm{A}_0\mathrm{A}_0$ and $\mathrm{A}_1\mathrm{A}_1$,

$$\frac{p_0}{\mathrm{G}}+\frac{v^2}{2g}=\frac{p_1}{\mathrm{G}}+\frac{v_1^2}{2g}\,.$$

Also, for the sections $\mathrm{A}_1\mathrm{A}_1$ and $\mathrm{A}_2\mathrm{A}_2$, allowing that the head due to the relative velocity v_1-v is lost in shock:—

$$\frac{p_1}{\mathrm{G}}+\frac{v_1^2}{2g}=\frac{p_2}{\mathrm{G}}+\frac{v^2}{2g}+\frac{(v_1-v)^2}{2g}\,;$$

$$\therefore\quad p_0-p_2=\mathrm{G}\,\frac{(v_1-v)^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2);$$

or, introducing the value in (1),

$$p_0-p_2=\frac{\mathrm{G}}{2g}\left(\frac{\Omega}{c_c(\Omega-\omega)}-1\right)^2 v^2 \quad . \quad . \quad . \quad . \quad (3).$$

Now the external forces in the direction of motion acting on the mass $\mathrm{A}_0\mathrm{A}_0\mathrm{A}_2\mathrm{A}_2$ are the pressures $p_0\Omega$, $-p_2\Omega$ at the ends, and the reaction $-\mathrm{R}$ of the plane on the water, which is equal and opposite to the pressure of the water on the plane. As these are in equilibrium,

$$(p_0-p_2)\Omega-\mathrm{R}=0\,;$$

$$\therefore\quad \mathrm{R}=\mathrm{G}\Omega\left(\frac{\Omega}{c_c(\Omega-\omega)}-1\right)^2\frac{v^2}{2g} \quad . \quad . \quad . \quad . \quad (4);$$

an expression like that for the pressure of an isolated jet on an indefinitely extended plane, with the addition of the term in brackets, which depends only on the areas of the stream and the plane. For a given plane, the expression in brackets diminishes as Ω increases. If $\frac{\Omega}{\omega}=\rho$, the equation (4) becomes

$$\mathrm{R}=\mathrm{G}\omega\,\frac{v^2}{2g}\left\{\rho\left(\frac{\rho}{c_c(\rho-1)}-1\right)^2\right\} \quad . \quad . \quad . \quad . \quad (4a),$$

which is of the form

$$\mathrm{R}=\mathrm{G}\omega\,\frac{v^2}{2g}\times\mathrm{K}\,,$$

where K depends only on the ratio of the sections of the stream and plane.

For example, let $c_c=0{\cdot}85$, a value which is probable, if we allow that the sides of the pipe act as internal borders to an orifice. Then

$$\mathrm{K}=\rho\left(1{\cdot}176\frac{\rho}{\rho-1}-1\right)^2.$$

$\rho=$	K=
1	∞
2	3·66
3	1·75
4	1·29
5	1·10
10	·94
50	2·00
100	3·50

The assumption that the coefficient of contraction c_c is constant for different values of ρ is probably only true when ρ is not very large. Further, the increase of K for large values of ρ is contrary to experience, and hence it may be inferred that the assumption that all the filaments have a common velocity v_1 at the section $\mathrm{A}_1\mathrm{A}_1$ and a common velocity v at the section $\mathrm{A}_2\mathrm{A}_2$ is not true when the stream is very much larger than the plane. Hence, in the expression

$$\mathrm{R}=\mathrm{KG}\omega\frac{v^2}{2g}\,,$$

K must be determined by experiment in each special case.

152. *Pressure on a Cylindrical Body of a Length about three times its Diameter.*—A contraction of the stream is formed at $\mathrm{A}_1\mathrm{A}_1$

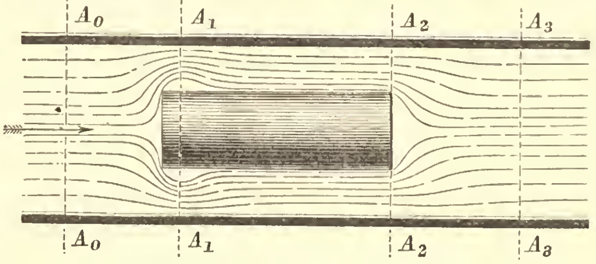

Fig. 168.

(fig. 168). Let the same notation be used, the subscript figures indicating the section to which the quantities belong.

For sections $\mathrm{A}_0\mathrm{A}_0$, $\mathrm{A}_1\mathrm{A}_1$,

$$\frac{p_0}{\mathrm{G}}+\frac{v^2}{2g}=\frac{p_1}{\mathrm{G}}+\frac{v_1^2}{2g}\,;$$

for sections $\mathrm{A}_1\mathrm{A}_1$ and $\mathrm{A}_2\mathrm{A}_2$, allowing for the abrupt enlargement of the stream,

$$\frac{p_1}{\mathrm{G}}+\frac{v_1^2}{2g}=\frac{p_2}{\mathrm{G}}+\frac{v_2^2}{2g}+\frac{(v_1-v_2)^2}{2g}\,;$$

and for sections $\mathrm{A}_2\mathrm{A}_2$, $\mathrm{A}_3\mathrm{A}_3$, allowing for another abrupt enlargement,

$$\frac{p_2}{\mathrm{G}}+\frac{v_2^2}{2g}=\frac{p_3}{\mathrm{G}}+\frac{v^2}{2g}+\frac{(v_2-v)^2}{2g}\,.$$

Adding the three equations,

$$p_0-p_3=\mathrm{G}\left\{\frac{(v_1-v_2)^2}{2g}+\frac{(v_2-v)^2}{2g}\right\}.$$

From the principle of momentum,

$$(p_0-p_3)\Omega-\mathrm{R}=0\,;$$

$$\mathrm{R}=\mathrm{G}\Omega\left\{\frac{(v_1-v_2)^2}{2g}+\frac{(v_2-v)^2}{2g}\right\}.$$

Putting ω for the section of the body, c_c for the coefficient of contraction, $c_c(\Omega-\omega)$ for the area of the stream at A_1A_1,

$$v_1 = v\frac{\Omega}{c_c(\Omega-\omega)}\ ;\ v_2 = v\frac{\Omega}{\Omega-\omega}\ ;$$

or, putting $\rho = \frac{\Omega}{\omega}$,

$$v_1 = v\frac{\rho}{c_c(\rho-1)}\ ,\ v_2 = v\frac{\rho}{\rho-1}\ .$$

Then

$$R = K_1 G\omega\frac{v^2}{2g}\ ,$$

where

$$K_1 = \rho\left\{\left(\frac{\rho}{\rho-1}\right)^2\left(\frac{1}{c_c}-1\right)^2+\left(\frac{\rho}{\rho-1}-1\right)^2\right\}.$$

Taking $c_c = 0{\cdot}85$ and $\rho = 4$, $K_1 = 0{\cdot}467$, a value less than before. Hence there is less pressure on the cylinder than on the thin plane.

153. *Distribution of Pressure on a Surface on which a Jet impinges normally.*—The principle of momentum gives readily enough the total or resultant pressure of a jet impinging on a plane surface, but in some cases it is useful to know the distribution of the pressure. The problem in the case in which the plane is struck normally, and the jet spreads in all directions, is one of great complexity, but even in that case the maximum intensity of the pressure is easily assigned. Each layer of water flowing from an orifice is gradually deviated (fig. 169) by contact with the surface, and during deviation exercises a centrifugal pressure towards the axis of the jet. The force exerted by each small mass of water is normal to its path, and inversely as the radius of curvature of the path. Hence the greatest pressure on the plane must be at the axis of the jet, and the pressure must decrease from the axis outwards, in some such way as is shown by the curve of pressure in fig. 170, the branches of the curve being probably asymptotic to the plane.

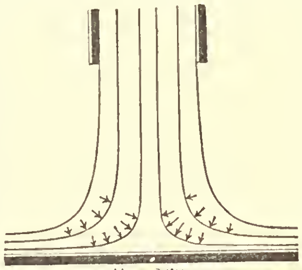

Fig. 169.

For simplicity suppose the jet is a vertical one. Let h_1 be the depth of the orifice from the free surface, and v_1 the velocity of discharge. Then, if ω is the area of the orifice, the quantity of water impinging on the plane is obviously

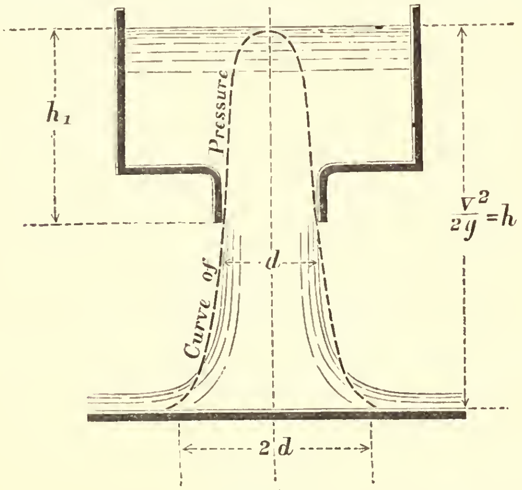

Fig. 170.

$$Q = \omega v_1 = \omega\sqrt{2gh_1}\ ;$$

that is, supposing the orifice rounded, and neglecting the coefficient of discharge.

The velocity with which the fluid reaches the plane is, however, greater than this, and may reach the value

$$v = \sqrt{2gh}\ ;$$

where h is the depth of the plane below the free surface. The external layers of fluid subjected throughout, after leaving the orifice, to the atmospheric pressure will attain the velocity v, and will flow away with this velocity unchanged except by friction. The layers towards the interior of the jet, being subjected to a pressure greater than atmospheric pressure, will attain a less velocity, and so much less as they are nearer the centre of the jet. But the pressure can in no case exceed the pressure $\frac{v^2}{2g}$ or h measured in feet of water, or the direction of motion of the water would be reversed, and there would be reflux. Hence the maximum intensity of the pressure of the jet on the plane is h feet of water. If the pressure curve is drawn with pressures represented by feet of water, it will touch the free water surface at the centre of the jet.

Suppose the pressure curve rotated so as to form a solid of revolution. The weight of water contained in that solid is the total pressure of the jet on the surface, which has already been determined. Let V = volume of this solid, then GV is its weight in pounds. Consequently

$$GV = \frac{G}{g}\omega v_1 v\ ;$$

$$V = 2\omega\sqrt{hh_1}\ .$$

We have already, therefore, two conditions to be satisfied by the pressure curve.

Some very interesting experiments on the distribution of pressure on a surface struck by a jet have been made by Mr J. S. Beresford (*Prof. Papers on Indian Engineering*, No. cccxxii.), with a view to afford information as to the forces acting on the aprons of weirs. Cylindrical jets ½ inch to 2 inches diameter, issuing from a vessel in which the water level was constant, were allowed to fall vertically on a brass plate 9 inches in diameter. A small hole in the brass plate communicated by a flexible tube with a vertical pressure column. Arrangements were made by which this aperture could be moved $\frac{1}{20}$ inch at a time across the area struck by the jet. The height of the pressure column, for each position of the aperture, gave the pressure at that point of the area struck by the jet. When the aperture was exactly in the axis of the jet, the pressure column was very nearly level with the free surface in the reservoir supplying the jet; that is, the pressure was very nearly $\frac{v^2}{2g}$. As the aperture moved away from the axis of the jet, the pressure diminished, and it became insensibly small at a distance from the axis of the jet about equal to the diameter of the jet. Hence, roughly, the pressure due to the jet extends over an area about four times the area of section of the jet.

Fig 171 shows the pressure curves obtained in three experiments with three jets of the sizes shown, and with the free surface level in the reservoir at the heights marked.

As the general form of the pressure curve has been already indicated, it may be assumed that its equation is of the form

$$y = ab^{-x^2}\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

But it has already been shown that for $x=0$, $y=h$, hence $a=h$.

To determine the remaining constant, the other condition may be used, that the solid formed by rotating the pressure curve represents the total pressure on the plane. The volume of the solid is

$$V = \int_0^\infty 2\pi xy dx$$

$$= 2\pi h \int_0^\infty b^{-x^2} x dx$$

$$= \frac{\pi h}{\log_\epsilon b}\Big[-b^{-x^2} \Big]_0^\infty$$

$$= \frac{\pi h}{\log_\epsilon b} .$$

Using the condition already stated,

$$2\omega\sqrt{hh_1} = \frac{\pi h}{\log_\epsilon b} ;$$

$$\log_\epsilon b = \frac{\pi}{2\omega}\sqrt{\frac{h}{h_1}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Putting the value of b in (2) in eq. (1), and also r for the radius of the jet at the orifice, so that $\omega = \pi r^2$, the equation to the pressure curve is

$$y = h\epsilon^{-\frac{1}{2}\sqrt{\frac{h}{h_1}}\frac{x^2}{r^2}} .$$

154. *Resistance of a Plane moving through a Fluid, or Pressure of a Current on a Plane.*—When a thin plate moves through the air, or through an indefinitely large mass of still water, in a direction normal to its surface, there is an excess of pressure on the anterior face and a diminution of pressure on the posterior face. Let v be the relative velocity of the plate and fluid, Ω the area of the plate, G the density of the fluid, h the height due to the velocity, then the total resistance is expressed by the equation

$$R = f G\Omega \frac{v^2}{2g} \text{ pounds} = f G\Omega h ;$$

where f is a coefficient having about the value 1·3 for a plate moving in still fluid, and 1·8 for a current impinging on a fixed plane, whether the fluid is air or water. The difference in the value of the coefficient in the two cases is perhaps due to errors of experiment. There is a similar resistance to motion in the case of all bodies of "*unfair*" form, that is, in which the surfaces over which the water slides are not of gradual and continuous curvature.

The stress between the fluid and plate arises chiefly in this way. The streams of fluid deviated in front of the plate, supposed for definiteness to be moving through the fluid, receive from it forward momentum. Portions of this forward moving water are thrown off laterally at the edges of the plate, and diffused through the surrounding fluid, instead of falling to their original position behind the plate. Other portions of comparatively still water are dragged into motion to fill the space left behind the plate; and there is thus a pressure less than hydrostatic pressure at the back of the plate. The whole resistance to the motion of the plate is the sum of the excess of pressure in front and deficiency of pressure behind. This resistance is independent of any friction or viscosity in the fluid, and is due simply to its inertia resisting a sudden change of direction at the edge of the plate.

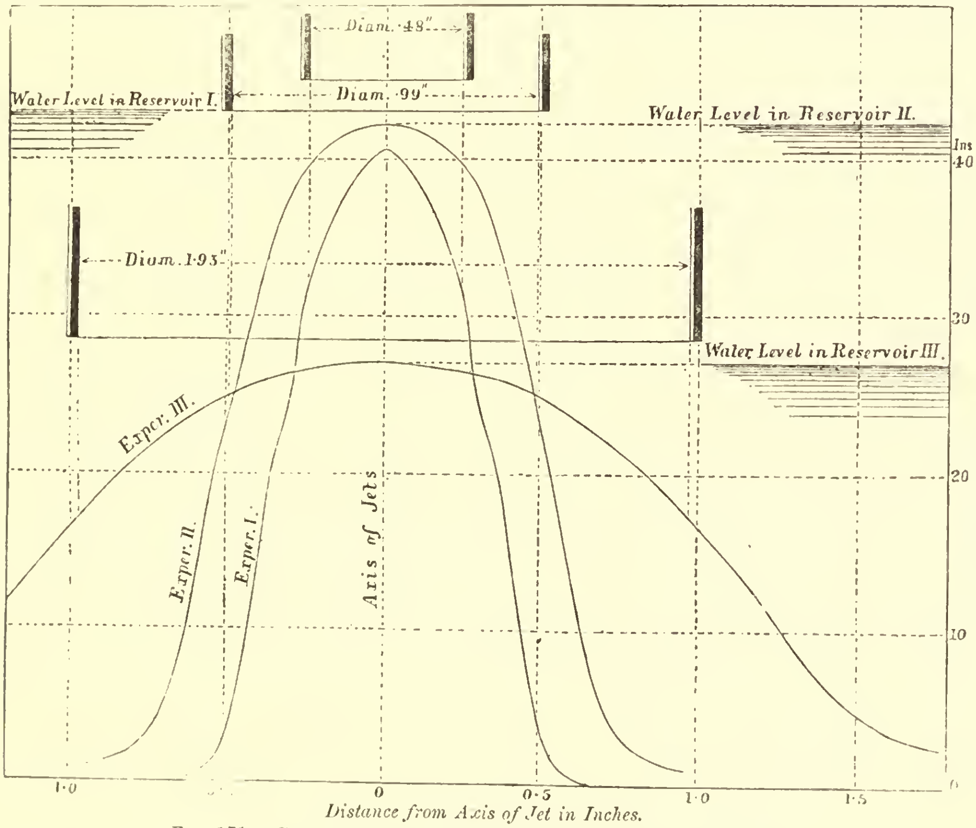

Fig. 171.—Curves of Pressure of Jets impinging normally on a Plane.

Experiments made by a whirling machine, in which the plate is fixed on a long arm and moved circularly, gave the following values of the coefficient f. The method is not free from objection, as the centrifugal force causes a flow outwards across the plate.

Approximate Area of Plate in sq. ft.	Values of f.		
	Borda.	Hutton.	Thibault.
0·13	1·39	1·24	...
0·25	1·49	1·43	1·525
0·63	1·64	...	...
1·11	...	...	1·784

There is a steady increase of resistance with the size of the plate, in part or wholly due to centrifugal action.

Dubuat made experiments on a plane one foot square, moved in a straight line in water at 3 to 6½ feet per second. Calling m the coefficient of excess of pressure in front, and n the coefficient of deficiency of pressure behind, so that $f = m + n$, he found the following values:—

$$m = 1 ; \; n = 0{\cdot}433 ; \; f = 1{\cdot}433.$$

The pressures were measured by pressure columns. Experiments by Morin, Piobert, and Didion on plates of 0·3 to 2·7 square feet area, drawn vertically through water, gave $f = 2{\cdot}18$; but the experiments were made in a reservoir of comparatively small depth. For similar plates moved through air they found $f = 1{\cdot}36$, a result more in accordance with those which precede.

For a fixed plane in a moving current of water Mariotte found $f = 1{\cdot}25$. Dubuat, in experiments in a current of water like those mentioned above, obtained the values $m = 1{\cdot}186$; $n = 0{\cdot}670$; $f = 1{\cdot}856$. Thibault exposed to wind pressure planes of 1·17 and 2·5 square feet area, and found f to vary from 1·568 to 2·125, the mean value being $f = 1{\cdot}834$, a result agreeing well with Dubuat.

155. *Case when the Direction of Motion is oblique to the Plane.*—The determination of the pressure between a fluid and surface in this case is of importance in many practical questions, for instance, in assigning the load due to wind pressure on sloping and curved roofs, and experiments have been made by Hutton, Vince, and Thibault on planes moved circularly through air and water on a whirling machine.

Let AB (fig. 172) be a plane moving in the direction R making an angle ϕ with the plane. The resultant pressure between the fluid and the plane will be a normal pressure N. The component R of this normal pressure is the resistance to the motion of the plane and the other component L is a lateral force resisted by the guides which support the plane. Obviously

$$R = N \sin \phi ;$$
$$L = N \cos \phi .$$

In the case of wind pressure on a sloping roof surface, R is the horizontal and L the vertical component of the normal pressure.

In experiments with the whirling machine it is the resistance to motion, R, which is directly measured. Let P be the pressure on a plane moved normally through a fluid. Then, for the same plane inclined at an angle ϕ to its direction of motion, the resistance was found by Hutton to be

$$R = P(\sin \phi)^{1 \cdot 842 \cos \phi}.$$

A simpler and more convenient expression given by Colonel Duchemin is

$$R = P \frac{2 \sin^2\phi}{1 + \sin^2\phi}.$$

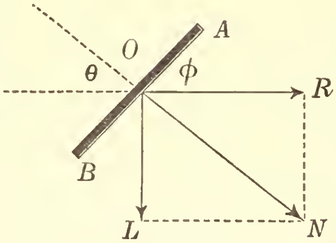

Fig. 172.

Consequently, the total pressure between the fluid and plane is

$$N = P \frac{2 \sin \phi}{1 + \sin^2\phi} = \frac{2P}{\operatorname{cosec} \phi + \sin \phi},$$

and the lateral force is

$$L = P \frac{2 \sin \phi \cos \phi}{1 + \sin^2\phi}.$$

In 1872 some experiments were made for the Aeronautical Society on the pressure of air on oblique planes. These plates, of 1 to 2 feet square, were balanced by ingenious mechanism designed by Mr Wenham and Mr Spencer Browning, in such a manner that both the pressure in the direction of the air current and the lateral force were separately measured. These planes were placed opposite a blast from a fan issuing from a wooden pipe 18 inches square. The pressure of the blast varied from $\frac{6}{10}$ to 1 inch of water pressure. The following are the results given in pounds per square foot of the plane, and a comparison of the experimental results with the pressures given by Duchemin's rule. These last values are obtained by taking $P = 3 \cdot 31$, the observed pressure on a normal surface:—

Angle between Plane and Direction of Blast.	15°	20°	60°	90°
Horizontal pressure R	0·4	0·61	2·73	3·31
Lateral pressure L	1·6	1·96	1·26	...
Normal pressure $\sqrt{L^2 + R^2}$	1·65	2·05	3·01	3·31
Normal pressure by Duchemin's rule	1·605	2·027	3·276	3·31

Resistance of Ships.

156. Down to a recent period the resistance of ships was supposed to be due to a difference between the pressure on the bow and stern, caused by the pushing aside of the water, precisely as in the case of the "unfair" bodies whose resistance has just been discussed. Hence the resistance was supposed to be proportional to the immersed midship sectional area of the vessel. It will be shown immediately, however, that in a "fair" body, completely immersed, there is no resistance of this kind, the pressure of the water closing in behind exactly balancing the excess of pressure on the bow. In such a body, therefore, the resistance is almost entirely due to the frictional drag of the water on the surface of the body, and is proportional to its skin area. In a ship, which is only partially immersed, a further resistance, which in some cases becomes very large, is due to the alteration of the surface level of the water causing a dissipation of energy in producing waves.

157. *Stream Line Motion of a Fluid past a submerged Body.*—Consider a shipshape body, or body of *fair* form, that is, bounded by surfaces of continuous curvature, moving below the surface of a fluid, and for the moment let the friction of the fluid against the

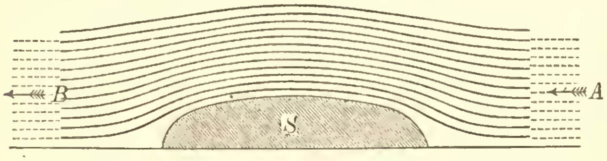

Fig. 173.

surface of the body be supposed absent. In such conditions, the particles of fluid are gradually deviated sideways as the body passes, and gradually close together again behind it. They are left after the operation in their original position with momentum unchanged; there is, therefore, in this case no resistance due to the direct action of the inertia of the water.

The nature of the action is more conveniently studied by supposing the body at rest and the fluid flowing past it. Let S, fig 173, represent the immersed body surrounded by fluid which is flowing past it. The fluid particles, arriving at A in the direction shown by the arrow, are gradually deviated as they approach S, gradually unite again after passing it; and, if the body is of fair form, that is, if it presents no abrupt changes of section or discontinuity of curvature, the stream lines or paths of the particles will be continuous lines, which take, at a sufficient distance B sternwards of S, their original direction of motion. The fluid surrounding S may then be conceived to be divided into an infinite number of elementary streams of continuous curvature. Suppose, for simplicity, S is a solid of revolution. Then, from the similarity of conditions in all directions, the elementary streams will be in planes drawn through the axis of S.

Each elementary stream may be conceived as a mass of fluid flowing steadily in an infinitely thin frictionless pipe. But it has already been shown that in a tortuous pipe, the ends of which are in the same direction, there is no resultant force due to the motion of the fluid which tends to displace the pipe, either due to its curvature or its changes of section. Consequently the whole mass of fluid exerts no resultant pressure on the body S past which it is flowing. Nor, if the fluid is at rest, will there be any resistance to the uniform motion of the body S through it. The resistance of the ship therefore cannot be due, like that of an unshipshape body, to the forward momentum impressed directly on the fluid. In a frictionless fluid, and for a uniformly moving and wholly immersed body of fair form, the resistance would be *nil*.

With a fluid which is not perfectly frictionless, however, a resistance may be generated in this way. The particles of water exert a drag on the surface of the body over which they slide. They receive, either in consequence of their adhesion to the surface, or in consequence of impact on the roughnesses which project from it, a forward momentum, and the velocity at B is no longer, as in a frictionless fluid, the same as the velocity at A.

In the case of a ship which is only in part immersed there is another source of resistance. Considering the elementary streams already defined as flowing along indefinitely thin frictionless pipes, it is obvious that there would be greater pressure in those parts where the cross section was large and the velocity small, and less pressure where the section was small and the velocity high. It will be seen from the diagram that the streams are large in cross section in the neighbourhood of the bow and stern, and small along the sides. There will therefore be an excess of pressure at bow and stern, and a diminution at the sides. But the free surface of the water in which the ship floats is a surface of uniform pressure. Hence the water will be forced up at the bow and stern, and sink down in the space between, the variation of the hydrostatic pressure due to depth balancing the variation of pressure in the stream lines. There are thus formed waves accompanying the ship. So far as the ship in its passage through the water has to supply the waste of energy due to the diffusion of this wave motion in the surrounding liquid, it suffers a resistance which may be termed the wave-making resistance. This resistance would arise even in a frictionless fluid.

It will be seen from the foregoing that the two principal causes of the resistance to the motion of a ship are the skin friction and the production of waves. The frictional resistance depends on the immersed surface of the ship, its roughness, and the velocity of the water relatively to the surface. Mr Froude concludes that no sensible error is committed if the frictional resistance is taken to be equivalent to that of a rectangular surface of equal area and of length (in the line of motion) equal to that of the ship and moving at the same speed. For such a rectangular surface Mr Froude's experiments already described furnish the means of calculating the resistance.

Experiments made on H.M. ship "Greyhound" appear to show that in well-formed, clean-bottomed ships, at speeds not exceeding 8 knots per hour, the frictional resistance is from 80 to 90 per cent. of the whole resistance, and that at the greatest speeds of the quickest ships the frictional resistance is from 60 to 70 per cent. of the whole resistance. For ships with foul bottoms the frictional resistance is a still larger fraction of the whole resistance.

The wave-making resistance is not yet fully understood, and involves considerations beyond the scope of the present article. For any given length of ship, with given proportions of entrance, middle body, and run, there is a limit of speed beyond which the resistance due to dissipation of energy in waves rapidly increases. Below that limit the resistance, being chiefly due to friction, increases nearly as the square of the speed. Above that limit the resistance increases as a higher power of the speed. In the trials of the "Greyhound" the resistance varied nearly as the square of the speed up to 8 knots per hour, as the cube of the speed at 10 knots, and as the fourth power of the speed at 12 knots.

158. *Ratio of the Resistance of Models and of Actual Ships.*—It will be understood from the foregoing explanations that the laws of the resistance of ships are complicated and at present imperfectly

known. Mr Froude has, however, indicated a way in which experiments, on comparatively small models, may be made so as to furnish very useful data as to the resistance of ships. In order that experiments on models may be serviceable, it is necessary that their resistance should be measured at speeds for which the different resistances bear the same proportion to each other as in the actual ship. Let d be the ratio of the dimensions of the model to that of the ship. Let R_1, R_2, R_3 . . . be the resistances of the model at speeds v_1, v_2, v_3 . . . Then it may be expected that the actual ship at speeds $v_1\sqrt{d}$, $v_2\sqrt{d}$, $v_3\sqrt{d}$ . . . will have resistances d^3R_1, d^3R_2, d^3R_3.

This law, however, is not strictly applicable to that part of the resistance which is due to friction, because of the diminution of the coefficient of friction for a given surface as the length increases. Hence, when the resistance of the model has been ascertained, a correction must be made to allow for the different coefficient of friction of the ship. The frictional resistances of the model and of the ship are calculated from their immersed surfaces, using the coefficients of friction suitable for their respective lengths. Deducting the former and adding the latter to the observed resistance at the corresponding speeds, the total resistance of the ship is ascertained.

XIII. HYDRAULIC MACHINERY.

159. Hydraulic machinery may be broadly divided into hydraulic motor machines and pumps. In the former class, a quantity of water descending from a higher to a lower level, or from a higher to a lower pressure, drives a machine which receives energy from the water, and applies it to overcoming the resistances of other machines doing useful work. In the latter class, work done on the machine by a steam engine or other source of energy is employed in lifting water from a lower to a higher level. A few machines such as the ram and jet pump combine the functions of motors and pumps.

Water Motors.

In every system of machinery deriving energy from a natural water fall there exist the following parts :—

(1) A supply channel or head race, leading the water from the highest accessible level to the site of the machine. This may be an open channel of earth, masonry, or wood, laid at as small a slope as is consistent with the delivery of the necessary supply of water, or it may be a closed cast or wrought-iron pipe, laid at the natural slope of the ground, and about 3 feet below the surface. In some cases part of the head race is an open channel, part a closed pipe. The channel often starts from a small storage reservoir, constructed near the stream supplying the water motor, in which the water accumulates when the motor is not working. There are sluices or penstocks by which the supply can be cut off when necessary.

(2) Leading from the motor there is a tail race, culvert, or discharge pipe delivering the water after it has done its work at the lowest convenient level.

(3) A waste channel, weir, or bye-wash is placed on or at the origin of the head race, by which surplus water, in floods, escapes.

(4) The motor itself, of one of the kinds to be described presently, which either overcomes a useful resistance directly, as in the case of a ram acting on a lift or crane chain, or indirectly by actuating transmissive machinery, as when a turbine drives the shafting, belting, and gearing of a mill. With the motor is usually combined regulating machinery for adjusting the power and speed to the work done. This may be controlled in some cases by automatic governing machinery.

Water Motors with Artificial Sources of Energy.—The great convenience and simplicity of water motors has led to their adoption in certain cases, where no natural source of water power is available. In these cases, an artificial source of water power is created by using a steam engine to pump water to a reservoir at a great elevation, or to pump water into a closed reservoir in which there is great pressure. The water flowing from the reservoir through hydraulic engines gives back the energy expended, less so much as has been wasted in friction. Such arrangements are most useful where a continuously acting steam engine stores up energy by pumping the water, while the work done by the hydraulic engines is done intermittently.

160. *Energy of a Water Fall.*—Let H_t be the total fall of level from the point where the water is taken from a natural stream to the point where it is discharged into it again. Of this total fall a portion, which can be estimated independently, is expended in overcoming the resistances of the head and tail races or the supply and discharge pipes. Let this portion of head wasted be $\mathfrak{h}_r$. Then the available head to work the motor is $H = H_t - \mathfrak{h}_r$. It is this available head which should be used in all calculations of the proportions of the motor. Let Q be the supply of water per second. Then

$$GQH \text{ foot-pounds per second}$$

is the gross available work of the fall. The power of the fall may be rendered available in three ways. The GQ pounds of water may be placed on a machine at the highest level, and descending in contact with it a distance of H feet, the work done will be (neglecting losses from friction or leakage)

$$GQH \text{ foot-pounds per second.}$$

Or the water may descend in a closed pipe from the higher to the lower level, in which case, with the same reservation as before, the pressure at the foot of the pipe will be $p = GH$ pounds per square foot. If the water with this pressure acts on a movable piston like that of a steam engine, it will drive the piston so that the volume described is Q cubic feet per second. Then the work done will be

$$pQ = GHQ \text{ foot-pounds per second}$$

as before. Or lastly, the water may be allowed to acquire the velocity $v = \sqrt{2gH}$ by its descent. The kinetic energy of Q cubic feet will then be $\frac{G}{g}Q\frac{v^2}{2} = GQH$, and if the water is allowed to impinge on surfaces suitably curved which bring it finally to rest, it will impart to these the same energy as in the previous cases. Generally, if Q feet per second of water act by weight through a distance h_1, at a pressure p due to h_2 feet of fall, and with a velocity v due to h_3 feet of fall, so that

$$h_1 + h_2 + h_3 = H,$$

then, apart from energy wasted by friction or leakage or imperfection of the machine, the work done will be

$$GQh_1 + pQ + \frac{G}{g}\cdot Q\frac{v^2}{2g} = GQH \text{ foot pounds,}$$

the same as if the water acted simply by its weight while descending H feet.

161. *Site for Water Motor.*—Wherever a stream flows from a higher to a lower level it is possible to erect a water motor. The amount of power obtainable depends on the available head and the supply of water. In choosing a site the engineer will select a portion of the stream where there is an abrupt natural fall, or at least a considerable slope of the bed. He will have regard to the facility of constructing the channels which are to convey the water, and will take advantage of any bend in the river which enables him to shorten them. He will have accurate measurements made of the quantity of water flowing in the stream, and he will endeavour to ascertain the average quantity available throughout the year, the minimum quantity in dry seasons, and the maximum for which bye-wash channels must be provided. In many cases the natural fall can be increased by a dam or weir thrown across the stream. The engineer will also examine to what extent the head will vary in different seasons, and whether it is necessary to sacrifice part of the fall and give a steep slope to the tail race to prevent the motor being drowned by backwater in floods.

In designing or selecting a water motor it is not sufficient to consider only its efficiency in normal conditions of working. It is generally quite as important to know how it will act with a scanty water supply or a diminished head. The greatest difference in water motors is in their adaptability to varying conditions of working.

162. *Action of Water in a Water Motor.*—Water motors may be divided into water-pressure engines, water wheels, and turbines.

Water-pressure engines are machines with a cylinder and piston or ram, in principle identical with the corresponding part of a steam engine. The water is alternately admitted to and discharged from the cylinder, causing a reciprocating action of the piston or ram. It is admitted at a high pressure and discharged at a low one, and consequently work is done on the piston. The water in these machines never acquires a high velocity, and for the most part the kinetic energy of the water is wasted. The useful work is due to the difference of the pressure of admission and discharge, whether that pressure is due to the weight of a column of water of more or less considerable height, or is artificially produced in ways to be described presently.

Water wheels are large vertical wheels driven by water falling from a higher to a lower level. In most water wheels, the water acts directly by its weight loading one side of the wheel and so causing rotation. But in all water wheels a portion and in some a considerable portion of the work due to gravity is first employed to generate kinetic energy in the water; during its action on the water wheel the velocity of the water diminishes, and the wheel is therefore in part driven by the impulse due to the change of the water's momentum. Water wheels are therefore motors on which the water acts, partly by weight, partly by impulse.

Turbines are wheels, generally of small size compared with water wheels, driven chiefly by the impulse of the water. Before entering the moving part of the turbine, the water is allowed to acquire a considerable velocity; during its action on the turbine this velocity is diminished, and the impulse due to the change of momentum drives the turbine.

Roughly speaking, the fluid acts in a water-pressure engine directly by its pressure, in a water wheel chiefly by its weight causing a pressure, but in part by its kinetic energy, and in a turbine chiefly by its kinetic energy, which again causes a pressure.

Water-Pressure Engines.

163. In these water acts by simple pressure due to the height of the column in the supply pipe or the pressure in the supply reservoir. The water acts on a piston or ram which it displaces. When the height of the column exceeds 100 or 200 feet, or there is a pressure equivalent to this, water wheels are inapplicable, and turbines have the disadvantage that in such circumstances their speed is very great. Then water-pressure engines maybe very conveniently adopted. In other cases they are generally too cumbrous.

When an incompressible fluid such as water is used to actuate piston engines, two special difficulties arise. One is that the waste of work in friction is very great, if the water attains considerable velocity; another is that there is great straining action on the machinery. The violent straining action due to the more or less sudden arrest of the motion of water in machinery is termed hydraulic shock. For these reasons the maximum velocity of flow of water in hydraulic machines should generally not exceed 5 to 10 feet per second. Under very high pressure, where there is less object in economizing energy, and it is very important to keep the dimensions of the machinery small, Mr Anderson gives 24 feet per second as the limiting velocity. In large water-pressure engines used for pumping mines the average piston speed does not exceed ½ to 2 feet per second.

Direct-Acting Hydraulic Lift (fig. 174).—This is the simplest of all kinds of hydraulic motor. A cage W is lifted directly by water pressure acting in a cylinder C, the length of which is a little greater than the lift. A ram or plunger R of the same length is attached to the cage. The water pressure admitted by a cock to the cylinder forces up the ram, and when the supply valve is closed and the discharge valve opened, the ram descends. In this case the ram is 9 inches diameter, with a stroke of 49 feet. It consists of lengths of wrought-iron pipe screwed together perfectly water-tight, the lower end being closed by a cast-iron plug. The ram works in a cylinder 11 inches diameter, of 9 feet lengths of flanged cast-iron pipe. The ram passes water-tight through the cylinder cover, which is provided with double hat leathers to prevent leakage outwards or inwards. As the weight of the ram and cage is much more than sufficient to cause a descent of the cage, part of the weight is balanced. A chain attached to the cage passes over a pulley at the top of the lift, and carries at its free end a balance weight B, working in T iron guides. Water is admitted to the cylinder from a 4-inch supply pipe through a two-way slide, worked by a rack, spindle, and endless rope. The lift works under 73 feet of head, and lifts 1350 ℔ at 2 feet per second. The efficiency is given by Mr Anderson at 75 to 80 per cent.[1]

The principal prejudicial resistance to the motion of a ram of this kind is the friction of the cup leathers, which make the joint between the cylinder and ram. Some experiments by Mr John Hick give for the friction of these leathers the following formula. Let F= the total friction in pounds; d= diameter of ram in feet; p= water pressure in pounds per square foot; k a coefficient.

$F = k\,p\,d$

$k = 0{\cdot}00393$ if the leathers are new or badly lubricated;

$= 0{\cdot}00262$ if the leathers are in good condition and well lubricated.

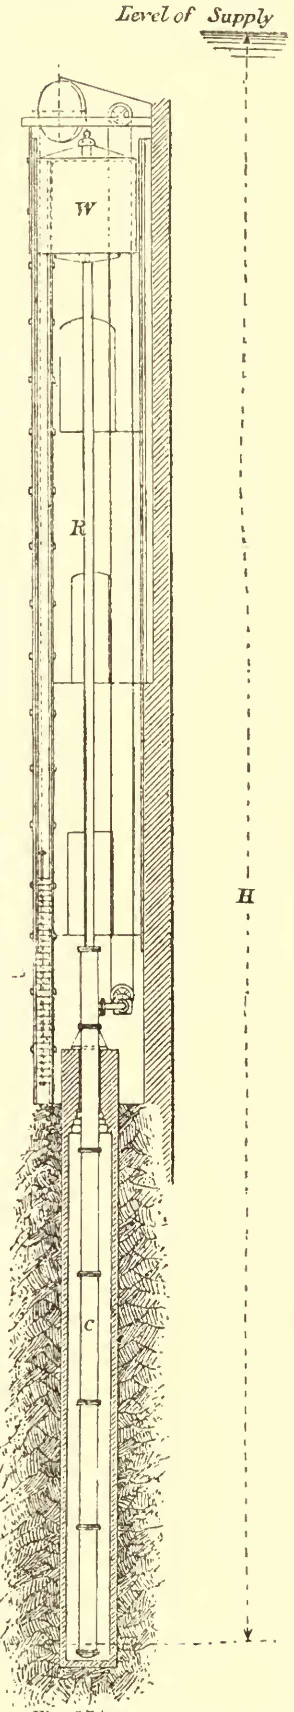

Fig. 174.

[1] The drawing and description of this ram are taken from Mr Anderson's *Chatham Lectures on Hydraulic Machinery*.

Since the total pressure on the ram is $\frac{\pi}{4}d^2p$, the fraction of the total pressure expended in overcoming the friction of the leathers is $\frac{\cdot 005}{d}$ to $\frac{\cdot 0033}{d}$, d being in feet.

Let H be the height of the pressure column measured from the free surface of the supply reservoir to the bottom of the ram in its lowest position, H_b the height from the discharge reservoir to the same point, h the height of the ram above its lowest point at any moment, S the length of stroke, Ω the area of the ram, W the weight of cage, R the weight of ram, B the weight of balance weight, w the weight of balance chain per foot run, F the friction of the cup leather and slides. Then, neglecting fluid friction, if the ram is rising the accelerating force is

$$P_1 = G(H-h)\Omega - R - W + B - w(S-h) + wh - F,$$

and if the ram is descending

$$P_2 = -G(H_b - h)\Omega + W + R - B + w(S-h) - wh - F.$$

If $w = \frac{1}{2}G\Omega$, P_1 and P_2 are constant throughout the stroke; and the moving force in ascending and descending is the same, if

$$B = W + R + wS - G\Omega\frac{H+H_b}{2}.$$

Using the values just found for w and B,

$$P_1 = P_2 = \tfrac{1}{2}G\Omega(H - H_b) - F.$$

Let $W + R + wS + B = U$, and let P be the constant accelerating force acting on the system, then the acceleration is

$$\frac{P}{U}g.$$

The velocity at the end of the stroke is (assuming the friction to be constant)

$$v = \sqrt{\left(2\frac{P}{U}gS\right)};$$

and the mean velocity of ascent is

$$\tfrac{1}{2}v.$$

164. *Self-Acting Hydraulic Engines.*—The admission and discharge valve in the lift just described is worked by hand at the required times. It is easy to see that mechanism like that used in steam engines can be applied to actuate the admission and discharge valves periodically, and the lift is then converted into a continuously acting engine.

Let H be the available fall to work the engine after deducting the loss of head in the supply and discharge pipes, Q the supply of water in cubic feet per second, and η the efficiency of the engine. Then the horse-power of the engine is

$$H.P. = \frac{\eta GQH}{550}.$$

The efficiency of large slow-moving pressure engines is $\eta = \cdot 66$ to $\cdot 8$. In small motors of this kind probably η is not greater than $\cdot 5$. Let v be the mean velocity of the piston, then its diameter d is given by the relation

$$Q = \frac{\pi}{4}d^2v \text{ in double-acting engines,}$$

$$= \frac{\pi}{8}d^2v \text{ in single-acting engines.}$$

If there are n cylinders put $\frac{Q}{n}$ for Q in these equations.

The mean velocity v is from $\frac{1}{2}$ to 2 feet per second in large engines. Smaller engines working on high lifts may be run at a greater speed, but with a sacrifice of efficiency. The usual piston speed of Messrs Hastie's engines described below is 100 feet per minute. For pressures of less than 200 feet of head, the speed is less. The velocity of the water in the supply pipes may be 3 to 6 feet per second.

In large engines the admission and discharge valves are of very large size, and require very considerable force to move them. It is also desirable that they should open and close more rapidly than the eccentric-moved valves used in steam engines. In these engines the valves are made cylindrical, so that the water pressure causes no friction of the valve on its seating. They are moved by a weight which is released at the proper moment, or by a subsidiary water-pressure engine, the valves of which being small can be actuated automatically. Tolerably full details of engines with mechanism of this kind are to be found in Weisbach's *Mechanics of Engineering*.

Small pressure engines form extremely convenient motors for hoists, capstans, or winches, and for driving small machinery. They are usually rotative engines, and may be single or double acting. The single-acting engine has the advantage that the pressure of the piston on the crank pin is always in one direction; there is then no knocking as the dead centres are passed. Generally three single-acting cylinders are used, so that the engine will readily start in all positions, and the driving effort on the crank pin is very uniform.

Mr Brotherhood's well-known three-cylinder steam engine has been modified so as to be used as a water-pressure engine. The three cylinders are formed in one casting. The valve is a circular revolving disc with segmental ports, which pass over corresponding apertures in the valve seating during rotation. The valve seating is of lignum vitæ.

Fig. 175 shows a similar engine made by Messrs Hastie of Greenock. G, G, G are the three plungers which pass out of the cylinders through cup leathers, and act on the same crank pin. A is the inlet pipe which communicates with the cock B. This cock controls the action of the engine, being so constructed that it acts as a reversing valve when the handle C is in its extreme positions and as a brake when in its middle position. With the

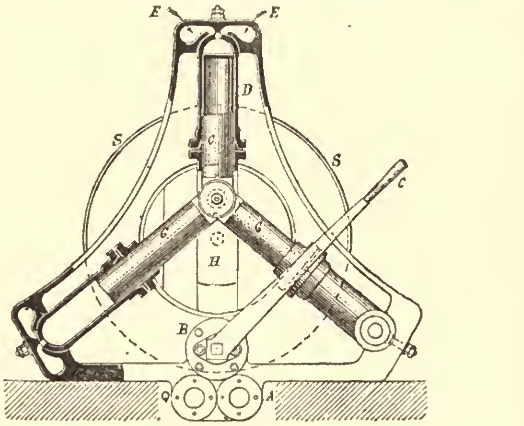

Fig. 175.

handle in its middle position, the ports of the cylinders are in communication with the exhaust. Two passages are formed in the framing leading from the cock B to the ends of the cylinders, one being in communication with the supply pipe A, the other with the discharge pipe Q. These passages end as shown at E. The oscillation of the cylinders puts them alternately in communication with each of these passages, and thus the water is alternately admitted and exhausted.

In any ordinary rotative engine the length of stroke is invariable. Consequently the consumption of water depends simply on the speed of the engine, irrespective of the effort overcome. If the power of the engine must be varied without altering the number of rotations, then the stroke must be made variable. Messrs Hastie have contrived an exceedingly ingenious method of varying the stroke automatically, in proportion to the amount of work to be done (fig. 176). The crank pin I is carried in a slide H moving in a disk M. In this is a double cam K acting on two small steel rollers J, L attached to the slide H. If the cam rotates it moves the slide and increases or decreases the radius of the circle in which the crank pin I rotates. The disk M is keyed on a hollow shaft surrounding the driving shaft P, to which the cams are attached. The hollow shaft N has two snugs to which the chains RR are attached (fig. 177). The shaft P carries the spring case SS to which also are attached the other ends of the chains. When the engine is at rest the springs extend themselves, rotating the hollow shaft N and the frame M, so as to place the crank pin I at its nearest position to the axis of rotation. When

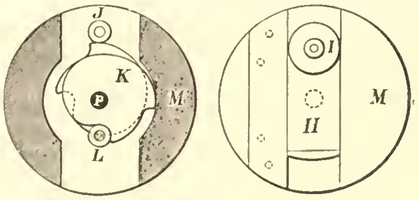

Fig. 176.

a resistance has to be overcome, the shaft N rotates relatively to P, compressing the springs, till their resistance balances the pressure due to the resistance to the rotation of P. The engine then commences to work, the crank pin being in the position in which the turning effort just overcomes the resistance. If the resistance diminishes, the springs force out the chains and shorten the stroke of the plungers, and *vice versa.* The following experiments, on an engine of this kind working a hoist, show how the automatic arrangement adjusted the water used to the work done. The lift was 22 feet and the water pressure in the cylinders 80 lb per square inch.

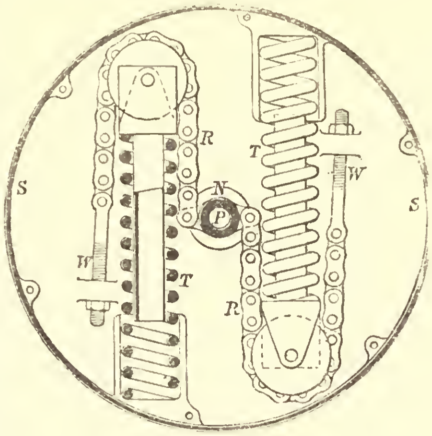

Fig. 177.

Weight lifted, in pounds	Chain only	427	633	745	857	969	1081	1193
Water used, in gallons.....	$7\frac{1}{2}$	10	14	16	17	20	21	22

165. *Accumulator Machinery.*—It has already been pointed out that it is in some cases convenient to use a steam engine to create an artificial head of water, which is afterwards employed in driving water-pressure machinery. Where power is required intermittently, for short periods, at a number of different points, as, for instance, in moving the cranes, lock gates, &c., of a dockyard, a separate steam engine and boiler at each point is very inconvenient; nor can engines worked from a common boiler be used, because of the great loss of heat and the difficulties which arise out of condensation in the pipes. If a tank, into which water is continuously pumped, can be placed at a great elevation, the water can then be used in hydraulic machinery in a very convenient way. Each hydraulic machine is put in communication with the tank by a pipe, and on opening a valve it commences work, using a quantity of water directly proportional to the work done. No attendance is required when the machine is not working.

A site for such an elevated tank is, however, seldom available, and in place of it a beautiful arrangement termed the accumulator, invented by Sir W. Armstrong, is used. This consists of a tall vertical cylinder; into this works a solid ram through cup leathers or hemp packing, and the ram is loaded by fixed weights, so that the pressure in the cylinder is 700 lb or 800 lb per square inch. The pumping engines which supply the energy that is stored in the accumulator should be a pair coupled at right angles, so as to start in any position. The engines pump into the accumulator cylinder till the ram is at the top of its stroke, when by a catch arrangement the engines are stopped. If the accumulator ram descends, in consequence of water being taken to work machinery, the engines immediately recommence working. Pipes lead from the accumulator to each of the machines requiring to be driven. These pipes do not require to be of large size, as the pressure is so great. They are generally flanged pipes about $1\frac{1}{4}$ inches bore, the joints being made by a gutta-percha ring.

Fig. 178 shows in a diagrammatic way the scheme of a system of accumulator machinery. A is the accumulator, with its ram carrying a cylindrical wrought-iron tank W, in which weights are placed to load the accumulator. At R is one of the pressure engines worked from the accumulator, discharging the water after use into the tank T. In this case the pressure engine is shown working a set of blocks, the fixed block being on the ram cylinder, the running block on the ram. The chain running over these blocks works a lift cage C, the speed of which is as many times greater than that of the ram as there are plies of chain on the block tackle. B is the balance weight of the cage.

In the use of accumulators on shipboard for working gun gear or steering gear, the accumulator ram is loaded by springs, or by steam pressure acting on a piston much larger than the ram.

Mr Tweddell has used accumulators with a pressure of 2000 lb per square inch to work hydraulic riveting machinery.

The amount of energy stored in the accumulator, having a ram d inches in diameter, a stroke of S feet, and working at p pounds pressure per square inch, is

$$\frac{\pi}{4} p d^2 S \text{ foot-pounds.}$$

Thus, if the ram is 9 inches, the stroke 20 feet, and the pressure 800 lb per square inch, the work stored in the accumulator when the ram is at the top of the stroke is 1,017,600 foot-pounds, that is, enough to drive a machine requiring one horse power for about half an hour. As, however, the pumping engine replaces water as soon as it is drawn off, the working capacity of the accumulator is very much greater than this.

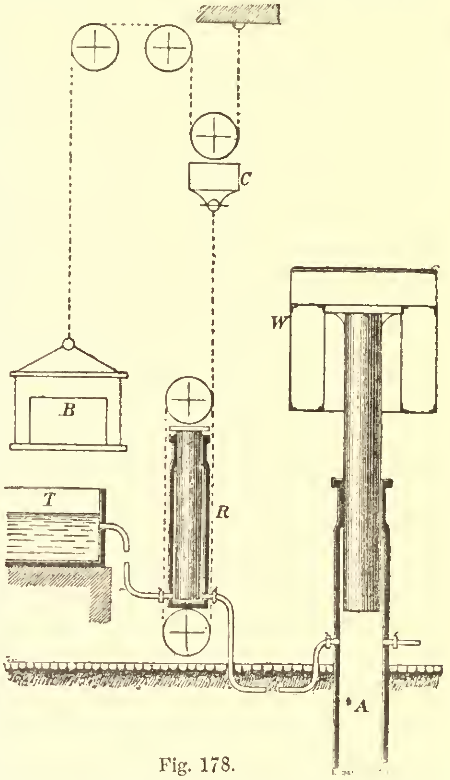

Fig. 178.

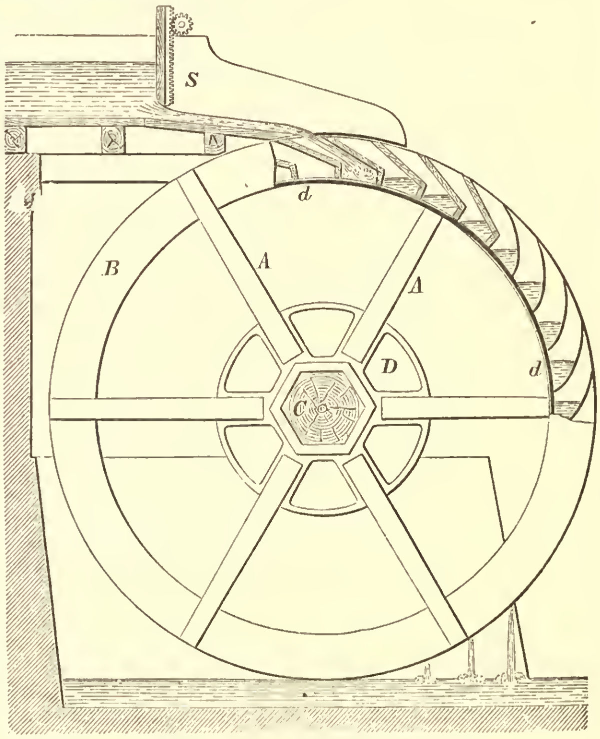

Fig. 179.

Water Wheels.

166. *Overshot and High Breast Wheels.*—When a water fall ranges between 10 and 70 feet, and the water supply

is from 3 to 25 cubic feet per second, it is possible to construct a bucket wheel on which the water acts chiefly by its weight. If the variation of the head-water level does not exceed 2 feet, an overshot wheel may be used (fig. 179). The water is then projected over the summit of the wheel, and falls in a parabolic path into the buckets. With greater variation of head-water level, a pitch-back or high breast wheel is better. The water falls over the top of a sliding sluice into the wheel, on the same side as the head race channel. By adjusting the height of the sluice, the requisite supply is given to the wheel in all positions of the head-water level.

The wheel consists of a cast-iron or wrought-iron axle C supporting the weight of the wheel. To this are attached two sets of arms A of wood or iron, which support circular segmental plates termed shrouds B. A cylindrical sole plate *dd* extends between the shrouds on the inner side. The buckets are formed by wood planks or curved wrought-iron plates extending from shroud to shroud, the back of the buckets being formed by the sole plate.

The efficiency may be taken at 0·75. Hence, if *h.p.* is the effective horse power, H the available fall, and Q the available water supply per second,

$$h.p. = 0{\cdot}75\ \frac{GQH}{550} = 0{\cdot}085\ QH.$$

If the peripheral velocity of the water wheel is too great, water is thrown out of the buckets before reaching the bottom of the fall. In practice, the circumferential velocity of water wheels of the kind now described is from $4\frac{1}{2}$ to 10 feet per second, about 6 feet being the usual velocity of good iron wheels not of very small size. In order that the water may enter the buckets easily, it must have a greater velocity than the wheel. Usually the velocity of the water at the point where it enters the wheel is from 9 to 12 feet per second, and to produce this it must enter the wheel at a point 16 to 27 inches below the head-water level. Hence the diameter of an overshot wheel may be

$$D = H - 1\tfrac{1}{3} \text{ to } H - 2\tfrac{1}{4} \text{ feet.}$$

Overshot and high breast wheels work badly in back-water, and hence if the tail-water level varies, it is better to reduce the diameter of the wheel so that its greatest immersion in flood is not more than 1 foot. The depth *d* of the shrouds is about 10 to 16 inches. The number of buckets may be about

$$N = \frac{\pi D}{d}.$$

Let *v* be the peripheral velocity of the wheel. Then the capacity of that portion of the wheel which passes the sluice in one second is

$$Q_1 = \frac{vb}{D}(Dd - d^2)$$
$$= v\,b\,d \text{ nearly,}$$

b being the breadth of the wheel between the shrouds. If, however, this quantity of water were allowed to pass on to the wheel the buckets would begin to spill their contents almost at the top of the fall. To diminish the loss from spilling, it is not only necessary to give the buckets a suitable form, but to restrict the water supply to one-fourth or one-third of the gross bucket capacity. Let *m* be the value of this ratio; then, Q being the supply of water per second,

$$Q = mQ_1 = mbdv.$$

This gives the breadth of the wheel if the water supply is known. The form of the buckets should be determined thus. The outer element of the bucket should be in the direction of motion of the water entering relatively to the wheel, so that the water may enter without splashing or shock. The buckets should retain the water as long as possible, and the width of opening of the buckets should be 2 or 3 inches greater than the thickness of the sheet of water entering.

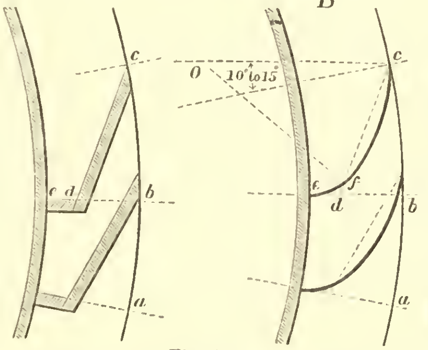

Fig. 180.

For a wooden bucket (fig. 180, A), take *ab* = distance between two buckets on periphery of wheel. Make $cd = \frac{1}{2}\,cb$, and $bc = \frac{5}{8}$ to $\frac{3}{4}\,ab$. Join *cd*. For an iron bucket (fig. 180, B), take $cd = \frac{1}{3}\,cb$; $bc = \frac{5}{6}\,ab$. Draw *c*O making an angle of 10° to 15° with the radius at *c*. On O*c* take a centre giving a circular arc passing near *d*, and round the curve into the radial part of the bucket *de*.

There are two ways in which the power of a water wheel is given off to the machinery driven. In wooden wheels and wheels with rigid arms, a spur or bevil wheel keyed on the axle of the turbine will transmit the power to the shafting. It is obvious that the whole turning moment due to the weight of the water is then transmitted through the arms and axle of the water wheel. When the water wheel is an iron one, it usually has light iron suspension arms incapable of resisting the bending action due to the transmission of the turning effort to the axle. In that case spur segments are bolted to one of the shrouds, and the pinion to which the power is transmitted is placed so that the teeth in gear are, as nearly as may be, on the line of action of the resultant of the weight of the water in the loaded arc of the wheel.

167. *The Poncelet Water Wheel.*—When the fall does not exceed 6 feet, the best water motor to adopt in many cases is the Poncelet undershot water wheel. In this the water acts very nearly in the same way as in a turbine, and the Poncelet wheel, although slightly less efficient than the best turbines, in normal conditions of working, is superior to most of them when working with a reduced supply of water. A general notion of the action of the water on a Poncelet wheel has already been given in § 145. Fig. 181 shows its construction. The water penned back

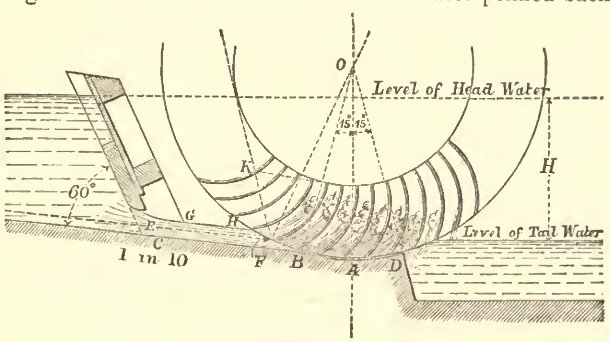

Fig. 181.

between the side walls of the wheel pit is allowed to flow to the wheel under a movable sluice, at a velocity nearly equal to the velocity due to the whole fall. The water is guided down a slope of 1 in 10, or a curved race, and enters the wheel without shock. Gliding up the curved floats it comes to rest, falls back, and acquires at the point of discharge a backward velocity relative to the wheel nearly equal to the forward velocity of the wheel. Consequently it leaves the wheel deprived of nearly the whole of its original kinetic energy.

Taking the efficiency at 0·60, and putting H for the available fall, *h.p.* for the horse-power, and Q for the water supply per second,

$$h.p. = 0{\cdot}068\ QH.$$

The diameter D of the wheel does not depend on the fall. With a straight channel of approach the smallest convenient diameter is about 14 feet, with a curved channel 10 feet. The diameter is often taken at four times the fall.

Let H′ be the fall measured from the free surface of the head-water to the point F where the mean layer enters the wheel; then the velocity at which the water enters is $v = \sqrt{2gH'}$, and the best circumferential velocity of the wheel is $V = 0{\cdot}55v$ to $0{\cdot}6v$. The number of rotations of the wheel per second is $N = \dfrac{V}{\pi D}$.

The thickness of the sheet of water entering the wheel is very important. The best thickness according to experiment is 8 to 10 inches. The maximum thickness should not exceed 12 to 15 inches, when there is a surplus water supply. Let *e* be the thickness of the sheet of water entering the wheel, and *b* its width; then

$$bev = Q;\quad \text{or } b = \frac{Q}{ev}.$$

Grashof takes $e=\frac{1}{6}H$, and then

$$b=6\frac{Q}{H\sqrt{2gH}}.$$

Allowing for the contraction of the stream, the area of opening through the sluice may be 1·25 be to 1·3 be. The inside width of the wheel is made about 4 inches greater than b.

Several constructions have been given for the floats of Poncelet wheels. One of the simplest is that shown in figs. 181, 182.

Let OA (fig. 181) be the vertical radius of the wheel. Set off OB, OD making angles of 15° with OA. Then BD may be the length of

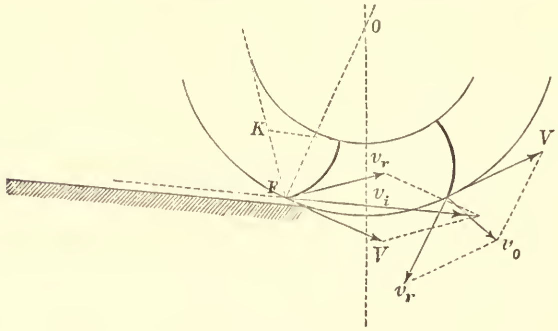

Fig. 182.

the close breasting fitted to the wheel. Draw the bottom of the head race BC at a slope of 1 in 10. Parallel to this, at distances $\frac{1}{2}e$ and e, draw EF and GH. Then EF is the mean layer and GH the surface layer entering the wheel. Join OF, and make OFK = 23°. Take FK = 0·5 to 0·7 H. Then K is the centre from which the bucket curve is struck and KF is the radius. The depth of the shrouds must be sufficient to prevent the water from rising over the top of the float. It is $\frac{1}{2}$H to $\frac{2}{3}$H. The number of buckets is not very important. They are usually 1 foot apart on the circumference of the wheel.

The efficiency of a Poncelet wheel has been found in experiments to reach 0·68. It is better to take it at 0·6 in estimating the power of the wheel, so as to allow some margin.

In fig. 182 v_i is the initial and v_o the final velocity of the water, v_r parallel to the vane the relative velocity of the water and wheel, and V the velocity of the wheel.

Turbines.

168. The name turbine was originally given in France to any water motor which revolved in a horizontal plane, the axis being vertical. The rapid development of this class of motors dates from 1827, when a prize was offered by the Societé d'Encouragement for a motor of this kind, which should be an improvement on certain wheels then in use. The prize was ultimately awarded to M. Fourneyron, whose turbine, but little modified, is still constructed.

Classification of Turbines.—In some turbines the whole available energy of the water is converted into kinetic energy before the water acts on the moving part of the turbine. Such turbines are termed *Impulse Turbines*, and they are distinguished by this that the wheel passages are never entirely filled by the water. To ensure this condition they must be placed a little above the tail water and discharge into free air.

Turbines in which part only of the available energy is converted into kinetic energy, before the water enters the turbine wheel, may be termed *Reaction Turbines*. In these the pressure is greater at the inlet than at the outlet ends of the wheel passages. The wheel passages must therefore be entirely filled, and the wheel may be and generally is placed below the tail-water level.

Next there is a difference of constructive arrangement of turbines, which does not very essentially alter the mode of action of the water. In axial flow or so called parallel flow turbines, the water enters and leaves the turbine in a direction parallel to the axis of rotation, and the paths of the molecules lie on cylindrical surfaces concentric with that axis. In radial outward and inward flow turbines, the water enters and leaves the turbine in directions normal to the axis of rotation, and the paths of the molecules lie exactly or nearly in planes normal to the axis of rotation. In outward flow turbines the general direction of flow is away from the axis, and in inward flow turbines towards the axis. There are also mixed flow turbines in which the water enters normally and is discharged parallel to the axis of rotation.

Another difference of construction is this, that the water may be admitted equally to every part of the circumference of the turbine wheel or to a portion of the circumference only. In the former case, the condition of the wheel passages is always the same; they receive water equally in all positions during rotation. In the latter case, they receive water during a part of the rotation only. The former may be termed turbines with complete admission, the latter turbines with partial admission. A reaction turbine should always have complete admission. An impulse turbine may have complete or partial admission.

When two turbine wheels similarly constructed are placed on the same axis, in order to balance the pressures and diminish journal friction, the arrangement may be termed a twin turbine.

If the water, having acted on one turbine wheel, is then passed through a second on the same axis, the arrangement may be termed a compound turbine. The object of such an arrangement would be to diminish the speed of rotation.

Many forms of reaction turbine may be placed at any height not exceeding 30 feet above the tail water. They then discharge into an air-tight suction pipe. The weight of the column of water in this pipe balances part of the atmospheric pressure, and the difference of pressure, producing the flow through the turbine, is the same as if the turbine were placed at the bottom of the fall.

I. *Impulse Turbines.*	II. *Reaction Turbines.*
(Wheel passages not filled, and discharging above the tail water.)	(Wheel passages filled, discharging above or below the tail water or into a suction-pipe.)
(*a.*) Complete admission. (Rare.) (*b.*) Partial admission. (Usual.)	Always with complete admission.

Axial flow, outward flow, inward flow, or mixed flow.

Simple turbines; twin turbines; compound turbines.

169. *The Simple Reaction Wheel.*—It has been shown, in § 151, that, when water issues from a vessel, there is a reaction on the vessel tending to cause motion in a direction opposite to that of the jet. This principle was applied in a rotating water motor at a very early period, and the Scotch turbine, at one time much used, differs in no essential respect from the older form of reaction wheel.

The old reaction wheel consisted of a vertical pipe balanced on a vertical axis, and supplied with water (fig. 183). From the bottom of the vertical pipe two or more hollow horizontal arms extended, at the ends of which were orifices from which the water was discharged. The reaction of the jets caused the rotation of the machine.

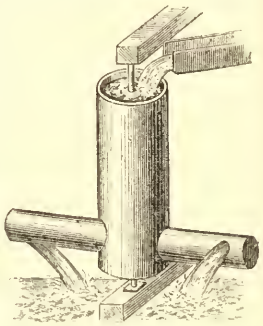

Fig. 183.

Let H be the available fall measured from the level of the water in the vertical pipe to the centres of the orifices, r the radius from the axis of rotation to the centres of the orifices, v the velocity of discharge through the jets, α the angular velocity of the machine. When the machine is at rest the water issues from the orifices with the velocity $\sqrt{2gH}$ (friction being neglected). But when the machine rotates the water in the arms rotates also, and is in the condition of a forced vortex, all the particles having the same angular velocity. Consequently the pressure in the arms at the orifices is

$$H+\frac{\alpha^2r^2}{2g}$$

feet of water, and the velocity of discharge through the orifices is

$$v=\sqrt{2gH+\alpha^2r^2}.$$

If the total area of the orifices is ω, the quantity discharged from the wheel per second is

$$Q=\omega v=\omega\sqrt{2gH+a^2r^2}.$$

While the water passes through the orifices with the velocity v, the orifices are moving in the opposite direction with the velocity ar. The absolute velocity of the water is therefore

$$v-ar=\sqrt{2gH+a^2r^2}-ar.$$

The momentum generated per second is $\frac{GQ}{g}(v-ar)$, which is numerically equal to the force driving the motor at the radius r. The work done by the water in rotating the wheel is therefore, per second,

$$\frac{GQ}{g}(v-ar)ar \text{ foot-pounds.}$$

The work expended by the water fall is GQH foot-pounds per second. Consequently the efficiency of the motor is

$$\eta=\frac{(v-ar)ar}{gH}=\frac{\left\{\sqrt{2gH+a^2r^2}-ar\right\}ar}{gH}$$

Let $\sqrt{2gH+a^2r^2}=ar+\frac{gH}{ar}-\frac{g^2H^2}{2a^3r^3}\;.\;.\;.\;.\;.$

then $\eta=1-\frac{gH}{2ar}+\;.\;.\;.\;.\;.$

which increases towards the limit 1 as ar increases towards infinity. Neglecting friction, therefore, the maximum efficiency is reached when the wheel has an infinitely great velocity of rotation. But this condition is impracticable to realize, and even, at practicable but high velocities of rotation, the friction would considerably reduce the efficiency. Experiment seems to show that the best efficiency is reached when $ar=\sqrt{2gH}$. Then the efficiency apart from friction is

$$\eta=\frac{(\sqrt{2a^2r^2}-ar)ar}{gH}$$
$$=\frac{0\cdot414a^2r^2}{gH}=0\cdot828,$$

about 17 per cent. of the energy of the fall being carried away by the water discharged. The actual efficiency realized appears to be about 60 per cent., so that about 21 per cent. of the energy of the fall is lost in friction, in addition to the energy carried away by the water.

170. *General Statement of Hydrodynamical Principles necessary for the Theory of Turbines.*

1. When water flows through any pipe-shaped passage, such as the passage between the vanes of a turbine wheel, the relation between the changes of pressure and velocity is given by Bernoulli's theorem (§ 26). Suppose that, at a section A of such a passage, h_1 is the pressure measured in feet of water, v_1 the velocity, and z_1 the elevation above any horizontal datum plane, and that at a section B the same quantities are denoted by h_2, v_2, z_2. Then

$$h_1-h_2=\frac{v_2^2-v_1^2}{2g}+z_2-z_1\;.\;.\;.\;.\;.\;.\;.\;(1).$$

If the flow is horizontal, $z_2=z_1$; and

$$h_1-h_2=\frac{v_2^2-v_1^2}{2g}\;.\;.\;.\;.\;.\;.\;.\;(1a).$$

2. When there is an abrupt change of section of the passage, or an abrupt change of section of the stream due to a contraction, then, in applying Bernoulli's equation allowance must be made for the loss of head in shock (§ 32). Let v_1, v_2 be the velocities before and after the abrupt change, then a stream of velocity v_1 impinges on a stream at a velocity v_2 and the relative velocity is v_1-v_2. The head lost is $\frac{(v_1-v_2)^2}{2g}$. Then equation $(1a)$ becomes

$$h_2-h_1=\frac{v_1^2-v_2^2}{2g}-\frac{(v_1-v_2)^2}{2g}=\frac{v_2(v_1-v_2)}{g}\;.\;.\;.\;(2).$$

To diminish as much as possible the loss of energy from irregular eddying motions, the change of section in the turbine passages must be very gradual, and the curvature without discontinuity.

3. *Equality of Angular Impulse and Change of Angular Momentum.*—Suppose that a couple, the moment of which is M, acts on a body of weight W for t seconds, during which it moves from A_1 to A_2 (fig. 184). Let v_1 be the velocity of the body at A_1, v_2 its velocity at A_2, and let p_1, p_2 be the perpendiculars from C on v_1 and v_2. Then Mt is termed the angular impulse of the couple, and the quantity

$$\frac{W}{g}(v_2p_2-v_1p_1)$$

is the change of angular momentum relatively to C. Then, from the equality of angular impulse and change of angular momentum

$$Mt=\frac{W}{g}(v_2p_2-v_1p_1),$$

or, if the change of momentum is estimated for one second,

$$M=\frac{W}{g}(v_2p_2-v_1p_1).$$

Let r_1, r_2 be the radii drawn from C to A_1, A_2, and let w_1, w_2 be the components of v_1, v_2, perpendicular to these radii, making angles β and a with v_1, v_2. Then

$$v_1=w_1\sec\beta\;;\;v_2=w_2\sec a;$$
$$p_1=r_1\cos\beta\;;\;p_2=r_2\cos a.$$
$$\therefore\;M=\frac{W}{g}(w_2r_2-w_1r_1)\cdot\;(3),$$

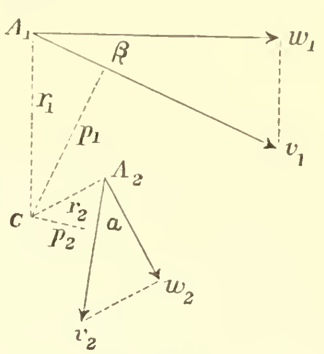

Fig. 184.

where the moment of the couple is expressed in terms of the radii drawn to the positions of the body at the beginning and end of a second, and the tangential components of its velocity at those points.

Now the water flowing through a turbine enters at the admission surface and leaves at the discharge surface of the wheel, with its angular momentum relatively to the axis of the wheel changed. It therefore exerts a couple $-M$ tending to rotate the wheel, equal and opposite to the couple M which the wheel exerts on the water. Let Q cubic feet enter and leave the wheel per second, and let w_1, w_2 be the tangential components of the velocity of the water at the receiving and discharging surfaces of the wheel, r_1, r_2 the radii of those surfaces. By the principle above,

$$-M=\frac{GQ}{g}(w_2r_2-w_1r_1)\;.\;.\;.\;.\;.\;(4).$$

If a is the angular velocity of the wheel, the work done by the water on the wheel is

$$T=Ma=\frac{GQ}{g}(w_1r_1-w_2r_2)a \text{ foot-pounds per second}\;.\;(5).$$

171. *Total and Available Fall.*—Let H_t be the total difference of level from the head-water to the tail-water surface. Of this total head a portion is expended in overcoming the resistances of the head race, tail race, supply pipe, or other channel conveying the water. Let $\mathfrak{h}_p$ be that loss of head, which varies with the local conditions in which the turbine is placed. Then

$$H=H_t-\mathfrak{h}_p$$

is the available head for working the turbine, and on this the calculations for the turbine should be based. In some cases it is necessary to place the turbine above the tail-water level, and there is then a fall $\mathfrak{h}$ from the centre of the outlet surface of the turbine to the tail-water level which is wasted, but which is properly one of the losses belonging to the turbine itself. In that case the velocities of the water in the turbine should be calculated for a head $H-\mathfrak{h}$, but the efficiency of the turbine for the head H.

172. *Gross Efficiency and Hydraulic Efficiency of a Turbine.*—Let T_d be the useful work done by the turbine, in foot-pounds per second, T_t the work expended in friction of the turbine shaft, gearing, &c., a quantity which varies with the local conditions in which the turbine is placed. Then the effective work done by the water in the turbine is

$$T=T_d+T_t.$$

The gross efficiency of the whole arrangement of turbine, races, and transmissive machinery is

$$\eta_t=\frac{T_d}{GQH_t}\;.\;.\;.\;.\;.\;.\;.\;(6).$$

And the hydraulic efficiency of the turbine alone is

$$\eta=\frac{T}{GQH}\;.\;.\;.\;.\;.\;.\;.\;.\;(7).$$

It is this last efficiency only with which the theory of turbines is concerned.

From equations (5) and (7) we get

$$\eta GQH=\frac{GQ}{g}(w_1r_1-w_2r_2)a\;;$$
$$\eta=\frac{(w_1r_1-w_2r_2)a}{gH}\;.\;.\;.\;.\;.\;.\;(8).$$

This is the fundamental equation in the theory of turbines. In general,[1] w_1 and w_2, the tangential components of the water's motion

[1] In general, because when the water leaves the turbine wheel it ceases to act on the machine. If deflecting vanes or a whirlpool are added to a turbine at the discharging side, then v_1 may in part depend on v_2, and the statement above is no longer true.

on entering and leaving the wheel, are completely independent. That the efficiency may be as great as possible, it is obviously necessary that $w_2 = 0$. In that case

$$\eta = \frac{w_1 r_1 a}{gH} \quad . \quad . \quad . \quad . \quad (9).$$

ar_1 is the circumferential velocity of the wheel at the inlet sur-

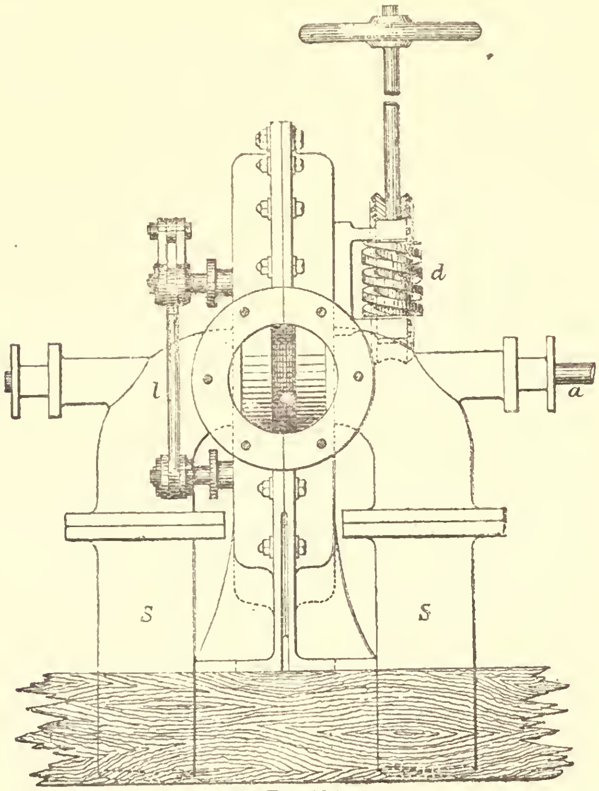

Fig. 185.

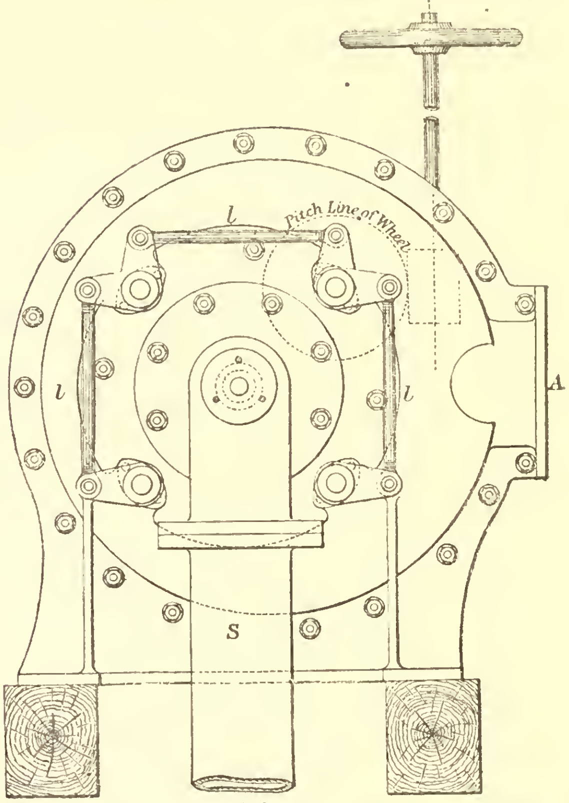

Fig. 186.

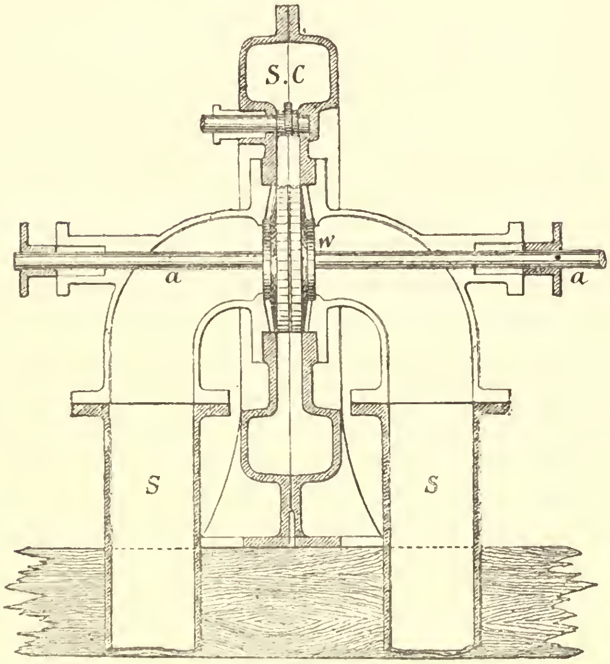

Fig. 187.

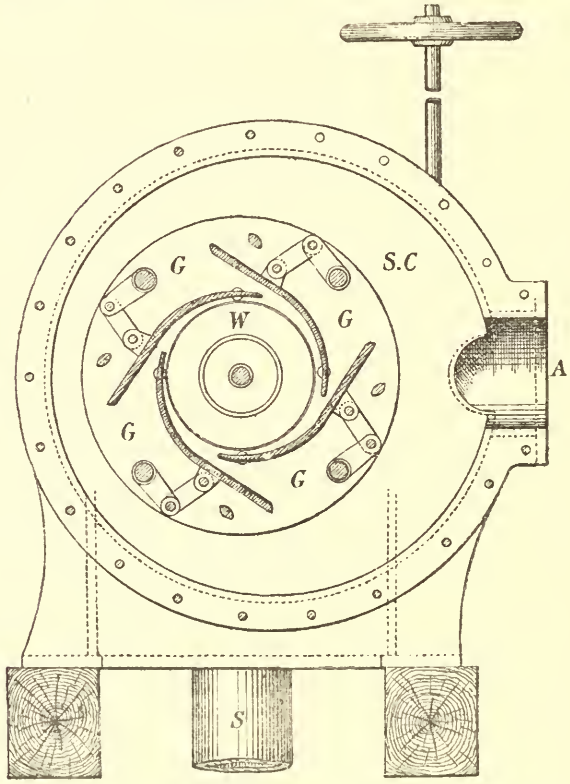

Fig. 188.

face. Calling this V_1, the equation becomes

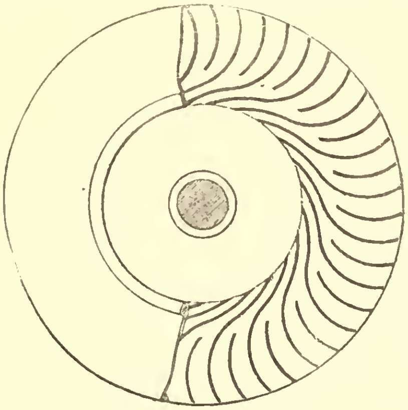
$$\eta = \frac{w_1 V_1}{gH} \quad . \quad . \quad . \quad . \quad (9a).$$

This remarkably simple equation is the fundamental equation in the theory of turbines. It was first given by Herr v. Reiche (*Turbinen-baues*, 1877).

173. *General Description of a Reaction Turbine.*—Professor James Thomson's inward flow or vortex turbine has been

selected as the type of reaction turbines. It is one of the best even in normal conditions of working, and the mode of regulation introduced is decidedly superior to that in most reaction turbines; it might almost be said to be the only mode of regulation which satisfies the conditions of efficient working, and it has been adopted in a modified form in the Leffel turbine, which is now largely used in America.

Figs. 185 and 186 are external views of the turbine case; figs. 187 and 188 are the corresponding sections; fig. 189 is



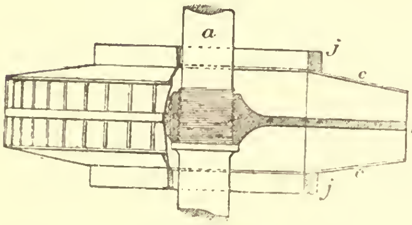


Fig. 189.

the turbine wheel. The example chosen for illustration has suction pipes, which permit the turbine to be placed at any height less than 30 feet above the tail-water level. The water enters the turbine by cast-iron supply pipes at A, and is discharged through two suction pipes S, S. The water on entering the case distributes itself through a rectangular supply chamber SC, from which it finds its way equally to the four guide-blade passages G, G, G, G. In these passages it acquires a velocity about equal to that due to half the fall, and is directed into the wheel at an angle of about 10° or 12° with the tangent to its circumference. The wheel W receives the water in equal proportions from each guide-blade passage. It consists of a centre plate p (fig. 189) keyed on the shaft aa, which passes through stuffing boxes on the suction pipes. On each side of the centre plate are the curved wheel vanes, on which the pressure of the water acts, and the vanes are bounded on each side by dished or conical coverplates c, c. Joint-rings j, j on the cover plates make a sufficiently water-tight joint with the casing, to prevent leakage from the guide-blade chamber into the suction pipes. The pressure near the joint rings is not very great, probably not one-fourth the total head. The wheel vanes receive the water without shock, and deliver it into central spaces, from which it flows on either side to the suction pipes. The mode of regulating the power of the turbine is very simple. The guide-blades are pivoted to the case at their inner ends, and they are connected by a linkwork, so that they all open and close simultaneously and equally. In this way the area of opening through the guide-blades is altered without materially altering the angle or the other conditions of the delivery into the wheel. The guide-blade gear may be variously arranged. In this example four spindles, passing through the case, are linked to the guide-blades inside the case, and connected together by the links l, l, l on the outside of the case. A worm wheel on one of the spindles is rotated by a worm d, the motion being thus slow enough to adjust the guide-blades very exactly. These turbines are made by Messrs Williamson Brothers of Kendal, who supplied the drawing of the turbine.

Fig. 190 shows another arrangement of the same turbine, with some adjuncts not shown in the other drawings. In this case the turbine rotates horizontally, and the turbine case is placed entirely below the tail water. The water is supplied to the turbine by a vertical pipe, over which is a wooden pentrough, containing a strainer, which prevents sticks and other solid bodies getting into the turbine.

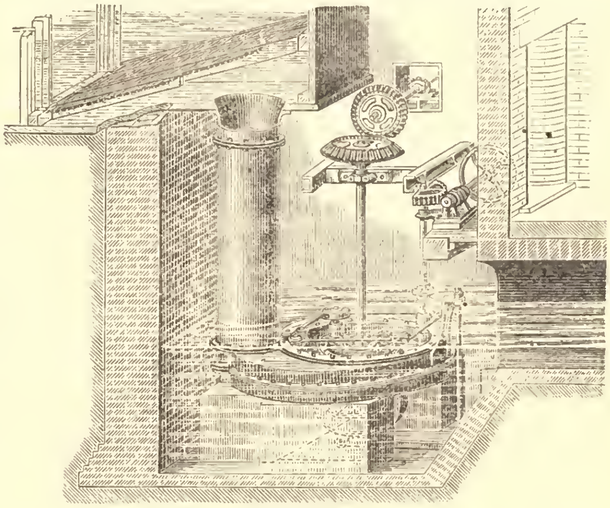

Fig. 190.

The turbine rests on three foundation stones, and, the pivot for the vertical shaft being under water, there is a screw and lever arrangement for adjusting it as it wears. The vertical shaft gives motion to the machinery driven by a pair of bevel wheels. On the right are the worm and wheel for working the guide-blade gear.

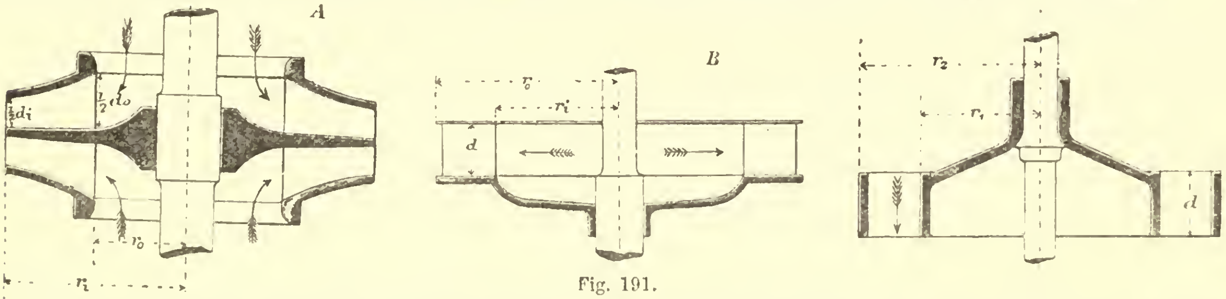

Fig. 191.

174. *Different Forms of Turbine Wheel.*—The wheel of a turbine or part of the machine on which the water acts is an annular space, furnished with curved vanes dividing it into passages exactly or roughly rectangular in cross section. For radial flow turbines the wheel may have the form A or B, fig. 191, A being most usual with inward, and B with outward flow turbines. In A the wheel vanes are fixed on each side of a centre plate keyed on the turbine shaft. The vanes are limited by slightly-coned annular cover plates. In B the vanes are fixed on one side of a disk, keyed on the shaft, and limited by a cover plate parallel to the disk. Parallel

flow or axial flow turbines have the wheel as in C. The vanes are limited by two concentric cylinders.

Reaction Turbines.

175. *Velocity of Whirl and Velocity of Flow.*—Let *acb* (fig. 192) be the path of the particles of water in a turbine wheel. That path will be in a plane normal to the axis of rotation in radial flow turbines, and on a cylindrical surface in axial flow turbines. At any point *c* of the path the water will have some velocity *v*, in the direction of a tangent to the path. That velocity may be resolved into two components, a whirling velocity *w* in the direction of the wheel's rotation at the point *c*, and a component *u* at right angles to this, radial in radial flow, and parallel to the axis in axial flow turbines. This second component is termed the velocity of flow. Let v_0, w_0, u_0 be the velocity of the water, the whirling velocity and velocity of flow at the outlet surface of the wheel, and v_i, w_i, u_i the same quantities at the inlet surface of the wheel. Let α and β be the angles which the water's direction of motion makes with the direction of motion of the wheel at those surfaces. Then

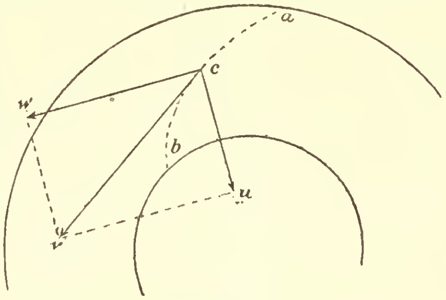

Fig. 192.

$$\left.\begin{aligned} w_0 &= v_0 \cos\beta\;;\; u_0 = v_0 \sin\beta \\ w_i &= v_0 \cos\alpha\;;\; u_i = v_i \sin\alpha \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (10).$$

The velocities of flow are easily ascertained independently from the dimensions of the wheel. The velocities of flow at the inlet and outlet surfaces of the wheel are normal to those surfaces. Let Ω_0, Ω_i be the areas of the outlet and inlet surfaces of the wheel, and Q the volume of water passing through the wheel per second; then

$$v_0 = \frac{Q}{\Omega_0}\;;\quad v_i = \frac{Q}{\Omega_i} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11).$$

Using the notation in fig. 191, we have, for an inward flow turbine (neglecting the space occupied by the vanes),

$$\Omega_0 = 2\pi r_0 d_0\;;\; \Omega_i = 2\pi r_i d_i \quad . \quad . \quad . \quad . \quad (12a).$$

Similarly, for an outward flow turbine,

$$\Omega_0 = 2\pi r_0 d\;;\; \Omega_i = 2\pi r_i d \quad . \quad . \quad . \quad . \quad . \quad (12b);$$

and, for an axial flow turbine,

$$\Omega_0 = \Omega_i = \pi\left(r_2^2 - r_1^2\right), \quad . \quad . \quad . \quad . \quad . \quad (12c).$$

Relative and Common Velocity of the Water and Wheel.—There is another way of resolving the velocity of the water. Let V be the velocity of the wheel at the point *c*, fig. 193. Then the velocity of the water may be resolved into a component V, which the water has in common with the wheel, and a component v_r, which is the velocity of the water relatively to the wheel.

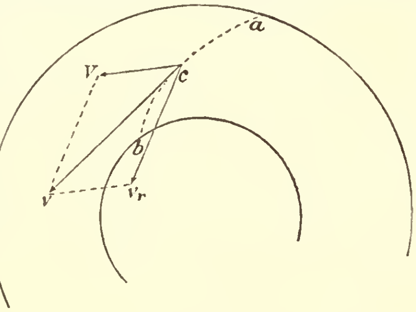

Fig. 193.

Velocity of Flow.—It is obvious that the frictional losses of head in the wheel passages will increase as the velocity of flow is greater, that is, the smaller the wheel is made. But if the wheel works under water, the skin friction of the wheel cover increases as the diameter of the wheel is made greater, and in any case the weight of the wheel and consequently the journal friction increase as the wheel is made larger. It is therefore desirable to choose, for the velocity of flow, as large a value as is consistent with the condition that the frictional losses in the wheel passages are a small fraction of the total head.

The values most commonly assumed in practice are these:—

In axial flow turbines, $u_0 = u_i = 0{\cdot}15$ to $0{\cdot}2\sqrt{2g\mathrm{H}}$;

In outward flow turbines, $u_i = 0{\cdot}25\sqrt{2g(\mathrm{H}-\mathfrak{h})}$,

$u_0 = 0{\cdot}21$ to $0{\cdot}17\sqrt{2g(\mathrm{H}-\mathfrak{h})}$;

In inward flow turbines, $u_0 = u_i = 0{\cdot}125\sqrt{2g\mathrm{H}}$.

176. *Speed of the Wheel.*—The best speed of the wheel depends partly on the frictional losses, which the ordinary theory of turbines disregards. It is best, therefore, to assume for V_0 and V_i values which experiment has shown to be most advantageous.

In axial flow turbines, the circumferential velocities at the mean radius of the wheel may be taken

$$\mathrm{V}_0 = \mathrm{V}_i = 0{\cdot}6\sqrt{2g\mathrm{H}} \text{ to } 0{\cdot}66\sqrt{2g\mathrm{H}}\ .$$

In a radial outward flow turbine,

$$\mathrm{V}_i = 0{\cdot}56\sqrt{2g(\mathrm{H}-\mathfrak{h})}$$

$$\mathrm{V}_0 = \mathrm{V}_i \frac{r_0}{r_i}\ ,$$

where r_0, r_i are the radii of the outlet and inlet surfaces.

In a radial inward flow turbine,

$$\mathrm{V}_i = 0{\cdot}66\sqrt{2g\mathrm{H}}\ ,$$

$$\mathrm{V}_0 = \frac{r_0}{r_i}\mathrm{V}_i\ .$$

If the wheel were stationary and the water flowed through it, the water would follow paths parallel to the wheel vane curves, at least when the vanes were so close that irregular motion was prevented. Similarly, when the wheel is in motion, the water follows paths relatively to the wheel, which are curves parallel to the wheel vanes. Hence the relative component, v_r, of the water's motion at *c* is tangential to a wheel vane curve drawn through the point *c*. Let v_0, V_0, v_{r0} be the velocity of the water and its common and relative components at the outlet surface of the wheel, and v_i, V_i, v_{ri} be the same quantities at the inlet surface; and let θ and ϕ be the angles the wheel vanes make with the inlet and outlet surfaces; then

$$\left.\begin{aligned} v_0^2 &= \surd(v_{r0}^2 + \mathrm{V}_0^2 - 2\mathrm{V}_0 v_{r0}\cos\phi) \\ v_i &= \surd(v_{ri}^2 + \mathrm{V}_i^2 - 2\mathrm{V}_i v_{ri}\cos\theta) \end{aligned}\right\} \quad . \quad . \quad . \quad (13),$$

equations which may be used to determine ϕ and θ.

177. *Condition determining the Angle of the Vanes at the Outlet Surface of the Wheel.* — It has been shown that, when the water leaves the wheel, it should have no tangential velocity, if the efficiency is to be as great as possible; that is, $w_0 = 0$. Hence, from (10), $\cos\beta = 0$, $\beta = 90°$, $u_0 = v_0$, and the direction of the water's motion is normal to the outlet surface of the wheel, radial in radial flow, and axial in axial flow turbines.

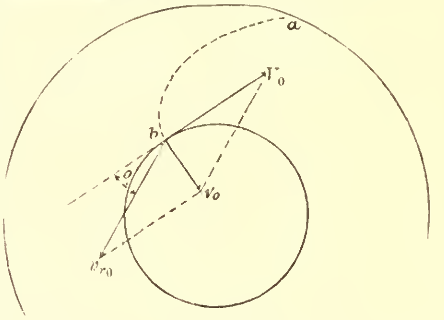

Fig. 194.

Drawing v_0 or u_0 radial or axial as the case may be, and V_0 tangential to the direction of motion, v_{r0} can be found by the parallelogram of velocities. From fig. 194,

$$\tan\phi = \frac{v_0}{\mathrm{V}_0} = \frac{u_0}{\mathrm{V}_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad (14);$$

but ϕ is the angle which the wheel vane makes with the outlet surface of the wheel, which is thus determined when the velocity of flow u_0 and velocity of the wheel V_0 are known. When ϕ is thus determined,

$$v_{r0} = u_0 \operatorname{cosec}\phi = \mathrm{V}_0\sqrt{1 + \frac{u_0^2}{\mathrm{V}_0^2}} \quad . \quad . \quad . \quad . \quad (14a).$$

Correction of the Angle ϕ to allow for Thickness of Vanes.—In determining ϕ, it is most convenient to calculate its value approximately at first, from a value of u_0 obtained by neglecting the thickness of the vanes. As, however, this angle is the most important angle in the turbine, the value should be afterwards corrected to allow for the vane thickness.

Let

$$\phi' = \tan^{-1}\frac{u_0}{\mathrm{V}_0} = \tan^{-1}\frac{\mathrm{Q}}{\Omega_0 \mathrm{V}_0}$$

be the first or approximate value of ϕ, and let t be the thickness, and n the number of wheel vanes which reach the outlet surface of the wheel. As the vanes cut the outlet surface approximately at the angle ϕ', their width measured on that surface is $t\operatorname{cosec}\phi'$. Hence the space occupied by the vanes on the outlet surface is

$$\left.\begin{aligned} &\text{For A, fig. 191, } ntd_0 \operatorname{cosec}\phi \\ &\text{B, fig. 191, } ntd \operatorname{cosec}\phi \\ &\text{C, fig. 191, } nt(r_2 - r_1)\operatorname{cosec}\phi \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (15).$$

Call this area occupied by the vanes ω. Then the true value of the clear discharging outlet of the wheel is $\Omega_0 - \omega$, and the true value of u_0 is $\frac{Q}{\Omega_0 - \omega}$. The corrected value of the angle of the vanes will be

$$\phi = \tan^{-1}\frac{Q}{(\Omega_0 - \omega)V_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16).$$

178. *Head producing Velocity with which the Water enters the Wheel.*—Consider the variation of pressure in a wheel passage, which satisfies the condition that the sections change so gradually that there is no loss of head in shock. When the flow is in a horizontal plane, there is no work done by gravity on the water passing through the wheel. In the case of an axial flow turbine, in which the flow is vertical, the fall d between the inlet and outlet surfaces should be taken into account.

Let V_i, V_0 be the velocities of the wheel at the inlet and outlet surfaces,
v_i, v_0 the velocities of the water,
u_i, u_0 the velocities of flow,
v_{ri}, v_{r0} the relative velocities,
h_i, h_0 the pressures, measured in feet of water,
r_i, r_0 the radii of the wheel,
a the angular velocity of the wheel.

At any point in the path of a portion of water, at radius r, the velocity v of the water may be resolved into a component $V = ar$ equal to the velocity at that point of the wheel, and a relative component v_r. Hence the motion of the water may be considered to consist of two parts:—(*a*) a motion identical with that in a forced vortex of constant angular velocity a; (*b*) a flow along curves parallel to the wheel vane curves. Taking the latter first, and using Bernoulli's theorem, the change of pressure due to flow through the wheel passages is given by the equation

$$h'_i + \frac{v_{ri}^2}{2g} = h'_0 + \frac{v_{r0}^2}{2g};$$

$$h'_i - h'_0 = \frac{v_{r0}^2 - v_{ri}^2}{2g}.$$

The variation of pressure due to rotation in a forced vortex is

$$h''_i - h''_0 = \frac{V_i^2 - V_0^2}{2g}.$$

Consequently the whole difference of pressure at the inlet and outlet surfaces of the wheel is

$$h_i - h_0 = h'_i + h''_i - h'_0 - h''_0$$

$$= \frac{V_i^2 - V_0^2}{2g} + \frac{v_{r0}^2 - v_{ri}^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad (17).$$

Case 1. *Axial Flow Turbines.*—$V_i = V_0$; and the first term on the right, in equation 17, disappears. Adding, however, the work of gravity due to a fall of d feet in passing through the wheel,

$$h_i - h_0 = \frac{v_{r0}^2 - v_{ri}^2}{2g} - d \quad . \quad . \quad . \quad . \quad . \quad (17a).$$

Case 2. *Outward Flow Turbines.*—The inlet radius is less than the outlet radius, and $\frac{V_i^2 - V_0^2}{2g}$ is negative. The centrifugal head diminishes the pressure at the inlet surface, and increases the velocity with which the water enters the wheel. This somewhat increases the frictional loss of head. Further, if the wheel varies in velocity from variations in the useful work done, the quantity $\frac{V_i^2 - V_0^2}{2g}$ increases when the turbine speed increases, and *vice versa*. Consequently the flow into the turbine increases when the speed increases, and diminishes when the speed diminishes, and this again augments the variation of speed. The action of the centrifugal head in an outward flow turbine is therefore prejudicial to steadiness of motion. For this reason $r_0 : r_i$ is made small, generally about 5 : 4. Even then a governor is sometimes required to regulate the speed of the turbine.

Case 3. *Inward Flow Turbines.*—The inlet radius is greater than the outlet radius, and the centrifugal head diminishes the velocity of flow into the turbine. This tends to diminish the frictional losses, but it has a more important influence in securing steadiness of motion. Any increase of speed diminishes the flow into the turbine, and *vice versa*. Hence the variation of speed is less than the variation of resistance overcome. In the so-called centre vent wheels in America, the ratio $r_i : r_0$ is about 5 : 4, and then the influence of the centrifugal head is not very important. Professor James Thomson first pointed out the advantage of a much greater difference of radii. By making $r_i : r_0 = 2 : 1$, the centrifugal head balances about half the head in the supply chamber. Then the velocity through the guide-blades does not exceed the velocity due to half the fall, and the action of the centrifugal head in securing steadiness of speed is considerable.

Since the total head producing flow through the turbine is $H - \mathfrak{h}$, and of this $h_i - h_0$ is expended in overcoming the pressure in the wheel, the velocity of flow into the wheel is

$$v_i = c_v \sqrt{\left\{2g\left(H - \mathfrak{h} - \frac{V_i^2 - V_0^2}{2g} + \frac{v_{r0}^2 - v_{ri}^2}{2g}\right)\right\}} \quad . \quad . \quad . \quad (18),$$

where c_v may be taken 0·96.

From (14*a*),

$$v_{r0} = V_0 \sqrt{\left(1 + \frac{u_0^2}{V_0^2}\right)}.$$

It will be shown immediately that

$$v_{ri} = u_i \operatorname{cosec} \theta;$$

or, as this is only a small term, and θ is on the average 90°, we may take, for the present purpose, $v_{ri} = u_i$ nearly.

Inserting these values, and remembering that for an axial flow turbine $V_i = V_0$, $\mathfrak{h} = 0$, and the fall d in the wheel is to be added,

$$v_i = c_v \sqrt{\left\{2g\left(H - \frac{V_i^2}{2g}\left(1 + \frac{u_0^2}{V_0^2}\right) + \frac{u_i^2}{2g} - d\right)\right\}}.$$

For an outward flow turbine,

$$v_i = c_v \sqrt{\left[2g\left\{H - \mathfrak{h} - \frac{V_i^2}{2g}\left(1 + \frac{u_0^2}{V_i^2}\right) + \frac{u_i^2}{2g}\right\}\right]}.$$

For an inward flow turbine,

$$v_i = c_v \sqrt{\left[2g\left\{H - \frac{V_i^2}{2g}\left(1 + \frac{u_0^2}{V_i^2}\right) + \frac{u_i^2}{2g}\right\}\right]}.$$

179. *Angle which the Guide-Blades make with the Circumference of the Wheel.*—At the moment the water enters the wheel, the radial component of the velocity is u_i, and the velocity is v_i. Hence, if γ is the angle between the guide-blades and a tangent to the wheel

$$\gamma = \sin^{-1}\frac{u_i}{v_i}.$$

This angle can, if necessary, be corrected to allow for the thickness of the guide-blades.

180. *Condition Determining the Angle of the Vanes at the Inlet Surface of the Wheel.*—The single condition necessary to be satisfied at the inlet surface of the wheel is that the water should enter the wheel without shock. This condition is satisfied if the direction of relative motion of the water and wheel is parallel to the first element of the wheel vanes.

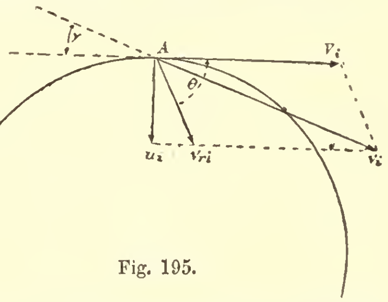

Fig. 195.

Let A (fig. 195) be a point on the inlet surface of the wheel, and let v_i represent in magnitude and direction the velocity of the water entering the wheel, and V_i the velocity of the wheel. Completing the parallelogram, v_{ri} is the direction of relative motion. Hence the angle between v_{ri} and V_i is the angle θ which the vanes should make with the inlet surface of the wheel.

181. *Example of the Method of Designing a Turbine. Professor James Thomson's Inward Flow Turbine.*—

Let H = the available fall after deducting loss of head in pipes and channels from the gross fall;
Q = the supply of water in cubic feet per second; and
η = the efficiency of the turbine.

The work done per second is

$$\eta GQH,$$

and the horse-power of the turbine is

$$h.p. = \frac{\eta GQH}{550}.$$

If η is taken at 0·75, an allowance will be made for the frictional losses in the turbine, the leakage, and the friction of the turbine shaft. Then $h.p. = 0·085QH$.

The velocity of flow through the turbine (uncorrected for the space occupied by the vanes and guide-blades) may be taken

$$u_i = u_0 = 0·125\sqrt{2gH},$$

in which case about $\frac{1}{64}$th of the energy of the fall is carried away by the water discharged.

The areas of the outlet and inlet surface of the wheel are then

$$2\pi r_0 d_0 = 2\pi r_i d_i = \frac{Q}{0{\cdot}125\sqrt{2gH}} .$$

If we take r_0, so that the axial velocity of discharge from the central orifices of the wheel is equal to u_0, we get

$$r_0 = 0{\cdot}3984 \sqrt{\frac{Q}{\sqrt{H}}},$$

$$d_0 = r_0.$$

If, to obtain considerable steadying action of the centrifugal head,

$r_i = 2r_0$, then $d_i = \frac{1}{2}d_0$.

Speed of the Wheel.—Let $V_i = 0{\cdot}66\sqrt{2gH}$, or the speed due to half the fall nearly. Then the number of rotations of the turbine per second is

$$N = \frac{V_i}{2\pi r_i} = 1{\cdot}0579 \sqrt{\left\{\frac{H\sqrt{H}}{Q}\right\}} ;$$

also $$V_0 = \frac{r_0}{r_i}V_i = 0{\cdot}33\sqrt{2gH} .$$

Angle of Vanes with Outlet Surface.

$$\text{Tan } \phi = \frac{u_0}{V_0} = \frac{0{\cdot}125}{0{\cdot}33} = {\cdot}3788 ;$$

$$\phi = 21° \text{ nearly} .$$

If this value is revised for the vane thickness it will ordinarily become about 25°.

Velocity with which the Water enters the Wheel.—The head producing the velocity is

$$H - \frac{V_i^2}{2g}\left(1 + \frac{u_0^2}{V_i^2}\right) + \frac{u_i^2}{2g}$$

$$= H\left\{1 - {\cdot}4356(1 + 0{\cdot}0358) + {\cdot}0156\right\}$$

$$= 0{\cdot}5646H.$$

Then the velocity is

$$= {\cdot}96\sqrt{2g({\cdot}5646H)} = 0{\cdot}721\sqrt{2gH}.$$

Angle of Guide-Blades.

$$\text{Sin } \gamma = \frac{u_i}{v_i} = \frac{{\cdot}125}{{\cdot}721} = 0{\cdot}173 ;$$

$$\gamma = 10° \text{ nearly}.$$

Tangential Velocity of Water entering Wheel.

$$w_i = v_i \cos \gamma = 0{\cdot}7101\sqrt{2gH}.$$

Angle of Vanes at Inlet Surface.

$$\text{Cot } \theta = \frac{w_i - V_i}{u_i} = \frac{{\cdot}7101 - {\cdot}66}{{\cdot}125} = {\cdot}4008 ;$$

$$\theta = 68° \text{ nearly}.$$

Hydraulic Efficiency of Wheel.

$$\eta = \frac{w_i V_i}{gH} = {\cdot}7101 \times {\cdot}66 \times 2$$

$$= 0{\cdot}9373.$$

This, however, neglects the friction of wheel covers and leakage. The efficiency from experiment has been found to be 0·75 to 0·80.

Impulse and Partial Admission Turbines.

182. The principal defect of most turbines with complete admission is the imperfection of the arrangements for working with less than the normal supply. With most forms of turbine the efficiency is considerably reduced when the regulating sluices are partially closed, but it is exactly when the supply of water is deficient that it is most important to get out of it the greatest possible amount of work. The imperfection of the regulating arrangements is, therefore, from the practical point of view, a serious defect. All turbine makers have sought by various methods to improve the regulating mechanism. Fourneyron, by dividing his wheel by horizontal diaphragms, virtually obtained three or more separate radial flow turbines, which could be successively set in action at their full power, but the arrangement is not altogether successful, because of the spreading of the water in the space between the wheel and guide-blades. M. Fontaine similarly employed two concentric axial flow turbines formed in the same casing. One was worked at full power, the other regulated. By this arrangement the loss of efficiency due to the action of the regulating sluice affected only half the water power. Many makers have adopted the expedient of erecting two or three separate turbines on the same waterfall. Then one or more could be put out of action and the others worked at full power. This is an excellent plan, but the separate turbines cost more than a single one. All these methods are rather palliatives than remedies. The movable guide-blades of Professor James Thomson meet the difficulty directly, but of course they are not applicable to every form of turbine.

A subsidiary defect of turbines with complete admission is their very great speed of rotation on high falls. The turbine wheel cannot be increased in diameter without great increase of the fluid friction in the passages and on the surface of the wheel, and it also becomes impossible in radial flow turbines to adjust properly the vane angles, if the diameter is made very large.

M. Callon, in 1840, patented an arrangement of sluices for axial or outward flow turbines, which were to be closed successively as the water supply diminished. By preference the sluices were closed by pairs, two diametrically opposite sluices forming a pair. The water was thus admitted to opposite but equal arcs of the wheel, and the forces driving the turbine were symmetrically placed. As soon as this arrangement was adopted, a modification of the mode of action of the water in the turbine became necessary. If the turbine wheel passages remain full of water during the whole rotation, the water contained in each passage must be put into motion each time it passes an open portion of the sluice, and stopped each time it passes a closed portion of the sluice. It is thus put into motion and stopped twice in each rotation. This gives rise to violent eddying motions and great loss of energy in shock. To prevent this, the turbine wheel with partial admission must be placed above the tail water, and the wheel passages be allowed to clear themselves of water, while passing from one open portion of the sluices to the next.

But if the wheel passages are free of water when they arrive at the open sluices, then there can be no pressure other than atmospheric pressure in the space between the sluices and wheel. The water must issue from the sluices with the whole velocity due to the head; received on the curved vanes of the wheel, the jets must be gradually deviated and discharged with a radial velocity only, precisely in the same way as when a single jet strikes a curved vane in the free air. Turbines of this kind are therefore termed turbines of free deviation. There is no variation of pressure in the jet during the whole time of its action on the wheel, and the whole energy of the jet is imparted to the wheel, simply by the impulse due to its gradual change of momentum. It is clear that the water may be admitted in exactly the same way to any fraction of the circumference at pleasure, without altering the efficiency of the wheel. The diameter of the wheel may be made as large as convenient, and thus the speed of rotation on high falls may be kept down to a manageable amount. The Poncelet water wheel is a turbine of free deviation, in which, however, the action of gravity causes the water to flow back along the vanes, so that it is discharged at the same point of the wheel at which it enters.

So long as the tail-water level is invariable, no difficulty arises in adopting the system of partial admission. But if, as is more commonly the case, the tail-water level varies, then there is danger that the turbine will be drowned in flood time, and the essential condition of the system that the wheel passages should be empty when they come in front of the open sluices will not be satisfied. If the fall is considerable, a portion of it may be sacrificed without much harm, and the wheel placed sufficiently high above the tail water to secure it from being drowned; but with low falls this is impossible. The difficulty has been overcome by a method invented by M. L. D. Girard in 1849, and termed the hydropneumatic system. The turbine is

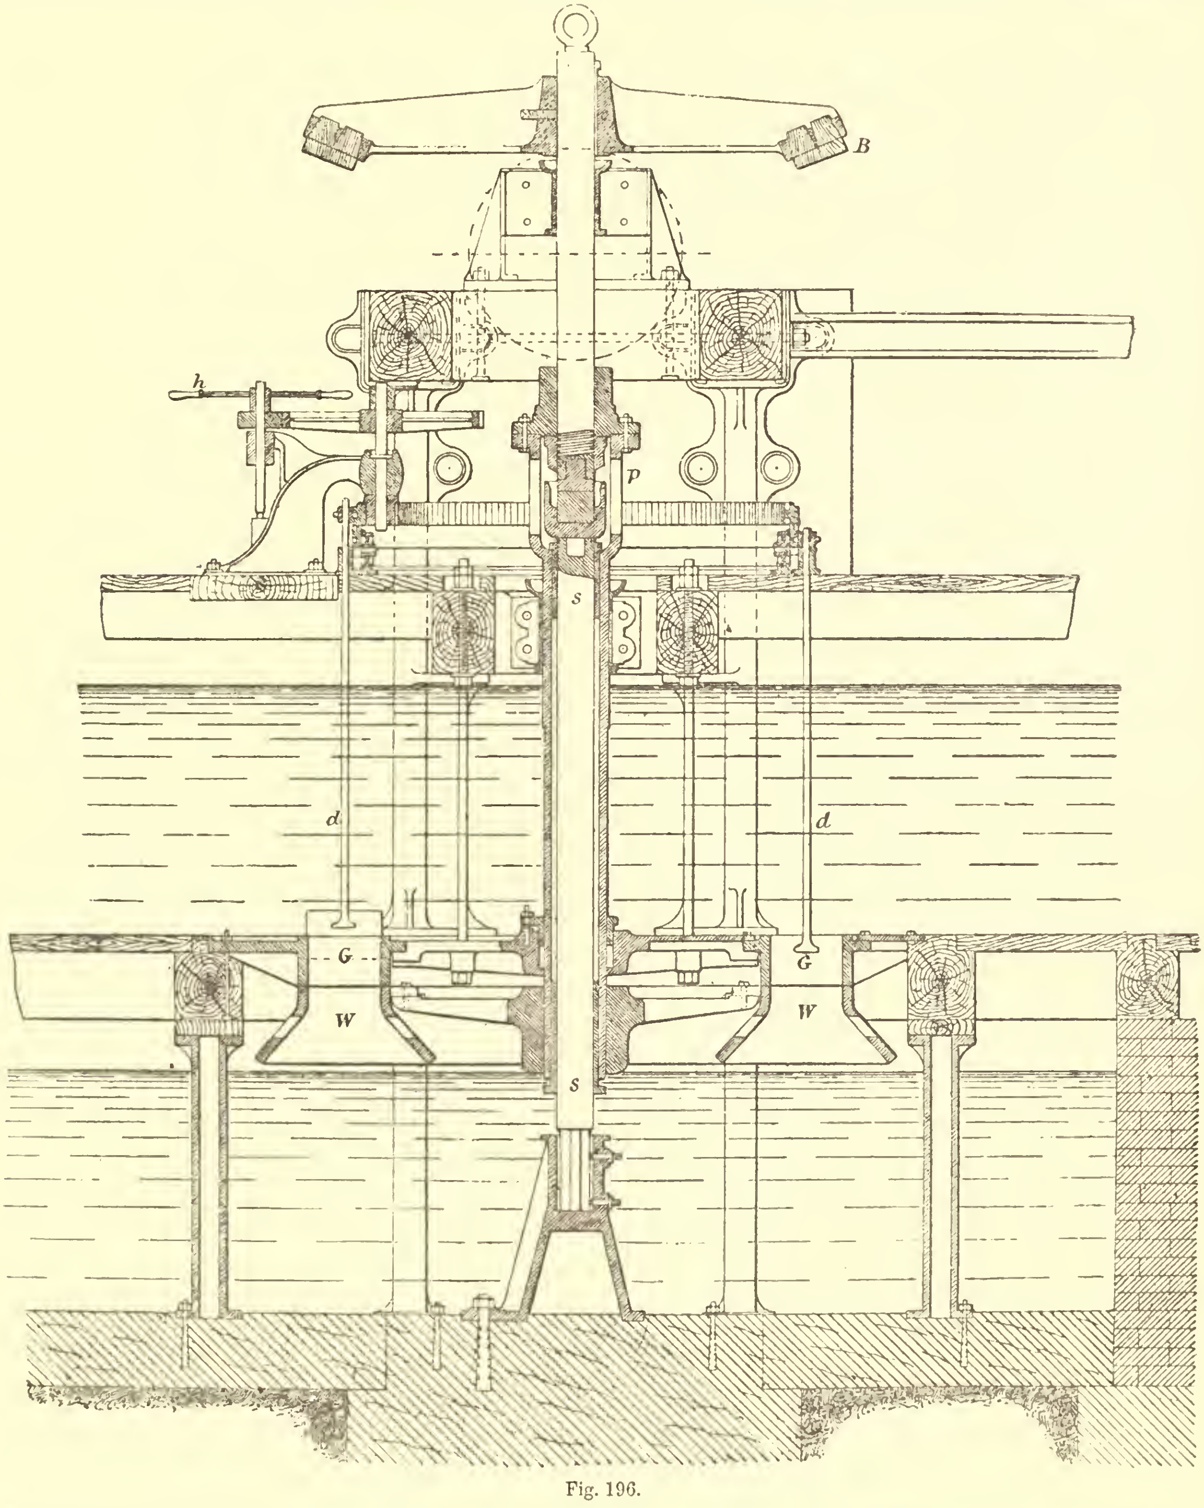

Fig. 196.

placed below the tail-water level in a casing supplied with air by a small air-pump. It therefore always discharges freely into an atmosphere of air, the pressure of which, however, varies with the height of the tail-water level outside the casing. Inside the casing the free water surface is maintained at an invariable level just below the discharge orifices of the wheel.

183. *General Description of an Impulse Turbine or Turbine with Free Deviation.*—Fig. 196 shows a general sectional elevation of a Girard turbine, in which the flow is axial. The water, admitted

above a horizontal floor, passes down through the annular wheel containing the guide-blades G, G, and thence into the revolving wheel WW. The revolving wheel is fixed to a hollow shaft suspended from the pivot p. The solid internal shaft ss is merely a fixed column supporting the pivot. The advantage of this is that the pivot is accessible for lubrication and adjustment. B is the mortise bevel wheel by which the power of the turbine is given off. The sluices are worked by the hand wheel h, which raises them successively, in a way to be described presently. a, a are the sluice rods. Figs. 197, 198 show the sectional form of the guide-blade chamber and wheel and the curves of the wheel vanes and guide-blades, when drawn on a plane development of the cylindrical section of the wheel; a, a, a are the sluices for cutting off the water; b, b, b are apertures by which the entrance or exit of air is facilitated as the buckets empty and fill. Figs. 199, 200 show the guide-blade gear. a, a, a are the sluice rods as before. At the top of each sluice rod is a small block c, having a projecting tongue, which slides in the groove of the circular cam plate d, d. This circular plate is supported on the frame e, and

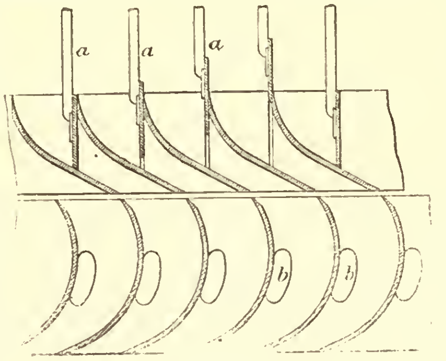

Fig. 197.

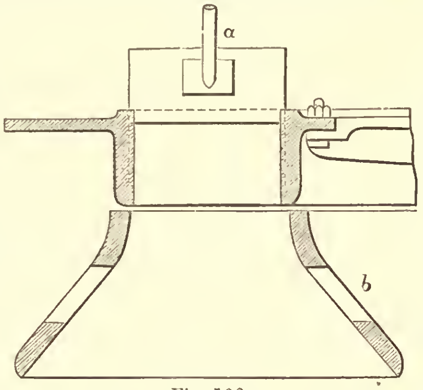

Fig. 198.

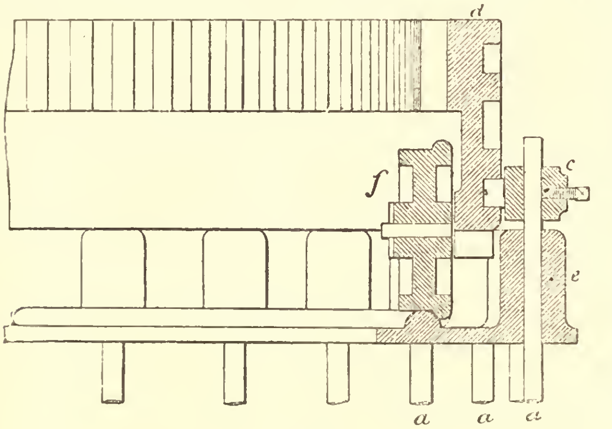

Fig. 199.

revolves on it by means of the flanged rollers f. Inside, at the top, the cam plate is toothed, and gears into a spur pinion connected with the hand wheel h. At gg is an inclined groove or shunt.

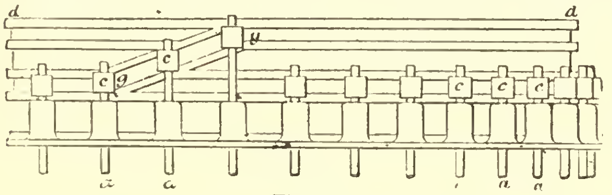

Fig. 200.

When the tongues of the blocks c, c arrive at g, they slide up to a second groove, or the reverse, according as the cam plate is revolved in one direction or in the other. As this operation takes place with each sluice successively, any number of sluices can be opened or closed as desired. The turbine is of 48 horse power on 5·12 feet fall, and the supply of water varies from 35 to 112 cubic feet per second. The efficiency in normal working is given as 73 per cent. The mean diameter of the wheel is 6 feet, and the speed 27·4 revolutions per minute.[1]

184. *Theory of the Impulse Turbine.*—The theory of the impulse turbine does not essentially differ from that of the reaction turbine, except that there is no pressure in the wheel opposing the discharge from the guide-blades. Hence the velocity with which the water enters the wheel is simply

$$v_i = 0{\cdot}96\sqrt{2g(\mathrm{H}-\mathfrak{h})},$$

where $\mathfrak{h}$ is the height of the top of the wheel above the tail water. If the hydropneumatic system is used, then $\mathfrak{h}=0$. Let Q_m be the maximum supply of water, r_1, r_2 the internal and external radii of the wheel at the inlet surface; then

$$u_i = \frac{\mathrm{Q}_m}{\pi(r_2^{\,2} - r_1^{\,2})}.$$

The value of u_i may be about $0{\cdot}45\sqrt{2g(\mathrm{H}-\mathfrak{h})}$, whence r_1, r_2 can be determined.

The guide-blade angle is then given by the equation

$$\sin\gamma = \frac{u_i}{v_i} = \frac{0{\cdot}45}{0{\cdot}94} = {\cdot}48\ ;$$
$$\gamma = 29^\circ.$$

The value of u_i should, however, be corrected for the space occupied by the guide-blades.

The tangential velocity of the entering water is

$$w_i = v_i\cos\gamma = 0{\cdot}82\sqrt{2g(\mathrm{H}-\mathfrak{h})}.$$

The circumferential velocity of the wheel may be (at mean radius)

$$\mathrm{V}_i = 0{\cdot}5\sqrt{2g(\mathrm{H}-\mathfrak{h})}.$$

Hence the vane angle at inlet surface is given by the equation

$$\cot\theta = \frac{w_i - \mathrm{V}_i}{u_i} = \frac{0{\cdot}82 - 0{\cdot}5}{0{\cdot}45} = {\cdot}71\ ;$$
$$\theta = 55^\circ.$$

The relative velocity of the water striking the vane at the inlet edge is $v_{ri} = u_i \operatorname{cosec}\theta = 1{\cdot}22u_i$. This relative velocity remains unchanged during the passage of the water over the vane; consequently the relative velocity at the point of discharge is $v_{ro} = 1{\cdot}22u_i$. Also in an axial flow turbine $\mathrm{V}_0 = \mathrm{V}_i$.

If the final velocity of the water is axial, then

$$\cos\phi = \frac{\mathrm{V}_0}{\mathrm{V}_{ro}} = \frac{\mathrm{V}_i}{\mathrm{V}_{ri}} = \frac{0{\cdot}5}{1{\cdot}22\times 0{\cdot}45} = \cos 24^\circ\ 23'.$$

This should be corrected for the vane thickness. Neglecting this, $u_0 = v_{ro}\sin\phi = v_{ri}\sin\phi = u_i\operatorname{cosec}\theta\sin\phi = 0{\cdot}5u_i$. The discharging area of the wheel must therefore be greater than the inlet area in the ratio of at least 2 to 1. In some actual turbines the ratio is 7 to 3. This greater outlet area is obtained by splaying the wheel, as shown in the section (fig. 198).

185. *The Hydraulic Ram.*—The hydraulic ram is an arrangement by which a quantity of water falling a distance h forces a portion of the water to rise to a height h_1, greater than h. It consists of a supply reservoir (A, fig. 201), into which the water enters from some natural stream. A pipe s of considerable length conducts the water to a lower level, where it is discharged intermittently through a self-acting pulsating valve at d. The supply pipe s may be fitted with a flap-valve for stopping the ram, and this is attached in some cases to a float, so that the ram starts and stops itself automatically, according as the supply cistern fills or empties. The pipe s should be as long and as straight as possible, and as it is subjected to considerable pressure from the sudden arrest of the motion of the water, it must be strong and strongly jointed. d is an air vessel, and e the delivery pipe leading to the reservoir at a higher level than A, into which water is to be pumped. Fig. 202 shows in section the construction of the ram itself. d is the pulsating discharge valve already mentioned, which opens inwards and downwards. The stroke of the valve is regulated by the cotter through the spindle, under which are washers by

[1] The drawings of this turbine have been taken partly from Meissner, *Die Hydraulik*, partly from Uhland, *Skizzenbuch*.

which the amount of fall can be regulated. At o is a delivery valve, opening outwards, which is often a ball-valve but sometimes a flap-valve. The water which is pumped passes through this valve into the air vessel a, from which it flows by the delivery pipe in a regular stream into the cistern to which the water is to be raised. In the vertical chamber behind the outer valve a small air vessel is formed,

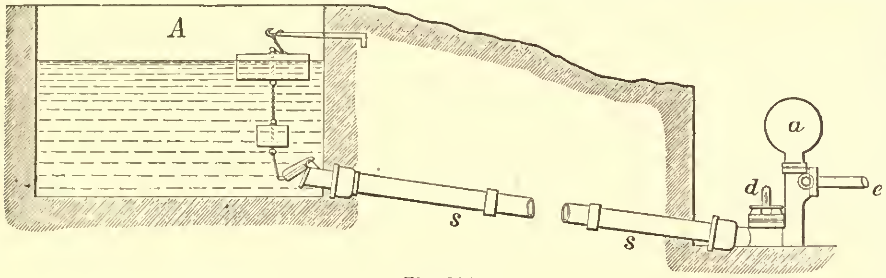

Fig. 201.

and into this opens an aperture $\frac{1}{4}$ inch in diameter, made in a brass screw plug b. The hole is reduced to $\frac{1}{16}$ inch in diameter at the outer end of the plug and is closed by a small valve opening inwards. Through this, during the rebound after each stroke of the ram, a small quantity of air is sucked in which keeps the air vessel supplied with its elastic cushion of air.

The discharge valve d is of greater weight than the statical pressure of the water on its under side. When, therefore, the water is at rest in the supply pipe this valve opens. In consequence of the flow through this valve, the water in the supply pipe acquires a gradually increasing velocity. The upward flow o the water, towards the valve d, increases the pressure tending to lift the valve, and at last, if the valve is not too heavy, lifts and closes it. The forward momentum of the column in the supply pipe being destroyed by the stoppage of the flow, the water exerts a pressure at the end of the pipe sufficient to open the delivery valve o, and to cause a portion of the water to flow into the air vessel. As the water in the supply pipe comes to rest, the valve d opens again and the operation is repeated. Part of the energy of the descending column is employed in compressing the air at the end of the supply pipe and expanding the pipe itself. This causes a recoil of the water which momentarily diminishes the pressure in the pipe below the pressure due to the statical head. This assists in opening the valve d. Mr W. Anderson states that the recoil of the water is sufficiently great to enable a pump to be attached to the ram body instead of the direct rising pipe. With this arrangement a ram working with muddy water may be employed to raise clear spring water. Instead of lifting the delivery valve as in the ordinary ram, the momentum of the column drives a sliding or elastic piston, and the recoil brings it back. This piston lifts and forces alternately the clear water through ordinary pump valves.

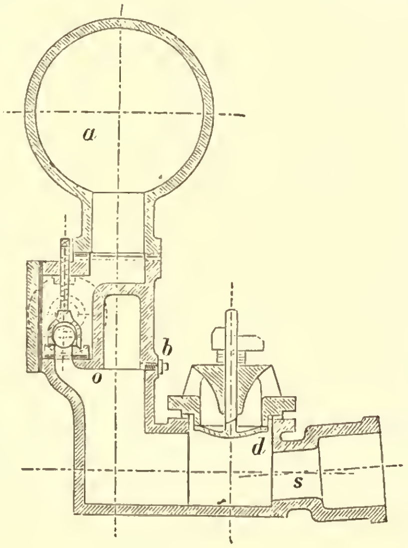

Fig. 202.

Pumps.

186. The different classes of pumps correspond almost exactly to the different classes of water motors, although the mechanical details of the construction are somewhat different. They are properly reversed water motors. Ordinary reciprocating pumps correspond to water-pressure engines. Chain and bucket pumps are in principle similar to water wheels in which the water acts by weight. Scoop wheels are similar to undershot water wheels, and centrifugal pumps to turbines.

Reciprocating Pumps are single or double acting, and differ from water-pressure engines in that the valves are moved by the water instead of by automatic machinery. They may be classed thus :—

(1.) *Lift Pumps.*—The water drawn through a foot valve on the ascent of the pump bucket is forced through the bucket valve when it descends, and lifted by the bucket when it reascends. Such pumps give an intermittent discharge.

(2.) *Plunger* or *Force Pumps*, in which the water drawn through the foot valve is displaced by the descent of a solid plunger, and forced through a delivery valve. They have the advantage that the friction is less than that of lift pumps, and the packing round the plunger is easily accessible, whilst that round a lift pump bucket is not. The flow is intermittent.

(3.) *The Double-acting Force Pump* is in principle a double plunger pump. The discharge fluctuates from zero to a maximum and back to zero each stroke, but is not arrested for any appreciable time.

(4.) *Bucket and Plunger Pumps* consist of a lift pump bucket combined with a plunger of half its area. The flow varies as in a double-acting pump.

(5.) *Diaphragm Pumps* have been used, in which the solid plunger is replaced by an elastic diaphragm, alternately depressed into and raised out of a cylinder.

The variation of velocity of discharge would cause great waste of work in the delivery pipes when they are long, and even danger from the hydraulic ramming action of the long column of water. An air vessel is interposed between the pump and the delivery pipes, of a volume from 5 to 100 times the space described by the plunger per stroke. The air in this must be replenished from time to time, or continuously, by a special air-pump. At low speeds not exceeding 30 feet per minute the delivery of a pump is about 90 to 95 per cent. of the volume described by the plunger or bucket, from 5 to 10 per cent. of the discharge being lost by leakage. At high speeds the quantity pumped occasionally exceeds the volume described by the plunger, the momentum of the water keeping the valves open after the turn of the stroke.

The velocity of large mining pumps is about 140 feet per minute, the indoor or suction stroke being sometimes made at 250 feet per minute. Rotative pumping engines of large size have a plunger speed of 90 feet per minute. Small rotative pumps are run faster, but at some loss of efficiency. Fire-engine pumps have a speed of 180 to 220 feet per minute.

The efficiency of reciprocating pumps varies very greatly. Small reciprocating pumps, with metal valves on lifts of 15 feet, were found by Morin to have an efficiency of 16 to 40 per cent., or on the average 25 per cent. When used to pump water at considerable pressure, through hose pipes, the efficiency rose to from 28 to 57 per cent., or on the average, with 50 to 100 feet of lift, about 50 per cent. A large pump with barrels 18 inches diameter, at speeds under 60 feet per minute, gave the following results :—

Lift in feet	$14\frac{1}{2}$	34	47
Efficiency	·46	·66	·70

The very large steam-pumps employed for waterworks, with 150 feet or more of lift, appear to reach an efficiency of 90 per cent., not including the friction of the discharge pipes.

The Centrifugal Pump.

187. The efficiency of reciprocating pumps diminishes with the lift. When large quantities of water are to be raised on a low lift, no pump is so suitable as a centrifugal pump. The first pump of this kind which attracted notice was one exhibited by Mr Appold in 1851, and the special features of his pump have been retained in the best pumps since constructed. Mr Appold's pump raised continuously a volume of water equal to 1400 times its own capacity per minute. It had no valves, and it permitted the passage of solid bodies, such as walnuts and oranges, without obstruction to its working. Its efficiency was also found to be good.

Fig. 203 shows a centrifugal pump differing from ordinary centrifugal pumps in one feature only. The water rises through a suction pipe S, which divides so as to enter the pump wheel at the centre on each side. The pump disk or wheel is very similar to a turbine wheel. It is keyed on a shaft driven by a belt on a fast and loose pulley arrangement at P. The water rotating in the pump disk presses outwards, and if the speed is sufficient a continuous flow is maintained through the pump and into the discharge pipe D. The special feature in this pump is that the water, discharged by the pump disk with a whirling velocity of not inconsiderable magnitude, is allowed to continue

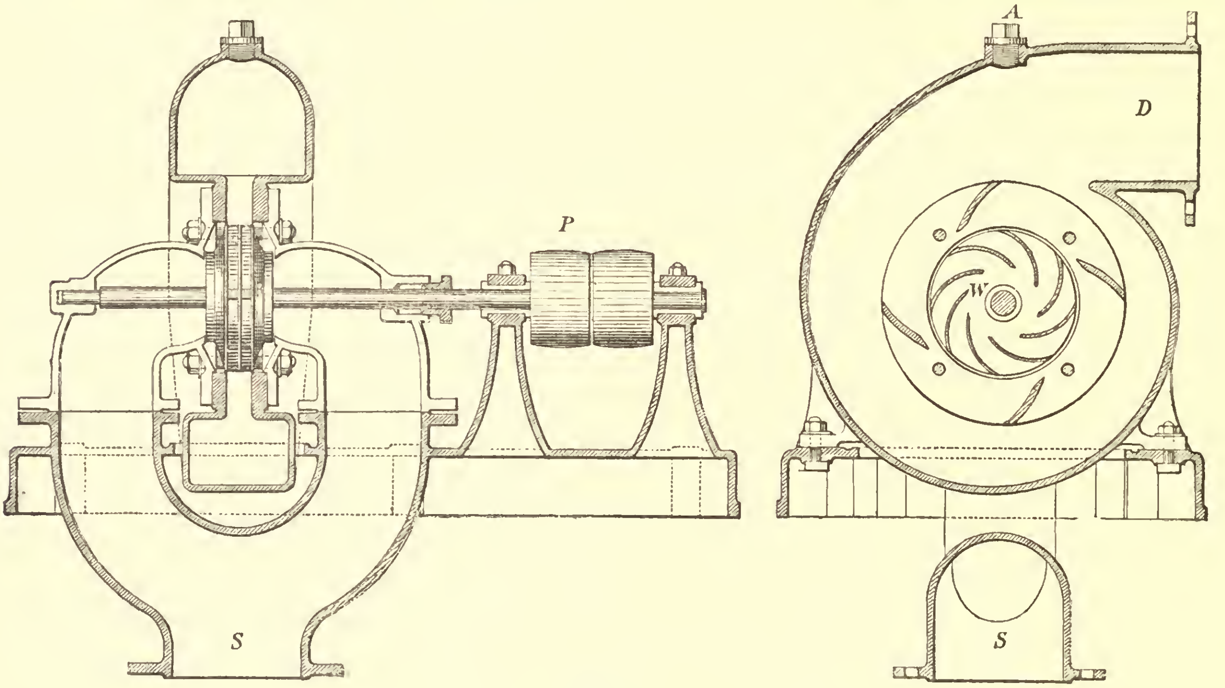

Fig. 203.

rotation in a chamber somewhat larger than the pump. The use of this whirlpool chamber was first suggested by Professor James Thomson. It utilizes the energy due to the whirling velocity of the water which in most pumps is wasted in eddies in the discharge pipe. In the pump shown guide-blades are also added which have the direction of the stream lines in a free vortex. They do not therefore interfere with the action of the water when pumping the normal quantity, but only prevent irregular motion. At A is a plug by which the pump case is filled before starting. If the pump is above the water to be pumped, a foot valve is required to permit the pump to be filled. Sometimes instead of the foot valve a delivery valve is used, an air-pump or steam jet pump being employed to exhaust the air from the pump case.

188. *Design and Proportions of a Centrifugal Pump.*—The design of the pump disk is very simple. Let r_i, r_0 be the radii of the inlet and outlet surfaces of the pump disk, d_i, d_0 the clear axial width at those radii. The velocity of flow through the pump may be taken the same as for a turbine. If Q is the quantity pumped, and H the lift,

$$u_i = 0{\cdot}25\sqrt{2g\mathrm{H}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

$$2\pi r_i d_i = \frac{\mathrm{Q}}{u_i}.$$

Also in practice

$$d_i = 1{\cdot}2 r_i \quad . \quad . \quad .$$

Hence,

$$r_i = {\cdot}2571 \sqrt{\frac{\mathrm{Q}}{\sqrt{\mathrm{H}}}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Usually $r_0 = 2r_i$,

and $d_0 = d_i$ or $\frac{1}{2} d_i$

according as the disk is parallel-sided or coned. The water enters the wheel radially with the velocity u_i, and

$$u_0 = \frac{\mathrm{Q}}{2\pi r_0 d_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Fig. 204 shows the notation adopted for the velocities. Suppose the water enters the wheel with the velocity v_i, while the velocity of the wheel is V_i. Completing the parallelogram, v_{ri} is the relative velocity of the water and wheel, and is the proper direction of the wheel vanes. Also, by resolving, u_i and w_i are the component velocities of flow and velocities of whir of the velocity v_i of the water. At the outlet surface, v_0 is the final velocity of discharge, and the rest of the notation is similar to that for the inlet surface.

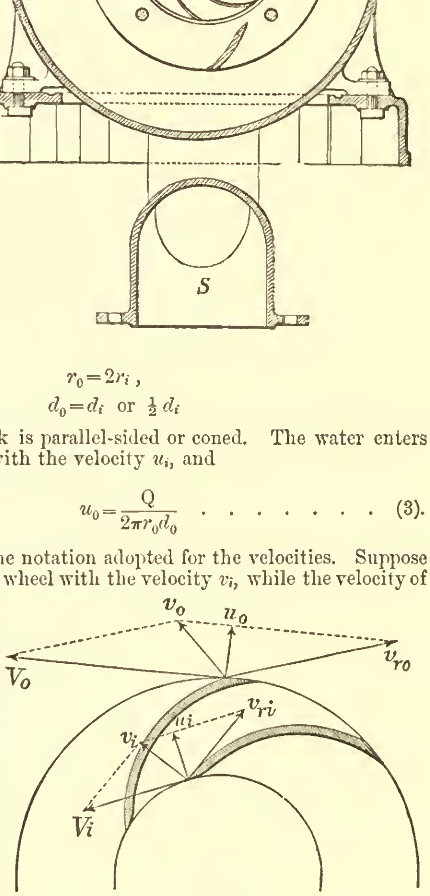

Fig. 204.

Usually the water flows equally in all directions in the eye of the wheel, in that case v_i is radial. Then, in normal conditions of working, at the inlet surface,

$$\left.\begin{array}{l} v_i = u_i \\ w_i = 0 \\ \tan\theta = \dfrac{u_i}{V_i} \\ v_{ri} = u_i \operatorname{cosec}\theta = \sqrt{u_i^2 + V_i^2} \end{array}\right\} \quad . \quad . \quad . \quad . \quad (4).$$

If the pump is raising less or more than its proper quantity, θ will not satisfy the last condition, and there is then some loss of head in shock.

At the outer circumference of the wheel or outlet surface,

$$\left.\begin{array}{l} v_{r0} = u_0 \operatorname{cosec}\phi \\ w_0 = V_0 - u_0 \cot\phi \\ v_0 = \sqrt{\{u_0^2 + (V_0 - u_0 \cot\phi)^2\}} \end{array}\right\} \quad . \quad . \quad . \quad (5).$$

Variation of Pressure in the Pump Disk.—Precisely as in the case of turbines, it can be shown that the variation of pressure between the inlet and outlet surfaces of the pump is

$$h_0 - h_i = \frac{V_0^2 - V_i^2}{2g} - \frac{v_{r0}^2 - v_{ri}^2}{2g}.$$

Inserting the values of v_{r0}, v_{ri} in (4) and (5), we get for normal conditions of working

$$h_0 - h_i = \frac{V_0^2 - V_i^2}{2g} - \frac{u_0^2 \operatorname{cosec}^2\phi}{2g} + \frac{u_i^2 + V_i^2}{2g}$$

$$= \frac{V_0^2}{2g} - \frac{u_0^2 \operatorname{cosec}^2\phi}{2g} + \frac{u_i^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Hydraulic Efficiency of the Pump.—Neglecting disk friction, journal friction, and leakage, the efficiency of the pump can be found in the same way as that of turbines (§ 172). Let M be the moment of the couple rotating the pump, and α its angular velocity; w_0, r_0 the tangential velocity of the water and radius at the outlet surface; w_i, r_i the same quantities at the inlet surface. Q being the discharge per second, the change of angular momentum per second is

$$\frac{GQ}{g}(w_0 r_0 - w_i r_i).$$

Hence
$$M = \frac{GQ}{g}(w_0 r_0 - w_i r_i).$$

In normal working, $w_i = 0$. Also, multiplying by the angular velocity, the work done per second is

$$M\alpha = \frac{GQ}{g} w_0 r_0 \alpha.$$

But the useful work done in pumping is GQH. Therefore the efficiency is

$$\eta = \frac{GQH}{M\alpha} = \frac{gH}{w_0 r_0 \alpha} = \frac{gH}{w_0 V_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

189. Case 1. *Centrifugal Pump with no Whirlpool Chamber.*—When no special provision is made to utilize the energy of motion of the water leaving the wheel, and the pump discharges directly into a chamber in which the water is flowing to the discharge pipe, nearly the whole of the energy of the water leaving the disk is wasted. The water leaves the disk with the more or less considerable velocity v_0, and impinges on a mass flowing to the discharge pipe at the much slower velocity v_s. The radial component of v_0 is almost necessarily wasted. From the tangential component there is a gain of pressure

$$\frac{w_0^2 - v_s^2}{2g} - \frac{(w_0 - v_s)^2}{2g}$$

$$= \frac{v_s(w_0 - v_s)}{g},$$

which will be small, if v_s is small compared with w_0. Its greatest value, if $v_s = \frac{1}{2}w_0$, is $\frac{1}{2}\frac{w_0^2}{2g}$, which will always be a small part of the whole head. Suppose this neglected. The whole variation of pressure in the pump disk then balances the lift and the head $\frac{u_i^2}{2g}$ necessary to give the initial velocity of flow in the eye of the wheel.

$$\frac{u_i^2}{2g} + H = \frac{V_0^2}{2g} - \frac{u_0^2 \operatorname{cosec}^2\phi}{2g} + \frac{u_i^2}{2g},$$

$$\left.\begin{array}{l} H = \dfrac{V_0^2}{2g} - \dfrac{u_0^2 \operatorname{cosec}^2\phi}{2g} \\ \text{or} \quad V_0 = \sqrt{(2gH + u_0^2 \operatorname{cosec}^2\phi)} \end{array}\right\} \quad . \quad . \quad . \quad . \quad (8);$$

and the efficiency of the pump is, from (7),

$$\eta = \frac{gH}{V_0 w_0} = \frac{gH}{V_0(V_0 - u_0 \cot\phi)}$$

$$= \frac{V_0^2 - u_0^2 \operatorname{cosec}^2\phi}{2V_0(V_0 - u_0 \cot\phi)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

For $\phi = 90°$,
$$\eta = \frac{V_0^2 - u_0^2}{2V_0^2},$$

which is necessarily less than $\frac{1}{2}$. That is, half the work expended in driving the pump is wasted. By recurving the vanes, a plan introduced by Mr Appold, the efficiency is increased, because the velocity v_0 of discharge from the pump is diminished. If ϕ is very small,

$$\operatorname{cosec}\phi = \cot\phi;$$

and then
$$\eta = \frac{V_0^2 + u_0 \operatorname{cosec}\phi}{2V_0},$$

which may approach the value 1, as ϕ tends towards 0. Equation (8) shows that $u_0 \operatorname{cosec}\phi$ cannot be greater then V_0. Putting

$$u_0 = 0{\cdot}25\sqrt{2gH}$$

we get the following numerical values of the efficiency and the circumferential velocity of the pump:—

ϕ	η	V_0
90°	0·47	$1{\cdot}03\sqrt{2gH}$
45°	0·56	1·06 ,,
30°	0·65	1·12 ,,
20°	0·73	1·24 ,,
10°	0·84	1·75 ,,

ϕ cannot practically be made less than 20°; and, allowing for the frictional losses neglected, the efficiency of a pump in which $\phi = 20°$ is found to be about ·60.

190. Case 2. *Pump with a Whirlpool Chamber*, as in fig. 203.—Professor James Thomson first suggested that the energy of the water after leaving the pump disk might be utilized, if a space were left in which a free vortex could be formed. In such a free vortex the velocity varies inversely as the radius. The gain of pressure in the vortex chamber is, putting r_0, r_w for the radii to the outlet surface of wheel and to outside of free vortex,

$$\frac{v_0^2}{2g}\left(1 - \frac{r_0^2}{r_w^2}\right) = \frac{v_0^2}{2g}\left(1 - k^2\right),$$

if
$$k = \frac{r_0}{r_w}.$$

The lift is then, adding this to the lift in the last case,

$$H = \frac{1}{2g}\left\{V_0^2 - u_0^2 \operatorname{cosec}^2\phi + v_0^2(1 - k^2)\right\}.$$

But
$$v_0^2 = V_0^2 - 2V_0 u_0 \cot\phi + u_0^2 \operatorname{cosec}^2\phi;$$

$$\therefore \quad H = \frac{1}{2g}\left\{(2 - k^2)V_0^2 - 2kV_0 u_0 \cot\phi - k^2 u_0^2 \operatorname{cosec}^2\phi\right\} \quad (10).$$

Putting this in the expression for the efficiency, we find a considerable increase of efficiency. Thus with

$\phi = 90°$ and $k = \frac{1}{2}$, $\eta = \frac{7}{8}$ nearly;
ϕ a small angle and $k = \frac{1}{2}$, $\eta = 1$ nearly.

With this arrangement of pump, therefore, the angle at the outer ends of the vanes is of comparatively little importance. A moderate angle of 30° or 40° may very well be adopted. The following numerical values of the velocity of the circumference of the pump have been obtained by taking $k = \frac{1}{2}$, and $u_0 = 0{\cdot}25\sqrt{2gH}$.

ϕ	v_0
90°	$\cdot762\sqrt{2gH}$
45°	·842 ,,
30°	·911 ,,
20°	1·023 ,,

The quantity of water to be pumped by a centrifugal pump necessarily varies, and an adjustment for different quantities of water cannot easily be introduced. Hence it is that the average efficiency of pumps of this kind is in practice less than the efficiencies given above. The advantage of a vortex chamber is also generally neglected. The velocity in the supply and discharge pipes is also often made greater than is consistent with a high degree of efficiency. Velocities of 6 or 7 feet per second in the discharge and suction pipes, when the lift is small, cause a very sensible waste of energy; 3 to 6 feet would be much better. Centrifugal pumps of very large size have been constructed. Messrs Easton and Anderson have made pumps for the North Sea Canal in Holland which deliver each 670 tons of water per minute on a lift of 5 feet. The pump disks are 8 feet diameter. Messrs J. and H. Gwynne constructed some pumps for draining the Ferrarese Marshes, which together deliver 2000 tons per minute. A pump made under Professor J. Thomson's direction for drainage works in Barbados had a pump disk 16 feet in diameter and a whirlpool chamber 32 feet in diameter. The efficiency of centrifugal pumps when delivering less or more than the normal quantity of water is discussed in a paper in the *Proc. Inst. of Civil Engineers*, vol. liii. (W. C. U.)

HYDROMETER. The object of the hydrometer is the determination of the density of bodies, generally of fluids, but some forms of the instrument are adapted to the determination of the density of solids.

It is shown in the article HYDROMECHANICS that, when a body floats in a fluid under the action of gravity, the weight of the body is equal to that of the fluid which it displaces. It is upon this principle that the hydrometer is constructed, and it obviously admits of two modes of application in the case of fluids: either we may compare the weights of floating bodies which are capable of displacing the same volume of different fluids, or we may compare the volumes of the different fluids which are displaced by the same weight. In the latter case, the densities of the fluids will be inversely proportional to the volumes thus displaced.

Perhaps the simplest method of experimentally determining the densities of different liquids is afforded by the series of areometrical glass beads, or hollow balls, first proposed by Dr Wilson, professor of astronomy in the university of Glasgow. As subsequently improved by Mrs Lovi, these beads were constructed in sets, each bead in the set differing in density from its predecessor by ·002 (of the density of water). Each bead is numbered according to its density, and in order to determine the specific gravity of a liquid it is only necessary to throw into it the set of beads, or so many of them as are known to include between their extremes the density of the liquid, when all the beads whose densities exceed that of the liquid will sink, while those whose densities are less than that of the liquid will float. If there is a bead of exactly the same density as the liquid, it will rest in any position, provided it is completely immersed. Failing this, all that is immediately apparent is that the density is intermediate between that of the lightest bead that sinks and that of the heaviest that floats. For example, if all the beads numbered 1·466 and upwards sink, while those below 1·466 float, it is obvious that the density of the liquid is intermediate between 1·464 and 1·466. In the case of most fluids the intervals may be divided approximately by slightly warming the liquid. Thus, if on heating the liquid 6° C. it is found that the bead 1·466 begins to sink, and on heating it still farther through 12° C. (*i.e.*, through 18° C. altogether) the bead 1·468 begins to sink, then the density of the liquid is approximately 1·465.

The hydrometer is said by Synesius Cyreneus in his fifth letter to have been invented by Hypatia at Alexandria,[1] but appears to have been neglected until it was reinvented by Robert Boyle, whose "New Essay Instrument," as described in the *Phil. Trans.* for June 1675, differs in no essential particular from Nicholson's hydrometer. This instrument was devised for the purpose of detecting counterfeit coin, especially guineas and half-guineas. In the first section of the paper (*Phil. Trans.*, No. 115, p. 329) the author refers to a glass instrument exhibited by himself many years before, and "consisting of a bubble furnished with a long and slender stem, which was to be put into several liquors, to compare and estimate their specific gravities." This seems to be the first reference to the hydrometer in modern times.

In fig. 1 C represents the instrument used for guineas, the circular plates A representing plates of lead, which are used as ballast when lighter coins than guineas are examined. B represents "a small glass instrument for estimating the specific gravities of liquors," an account of which was promised by Boyle in the following number of the *Phil. Trans.*, but did not appear.

[1] In *Nicholson's Journal*, vol. iii. p. 89, Citizen Eusebe Salverte calls attention to the poem "De Ponderibus et Mensuris" generally ascribed to Rhemnius Fannius Palæmon, and consequently 300 years older than Hypatia, in which the hydrometer is described, and attributed to Archimedes.

The instrument represented at B (fig. 1), which is copied from Robert Boyle's sketch in the *Phil. Trans.* for 1675, is generally known as the common hydrometer. It is usually made of glass, the lower bulb being loaded with mercury or small shot which serves as ballast, causing the instrument to float with the stem vertical. The quantity of mercury or shot inserted depends upon the density of the liquids for which the hydrometer is to be employed, it being essential that the whole of the bulb should be immersed in the heaviest liquid for which the instrument is used, while the length and diameter of the stem must be such that the hydrometer will float in the lightest liquid for which it is required. The stem is usually divided into a number of equal parts, the divisions of the scale being varied in different instruments, according to the purposes for which they are employed.

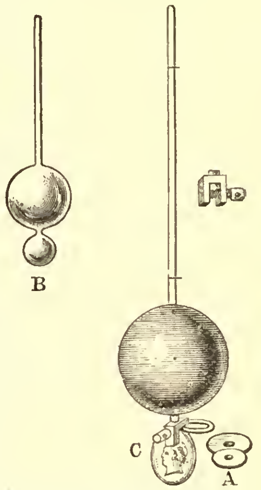

FIG. 1.—Boyle's New Essay Instrument.

Let V denote the volume of the instrument immersed (*i.e.*, of liquid displaced) when the surface of the liquid in which the hydrometer floats coincides with the lowest division of the scale, A the area of the transverse section of the stem, l the length of a scale division, n the number of divisions on the stem, and W the weight of the instrument. Suppose the successive divisions of the scale to be numbered 0, 1, 2 . . . . n starting with the lowest, and let w_0, w_1, w_2 . . . w_n be the weights of unit volume of the liquids in which the hydrometer sinks to the divisions 0, 1, 2 . . . . n respectively. Then, by the principle of Archimedes,

$$W = Vw_0 ;$$

or

$$w_0 = \frac{W}{V} .$$

Also

$$W = (V + lA)w_1$$

or

$$w_1 = \frac{W}{V + lA} .$$

So

$$w_p = \frac{W}{V + plA} ,$$

and

$$w_n = \frac{W}{V + nlA} ;$$

or the densities of the several liquids vary inversely as the respective volumes of the instrument immersed in them; and, since the divisions of the scale correspond to equal increments of volume immersed, it follows that the densities of the several liquids in which the instrument sinks to the successive divisions form a harmonic series.

If $V = NlA$ then N expresses the ratio of the volume of the instrument up to the zero of the scale to that of one of the scale-divisions. If we suppose the lower part of the instrument replaced by a uniform bar of the same sectional area as the stem and of volume V, the indications of the instrument will be in no respect altered, and the bottom of the bar will be at a distance of N scale-divisions below the zero of the scale.

In this case we have

$$w_p = \frac{W}{(N + p)lA} ;$$

or the density of the liquid varies inversely as $N + p$, that is, as the whole number of scale-divisions between the bottom of the tube and the plane of flotation.

If we wish the successive divisions of the scale to correspond to equal increments in the density of the corresponding liquids, then the volumes of the instrument, measured up to the successive divisions of the scale, must form a series in harmonical progression, the lengths of the divisions increasing as we go up the stem.

The greatest density of the liquid for which the instrument described above can be employed is $\frac{W}{V}$, while the least density is $\frac{W}{V + nlA}$, or $\frac{W}{V + v}$, where v represents the volume of the stem between the extreme divisions of the scale. Now, by increasing v, leaving W and V unchanged, we may increase the range of the instrument indefinitely. But it is clear that if we increase A, the sectional area of the stem, we shall diminish l, the length of a scale-division corresponding to a given variation of density, and thereby proportionately diminish the sensibility of the instrument, while diminishing the section A will increase l and proportionately increase the sensibility, but will diminish the range over which the instrument can be employed, unless we increase the length of the stem in the inverse ratio of the sectional area. Hence, to obtain great sensibility along with a considerable range, we require very long slender stems, and to these two objections apply in addition to the question of portability; for, in the first place, an instrument with a very long stem requires a very deep vessel of liquid for its complete immersion, and, in the second place, when most of the stem is above the plane of flotation, this diminishes or may destroy the stability of the instrument when floating. The various devices which have been adopted to overcome this difficulty will be described in the account given of the several hydrometers which have been hitherto generally employed.

The plan commonly adopted to obviate the necessity of inconveniently long stems is to construct a number of hydrometers as nearly alike as may be, but to load them differently, so that the scale-divisions at the bottom of the stem of one hydrometer just overlap those at the top of the stem of the preceding. By this means a set of six hydrometers, each having a stem rather more than five inches long, will be equivalent to a single hydrometer with a stem of thirty inches. But, instead of employing a number of instruments differing only in the weights with which they are loaded, we may employ the same instrument, and alter its weight either by adding mercury or shot to the interior (if it can be opened) or by attaching weights to the exterior. These two operations are not quite equivalent, since a weight added to the interior does not affect the volume of liquid displaced when the instrument is immersed up to a given division of the scale, while the addition of weights to the exterior increases the displacement. This difficulty may be met, as in Keene's hydrometer, by having all the weights of precisely the same volume but of different masses, and never using the instrument except with one of these weights attached.

The first hydrometer intended for the determination of the densities of liquids, and furnished with a set of weights to be attached when necessary, was that constructed by Mr Clarke, and described by Dresaguliers in the *Philosophical Transactions* for March and April 1730, No. 413, p. 278. The following is Desaguliers's account of the instrument (fig. 2):—

"After having made several fruitless trials with ivory, because it imbibes spirituous liquors, and thereby alters its gravity, he (Mr Clarke) at last made a copper hydrometer, represented in fig. 2, having a brass wire of about 1 inch thick going through, and soldered into the copper ball B*b*. The upper part of this wire is filed flat on one side, for the stem of the hydrometer, with a mark at *m*, to which it sinks exactly in proof spirits. There are two other marks, A and B, at top and bottom of the stem, to show whether the liquor be $\frac{1}{10}$th above proof (as when it sinks to A), or $\frac{1}{10}$th under proof (as when it emerges to B), when a brass weight such as C has been screwed on to the bottom at *c*. There are a great many such weights, of different sizes, and marked to be screwed on instead of C, for liquors that differ more than $\frac{1}{10}$th from proof, so as to serve for the specific gravities in all such proportions as relate to the mixture of spirituous liquors, in all the variety made use of in trade. There are also other balls for showing the specific gravities quite to common water, which make the instrument perfect in its kind."

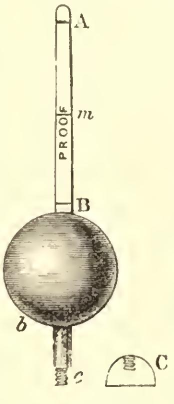

Fig. 2.—Clarke's Hydrometer.

Clarke's hydrometer, as afterwards constructed for the purposes of the excise, was provided with thirty-two weights to adapt it to spirits of different specific gravities, and eleven smaller weights, or "weather weights" as they were called, which were attached to the instrument in order to correct for variations of temperature. The weights were adjusted for successive intervals of 5° Fahr., but for degrees intermediate between these no additional correction was applied. The correction for temperature thus afforded was not sufficiently accurate for excise purposes, and Mr Speer in his essay on the hydrometer (Tilloch's *Phil. Mag.*, vol. xiv.) mentions cases in which this imperfect compensation led to the extra duty payable upon spirits which were more than 10 per cent. over proof being demanded on spirits which were purposely diluted to below 10 per cent. over proof in order to avoid the charge.

Desaguliers himself constructed a hydrometer of the ordinary type for comparing the specific gravities of different kinds of water (Desaguliers's *Experimental Philosophy*, vol. ii. p. 234). In order to give great sensibility to the instrument, the large glass ball was made nearly 3 inches in diameter, while the stand consisted of a wire 10 inches in length and only $\frac{1}{40}$ inch in diameter. The instrument weighed 4000 grains, and the addition of a grain caused it to sink through an inch. By altering the quantity of shot in the small balls the instrument could be adapted for liquids other than water.

To an instrument constructed for the same purpose, but on a still larger scale than that of Desaguliers, M. Deparcieux added a small dish on the top of the stem for the reception of the weights necessary to sink the instrument to a convenient depth. The effect of weights placed in such a dish or pan is of course the same as if they were placed within the bulb of the instrument, since they do not alter the volume of that part which is immersed.

The first important improvement in the hydrometer after its reinvention by Boyle was introduced by Fahrenheit, who adopted the second mode of construction above referred to, arranging his instrument so as always to displace the same volume of liquid, its weight being varied accordingly. Instead of a scale, only a single mark is placed upon the stem, which is very slender, and bears at the top a small scale pan into which weights are placed until the instrument sinks to the mark upon its stem. The volume of the displaced liquid being then always the same, its density will be proportional to the whole weight supported, that is, to the weight of the instrument together with the weights required to be placed in the scale pan.

Nicholson's hydrometer (fig. 3) combines the characteristics of Fahrenheit's hydrometer and of Boyle's essay instrument.[1] The following is the description given of it by Nicholson in the *Manchester Memoirs*, vol. ii. p. 374.

"AA represents a small scale. It may be taken off at D. Diameter $1\frac{1}{2}$ inch, weight 44 grains.

"B a stem of hardened steel wire. Diameter $\frac{1}{100}$ inch.

"E a hollow copper globe. Diameter $2\frac{8}{10}$ inches. Weight with stem 369 grains.

"FF a stirrup of wire screwed to the globe at C.

"G a small scale, serving likewise as a counterpoise. Diameter $1\frac{1}{2}$ inch. Weight with stirrup 1634 grains.

"The other dimensions may be had from the drawing which is one-sixth of the linear magnitude of the instrument itself.

"In the construction, it is assumed that the upper scale shall constantly carry 1000 grains when the lower scale is empty, and the instrument sunk in distilled water at the temperature of 60° Fahrenheit to the middle of the wire or stem. The length of the stem is arbitrary, as is likewise the distance of the lower scale from the surface of the globe. But, the length of the stem being settled, the lower scale may be made lighter, and, consequently, the globe less, the greater its distance is taken from the surface of the globe; and the contrary."

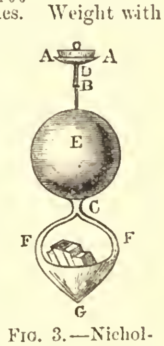

Fig. 3.—Nicholson's Hydrometer.

In comparing the densities of different liquids, it is clear that this instrument is precisely equivalent to that of Fahrenheit, and must be employed in the same manner, weights being placed in the top scale only until the hydrometer sinks to the mark on the wire, when the specific gravity of the liquid will be proportional to the weight of the instrument together with the weights in the scale.

In the subsequent portion of the paper above referred to,

[1] *Nicholson's Journal*, vol. i. p. 111, footnote.

Nicholson explains how the instrument may be employed as a thermometer, since, fluids generally expanding more than the solids of which the instrument is constructed, the instrument will sink as the temperature rises.

To determine the density of solids heavier than water with this instrument, let the solid be placed in the upper scale pan, and let the weight now required to cause the instrument to sink in distilled water at standard temperature to the mark B be denoted by w, while W denotes the weight required when the solid is not present. Then $W - w$ is the weight of the solid. Now let the solid be placed in the lower pan, care being taken that no bubbles of air remain attached to it, and let w_1 be the weight now required in the scale pan. This weight will exceed w in consequence of the water displaced by the solid, and the weight of the water thus displaced will be $w_1 - w$, which is therefore the weight of a volume of water equal to that of the solid. Hence, since the weight of the solid itself is $W - w$, its density must be $\frac{W - w}{w_1 - w}$.

The above example illustrates how Nicholson's or Fahrenheit's hydrometer may be employed as a weighing machine for small weights.

In all hydrometers in which a part only of the instrument is immersed, there is a liability to error in consequence of the surface tension, or capillary action, as it is frequently called, along the line of contact of the instrument and the surface of the liquid (see CAPILLARY ACTION). This error diminishes as the diameter of the stem in reduced, but is sensible in the case of the thinnest stem which can be employed, and is the chief source of error in the employment of Nicholson's hydrometer, which otherwise would be an instrument of extreme delicacy and precision. The following is Nicholson's statement on this point:—

"One of the greatest difficulties which attends hydrostatical experiments arises from the attraction or repulsion that obtains at the surface of the water. After trying many experiments to obviate the irregularities arising from this cause, I find reason to prefer the simple one of carefully wiping the whole instrument, and especially the stem, with a clean cloth. The weights in the dish must not be esteemed accurate while there is either a cumulus or a cavity in the water round the stem."

It is possible by applying a little oil to the upper part of the bulb of a common or of a Sikes's hydrometer, and carefully placing it in pure water, to cause it to float with the upper part of the bulb and the whole of the stem emerging as indicated in fig. 4, when it ought properly to sink almost to the top of the stem, the surface tension of the water around the circumference of the circle of contact, AA′, providing the additional support required.

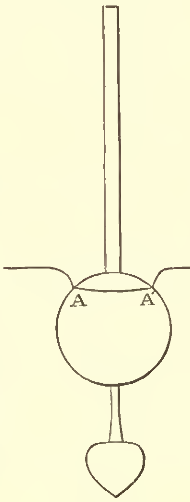

Fig. 4.

The universal hydrometer of Mr G. Atkins, described in the *Phil. Mag.* for 1808, vol. xxxi. p. 254, is merely Nicholson's hydrometer with the screw at C projecting through the collar into which it is screwed, and terminating in a sharp point above the cup G. To this point soft bodies lighter than water (which would float if placed in the cup) could be attached, and thus completely immersed. Atkins's instrument was constructed so as to weigh 700 grains, and when immersed to the mark on the stem in distilled water at 60° F., it carried 300 grains in the upper dish. The hydrometer therefore displaced 1000 grains of distilled water at 60° F., and hence the specific gravity of any other liquid was at once indicated by adding 700 to the number of grains in the pan required to make the instrument sink to the mark on the stem. The small divisions on the scale corresponded to differences of $\frac{1}{10}$th of a grain in the weight of the instrument.

The "Gravimeter," constructed by Citizen Guyton and described in *Nicholson's Journal*, 4to, vol. i. p. 110, differs from Nicholson's instrument in being constructed of glass, and having a cylindrical bulb about 21 centimetres in length and 22 millimetres in diameter. Its weight is so adjusted that an additional weight of 5 grammes must be placed in the upper pan to cause the instrument to sink to the mark on the stem in distilled water at the standard temperature. The instrument is provided with an additional piece, or "plongeur," whose weight exceeds 5 grammes by the weight of water which it displaces; that is to say, it is so constructed as to weigh 5 grammes in water, and consists of a glass envelope filled with mercury. It is clear that the effect of this "plongeur," when placed in the lower pan, is exactly the same as that of the 5 gramme weight in the upper pan. Without the extra 5 grammes the instrument weighs about 20 grammes, and therefore floats in a liquid of specific gravity ·8. Thus deprived of its additional weight it may be used for spirits. To use the instrument for liquids of much greater density than water additional weights must be placed in the upper pan, and the "plongeur" is then placed in the lower pan for the purpose of giving to the instrument the requisite stability.

Charles's balance areometer is similar to Nicholson's hydrometer, except that the lower basin admits of inversion, thus enabling the instrument to be employed for solids lighter than water, the inverted basin serving the same purpose as the pointed screw in Atkins's modification of the instrument.

Adie's sliding hydrometer is of the ordinary form, but can be adjusted for liquids of widely differing specific gravities by drawing out a sliding tube, thus changing the volume of the hydrometer while its weight remains constant.

Adie's statical hydrometer is really a specific gravity balance, one of the arms of which is $2\frac{1}{2}$ inches in length, and the other 8 inches. A brass ball, whose volume is ·01 gallon, is suspended from the shorter arm, and immersed in the liquid whose density is to be determined. The ball is balanced by means of a weight which slides along the beam, and a smaller weight which also slides along the beam serves to make the necessary correction for temperature.

The hydrometer of Beaumé, which has been extensively used in France, consists of a common hydrometer graduated in the following manner. Certain fixed points were first determined upon the stem of the instrument. The first of these was found by immersing the hydrometer in pure water, and marking the stem at the level of the surface. This formed the zero of the scale. Fifteen standard solutions of pure common salt in water were then prepared, containing respectively 1, 2, 3, ... 15 per cent. (by weight) of dry salt. The hydrometer was plunged in these solutions in order, and the stem having been marked at the several surfaces, the degrees so obtained were numbered 1, 2, 3, ... 15. These degrees were, when necessary, repeated along the stem by the employment of a pair of compasses till 80 degrees were marked off. The instrument thus adapted to the determination of densities exceeding that of water was called the hydrometer for salts.

The hydrometer intended for densities less than that of water, or the hydrometer for spirits, is constructed on a similar principle. The instrument is so arranged that it floats in pure water with most of the stem above the surface. A solution containing 10 per cent. of pure salt is used to indicate the zero of the scale, and the point at which the instrument floats when immersed in distilled water at 10° R. ($54\frac{1}{2}$° F.) is numbered 10. Equal divisions are then marked off upwards along the stem as far as the 50th degree.

The densities corresponding to the several degrees of Beaumé's hydrometer are given by Nicholson (*Journal of Philosophy*, vol. i. p. 89) as follows:—

Beaumé's Hydrometer for Spirits. Temperature 10° R.

Degrees.	Density.	Degrees.	Density.	Degrees.	Density.
10	1·000	21	·922	31	·861
11	·990	22	·915	32	·856

Cartier's hydrometer was very similar to that of Beaumé, Cartier having been employed by the latter to construct his instruments for the French revenue. The point at which the instrument floated in distilled water was marked 10° by Cartier, and 30° on Cartier's scale corresponded to 32° on Beaumé's.

Though constructed upon a very different principle from ordinary hydrometers, we may briefly refer here to Brewster's capillary hydrometer or staktometer, which is based upon the difference in the surface tension and density of pure water, and of mixtures of alcohol and water in varying proportions. If a small piece of paper be bent into such a shape as this, /\, it may be made to rest upon the surface of water without being immersed. If now a drop of alcohol be placed on one corner of the paper, it will rush violently away and generally spin round, somewhat resembling the action of pieces of camphor, indicating that the surface tension of the water is diminished by the presence of alcohol. If the water be very pure it is sufficient to bring a drop of alcohol on the extremity of a pipette near to the paper, without touching either it or the water, and the vapour absorbed will produce the same effect. For other proofs of the same action see the article CAPILLARY ACTION. Now, if a drop of water be allowed to form at the extremity of a fine tube, it will go on increasing until its weight overcomes the surface tension by which it clings to the tube, and then it will fall. Hence any impurity which diminishes the surface tension of the water will diminish the size of the drop (unless the density is proportionately diminished). Now, according to Quincke, the surface tension of pure water in contact with air at 20° C. is 81 dynes per linear centimetre, while that of alcohol is only 25·5 dynes. Also, a small percentage of alcohol produces much more than a proportional decrease in the surface tension when added to pure water. The capillary hydrometer consists simply of a small pipette with a bulb in the middle of the stem, the pipette terminating in a very fine capillary point. The instrument being filled with distilled water, the number of drops required to empty the bulb and portions of the stem between two marks m and n (fig. 5) on the latter is carefully counted, and the experiments repeated at different temperatures. The pipette having been carefully dried, the process is repeated with pure alcohol or with proof spirits, and the strength of any admixture of water and spirits is determined from the corresponding number of drops, but the formula generally given is not based upon sound data. Sir David Brewster found with one of these instruments that the number of drops of pure water was 734, while of proof spirit, sp. gr. 920, the number of drops required was 2117.

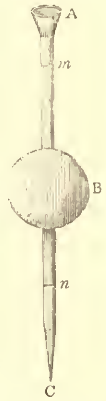

FIG. 5.—Brewster's Staktometer.

Perhaps the main object for which hydrometers have been constructed is the determination of the value of spirituous liquors, chiefly for revenue purposes. To this end an immense variety of hydrometers have been constructed, differing mainly in the character of their scales.

In Speer's hydrometer the stem has the form of an octagonal prism, and upon each of the eight faces a scale is engraved, indicating the percentage strength of the spirit corresponding to the several divisions of the scale, the eight scales being adapted respectively to the temperatures 35°, 40°, 45°, 50°, 55°, 60°, 65°, and 70° F. Four small pins, which can be inserted into the counterpoise of the instrument, serve to adapt the instrument to the temperatures intermediate between those for which the scales are constructed. William Speer was supervisor and chief assayer of spirits in the port of Dublin. For a more complete account of this instrument see Tilloch's *Phil. Mag.*, vol. xiv. p. 151.

The hydrometer constructed by Mr Jones of Holborn, consists of a spheroidal bulb with a rectangular stem (fig. 6). Between the bulb and counterpoise is placed a thermometer, which serves to indicate the temperature of the liquid, and the instrument is provided with three weights which can be attached to the top of the stem. On the four sides of the stem AD are engraved four scales corresponding respectively to the unloaded instrument, and to the instrument loaded with the respective weights. The instrument when unloaded serves for the range from 74 to 47 above proof; when loaded with the first weight it indicates from 46 to 13 over proof, with the second weight from 13 over proof to 29 under proof, and with the third from 29 under proof to pure water, the graduation corresponding to which is marked W at the bottom of the fourth scale. One side of the stem AD is shown in fig. 6, the other three in fig. 7. The thermometer is also provided with four scales corresponding to the scales above mentioned. Each scale has its zero in the middle corresponding to 60° F. If the mercury in the thermometer stand above this zero the spirit must be reckoned weaker than the hydrometer indicates by the number on the thermometer scale level with the top of the mercury, while if the thermometer indicate a temperature lower than the zero of the scale (60° F.) the spirit must be reckoned stronger by the scale reading. At the side of each of the four scales on the stem of the hydrometer is engraved a set of small numbers indicating the contraction in volume which would be experienced if the requisite amount of water (or spirit) were added to bring the sample tested to the proof strength.

FIG. 6.—Jones's Hydrometer.

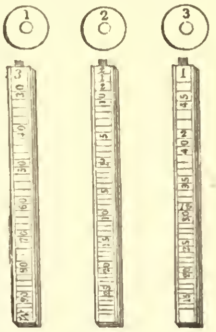

Fig. 7.

The hydrometer constructed by Mr Dicas of Liverpool is provided with a sliding scale which can be adjusted for different temperatures, and which also indicates the contraction in volume incident on bringing the spirit to proof strength. It is provided with thirty-six different weights which, with the ten divisions on the stem, form a scale from 0 to 370. The employment of so many weights renders the instrument ill-adapted for practical work where speed is an object. It was adopted for the United States revenue by Act of Congress, August 10, 1790.

Quin's universal hydrometer is described in the *Transactions of the Society of Arts*, vol. viii. p. 98. It is provided with a sliding rule to adapt it to different temperatures, and has four scales, one of which is graduated for spirits and the other three serve to show the strengths of worts. The peculiarity of the instrument consists in the pyramidal form given to the stem, which renders the scale-divisions more nearly equal in length than they would be on a prismatic stem.

Atkins's hydrometer, as originally constructed, is described in *Nicholson's Journal*, 8vo, vol. ii. p. 276. It is made of brass, and is provided with a spheroidal bulb whose axis is 2 inches in length, the conjugate diameter being $1\frac{1}{2}$ inches. The whole length of the instrument is 8 inches, the stem square of about $\frac{1}{8}$ inch side, and the weight about 400 grains. It is provided with four weights, marked 1, 2, 3, 4, and weighing respectively 20, 40, 61, and 84 grains, which can be attached to the shank of the instrument at C (fig. 8), and retained there by the fixed weight B. The scale engraved upon one face of the stem contains fifty-five divisions, the top and bottom being marked 0 or zero, and the alternate intermediate divisions (of which there are twenty-six) being marked with the letters of the alphabet in order. The four weights are so adjusted that, if the instrument floats with the stem emerging as far as the lower division 0 with one of the weights attached, then replacing the weight by the next heavier causes the instrument to sink through the whole length of the scale to the upper division 0, and the first weight produces the same effect when applied to the naked instrument. The stem is thus virtually extended to five times its length, and the number of divisions increased practically to 272. When no weight is attached the instrument indicates densities from ·806 to ·843; with No. 1 it registers from ·843 to ·880, with No. 2 from ·880 to ·918, with No. 3 from ·918 to ·958, and with No. 4 from ·958 to 1·000, the temperature being 55° F. It will thus be seen that the whole length of the stem corresponds to a difference of density of about ·04, and one division to about ·00074, indicating a difference of little more than $\frac{1}{8}$ per cent. in the strength of any sample of spirits.

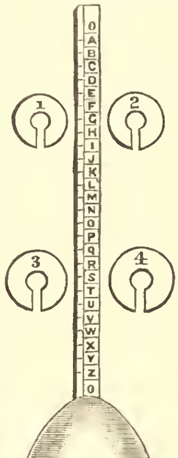

FIG. 8.—Atkins's Hydrometer.

The instrument is provided with a sliding rule, with scales corresponding to the several weights, which indicate the specific gravity corresponding to the several divisions of the hydrometer scale compared with water at 55° F. The slider upon the rule serves to adjust the scale for different temperatures, and then indicates the strength of the spirit in percentages over or under proof. The slider is also provided with scales, marked respectively Dicas and Clarke, which serve to show the readings which would have been obtained had the instruments of those makers been employed. The line on the scale marked "concentration" indicates the diminution in volume consequent upon reducing the sample to proof strength (if it is O. P.) or upon reducing proof spirit to the strength of the sample (if it is U. P.). By applying the several weights in succession in addition to No. 4, the instrument can be employed for liquids heavier than water; and graduations on the other three sides of the stem, together with an additional slide rule, adapt the instrument for the determination of the strength of worts.

Mr Atkins subsequently modified the instrument (*Nicholson's Journal*, 8vo, vol. iii. p. 50) by constructing the different weights of different shapes, viz., circular, square, triangular, and pentagonal, instead of numbering them 1, 2, 3 and 4 respectively, a figure of the weight being stamped on the sliding rule opposite to every letter in the series to which it belongs, thus diminishing the probability of mistakes. He also replaced the letters on the stem by the corresponding specific gravities referred to water as unity. Further information concerning these instruments and the state of hydrometry in 1803 will be found in Mr Atkins's pamphlet *On the Relation between the Specific Gravities and the Strength of Spirituous Liquors*, 1803; or *Phil. Mag.*, vol. xvi. pp. 26–33, 205–212, 305–312; vol. xvii. pp. 204–210 and 329–341.

In Gay Lussac's alcoholometer the scale is divided into 100 parts corresponding to the presence of 1, 2, . . . per cent. by volume of alcohol at 15° C., the highest division of the scale corresponding to the purest alcohol he could obtain (density ·7947) and the lowest division corresponding to pure water. A table provides the necessary corrections for other temperatures.

Tralles's hydrometer differs from Gay Lussac's only in being graduated at 4° C. instead of 15° C., and taking alcohol of density ·7939 at 15·5° C. for pure alcohol instead of ·7947 as taken by Gay Lussac (Keene's *Handbook of Hydrometry*).

In Beck's hydrometer the zero of the scale corresponds to density 1·000 and the division 30 to density ·850, and equal divisions on the scale are continued as far as is required in both directions. The following table serves to indicate the relation between the degrees and the corresponding densities:—

Relation between Degrees of Beck's Hydrometer and Densities.

Degrees.	Density. Greater than 1·000.	Density. Less than 1·000.	Degrees.	Density. Greater than 1·000.	Density. Less than 1·000.	Degrees.	Density. Greater than 1·000.	Density. Less than 1·000.

In the centesimal hydrometer of M. Francœur the volume of the stem between successive divisions of the scale is always $\frac{1}{100}$th of the whole volume immersed when the instrument floats in water at 4° C. In order to graduate the stem the instrument is first weighed, then immersed in distilled water at 4° C., and the line of flotation marked zero. The first degree is then found by placing on the top of the stem a weight equal to $\frac{1}{100}$th of the weight of the instrument, which increases the volume immersed by $\frac{1}{100}$th of the original volume. The addition to the top of the stem of successive weights, each $\frac{1}{100}$th of the weight of the instrument itself, serves to determine the successive degrees. The length of 100 divisions of the scale, or the length of the uniform stem the volume of which would be equal to that of the hydrometer up to the zero graduation, Francœur called the "modulus" of the hydrometer. He constructed his instruments of glass, using different instruments for different portions of the scale (Francœur, *Traité d'areometrie*, Paris, 1842).

Dr Boriés of Montpellier constructed an hydrometer which was based upon the results of his experiments on mixtures of alcohol and water. The interval between the points corresponding to pure alcohol and to pure water Boriés divided into 100 equal parts, though the stem was prolonged so as to contain only 10 of these divisions, the other 90 being provided for by the addition of 9 weights to the bottom of the instrument as in Clarke's hydrometer.

Sikes's hydrometer, on account of its similarity to that of Boriés, appears to have been borrowed from that instrument. It is made of brass, and consists of a spherical ball A (fig. 9), 1·5 inches in diameter, below which is a weight B connected with the ball by a short conical stem C. The stem D is rectangular in section, and about 3½ inches in length. This is divided into ten equal parts, each of which is subdivided into five. As in Boriés's instrument, a series of 9 weights, each of the form shown at E, serves to extend the scale to 100 principal divisions. In the centre of each weight is a hole capable of admitting the lowest and thickest end of the conical stem C, and a slot is cut into it just wide enough to allow the upper part of the cone to pass. Each weight can thus be dropped on to the lower stem so as to rest on the counterpoise B. The weights are marked 10, 20, ... 90; and in using the instrument that weight must be selected which will allow it to float in the liquid with a portion only of the stem submerged. Then the reading of the scale at the line of flotation, added to the number on the weight, gives the reading required. A small supernumerary weight F is added, which can be placed upon the top of the stem. F is so adjusted that when the 60 weight is placed on the lower stem the instrument sinks to the same point in distilled water when F is attached as in proof spirit when F is removed.

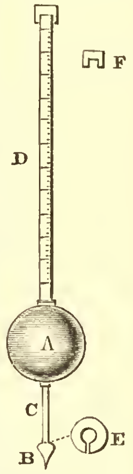

Fig. 9:—Sikes's Hydrometer.

The following table gives the specific gravities corresponding to the principal graduations on Sikes's hydrometer at 60° F. and at 62° F., together with the corresponding strengths of spirits. The latter are based upon the tables of Gilpin, for which the reader is referred to the *Phil. Trans.* for 1794.

Table showing the Densities corresponding to the Indications of Sikes's Hydrometer.

Sikes's Indications.	60° F. Density.	60° F. Proof Spirit per cent.	62° F. Density.	62° F. Proof Spirit per cent.	Sikes's Indications.	60° F. Density.	60° F. Proof Spirit per cent.	62° F. Density.	62° F. Proof Spirit per cent.

Table of the Densities of Bodies (from Mr Tod's series of Tables).

Name of Bodies.	Weight of a cubic foot in oz. and lb.		Weight of a cubic inch in oz.	Number of cubic in. in a lb.
	oz.	lb.	oz.	cub. in.
Metals.				
Antimony, cast	6702	418·8750	3·8748	3·8866
Zinc, cast	7190	449·3750	4·1608	3·8431
Iron, cast	7207	450·4375	4·1797	3·8364
Tin, cast	72[illegible]1	455·6875	4·2193	3·7920
Tin, hardened	7299	456·1875	4·2239	3·7878
Pewter	7471	466·9375	4·3234	3·7007
Iron, bar	7788	486·7500	4·5069	3·5500
Cobalt, cast	7811	488·1875	4·5202	3·5396
Steel, hard	7816	488·5000	4·5231	3·5373
Steel, soft	7833	489·5625	4·5329	3·5296
Iron, meteoric, hammered	7965	497·8125	4·6093	3·4792
Nickel, cast	8279	517·4375	4·7910	3·3395
Brass, cast	8395	524·6875	4·8582	3·2933
Brass, wire	8544	534·0000	4·9444	3·2359
Nickel, hammered	8666	541·6250	5·0150	3·1903
Gun metal	8784	549·0000	5·0833	3·1476
Copper, cast	8788	549·2500	5·0856	3·1461
Copper, wire	8878	554·8750	5·1377	3·1140
Copper, coin	8915	557·1875	5·1591	3·0959
Bismuth, cast	9822	613·8750	5·6840	2·8149
Silver, hammered	10510	656·8750	6·0821	2·6306
Silver, coin	10534	658·3750	6·0960	2·6246
Silver, pure, cast	10744	671·5000	6·2175	2·5733
Rhodium	11000	687·5000	6·3657	2·5134
Lead, cast	11352	709·5000	6·5694	2·4355
Palladium	11800	737·5000	6·8287	2·5134
Mercury (quicksilver), common	13568	848·0000	7·8518	2·0377
Mercury, „ pure	14000	875·0000	8·1018	1·9748
Gold, trinket	15709	981·8125	9·0908	1·7600
Gold, coin	17647	1102·9375	10·2123	1·6124
Gold, pure, cast	19258	1203·6250	11·1446	1·4356
Gold, hammered	19316	1210·0625	11·2042	1·4280
Platinum, pure	19500	1218·7500	11·2847	1·4178
Platinum, hammered	20336	1271·0000	11·7685	1·3595
Platinum, wire	21041	1315·0625	12·1765	1·3140
Platinum, laminated	22069	1379·3125	12·7714	1·2528
Iridium, hammered	23000	1437·5000	13·3101	1·2021

In the above table for Sikes's hydrometer two densities are given corresponding to each of the degrees 20, 30, 40, 50, 60, 70, 80, and 90, indicating that the successive weights belonging to the particular instrument for which the table has been calculated do not quite agree. The discrepancy, however, does not produce any sensible error in the strength of the corresponding spirit.

A table which indicates the weight per gallon of spirituous liquors for every degree of Sikes's hydrometer is printed in 23 and 24 Vict. c. 114, schedule B. This table differs slightly from that given above, which has been abridged from the table given in Keene's *Handbook of Hydrometry*, apparently from the equal divisions on Sikes's scale having been taken as corresponding to equal increments of density.

Sikes's hydrometer was established for the purpose of collecting the revenue of the United Kingdom by Act of Parliament, 56 Geo. III. c. 140, by which it was enacted that "all spirits shall be deemed and taken to be of the degree of strength which the said hydrometers called Sikes's hydrometers shall, upon trial by any officer or officers of the customs or excise, denote such spirits to be." This Act came into force on January 5, 1817, and was to have remained in force until August 1, 1818, but was repealed by 58 Geo. III. c. 28, which established Sikes's hydrometer on a permanent footing. By 3 and 4 Will. IV. c. 52, § 123, it was further enacted that the same instruments and methods should be employed in determining the duty upon imported spirits as should in virtue of any Act of Parliament be employed in the determination of the duty upon spirits distilled at home. It is the practice of the officers of the inland revenue to adjust Sikes's hydrometer at 62° F., that being the temperature at which the imperial gallon is defined as containing 10 lb avoirdupois of distilled water. The specific gravity of any sample of spirits thus determined, when multiplied by ten, gives the weight in pounds per imperial gallon, and the weight of any bulk of spirits divided by this number gives its volume at once in imperial gallons.

Mr J. B. Keene of the Hydrometer Office, London, has constructed an instrument after the model of Sikes's, but provided with twelve weights of different masses but equal volumes, and the instrument is never used without having one of these attached. When loaded with either of the lightest two weights the instrument is specifically lighter than Sikes's hydrometer when unloaded, and it may thus be used for specific gravities as low as that of absolute alcohol. The volume of each weight being the same, the whole volume immersed is always the same when it floats at the same mark whatever weight may be attached.

Besides the above, many hydrometers have been employed for special purposes. Twaddell's hydrometer is adapted for densities greater than that of water. The scale is so arranged that the reading multiplied by 5 and added to 1000 gives the specific gravity with reference to water as 1000. To avoid an inconveniently long stem, different instruments are employed for different parts of the scale as mentioned above.

The lactometer constructed by Dicas of Liverpool is adapted for the determination of the quality of milk. It resembles Sikes's hydrometer in other respects, but is provided with eight weights. It is also provided with a thermometer and slide rule, to reduce the readings to the standard temperature of 55° F.

The marine hydrometers, as supplied by the British Government to the royal navy and the merchant marine, are glass instruments with slender stems, and generally serve to indicate specific gravities from 1·000 to 1·040. Before being issued they are compared with a standard instrument, and their errors determined. They are employed for taking observations of the density of sea-water.

The salinometer is a hydrometer intended to indicate the strength of the brine in marine boilers in which sea-water is employed. Saunders's salinometer consists of an hydrometer which floats in a chamber through which the water from the boiler is allowed to flow in a gentle stream, at a temperature of 200° F. The peculiarity of the instrument consists in the stream of water, as it enters the hydrometer chamber, being made to impinge against a disk of metal, by which it is broken into drops, thus liberating the steam, which would otherwise disturb the instrument.

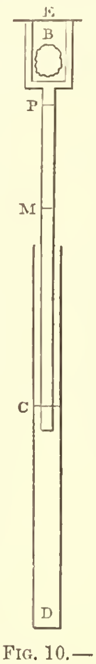

Fig. 10.—Say's Stereometer.

Say's stereometer is an instrument for the determination of the volumes, and hence of the densities, of bodies which cannot be conveniently measured by the ordinary hydrometer, as, for example, soluble and porous bodies, powders, &c. The instrument consists of a glass tube PC (fig. 10), of uniform bore, terminating in a cup PE, the mouth of which can be rendered air-tight by the plate of glass E. The substance whose volume is to be determined is placed in the cup PE, and the tube PC is immersed in the vessel of mercury D, until the mercury reaches the mark P. The plate E is then placed on the cup, and the tube PC raised until the surface of the mercury in the tube stands at M, that in the vessel D being at C, and the height MC is measured. Let k denote this height, and let PM be denoted by l. Let u represent the volume of air in the cup before the body was inserted, v the volume of the body, a the area of the horizontal section of the tube PC, and h the height of the mercurial barometer. Then, by Boyle's law,

$$(u-v+al)(h-k)=(u-v)h,$$

$$\therefore \quad v=u-al\frac{h-k}{k}.$$

The volume u may be determined by repeating the experiment when only air is in the cup. In this case $v=0$, and the equation becomes

$$(u+al')(h-k')=uh,$$

whence

$$u=al'\frac{h-k'}{k'}.$$

Substituting this value in the expression for v, the volume of the body inserted in the cup becomes known, and if m represents its mass its density is $\frac{m}{v}$. (W. G.)

HYDROPATHY is the treatment of disease by water, used outwardly and inwardly. Like many descriptive names, the word "hydropathy" is defective and even misleading, the active agents in the treatment being heat and cold, of which water is little more than the vehicle, and not the only one. Thermo-therapeutics (or thermotherapy) is a term less open to objection. The name "hydropathy," however, as being itself an advance on an earlier and less happy designation, "the water cure," as having obtained general currency, is here employed.

Hydropathy, as a system, or mode of treatment complete in itself, dates from about 1829, when Vincenz Priessnitz (1801–51), a farmer of Gräfenberg in Silesia, Austria, began his public career in the paternal homestead, extended so as to accommodate the increasing numbers attracted by the fame of his cures. Two English works, however, on the medical uses of water had been translated into German in the century preceding the rise of the movement under Priessnitz. One of these was by Sir John Floyer, a physician of Lichfield, who, struck by the remedial use of certain springs by the neighbouring peasantry, investigated the history of cold bathing, and published in 1702 his "*Ψυχρολουσία, or the History of Cold Bathing, both Ancient and Modern.*" The book ran through six editions within a few years, and the translation was largely drawn upon by Dr J. S. Hahn of Silesia, in a work published in 1738, *On the Healing Virtues of Cold Water, Inwardly and Outwardly applied, as proved by Experience.* The other work was that of Dr Currie of Liverpool, entitled *Medical Reports on the Effects of Water, Cold and Warm, as a Remedy in Fevers and other Diseases*, published in 1797, and soon after translated into German by Michaelis (1801) and Hegewisch (1807). It was highly popular, and first placed the subject on a scientific basis. Hahn's writings had meanwhile created much enthusiasm among his countrymen, societies having been everywhere formed to promote the medicinal and dietetic use of water; and in 1804 Professor Oertel of Ansbach republished them and quickened the popular movement by unqualified commendation of water drinking as a remedy for all diseases. In him the rising Priessnitz found a zealous advocate, and doubtless an instructor also. The origin of hydropathy is thus to be traced to an English source and to the medical profession. The broad conception that water had curative relations to the whole realm of disease seems to have been first grasped by a Capuchin monk of Sicily, Father Bernardo, who, at Malta, in 1724, obtained results by iced water alone, which, according to Hahn, caused a great stir throughout Europe; but, owing to the excesses of his imitators, it was of no long duration. With this exception there is, as regards the remedial use of water, nothing in the history of medicine that approaches in completeness the system of Priessnitz, though much leading up to it can be discovered. Among most primitive peoples, indeed, both in the Old and in the New World, the existence of one kind or another of hydropathic practice can be traced; and the fathers of medicine made frequent reference in their writings to the employment of water. The warm bath came into use at an early period (see BATHS, vol. iii. p. 434); and the clyster, shower bath, douche, plunge, wet compress, drop bath, head and foot baths, are mentioned from time to time, as also combinations of heat and cold and primitive modes of sweating, until, before the end of the 17th century, all the processes of modern hydropathy, the wet sheet pack and induced cutaneous crisis alone excepted, had become known and were in a measure practised. Prominent in the roll of names associated more or less with the advocacy of water in earlier times are those of Asclepiades of Prusa (90 B.C.), surnamed Ψυχρολούτης ("cold bather"), Antoninus Musa (30 B.C.), famed for his cure of Augustus by cold water (comp. Hor., *Epist.* i. 15, 3–5), Galen (130 A.D.), Rhazes (923), Avicenna (1036), Cardan, and Van der Heyden. Raymond of Marseilles (1755) gained a prize for the best treatise on the applications of cold water in disease, and another prize essay by Marteau shows what knowledge of the subject prevailed in his time.

At Gräfenberg, to which the fame of Priessnitz drew people of every rank and many countries, medical men were conspicuous by their numbers, some being attracted by curiosity, others by the desire of knowledge, but the majority by the hope of cure for ailments which had as yet proved incurable. Many records of experiences at Gräfenberg were published, all more or less favourable to the claims of Priessnitz, and some enthusiastic in their estimate of his genius and penetration; and from these alone can a knowledge of his practice and views be obtained, not a line having ever been written by this singular man. To Captain Claridge was due the introduction in 1840 of hydropathy to England, his writings and lectures, and later those of Drs Wilson, Gully, and Edward Johnson, making numerous converts, and filling the establishments opened soon after at Malvern and elsewhere. In Germany, France, and America hydropathic establishments multiplied with great rapidity. Antagonism ran high between the old practice and the new. Unsparing condemnation was heaped by each on the other; and a legal prosecution, leading to a royal commission of inquiry, served but to make Priessnitz and his system stand higher in public estimation.

But increasing popularity diminished before long that timidity which hitherto had in great measure prevented trial of the new method from being made on the weaker and more serious class of cases, and had caused hydropathists to occupy themselves mainly with a sturdy order of chronic invalids well able to bear a rigorous regimen and the severities of unrestricted crisis. The need of a radical adaptation to the former class was first adequately recognized by John Smedley, a manufacturer of Derbyshire, who, impressed in his own person with the severities as well as the benefits of "the cold water cure," practised among his workpeople a milder form of hydropathy, and began about 1852 a new era in its history, founding at Matlock a counterpart of the establishment at Gräfenberg.

Whilst hydropathy as a system has been gaining favour with the people, and receiving ample acknowledgment from the more liberal members of the medical profession, individual measures have from time to time been advocated in the medical journals and adopted more or less widely in particular diseases. Brand of Berlin, Räljen and Jürgensen of Kiel, and Liebermeister of Basel, between 1860 and 1870, employed the cooling bath in abdominal typhus with results which, after every deduction on the score of defective classification had been made, were striking enough, and led to its introduction to England by Dr Wilson Fox, whose able monograph commanded general acceptance. In the Franco-German war the cooling bath was largely employed, in conjunction frequently with quinine; and it now holds a recognized position in the treatment of hyperpyrexia. The wet sheet pack has of late been much used in fevers of all kinds both in private and hospital practice; and the Turkish bath, introduced about twenty-four years ago by Mr David Urquhart on his return from the East, and ardently adopted by Mr Barter of Cork, has become a public institution, and, with the "morning tub" and the general practice of water drinking, is the most noteworthy of the many contributions by hydropathy to public health.

The theoretical basis of hydropathy is wide and fundamental enough to include within its scope all disease. Each individual cell of the mass constituting in various forms and combinations the human body being in its growth and function dependent on and regulated by the nervous and vascular systems, themselves cellular, and every derangement of these cells originating in or being attended with a derangement of their nervous and vascular supply, and that supply being powerfully and in quite diverse ways influenced by heat and cold,—all morbid conditions of the economy may be influenced materially by the regulated employment of heat and cold, which are entitled therefore to rank as powerful factors in therapeutics.

Hydropathy insists in quite a special way on the necessity of regarding disease first in relation to its cause. It next requires that whatever assistance may be afforded to the *vis medicatrix naturæ* should in the first place be similar in kind (*i.e.*, should be natural or physiological), rather than alien to it and drawn from sources remote and strange; and, while proceeding on lines which have been common to all medical practice from an early period, it does so by agents hitherto strangely neglected, though not unknown, and effects its purpose in ways less open to objection than those it would displace. For example, when local depletion is required, as of the lung in pneumonia, or the brain in hæmorrhagic apoplexy, the final withdrawal from the general circulation of a quantity of blood is deprecated as unnecessary for the attainment of the object in view, and prejudicial in the after period of convalescence. Hydropathy substitutes a diversion to parts indifferent, as the extremities and general cutaneous surface, and so material and sustained as to be much more effectual; while at the same time it holds in reserve the abstracted blood to perform its part in the restoration of strength. Where purgation is employed to derive blood from the brain, liver, or kidneys, a highly sensitive and vital membrane is more or less injured thereby, and convalescence proportionately imperilled. Hydropathy selects the skin as more accessible than the mucous membrane of the alimentary tract, more serviceable also, and less, if at all, susceptible of injury, either temporary or permanent. The skin can with safety be used for counter-irritation, and is a reservoir of capacity almost unlimited, into which to divert the excess of blood from the brain or other part, while for purposes of excretion it is not inferior to the bowels themselves, and, unlike the latter, is left even more efficient than before. In the febrile state, a reduction of pulse and temperature, and relief from pain and sleeplessness, were commonly attempted, at the period when hydropathy was introduced, by depressants, as antimony, ipecacuanha, and perhaps large doses of alcohol, in combination with sedatives, as opium and chloral. Impaired digestion and depressed vitality were results in some measure inevitable, and always of moment, especially in the more protracted fevers, where recovery becomes a question often of simple physical endurance. By means of the wet sheet pack, cooling compresses, spongings, and allied measures, these ends are attained with comparative ease, certainty, and simplicity, and with entire freedom from objectionable secondary effects.

The agents of hydropathy are at once simple and complex,—simple in their elements, and complex in their combinations and modifications. They afford the physician a series of effects almost infinite in variety, both in kind and in degree, both immediate and remote. According as heat and cold[1] are used in their extreme or their intermediate degrees, singly or in combination, successively or alternately, momentarily or continuously, dry or moist, and according as the primary action is utilized or the secondary, do their effects differ. The direct or primary effect of cold is to depress, cool, and deplete the part concerned. If its exhibition is brief, reaction (an important factor in hydropathic practice) quickly establishes an opposite condition, stimulating the part, and determining an increased flow of blood to it, with increase of its temperature and vital activity. If it is continuous, the primary depression is maintained, and the revulsive or secondary effect delayed or averted. The direct effect of heat is to increase the amount of blood present; but if the exhibition is brief, and evaporation is permitted, the contrary effect is produced, viz., depression, coolness, and depletion; if it is continuous, the primary effect is preserved. Thus with truth it may be said that cold heats and heat cools, while the converse holds good, and that by simple variations of detail. From the intermediate temperatures (80° to 100°) simple sedative effects are obtained, with absence of secondary or revulsive effects in proportion as the temperature of the part is approximated to. Results vary also according to the heat of the subject. In local inflammations, continuous cold benumbs and contracts, continuous heat soothes and relaxes. Momentary cold excites, heats by reaction, and intensifies inflammation; while momentary heat soothes and ultimately cools the inflamed part by the after evaporation. In the earlier stages and acute varieties of inflammation, therefore, continuous cold or transient hot applications are appropriate, and brief applications of cold in the later, congestive, and chronic forms. But where the local inflammation coexists with general feverishness, continuous cold as the local application is preferable, helping, as it does, to reduce the general exaltation of temperature. In collapse the low general temperature makes heat the best local application. On internal parts the application of heat and cold externally has definite therapeutic effects either identical or opposite (as remarked by John Hunter) through reflex or sympathetic nervous action. Through the vascular system also remote effects are produced, as in heating the lower extremities to derive blood from the brain. The counter relation also of the entire cutaneous surface to the internal organs, as the kidneys and alimentary mucous membrane, is, in hydropathy, largely utilized for remedial purposes. This sympathy is familiar enough in the etiology of disease, which may be said likewise of all the physiological laws applied to curative purposes in hydropathy.

The appliances and arrangements by means of which heat and cold are brought to bear on the economy are—(*a*) Packings, hot and cold, general and local, sweating and cooling; (*b*) hot air and steam baths; (*c*) general baths, of hot water and cold; (*d*) sitz, spinal, head, and foot baths; (*e*) bandages (or compresses), wet and dry; also (*f*) fomentations and poultices, hot and cold, sinapisms, stupes, rubbings, and water potations, hot and cold.

(*a.*) Packings.—The full pack consists of a wet sheet enveloping the body, with a number of dry blankets packed tightly over it, including a macintosh covering or not. In an hour or less these are removed and a general bath administered. The pack is a derivative, sedative, sudorific, and stimulator of cutaneous excretion. There are numerous modifications of it, notably the cooling pack, where the wrappings are loose and scanty, permitting evaporation, and the application of indefinite duration, the sheet being rewetted as it dries; this is of great value in protracted febrile conditions. There are also local packs, to trunk, limbs, or head separately, which are derivative, soothing, or stimulating, according to circumstance and detail.

(*b.*) Hot air baths, the chief of which is the Turkish (properly, the Roman) bath, consisting of two or more chambers ranging in temperature from 120° to 212° or higher, but mainly used at 150° for curative purposes. Exposure is from twenty minutes up to two hours according to the effect sought, and is followed by a general bath, and occasionally by soaping and shampooing. It is stimulating, derivative, depurative, sudorific, and alterative, powerfully promoting tissue change by increase of the natural waste and repair. It determines the blood to the surface, reducing internal congestions, is a potent diaphoretic, and, through the extremes of heat and cold, is an effective nervous and vascular stimulant and tonic. Morbid growths and secretions, as also the uræmic, gouty, and rheumatic diathesis, are beneficially influenced by it. The full pack and Turkish bath have between them usurped the place and bettered the function of the once familiar hot bath. The Russian or steam bath and the lamp bath are primitive and inferior varieties of the modern Turkish bath, the atmosphere of which cannot be too dry and pure.

(*c.*) General baths comprise the rain (or needle), spray (or rose), shower, shallow, plunge, douche, wave, and common morning sponge baths, with the dripping sheet, and hot and cold spongings, and are combinations, as a rule, of hot and cold water. They are stimulating, tonic, derivative, and detergent.

(*d.*) Local baths comprise the sitz (or sitting), douche (or spouting), spinal, foot, and head baths, of hot or cold water, singly or in combination, successive or alternate. The sitz, head, and foot baths are used "flowing" on occasion. Rapid alternations of hot and cold water have a powerful effect in vascular stasis and lethargy of the nervous system and absorbents, yielding valuable results in local congestions and chronic inflammations.

(*e.*) Bandages (or compresses) are of two kinds,—*cooling*, of wet material left exposed for evaporation, used in local inflammations and fevers; and *heating*, of the same, covered with waterproof material, used in congestion, external or internal, for short or long periods. Poultices, warm, of bread, linseed, bran, &c., changed but twice in twenty-four hours, are identical in action with the heating bandage, and superior only in the greater warmth and consequent vital activity their closer application to the skin ensures.

(*f.*) Fomentations and poultices, hot or cold, sinapisms, stupes, rubefacients, irritants, frictions, kneadings, calisthenics, gymnastics, electricity, &c., are adjuncts largely employed in hydropathic practice. Water drinking, while still an important factor in hydropathy, has declined somewhat since the early times of the system.

But that which has from the first distinguished modern hydropathy, and still makes its strict practice a thing apart, is the "crisis" so called. It is related of Priessnitz that, when a boy of fourteen, and treating a sprain, as was the native custom, with wet cloths, he observed an eruption appear beneath them, with immediate recovery of the part. Gradually the significance and wider application of this eruption dawned upon him, until it came to hold so prominent a place in his practice as to be regarded by many as his greatest discovery. The eruption coinciding in point of time with recovery as a rule, it was called the crisis, involving doubtless a reference to the term as used by Hippocrates and his successors. But with Priessnitz crisis attained a higher rank, a wider application, and a more definite character. He first showed it to be producible at will under given conditions of the patient, and amenable to direction and control. This eruption, it is claimed, appears only in morbid states of the blood (cachexia) resulting from derangement or defect in the organs of assimilation or excretion or both (*e.g.*, gout, rheumatism), or from the presence of a specific poison (*e.g.*, syphilis). The continuous application to a given tract of skin of the heating bandage or poultice (mediums merely for the exhibition of warmth and moisture) stimulates, in a cumulative way, its vascular and nervous activity, and leads, it may be in a few days or weeks (in some cases hours, in others months), to an eruption, papular, then pustular, and ultimately resolving itself into a suppurating surface commensurate with the area covered by the bandage. There is, in the latter stage, a copious discharge of yellowish-green pus, usually fœtid, varied occasionally with patches of brown, blue, or metallic green, and accompanied with itching, sometimes intense. The general temperature is not, as a rule, disturbed; the pulse, except perhaps for the first day or two, falls, if previously quick, to a natural rate; the weight and strength, in the most favourable cases from the outset, and in the rest later on, increase, and it is not uncommon to find the anomaly of a patient exulting in freedom from suffering and a return of the impulses of health simultaneously with the appearance of an extensive inflammation of the skin. The applications, continued without intermission and unaltered (save as cleanliness requires) for weeks or months, according to the nature of the case, are at last no more stained with pus but with serum

[1] Roughly, and for practical purposes, temperature lower than 60° may be called cold; from 60° to 90°, temperate or tepid; from 90° to 100°, warm; and above 100°, hot (compare vol. iii. p. 440).

simply; and finally, still without change of application, the skin will heal, or, at most, show a little psoriasis, pityriasis, or eczema, or, it may be, but a faint tinge of red. The bandages are then withdrawn. The original symptoms meanwhile have disappeared with more or less celerity and completeness; and with the eruption has departed the disease that called for it and made it possible. Strength grows apace, no longer taxed by disease or crisis, until recovery in appropriate cases is absolute and secure.

Occasionally the cutaneous inflammation extends in the form of psoriasis, eczema, sudamina, a papular rash, or a succession of boils, invading parts untouched by the wet compress. This is called a general crisis; it usually occurs in the last stage of the local one, sometimes after it has ceased, and is advantageous and transient. Debility, whether pre-existing or consequent on the crisis, may call for some modification of its severity and duration, whether by instalments at proper intervals, or curtailment in the later stages, the natural emunctories being relied on to complete the work of purification at greater leisure. A residuum of incurable organic degeneration, as of the kidneys or liver, may likewise put limits to recovery, and provide perpetual material for crisis until the patient is worn out in a vain and ignorant attempt at cure. It was the failure of the earlier hydropathists—through inexperience, default of medical education, or inordinate enthusiasm—to recognize these limitations, that brought crisis into its present discredit and comparative desuetude. Where it is necessary from these or other causes to relieve the patient of the eruption, the substitution of simple ointment, unsalted lard, or other oleaginous or viscid material for the stimulating bandages or poultices, permits the excitement to subside, and, with occasional exceptions, the skin, in a few days, it may be hours, bears little trace of the eruption.

In the course of hydropathic treatment there occur, though rarely, attacks of diarrhœa, sickness, diuresis, or diaphoresis, which, having been observed frequently to mark the turning point in the history of the case, are held to be varieties of crisis, disturbances attendant on the expulsion of the materies morbi from the system.

The theory of crisis may be stated thus. The digestive and assimilative organs are, as is well known, involved, whether primarily or secondarily, in by far the majority of morbid conditions. Their product, the blood, undergoing constant renewal, becomes necessarily more or less impaired,—deprived of the blandness that pertains alone to a pure and perfect condition, with what may be termed an inflammatory disposition as the result. The most familiar, because pronounced, forms are the gouty, rheumatic, tubercular, and strumous diatheses. Later the excretory organs, in common with the whole economy, must more or less become deranged, with additions, in consequence, to the sum of morbid elements in the blood, such as uræmic and biliary matters. A vicious circle of action and reaction is established from which escape is difficult, if not impossible, in its more pronounced developments. The digestive disorder begets imperfect and impure blood, and the morbid blood keeps up, and *cæteris paribus* increases, the initial and originating digestive disorder. In all but its most advanced stages ordinary measures, hydropathic or other, may suffice to break this chain, and, by eliminating one or more of its links, render recovery possible, or accomplish it. It is when the complication is beyond their reach that the domain peculiar to crisis begins. The superior vascularity and vitality of the digestive organs—the alimentary tract of mucous membrane, the pancreas, and the liver—is what makes them (in addition to their susceptibility to injury through errors in diet) so commonly the seat of diseased action. The highly nervous and vascular structure of the skin makes easy its elevation to at least an equality in vital activity with the mucous membrane. Warmth and moisture continuously applied to a given portion will, in time, effect this, aided doubtless by maceration and denudation of the cuticle and exposure of the sensitive cutis vera. It thus becomes the seat of greatest vital activity; pre-eminence in morbid activity naturally follows, and a genuine metastasis is effected, such as the natural history of disease is rich in examples of. There is a decline, *pro tanto*, of the primary internal disorder under this combined pressure, first by the diversion of morbific elements, and then by the diversion of an appreciable quantity of the blood itself, and by counter-irritation, when the site of the vicarious inflammation has been selected with that in view. The aid of a sustained derivation to the entire cutaneous surface and the extremities is at the same time secured by means of the Turkish bath, full packs, and other stimulating agents, while, at the same time, due care is taken to eliminate and negative the original causes of disease. The sum of morbid activity is for the time being increased and intensified; but, in the new location, no longer self-supporting and self-perpetuating, it is sooner or later exhausted. The change in the relation of the materies morbi to the digestive system puts an end at one and the same time to the originating and sustaining conditions. The failure of simple counter-irritation (where, as by sinapisms, vesicatories, &c., the irritant is derived from without) to effect the same result in many of the cases afterwards cured by crisis negatives of itself the view that the results of the latter are to be attributed to the element in it of counter-irritation alone.

HYDROPHOBIA, from ὕδωρ, water, and φοβέω, to fear (Syn. *Rabies, Lyssa*), an acute infectious disease, occurring chiefly in certain of the lower animals, particularly the canine species, and liable to be communicated by them to other animals, and to man. The main features of the disease are similar alike in the lower animals and men, but that peculiar symptom from which the malady derives its name, viz., the dread of water, appears only to affect the latter. Rabies as it manifests itself in animals belongs to the subject of veterinary medicine; the present notice refers only to hydrophobia occurring in man. The disease has been known from early times, and is alluded to in the works of Aristotle, Xenophon, Plutarch, Virgil, Horace, Ovid, and many others, as well as in those of the early writers on medicine. Celsus gives detailed instructions respecting the treatment of men who have been bitten by rabid dogs, and dwells on the dangers attending such wounds. After recommending suction of the bitten part by means of a dry cupping glass, and thereafter the application of the actual cautery or of strong caustics, and the employment of baths and various internal remedies, he says: "Idque cum ita per triduum factum est, tutus esse homo a periculo videtur. Solet autem ex eo vulnere, ubi parum occursum est, aquæ timor nasci, ὑδροφοβίαν Græci appellant. Miserrimum genus morbi; in quo simul æger et siti et aquæ metu cruciatur; quo oppressis in angusto spes est." Subsequently Galen described minutely the phenomena of hydrophobia, and recommended the excision of the wounded part as a protection against the disease. Throughout many succeeding centuries little or nothing was added to the facts which the early physicians had made known upon the subject. The malady was regarded with universal horror and dread, and the unfortunate sufferers were generally abandoned by all around them and left to their terrible fate. In later times the investigations of Boerhaave, Van Swieten, John Hunter, Magendie, Breschet, Virchow, Reder, as also of Youatt, Fleming, Meynell, Hertwig, and others, have furnished important information; nevertheless much remains obscure as to the nature and pathology of this formidable disease.

Whatever may be said as to the spontaneous development of rabies in animals—a view which is now generally discredited—there can be no doubt that in man the disease is in every instance the result of the inoculation of the virus contained in the secretions of the mouth of the affected animal into a wound or abrasion of the skin or mucous membrane. In the great majority of cases (90 per cent.) this is due to the bite of a rabid dog, but bites of rabid cats, wolves, foxes, jackals, &c., are occasionally the means of conveying the disease. There is no evidence that the poison can be introduced into the system without an abrasion of the surface. But it must be observed that even of those who have undoubtedly been bitten by rabid animals, only a proportion subsequently suffer from hydrophobia. Thus where the bite has been inflicted on a part of the body protected by clothing, the virus may be wiped from the teeth of the animal before they penetrate the skin. Hence it is found that bites on exposed parts such as the face are very much more dangerous than on other parts which are ordinarily covered. But further, individual susceptibility must be taken into account, for it is undeniable that many persons in whom the virus of rabies has been inoculated escape hydrophobia. John Hunter mentions one remarkable instance in which of twenty-one persons bitten by a rabid dog only one subsequently died from hydrophobia; and a comparison of the best authorities would seem to show that the proportion of those who are attacked with the disease to those who are bitten is less than one-half, Numerous popular fallacies prevail on the subject of hydrophobia. Thus it is supposed that the bite of an angry dog may produce the disease, and all the more if the animal should subsequently develop symptoms of rabies. The ground for this erroneous notion is the fact, which is unquestionable, that animals in whom rabies is in the stage of incubation, during which there are few if any symptoms, may by their bites convey the disease, though fortunately during this early stage they are little disposed to bite. The bite of a non-rabid animal, however enraged, cannot give rise to hydrophobia. Another fallacious notion, not altogether of popular origin, but maintained by a few eminent professional authorities, is to the effect that there is no such disease as hydrophobia at all, but that the symptoms designated by that name are entirely mental phenomena produced by the effect of fear of the consequences following a bite. It might be sufficient as a reply to this to point to the uniform sequence of terrible symptoms which mark the progress of the malady when it has commenced, and to its acute course and invariably fatal termination; but there is the additional fact that very young children, in whom this feeling could scarcely be expected to operate, may suffer and die from hydrophobia.

The period of incubation of the disease, or that time which elapses between the introduction of the virus and the development of the symptoms, appears to vary in a remarkable degree, being in some cases as short as a fortnight, and in others as long as several months or even years. On an average it seems to be from about six weeks to three months. The rare instances of the appearance of hydrophobia many years after the introduction of the poison are always more or less open to question as to subsequent inoculation. During the period of latency, in which the patient seems perfectly well, it is supposed that the poison is undergoing a sort of multiplication, both in the previously wounded part and in the system at large, somewhat analogous to the fermentive process, and that ultimately it comes to tell with deadly effect upon certain portions of the nervous system.

When the disease is about to declare itself it not unfrequently happens that the wound, which had quickly and entirely healed after the bite, begins to exhibit evidence of irritation or inflammatory action, or at least to be the seat of morbid sensations such as numbness, tingling, or itching. The symptoms characterizing the premonitory stage are great mental depression and disquietude, together with restlessness and a kind of indefinite fear. There is an unusual tendency to talk, and the articulation is abrupt and rapid. Although in some instances the patients will not acknowledge that they have been previously bitten, and deny it with great obstinacy, yet generally they are well aware of the nature of their malady, and speak despairingly of its consequences. There is in this early stage a certain amount of constitutional disturbance showing itself by feverishness, loss of appetite, sleeplessness, headache, great nervous excitability, respiration of a peculiar sighing or sobbing character, and even occasionally a noticeable aversion to liquids. These symptoms—constituting what is termed the melancholic stage—continue in general for one or two days, when they are succeeded by the stage of excitement in which all the characteristic phenomena of the malady are fully developed. Sometimes the disease first shows itself in this stage, without antecedent symptoms.

The agitation of the sufferer now becomes greatly increased, and the countenance exhibits anxiety and terror. There is noticed a marked embarrassment of the breathing, but the most striking and terrible features of this stage are the effects produced by attempts to swallow fluids. The patient suffers from thirst and desires eagerly to drink, but on making the effort is seized with a most violent suffocative paroxysm produced by spasm of the muscles of swallowing and breathing, which continues for several seconds, and is succeeded by a feeling of intense alarm and distress. With great caution and determination the attempt is renewed, but only to be followed with a repetition of the seizure, until the unhappy sufferer ceases from sheer dread to try to quench the thirst which torments him. Indeed the very thought of doing so suffices to bring on a choking paroxysm, as does also the sound of the running of water. The patient is extremely sensitive to any kind of external impression; a bright light, a loud noise, a breath of cool air, contact with any one, are all apt to bring on one of these seizures. But besides these suffocative attacks there also occur general convulsions affecting the whole muscular system of the body, and occasionally a condition of tetanic spasm. These various paroxysms increase in frequency and severity with the advance of the disease, but alternate with intervals of comparative quiet, in which, however, there is intense anxiety and more or less constant difficulty of breathing, accompanied with a peculiar sonorous expiration, which has suggested the notion that the patient barks like a dog. In many instances there is great mental disturbance, with fits of maniacal excitement, in which he strikes at every one about him, and accuses them of being the cause of his sufferings,—these attacks being succeeded by calm intervals in which he expresses great regret for his violent behaviour. During all this stage of the disease the patient is tormented with a viscid secretion accumulating in his mouth, which from dread of swallowing he is constantly spitting about him. There may also be noticed snapping movements of the jaws as if he were attempting to bite, but these are in reality a manifestation of the spasmodic action which affects the muscles generally. There is no great amount of fever, but there is constipation, diminished flow of urine, and often sexual excitement.

After two or three days of suffering of the most terrible description the patient succumbs, death taking place either in a paroxysm of choking, or on the other hand in a tranquil manner from exhaustion, all the symptoms having abated, and the power of swallowing returned before the end. The duration of the disease from the first declaration of the symptoms is generally from three to five days.

Post-mortem examination has not hitherto thrown much light upon this malady, but the subject is at the present time engaging the special attention of certain eminent pathologists, and important and valuable information may be anticipated. The chief morbid changes which have been described are evidences of congestion and inflammatory action in certain portions of the brain and spinal cord, but more particularly in the locality known as the "respiratory centre" of the medulla oblongata, where the accumulation of "leucocytes" around the small blood-vessels and in the surrounding nervous substance are a prominent phenomenon. Similar changes have been found in the salivary glands. On the whole, however, it can scarcely be said that the formidable array of symptoms above narrated are accounted for by these appearances, which in the opinion of some are in all likelihood merely the results of antecedent processes of an occult nature affecting the nerve centres and forming the essence of the disease.

That emotional disturbance is present is undeniable, for it is found that those cases of hydrophobia are less severe where there is no suspicion on the part of the sufferer of the nature of his complaint; yet this only represents one of many elements. The function of the eighth pair of nerves (which are largely concerned in the processes of respiration and deglutition) is disturbed in a marked degree, and it is probable that this is the portion of the nervous system upon which the poison most powerfully exerts its specific action. But that the great nerve centres, viz., the brain and spinal cord as a whole, are profoundly affected, is manifest in the tendency to general convulsion, the remarkable hyperæsthesia, and the mental perturbation of the patient.

The treatment of most avail in this disease is that which is directed towards preventing the absorption of the poison into the system. This may be accomplished by excision of the part involved in the bite of the rabid animal, or, where this from its locality is impracticable, in the application to the wound of some chemical agent which will destroy the activity of the virus, such as potassa fusa, lunar caustic (nitrate of silver), or the actual cautery in the form of a red-hot wire. The part should be thoroughly acted on by these agents, no matter what amount of temporary suffering this may occasion. Such applications should be resorted to immediately after the bite has been inflicted, or as soon thereafter as possible. Further, even though many hours or days should elapse, these local remedies should still be applied; for if, as appears probable, some at least of the virus remains for long at the injured part, the removal or effectual destruction of this may prevent the dread consequences of its absorption. Every effort should be made to tranquillize and reassure the patient.

When once the symptoms of hydrophobia have declared themselves, little can be achieved by the resources of the physician beyond palliating the agonizing sufferings and rendering easier the inevitably fatal event.

Medicines cannot be administered by the mouth, owing to the impossibility of swallowing and the distress occasioned by the effort to do so; they must therefore be given either by the bowel in the form of enema, by hypodermic injection, or by inhalation. The most approved and potent agents are opium, belladonna, curara, chloral, and chloroform inhalation. The vapour bath is also recommended. It need scarcely be said that those coming in contact with the patient should guard against the risk of being bitten during the paroxysms of excitement, or of being inoculated by the saliva, for although there are few if any well-authenticated cases of the disease being communicated in this way, yet the possibility must be admitted.

It should be remarked that occasionally an individual who may have at some time been bitten by a non-rabid dog manifests symptoms strongly resembling in many points those of hydrophobia. These are often simply the effect of fear, and have much of the hysterical element mixed up with them. They are generally of much less severity in every way than those of the true disease, and yield readily to treatment appropriate to the disturbed nervous condition. (J. O. A.)

HYDROZOA

THE HYDROZOA form one of the three classes into which the *Cœlentera nematophora* (distinguished from the *Cœlentera porifera*, or Sponges) have been divided,—recognized as such in the article CŒLENTERA, to which the reader is referred. It results from observations made by Ernst Haeckel, since that article and the article ACTINOZOA were penned, that the *Ctenophora* should not be regarded as a class equivalent to the *Hydrozoa* and *Actinozoa*, nor as a subdivision of the latter class, but that they must be considered as a peculiar modification of the medusiform *Hydrozoa* (see final paragraph). If this conclusion be accepted, it will be necessary to divide the *Hydrozoa* into two primary groups or grades, for which the names *Polypomorpha* and *Ctenophora* are proposed.

The *Hydrozoa* correspond to the Linnæan genera *Hydra*, *Tubularia*, *Sertularia*, and *Medusa*. The name was applied by Huxley in 1856 to a group corresponding to that termed *Hydromedusæ* by Vogt (1851) and *Medusæ* by Leuckart (1853), and embracing the forms placed by Gegenbaur in his *Elements of Comparative Anatomy* (1878) in four classes, viz., *Hydromedusæ*, *Calycozoa*, *Thecomedusæ*, and *Medusæ*. Our knowledge of the structure and life-history of the *Hydrozoa*, many of which, on account of their delicacy and oceanic habits, are excessively difficult to obtain in a state fit for investigation, has greatly extended within the last five years. Whilst in the two decades preceding this period the admirable researches of Huxley, Gegenbaur, Agassiz, and Allman had brought to light and systematized a vast mass of information with regard to these organisms, the later observations of Claus, the Hertwigs, Haeckel, and Metschnikoff, have corrected, extended, and added to their history, especially in respect of embryological and histological detail. An epitome of the present condition of our knowledge of the group is afforded by the subjoined tabular classification of its families, orders, and sub-classes.

The definition and synonymy of the divisions recognized will be entered into, after a sketch has been given of the common structural features of typical *Hydrozoa*.

CLASS HYDROZOA.

	Examples.
Sub-Class I. **Scyphomedusæ** (syn. Ephyromedusæ).	
Order 1. LUCERNARIÆ.	
Fam. 1. Eleutherocarpidæ	Lucernaria (fig. 19). Haliclystus.
„ 2. Cleistocarpidæ	Craterolophus. Manania.
Order 2. DISCOMEDUSÆ (Haeckel).	
Sub-Order 1. Cubostomæ.	
Fam. 1. Protephyridæ.	
„ 2. Nausithoidæ	Nausithoe.
„ 3. Ephyrellidæ.	
„ 4. Atollidæ.	
„ 5. Cyclorchidæ.	
Sub-Order 2. Semostomæ.	
Fam. 1. Pelagidæ	Chrysaora (fig. 24, *b*) Pelagia.
„ 2. Cyanæidæ	Cyanæa.
„ 3. Sthenonidæ	Sthenonia.
„ 4. Aurelidæ	Aurelia (figs. 26–31).
Sub-Order 3. Rhizostomæ.	
Fam. 1. Tetragamellæ	Cephea. Cassiopeia.
„ 2. Monogameliæ	Rhizostoma (fig. 24, *a*). Crambessa.
Order 3. CONOMEDUSÆ (Haeckel).	
Fam. 1. Charybdeidæ	Charybdæa (figs. 20–23).
„ 2. Bursaridæ.	
„ 3. Chiropsalmidæ.	
Order 4. PEROMEDUSÆ (Haeckel).	
Fam. 1. Periphyllidæ.	
„ 2. Pericryptidæ.	

Sub-Class II. **Hydromedusæ.**

Order 1. Gymnoblastea-Anthomedusæ.

- Fam. 1. Tubularidæ .... Tubularia (fig. 35). Hybocodon. Corymorpha (fig. 34).
- „ 2. Pennaridæ .... Pennaria. Vorticlava.
- „ 3. Eudendridæ .... Bougainvillia (figs. 36, 37). Perigonium. Lizzia (fig. 44).
- „ 4. Cladonemidæ .... Cladonema. Clavatella.
- „ 5. Bimeridæ .... Garveia. Stylactis.
- „ 6. Dicorynidæ .... Dicoryne (fig. 40).
- „ 7. Corynidæ .... Sarsiadæ (fig. 45). Coryne. Syncoryne (figs. 41, 46).
- „ 8. Hydractinidæ .... Hydractinia (fig. 39). Podocoryne.
- „ 9. Clavidæ .... Clava-Turris (fig. 38). Cordylophora.
- „ 10. Hydridæ .... Hydra (fig. 42). Protohydra(?).

Order 2. Calyptoblastea-Leptomedusæ.

- Fam. 1. Plumularidæ .... Plumularia. Antennularia.
- „ 2. Sertularidæ .... Sertularia. Halecium.
- „ 3. Campanularidæ .... Eucopidæ. Campanularia (fig. 43). Laomedea. Obelia.
- „ 4. Thaumantiadæ .... Thaumantias. Lafoea. Melicertum. Tima.
- „ 5. Æquoridæ .... Æquorea. Zygodactyla. Rhegmatodes.

Order 3. Trachomedusæ (Haeckel).

- Fam. 1. Petasidæ .... Petasus.
- „ 2. Trachynemidæ .... Rhopalonema.
- „ 3. Aglauridæ .... Aglaura.
- „ 4. Geryonidæ .... Liriope. Carmarina (figs. 48, 49).

Order 4. Narcomedusæ (Haeckel).

- Fam. 1. Cunanthidæ .... Cunina (figs. 50, 51).
- „ 2. Peganthidæ .... Polyxenia.
- „ 3. Æginidæ .... Ægina. Æginopsis
- „ 4. Solmaridæ .... Solmissus. Solmaris.

Order 5. Hydrocorallinæ (Moseley).

- Fam. 1. Milleporidæ .... Millepora (figs. 52, 53).
- „ 2. Stylasteridæ .... Sporadopora. Distichopora. Astylus (fig. 54).

Order 6. Siphonophora.

Sub-Order 1. Physophoridæ.

- Fam. 1. Athorybiadæ .... Athorybia.
- „ 2. Physophoridæ .... Physophora (fig. 57, C).
- „ 3. Agalmidæ .... Forskallia. Halistemma. Agalma (fig. 57, E).
- „ 4. Apolemiadæ .... Apolemia.
- „ 5. Rhizophysidæ .... Rhizophysa.

Sub-Order 2. Physalidæ.

- Fam 1. Physalidæ .... Physalia.

Sub-Order 3. Calycophoridæ.

- Fam. 1. Hippopodiidæ .... Gleba.
- „ 2. Diphyidæ .... Praya. Diphyes (fig. 57, A). Abyla.
- „ 3. Monophyidæ .... Sphæronectes.

Sub-Order 4. Discoideæ.

- Fam. 1. Velellidæ .... Velella. Porpita.

The *Hydrozoa* present a greater simplicity of ultimate structure than do any animal organisms possessed of as great a complexity of external form. As in all *Metazoa* or *Enterozoa*, the life cycle of a hydrozoon starts with an egg which is at first a single cell or unit of protoplasm, but proceeds after fertilization to multiply by transverse fission in such a way that the resulting cells or units are arranged in two layers, each one cell deep, disposed around a central cavity—the enteron or archenteron. The sac thus formed is known as a diblastula (figs. 1, 2, and 25). By the formation[1] of a mouth to the sac, the enteron acquires the functions of a digestive retort in which food matters taken in at the mouth are brought into a chemical condition suitable for the nutrition of the surrounding cells. The two layers of cells (of which the outer only acquires additional layers[2] by the division of the primary cells, and that by no means in all cases) received from Allman (*Phil. Trans.*, 1855) the names respectively of the ectoderm and the endoderm, having previously been shown by Huxley (1849) to be the fundamental membranous constituents of which the most varied parts of the more complex *Hydrozoa*—such as tentacles, swimming bells, and air-bladders—are built up in the adult condition. Huxley also pointed out the identity of these membranes with the two primary layers of the vertebrate embryo. The endoderm and the ectoderm, which present themselves, as is now known, in the diblastula (or gastrula) phase of all *Enterozoa*, remain in *Hydrozoa* (and also in the allied groups of *Cœlentera*) as permanently distinguishable elements of structure. This important disposition is associated with and dependent on the simple character which the archenteron or primitive digestive space retains. Into whatever lobes or processes the sac-like body may be, so to speak, moulded, whether tentacles[3] or broader expansions, into these the cavity of the archenteron is extended in the first instance; and where the actual cavity is obliterated the endodermic cell-layer remains to represent it (Gefässplatte or endoderm-lamella, see figs. 7 and 16).

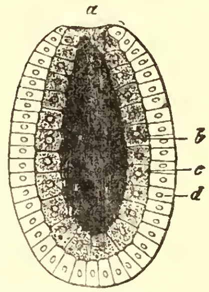

Fig. 1.—Diagram of a Diblastula. *a*, orifice of invagination (blastopore); *b*, archenteric cavity; *c*, endoderm; *d*, ectoderm. (From Gegenbaur's *Elements of Comparative Anatomy*)

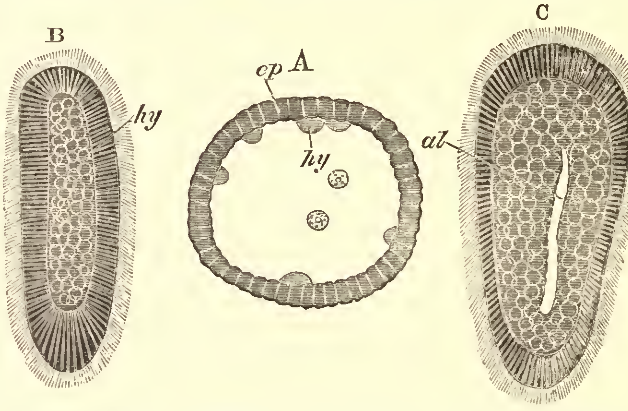

Fig. 2.—Formation of the Diblastula of *Eucope* (one of the Calyptoblastic *Hydromedusæ*) by delamination. (From Balfour, after Kowalewsky.) A, B, C, three successive stages. *ep*, ectoderm; *hy*, endoderm; *al*, enteric cavity.

Conversely, whatever canals or spaces are discovered in the substance of a hydrozoon (excepting only the cavity of ectodermal otocysts) are simple and direct continuations of the one original enteric cavity of the diblastula, and all such spaces are permanently in free communication with one another.[4]

The whole of the *Hydrozoa* seem to present a lower grade of structure than the *Actinozoa*, in so far as the latter, whilst retaining permanently free communication between all parts of the archenteric space, yet exhibit a differentiation of this space into an axial and a periaxial portion—a digestive tube and a body cavity. The differentiation has only to proceed a step further, namely, to the closure or shutting off of the axial from the periaxial portion of the archenteric space, and we obtain the condition which characterizes the adult forms of the *Cœlomata*, or animals

[1] In *Hydromedusæ* the inner layer of cells forms by delamination, in *Scyphomedusæ* by invagination. In the latter case the sac closes up, and the mouth is formed by a new opening.

[2] It is probable that the numerous rows of cells described in the endoderm of *Tubularia* and *Corymorpha* by Allman, in his great monograph of the *Tubularian Hydroids*, are due to a plication of the original endodermal cell-layer. The two kinds of cells in two layers figured by the same authority in the endoderm of *Gemmellaria implexa*, pl. vii. fig. 5, cannot, however, be thus explained.

[3] Some solid tentacles, with a single axial row of endodermal cells, form an exception to this statement.

[4] The observations of Eilhard Schulze cited in the article Cœlentera do not form any real exception to this statement.

with blood-lymph space distinct from digestive canal.[1] With the attainment of the cœlomate condition, the two fundamental cell-layers, ectoderm and endoderm, which still appear in the embryo, become so far interwoven, and their products so highly differentiated, that it is no longer possible to recognize them as anatomical structures in the adult.

The only deep-seated distinction between *Hydrozoa* and *Anthozoa* (the *Actinozoa* being thus termed when the *Ctenophora* are detached from them) appears to be the particular differentiation of the archenteric space in *Anthozoa* which has just been noted. It is no longer possible to separate the two groups from one another as *Exoarii* and *Endoarii*, as was proposed by Rapp (*Ueber die Polypen im Allgemeinen und die Actinien insbesondere*, Weimar, 1829)—the first term indicating the *Hydrozoa* as possessed of external generative organs, whilst by the latter term the *Anthozoa* are pointed to as having internal generative organs.[2] This distinction breaks down completely in the case of *Lucernaria*, and even in that of the so-called phanerocarpous and some other medusæ which discharge their genital products by the mouth, and quite rarely by rupture of the outer body-wall. The tendency to form calcareous deposits in the deep layers of the ectoderm, or mesoderm, as it has been termed, exhibited almost universally by the *Anthozoa* (whence the name *Coralligena* applied to them), is distinctive of them, though it has been shown first by Louis Agassiz, and more fully and recently by Moseley, to be paralleled among *Hydrozoa*, by the *external* calcareous deposits of the abundant and widely distributed Millepores and Stylasterids. A minute distinction between *Hydrozoa* and *Anthozoa*, which does not, however, hold good universally, is found in the form of the barbed threads ejected by the nematocysts. Instead of the complicated forms present in the latter group, the *Hydrozoa* are usually provided with either an unbarbed thread or one in which the barbs are confined to three at the base and a few minute barblets (fig. 5).

Fundamental Forms of the Hydrozoa.—The diblastula derived from the egg of a hydrozoon, when provided with a mouth, may be spoken of (as are the equivalent forms in other animals groups) as a person. Either this person elongates and develops tentacles in a circlet around or near the mouth, and usually becomes fixed by the aboral pole of the sac-like body, or the sac gradually assumes the form of a clapper-bell or of an umbrella with greatly thickened handle, the mouth being placed at the free end of the handle or of the clapper, and the animal freely swimming by the contractions and expansions of the dome of the bell (disc of the umbrella). The two forms of persons are known,—the former as the "hydriform" (2, 3 in fig. 16), the latter as the "medusiform" (4, 5, 6 in fig. 16).

The HYDRIFORM PERSONS usually occur as fixed branching colonies or trees (figs. 36 and 37) produced by lateral budding from an original hydra-form developed from a diblastula.

The hydriform person in its most fully developed state is seen in the colonies of *Tubularia*. In such a colony a number of hydriform persons are united like the flowers of a plant on its branches (whence Allman's terms hydranth, hydrophyton). Each hydriform person (fig. 35) has an elongated *body* with oral and aboral pole. The mouth is placed centrally at the oral pole, which is somewhat enlarged and conical. At the apex of the cone, immediately around the mouth, is a circlet of *small tentacles*; at the base of the cone is a second circlet of *larger tentacles*; the surface of the oral cone is termed the *hypostome*. In other genera (*e.g.*, *Hydra*, fig. 42) the smaller circle of tentacles is wanting; in others, again, the tentacles are irregularly placed and not concentrated into one circlet (fig. 38). We regard the former as the typical condition. In the hydriform persons of the *Scyphomedusæ* (figs. 26 and 27) the vertical axis is much shortened, the hypostome is flat, and the whole body cup-like or hemispherical.

The tentacles of the hydriform person are sometimes hollow (*Hydra*, *Garveia nutans*, *Hydrocorallinæ*), being mere prolongations of the sac-like body; but usually, though the endodermal cell-layer is continued into them, they are solid (2 in fig. 16). Very generally the tentacles of the hydra-form are indefinite in number, but in those belonging to the group of *Scyphomedusæ* a primary series indicating four radii (perradial) can be distinguished, to which are added four intermediate to these, marking four secondary radii (interradial), whilst eight more placed between the eight of the perradial and interradial series are known as adradial tentacles. The surface of the hydraform may be entirely naked, or encased in a horny tube (perisarc) formed by the ectoderm: this may be confined to the aboral portion of the hydranth and to the common stem which unites the persons of a colony, or it may rise up and form a cup (or hydrotheca) around the oral region of the hydranth (figs. 32 and 33).

The bodies of all hydriform persons, as well as the tentacles, are excessively contractile, and when hydrothecæ are present can be withdrawn into them.

The ectoderm or outer cell-layer furnishes the protective and contractile tissues of the hydra-form. Very usually it is not more than one or two cells deep, and is separated from the endoderm by a structureless lamella of firm consistence. In *Hydra* large cells of the ectoderm (neuro-muscular cells of Kleinenberg) bound the external surface (fig. 3) and give off horizontal muscular processes which lie side by side on the structureless lamella—forming thus a deep muscular coat, the fibrous elements of which are not independent cells. In larger species some of the fibres may become separated from the tegumentary or superficial cells, and acquire the character of independent nucleated corpuscles (*Hydractinia*, Van Beneden). No nervous elements nor sense-organs occur in any hydra-form (except perhaps the *Lucernariæ*). In *Antennularia* some ectoderm cells are amœbiform, and project processes which change shape (nematophors). Tactile hairs (palpocils),

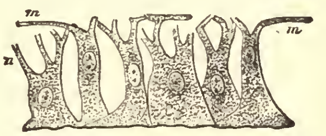

FIG. 3.—Epidermo-muscular cells of *Hydra*. *m*, muscular-fibre processes. (After Kleinenberg, from Gegenbaur.)

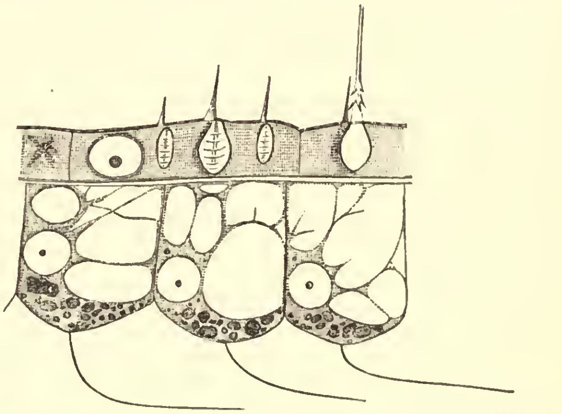

FIG. 4.—Portion of the body-wall of *Hydra*, showing ectoderm cells above, separated by "structureless lamella" from three flagellate endoderm cells below. The latter are vacuolated, and contain each a nucleus and several dark granules. In the middle ectoderm cell are seen a nucleus and three nematocysts, with trigger hairs projecting beyond the cuticle. A large nematocyst, with everted thread, is seen in the right-hand ectodermal cell. (After F. E. Schulze.)

---

[1] The *Enterozoa* or *Metazoa* admit of division into two grades—(1) the *Cœlentera*, including sponges, polyps, jelly-fish, and corals, and (2) the *Cœlomata*, including all remaining forms.

[2] See, however, note to the paragraph headed *Definition of the Hydrozoa*, p. 555.

however, occur on the ectodermal cells, and the solid tentacles are essentially tactile organs. Placed in and between the large cells of the ectoderm (*Hydra*, *Cordylophora*, Allman, Kleinenberg, F. E. Schulze) are small nucleated cells which become converted into vesicles containing a three-barbed (figs. 4 and 5) or simple filament (nematocysts). These are frequently grouped on the surface in wart-like processes or "batteries." Nematocysts also are found in the endoderm; but it is probable that their presence there is due to their having been swallowed.

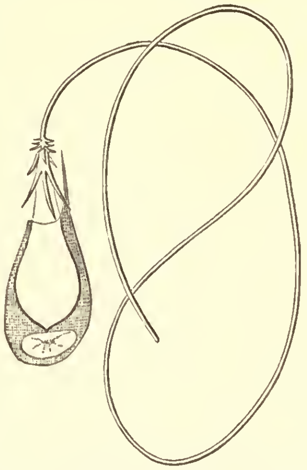

Fig. 5.—Nematocyst of *Hydra*, showing cell-substance and nucleus, cyst, trigger hair, and everted thread. (After F. E. Schulze.)

The endoderm is usually but one cell deep, and lines the entire cavity of the body starting from the margin of the mouth. In the region of the body proper, and in hollow tentacles, the cells are ciliated (fig. 4). In this region they are concerned in the secretion of digestive fluids and in absorption, and sometimes contain coloured granules (hepatic?). Allman found in *Myriothela* (*Phil. Trans.*, 1875) that the endoderm cells project processes like the pseudopodia of *Protozoa*, and suggests that solid food particles are incepted by them. T. J. Parker has published similar observation on *Hydra* (1880). In the solid tentacles the endodermal cells are greatly modified, forming a kind of skeletal tissue, each cell recalling by its vacuolation and firm cell-wall the characters of vegetable parenchyma (fig. 6). In the stems of *Siphonophora* endoderm cells give origin to muscular processes like those of the ectoderm (Claus). This latter fact has a morphological significance which cannot be too gravely estimated.

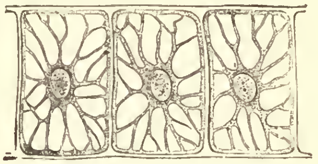

Fig. 6.—Vacuolated endoderm cells of cartilaginous consistence from the axis of the tentacle of a Medusa (*Cunina*). (From Gegenbaur's *Elements of Comparative Anatomy*.)

Generative products are not developed by any hydriform persons (excepting the *Lucernariæ*), the sexual process being carried on by a distinct set of buds developed on the sides of hydriform persons. These buds either become medusiform persons, or are degenerated representatives of such persons (sporosacs) (figs. 17 and 18). Even the fresh-water *Hydra* (fig. 42) does not appear to be an exception to this generalization. The single egg cell of *Hydra* projects at the breeding season in an ectodermal covering, as a wart, from the lower part of the body. A conical eminence or two nearer the mouth contains the spermatozoa. Each ovarium and each spermarium represents an aborted generative person. According to Kleinenberg the egg-cell and the sperm-cells are both derived from the ectoderm. The *Lucernariæ* develop internal generative organs (fig. 19) which correspond closely with those of the medusiform persons of the group *Scyphomedusæ* (see below), with which they are classified. Both ova and testis are endodermal in origin in *Lucernaria* and in the medusiform persons of the *Scyphomedusæ*, whilst they appear to be ectodermal in origin in the complete medusiform persons of *Hydromedusæ*, though in the degenerate medusiform persons known as sporosacs they may either or both have an endodermal origin.

Medusiform persons usually present themselves as isolated free-swimming individuals, but like hydriform persons they have the power of producing new persons by budding (figs. 44, 45, and 46), which may become detached or may remain connected with the primary person (fig. 57) to form a freely swimming colony (*Siphonophora*) comparable to the fixed colonies of hydriform persons. Medusiform persons are often produced as the immediate result of the development of the diblastula without any intermediate hydriform phase (*Pelagia* among *Scyphomedusæ*, *Trachomedusæ*, *Narcomedusæ*, and probably some *Anthomedusæ* and *Leptomedusæ*), but quite as frequently originate as lateral *buds* upon the body-walls of hydriform persons (figs. 34, 37, and 43), or of other medusiform persons (see below), or as metameric fission-products of hydra-forms. The typical medusa-form is a hemispherical cup (the *nectocalyx*, or *umbrella*, or *disc*), from the centre of which rises up a cylindrical or conical process (the *manubrium*, erroneously *polypite*) at the summit of which is the mouth (4, 5 in fig. 16). Four perradial (see above for use of this term) tentacle-like lobes very commonly surround the mouth, or numerous small tentacles (fig. 58), whilst the margin of the disc is beset with tentacles four in number, or a multiple of four (sometimes six, or one only, or indefinite). The aboral pole is dome-like, and is never attached except in those forms which take their origin as buds on a hydriform colony when the connexion exists at this point. The tentacles are, as in the hydriform persons, some solid, some hollow; both occur in the same individual.

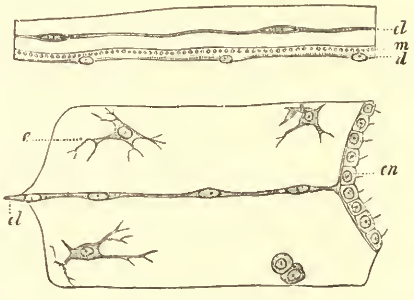

Fig. 7.—Portions of sections through the disc of medusæ,—the upper one of *Lizzia*, the lower of *Aurelia*. *el*, endoderm lamella, or vascular lamella; *m*, muscular processes of the ectoderm cells in cross section; *d*, ectoderm; *en*, endoderm lining the enteric cavity; *e*, wandering endoderm cells of the gelatinous substance. (After Hertwig.)

The body is not so completely hollowed out as in the hydriform persons. The mouth leads into a straight tube (the stomach) which occupies the axis of the manubrium, and expands at its insertion into the disc. The disc, even when thick and fleshy, is not fully excavated by the enteric cavity. In young forms the cavity does occupy it right up to the margin, but gradually the lumen disappears (fig. 29), leaving a series of canals and a continuous plate of endoderm (fig. 7) formed by the coalesced walls of the space (the endoderm-lamella of the Hertwigs, see *Organismus der Medusen*, 1878; the vascular-lamella of Claus, "Polypen und Quallen der Adria," *Wiener Denksch.*, 1878). The peripheral portion of the lumen of the original enteric cavity forms the ring-canal, which runs all round the margin of the disc, and is continued into the hollow tentacles. The lumen is further retained at intervals in the form of radiating canals connecting the axial enteric cavity with the ring-canal. These may be perradial, interradial, and adradial (see above as to tentacles of hydra-form), and may branch dichotomously in the disc or form networks.

The medusæ are thicker and more fleshy to the touch than are the hydra-forms, and are at the same time transparent. This is entirely due to the enormous development of a structureless substance between ectoderm and endoderm, corresponding to the "Stutz-lamella" or structureless lamella of the hydra-forms. (See figs. 49 and 51, representing sections of *Carmarina* and of *Cunina*.)

The remarkable development of this substance in a hyaline condition has led to the description of canals and spaces where none exist—the supposed spaces being really occupied by this hyaline substance. F. E. Schulze's statements as to extra-enteric spaces in *Sarsia* are thus explained—and more decidedly the supposed circular and longitudinal canals attributed by some authors to the scyphistoma phase of *Discomedusæ*. In the same manner (according to Claus) Allman's observations on *Stephanoscyphus* are reconciled with those of F. E. Schulze on *Spongicola*—clearly the same form. *Stephanoscyphus* is devoid of either circular or longitudinal canals, and though it has four remarkable ridges on the enteric wall like those of the scyphistoma of *Scyphomedusæ* (see fig. 26) stands in all probability very close indeed to the Tubularian genus, *Perigonimus*.

In a large number of medusa-forms the hyaline gelatinous substance is structureless, but in many of the larger *Scyphomedusæ* it is occupied by in-wandering amœboid cells derived from the endoderm and by fibrous trabeculæ (fig. 8).

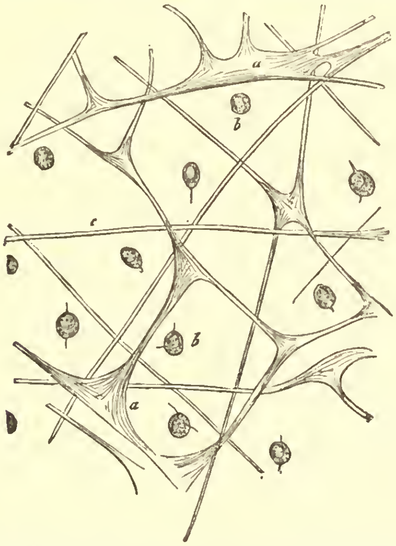

FIG. 8.—Gelatinous substance of the disc of *Aurelia*, showing—*a*, fibrous trabeculæ, and *b*, wandering endoderm cells, with amœboid movements. (From Gegenbaur.)

The wandering endodermal cells are nutrient in function, and represent so far isolated elements of the enteric canal system.

The medusiform person is fundamentally adapted to swimming movements. The muscular fibres are mostly transversely striated, and are as a rule outgrowths of superficial ectoderm cells as in *Hydra* (fig. 9), (though in some cases distinct cells); they are confined to a sheet spread on the oral face only of the disc or swimming-bell (sometimes called sub-umbrella), to the extensile manubrium and tentacles, and to an inwardly directed flap of the margin of the disc known as the *velum* (*Ve* in 4 of fig. 16), which is present in those medusæ that are not flattened but conical (bell-like). The muscular fibres on the oral face of the disc and on the velum have a circular direction, interrupted in some cases by radial tracts. The direction of the swimming movements is obvious from this arrangement.

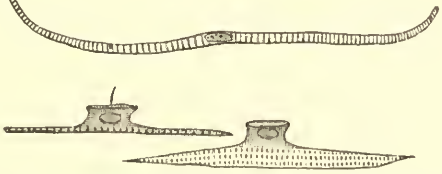

FIG. 9.—Muscular cells of medusæ (*Lizzia*). The uppermost is a purely muscular cell from the sub-umbrella; the two lower are epidermo-muscular cells from the base of a tentacle; the upstanding nucleated portion forms part of the epidermal mosaic on the free surface of the body. (After Hertwig.)

The velum is not a constant element in the medusa's disc; it serves to contract the space by which water is expelled from beneath the bell in the act of swimming. All fully-developed *Hydromedusæ* possess the velum, but only a few of the *Scyphomedusæ* (*Charybdæa*). In the former the endoderm plate (vascular lamella) is not continued into it; in the latter vessels of the enteric system are present in it (fig. 21), and, being probably morphologically distinct, it has been here termed the "pseudo-velum."

Unlike the hydra-forms, the medusa-forms of *Hydrozoa* possess in addition to the tentacles highly-developed sense-organs and ganglionic nerve-centres and nerves. The sense-organs appear to be either eye-spots, or else otocysts, or to combine the functions of both. In addition to these are olfactory tracts or pits connected with the preceding. The sense-organs are placed along the margin of the disc (hence called marginal bodies), and are of three kinds:—(1) ocelli—rounded pigment spots, rarely provided with a lens (*Lizzia*) (fig. 10), always placed at the base of a tentacle or in the radius of one on the oral surface (*Lizzia*), entirely ectodermal in origin; (2) vesiculi or otocysts—formed (as discovered by the Hertwigs, 1878) by an invagination of the ectoderm (fig. 11) containing concretions and hair cells; either open or entirely closed, generally numerous, and placed *between* tentacles, sometimes at the bases of tentacles (*Obelia*); (3) tentaculocysts—which are reduced and modified tentacles; into them alone of the three kinds of marginal bodies do the endoderm and, in the more complex, the enteric canal system enter (figs. 12, 13, and 30). The endodermal sac forms the axis of the tentaculocyst, its cells secrete crystalline concretions, and it functions as an otocyst; pigment spots, which may have cornea, lens, and retina well developed, are formed sometimes to the number of six (*Charybdæa*) on the ectoderm of the tentaculocyst (fig. 13). The olfactory sense-epithelium (fig. 14) is either distributed in a continuous band on the margin of the disc (*Hydromedusæ*, discovered here by the Hertwigs), or it is

confined to deep pits (foveæ nervosæ) from each of which a tentaculocyst arises (discovered in the *Scyphomedusæ* independently by Schäfer and Claus). With some exceptions, medusæ provided with ocelli are destitute of vesiculi, which alone occur in the vesiculate *Leptomedusæ*. Tentaculocysts

characterize to the exclusion of the ocelli and vesiculi the *Trachomedusæ* and *Narcomedusæ* among *Hydromedusæ* and all the *Scyphomedusæ*, except *Lucernaria*, where they are replaced by "colleto-cystophors."

The nervous system has only recently been correctly recognized in medusæ, though seen by Agassiz as long ago as 1849, and described both by Fritz Müller and Haeckel in certain forms (*Geryonidæ*) more recently (1860). It differs remarkably in the two great groups into which the *Hydrozoa* are divisible. In the *Scyphomedusæ* there is no continuous nerve-centre, but around and about each tentaculocyst nerve-fibres and cells are grouped in such a way as to divide the disc into zones of nerve supply corresponding to the number of tentaculocysts (usually eight).

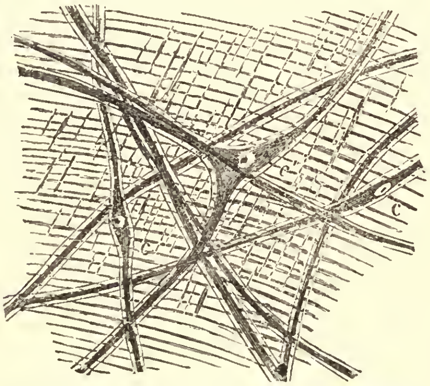

Fig. 15.—Scattered nerve ganglion cells, *c*, from the sub-umbrella of *Aurelia aurita*. (After Schäfer.)

Both the Hertwigs (*Nerven-System der Medusen*, 1878) and Eimer (*Die Medusen*, 1879) entirely missed in their researches the large nerve-fibres and prominent ganglion cells (fig. 15) which were discovered by Professor Schäfer of University College, London (*Phil. Trans.*, 1879), in the *Scyphomedusæ*. The writer can confirm Schäfer's observation of the existence of such fibres and ganglion cells in the region of the circular muscular zone on the oral face of the disc of *Aurelia*, immediately beneath the flattened epithelium of the ectoderm. Professor Claus of Vienna has independently described ("Polypen und Quallen der Adria," 1878) similar nerve-cells and fibres in *Chrysaora* and *Charybdæa*. Professor Schäfer failed to ascertain satisfactorily the origin and termination of the fibres, which appear, however, to originate in superficial ectodermal cells ("sense-epithelium") in the neighbourhood of the tentaculocysts and in the cells of those organs, and to terminate without any plexiform connexion with one another in the muscular fibres. Eimer has described very abundant and excessively fine fibres, often moniliform, which extend from epithelial cells in the neighbourhood of tentaculocysts and form a network traversing the gelatinous substance of the disc in every direction. This observation, though supported by the fact that such fibres are indicated by the extended experimental investigation of Eimer and of Romanes (Eimer, *Die Medusen*; Romanes, *Phil. Trans.*, 1876, *et seq.*), is not confirmed by other observers, and the fibres described are regarded as skeletal tissue. If Eimer's fibres do not exist, the muscular tissue of the medusæ must be regarded as acting to a large extent independently of nerve-control; and this is borne out by Claus's observation of the absence of sense-organs and nerve-fibres from the swimming-bells of the *Siphonophora* (compound medusæ). In the *Hydromedusæ* the nerve ganglion cells are grouped in a continuous ring around the margin of the disc, separated horizontally into an inferior and superior portion by the insertion of the velum. The difference in the form of the nervous system has led Eimer to propose the names *Cycloneura* for the *Hydromedusæ* and *Toponeura* for the *Scyphomedusæ*. Amongst the latter, however, *Charybdæa*, having a continuous velum like *Hydromedusæ*, has also a continuous nerve-ring.

Comparison and Relations of Hydriform and Medusiform Persons.—A simple shortening of the vertical axis, and a widening of the hypostome, with obliteration of the lumen (but not of the cells) of the endoderm over a considerable region of the disc thus produced, suffice to convert the hydraform into the medusa-form.[1] This change of proportion made (fig. 16), the sense-organs of the medusiform person have to be added, and the change is complete. Thus it becomes clear that we have to deal with one fundamental form, appearing in a lower, fixed, nutritive phase and a higher, locomotor, generative phase in the two cases respectively.

The phylogeny of the *Hydrozoa* and the historical relationship of the two phases (hydriform and medusiform) appears to be as follows.

A two-cell-layered sac-like form, with mouth and with or without tentacles, was the common ancestor of *Hydrozoa*, *Anthozoa*, and Sponges. The particular form which the proximate ancestor of the *Hydrozoa* took (1 in fig. 16) is most nearly exhibited at the present day in *Lucernaria* and in the scyphistoma larva (hydra-tuba) of *Discomedusæ*. It was a hemispherical cup-like polyp with tentacles in multiples of four, with four lobes to the wide enteric chamber. This polyp, after passing a portion of its life fixed by the aboral pole, loosened itself and swam freely by the contractions of the circular muscular fibres of its hypostome (sub-umbrella), and developed its ovaria and spermaria on the inner walls of the enteric chamber. This ancestor possessed, like its descendants, a very marked power of multiplication, either by buds or by detached fragments of its body. Accordingly it acquired definitely the character of multiplying by bud-formation during the earlier period of its life; each of the buds so formed completed in the course of time its growth into a free swimming person. We must suppose that the peculiarities of the two phases of development became more and more distinctly developed, the earlier budding phase exhibiting a more elongated form and simple enteric cavity (hydra-form), which subsequently

[1] This relationship, demonstrated by the Hertwigs' discovery of the endoderm layer of the medusa's disc, differs from that supposed to obtain by Professor Allman. He supposed the medusa's disc to represent the coalesced tentacles of a hydra-form, and cited the webbed tentacles of *Laomedea flexuosa* in support of the identification, which had at the time very much to commend it.

became changed in the course of the ontogeny (development of the individual) into the umbrella or disc-like form, with coalesced enteric walls and radial and circular surviving spaces (medusa-form). And now the ancestry took two distinct lines, which have given rise respectively to the two great groups into which the *Hydrozoa* are divisible—the *Scyphomedusæ* and the *Hydromedusæ*. In the one set the hydriform persons of a colony, instead of each becoming metamorphosed into a medusiform person, proceeded each to break up into a series of transverse divisions; each division became a medusiform person, and was liberated in its turn as a free swimming organism (figs. 26 and 27). We must suppose that this process began historically by the outgrowth of new tentacles around the point where the disc of a person fully transformed from the

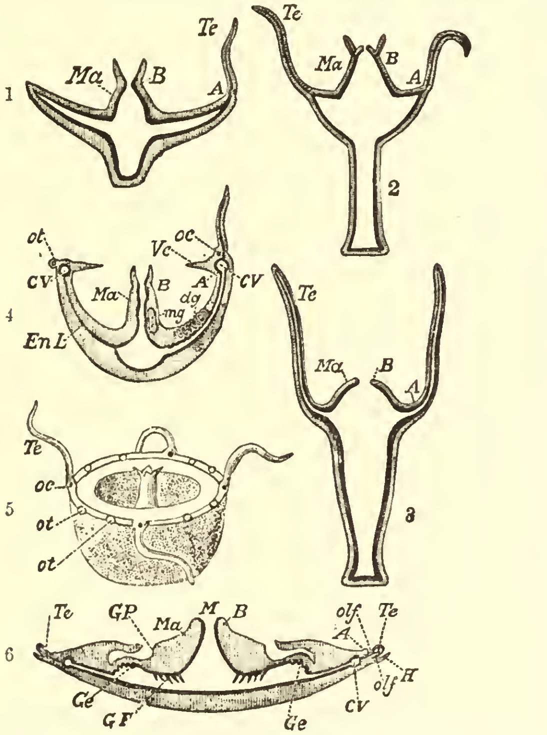

FIG. 16.—Diagrams to exhibit the plan of structure of hydriform and medusiform persons (all except 5 are vertical sections). *A*, base of tentacles, margin of the disc; *B*, oral margin; *Ma*, manubrium; *Te*, tentacle; *CV*, circular vessel; *EnL*, endoderm lamella; *ot*, otocyst; *oc*, ocellus *olf*, olfactory pit; *H*, hood of tentaculocyst; *mg*, genitalia developing in manubrium; *dg*, genitalia developing in the disc (wall of a radiating canal); *GP*, sub-genital pits of the sub-umbrella; *GF*, gastral filaments; *Ve*, velum. 1, Form intermediate between medusa-form and hydra-form. 2, Hydra-form with wide disc, manubrium, and solid tentacles (*Tubularian*). 3, Hydra-form with narrower disc, and hollow tentacles (*Hydra*). 4, Medusa-form with endoderm lamella on the left, the section passing through a radiating canal on the right; a velum, two possible positions of the genitalia, and two kinds of sense-organs are shown (*Hydromedusæ*). 5, A similar medusa-form seen from the surface. 6, Section of *Aurelia aurita*, to show especially the nature of the sub-genital pits, *GP*, outside the genital frills, and the position of the gastral filaments *GF*, as well as the flattened form of the disc.

hydriform to the medusiform phase was loosened in its attachment and about to separate from the colony. The "hastening of events," a well-known feature of organic growth-sequences, would complete the development of the newly sprouting person before the loosened medusa had got well away, and so on with a third, fourth, and even with twenty such successive buds. The separation of the adult form from its fixed larva by fission has been justly compared by Louis Agassiz to the separation of the *Comatula* from its pentacrinoid larval stalk. If the stalk could only produce new *Comatulæ*, the analogy would be complete. *Lucernaria* is in the same way comparable with the stalked crinoids, being an adult form which retains the characters exhibited by the immature phases of its congeners.

The *Scyphomedusæ* do not, however, all exhibit a hydriform phase, and a production of medusæ by the "strobilation" or "metamerizing" of a scyphistoma. Some of them (*Pelagia*) "hasten events" so far that the diblastula never fixes itself, but becomes at once a single medusa, the hydriform phase of the ontogeny being altogether omitted. Certain peculiarities of the medusa's structure, above all the possession of gastral filaments (solid filaments like tentacles projecting in four interradial groups near the genitalia into the enteric cavity), serve to unite *Pelagia*, which has no larval stage, and *Lucernaria* (which is always of intermediate character between hydra-form and medusa-form) with the numerous species which develop by the strobilation of hydriform larvæ.

The second line of descent which has given rise to those *Hydrozoa* known as *Hydromedusæ* not only acquired at the start a different mode of producing medusiform persons, but the medusiform persons acquired characters differing from those of the *Scyphomedusæ* in important (but not fundamental) features. The larval stage in this series developed the property of budding to a very great degree, so as often to form fixed tree-like colonies of considerable size. Then the transformation of the identical colony-forming persons into free-swimming persons was finally and definitively abandoned, and only a late-appearing set of buds proceeded to complete the typical changes and to become medusæ. The earlier-produced buds were thus arrested in development, and became specially modified for the purposes of a fixed life as members of a colony. Thus they acquired the elongate form and the sporadic position of the tentacles which we see in some hydriform persons of the *Hydromedusæ* group (figs. 38 and 40), and were adapted to nutrition solely (hence the term trophosome applied by Allman to such colonies). The characters of the mature generative person, with its power of detachment and free locomotion, being confined to the later buds borne on the sides of the hydriform persons or on special portions of the colony, we find that the former became more and more specialized as *sexual* medusiform persons in proportion as the latter became specialized as *asexual* hydriform persons, and thus it is that we have the remarkable phenomenon of hydriform colonies, developed from the eggs of medusæ, producing as it were crops of medusæ (figs. 34 and 37) which detach themselves and swim away to deposit their eggs (alternation of generations). The *Hydromedusæ* never produce medusæ by strobilation or transverse division of a hydriform person, although in rare cases the cicatrix left by a detached medusa-bud has been observed to sprout and produce a hydriform person. Neither medusiform nor hydriform persons of the *Hydromedusæ* series ever have gastral filaments (unless they are represented by the "villi" of the *Siphonophora* described by Huxley, *Oceanic Hydrozoa*), whilst the medusa-forms always possess a velum and a comparatively simple set (four, six, or eight) of radiating canals in the disc, the remains of the enteric lumen.

The complete differentiation of hydriform and medusiform persons existing on one and the same colony having been attained in the *Hydromedusæ*, further changes of a most remarkable character were brought about in some of the descendants of these forms. The condition which we have so far noted is perpetuated at the present day in *Bougainvillia* (*Eudendrium*), *Campanularia*, and a vast number of the so-called hydroid polyps; others have undergone further adaptational changes. We have to notice at least four important additional modifications independent of one another.

(1.) The hydriform stage was suppressed altogether, and, as in some *Scyphomedusæ*, so here too the diblastula developed directly into a medusa (*Trachomedusæ*, *Narcomedusæ*, and probably some *Leptomedusæ* like *Thaumantias* and *Æquorea*, and some *Anthomedusæ* like *Oceania* and *Turritopsis*).

(2.) The medusiform persons being early produced did not separate themselves from the colony, but the whole colony became free (if it ever were fixed), the medusiform persons carrying the hydriform persons away with them. Thus the highly differentiated swimming and floating colonies of the *Siphonophora* originated.

(3.) The medusiform persons ceased to detach themselves from the fixed hydriform persons or colonies, and developed the ova and sperm within themselves, whilst still small in size and attached to the hydriform stock. Having once abandoned the detached, free-swimming life, the medusæ underwent in different genera a varying amount of degeneration and atrophy, of which we have in existence all

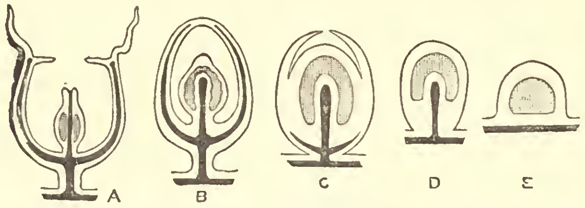

FIG. 17.—Diagrams illustrating the gradual degeneration of the medusa bud into the form of a sporosac. The black represents the enteric cavity and its continuations; the lighter shading represents the genital products (ova or sperm). A, medusiform person still attached by a stalk at the aboral pole to a colony (phanerocodonic gonophor of Allman); B, modified medusiform person, with margin of the disc (umbrella) united above and imperforate (mouthless) manubrium (adelocodonic gonophor of Allman); C, sporosac, with incomplete extension of the enteric cavity into the umbrella,—rudimentary invagination above to form the sub-umbrella cavity; D, sporosac with manubrial portion only of the enteric cavity; E, sporosac without any trace of manubrium.

possible degrees, leading from the fixed "phanerocodonic gonophors" (Allman, bell-like genital buds) of many *Siphonophora* through the "adelocodonic gonophors" (genital buds with the bell no longer open but closed by the union of the margins of the disc) of *Cordylophora* to the sporosacs of *Hydractinia*, and even to the simple genital warts of the little degenerate *Hydra viridis* of fresh waters (see fig. 17, and explanation). By this process a large number of *Hydromedusæ* (figs. 35, 38, 39, 40, and 42) have lost all evidence of the real characters of their medusa-forms, just as others have suppressed the evidence of their hydra-forms by direct development from the egg; and inasmuch as both these processes take place in genera having the closest affinity with genera in which both hydra-form and medusa-form are fully preserved, it is not possible to erect groups similar to the *Haplomorpha* of Carus or the *Monopsea* of Allman for their reception. The difficulty of classification is, however, rendered very great, for a double system becomes necessary, which shall deal with the characters of hydriform and medusiform persons in parallel equivalent series. The difficulty is considerably enhanced when we find that identical medusa-forms may spring from unlike hydra-forms, and, conversely, that closely allied hydra-forms may give rise to very different medusa-forms. The character first noticed by Rapp as distinguishing the hydroid polyps from the coral-polyps, namely, that of developing their genitalia as external bodies (*Exoarii*) instead of internally (*Endoarii*), is seen by the considerations just adduced to be fallacious. The *Hydromedusæ*, it is true, often (not always) develop their generative products from the ectoderm, and the genitalia frequently project as ridges and discharge themselves directly to the exterior in this division. The *Hydromedusæ* contrast in this respect with the *Scyphomedusæ* and *Anthozoa*, which develop their genitalia from the endoderm, and are (to use Rapp's terms) *Endoarii* whilst the former are *Exoarii*. But the bodies mistaken for external generative organs by Rapp and other early observers in many hydroids, and in *Hydra* itself, are aborted degenerate medusæ.

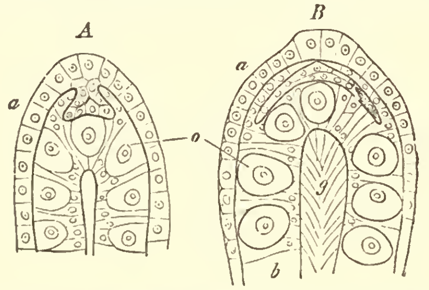

FIG. 18.—Two female sporosacs (degenerate medusæ) of *Hydractinia echinata*. (From Gegenbaur, after Van Beneden.) *a*, ectoderm; *b*, endoderm; *o*, egg-cells; *g*, enteric cavity. In A an invagination of the ectoderm, which is more complete in B, represents the rudiment of the sub-umbrella space.

(4.) A further set of changes, which have affected the original hydriform colonies and their medusa-buds so as to produce new complications of structure among the *Hydromedusæ*, are summed up under the head of "polymorphism." The differentiation of hydriform and medusiform persons is a case of dimorphism; a further distribution of functions, with corresponding modification of form, gives us "polymorphism." Polymorphism is unknown in the *Scyphomedusæ*, and it is chiefly confined to two groups of *Hydromedusæ* (the *Hydrocorallinæ* and the *Siphonophora*). In the hydriform colonies of *Hydractinia* (one of the *Gymnoblastea-Anthomedusæ*) the outer hydriform persons of the colony (fig. 39) differ in form from the rest, and have wart-like tentacles. In the same genus, and also in many *Calyptoblastea*, the hydriform persons which are destined especially to give origin to medusa-buds are devoid of tentacles and mouth, and are known as blastostyles (Allman), (fig. 43). In *Hydrocorallinæ* (fig. 53) elongated hydriform persons (dactylozooids) with no mouth and sporadic tentacles are set in series around a central short mouth-bearing person (gastrozooids) forming the "cyclo-systems" of Mr Moseley (figs. 52 and 55). In the *Siphonophora*, in addition to nutritive (hydriform) persons and generative (medusiform) persons, there may be rows of swimming-bells (medusæ devoid of mouth and of genitalia), covering-pieces (flattened medusæ), and tentacle-bearers (hydriform persons with one long highly-developed tentacle), (see figs. 56 and 57).

Hypothesis of the Individuation of Organs.—The building up of complex individualities, such as a hydrozoon colony, a flowering plant, or a segmented worm or arthropod—in any one of which a number of common units are repeated, but with varied form and function in each part of the compound body—is generally admitted to be explicable in two ways, and which of the two explanations may be adopted in any one case must depend on the ultimate inference from a wide series of observations. The first hypothesis, which undoubtedly applies to the ordinary hydriform colonies of *Hydrozoa*, to the segments of *Tænia*, and to plants formed by the repetition of phyllomes, is that an original unit like those which constitute the composite organism has freely budded, and repeated its own structure in the well-marked units which remain conjoined to form an aborescent or linear aggregate. This is "eumerogenesis," and such aggregates may be termed eumeristic. By a division of labour and consequent modification of form among the units of a eumeristic aggregate, such an aggregate may (in the course of phylogeny) acquire varied shape and definite grouping of its constituent units, and a high specialization as an individual. The high degree of individuation which may be thus attained is due to the more or less complete synthesis of a eumeristic colony. The more highly individuated Chætopods and Arthropods are synthesized linear colonies. The cyclo-systems of the *Hydrocorallinæ* are undoubted examples of synthesized colonies. The second hypothesis is one which is applicable to cases which, in the absence of special evidence to the contrary, might be regarded as highly synthesized colonies. According to this second hypothesis, such highly individuated composite organisms have not (in their phylogeny) passed through a eumeristic phase in which the units were well developed and alike, but the tendency to bud-formation (whether lateral, linear, or radial) has all along acted concurrently with a powerful synthetic tendency, so that new units have from the first made but a gradual and disguised appearance. This is "dysmerogenesis," and such aggregates as exhibit it may be called dysmeristic. In dysmeristic forms the individuality of the primary unit dominates from the first, and the merogenesis (segmentation or bud-formation) can only show itself by partially here and more completely there compelling (as it were) the organs or regions of the body of the primary unit to assume the form of new units. The arms of star-fishes are, when we consider them as derived from the antimera of a Holothurian, explained as examples of dysmerogenesis. So, too, the series of segments constituting a leech, and probably also the segments of a vertebrate. Eumerogenesis and dysmerogenesis are only variations of one process, merogenesis, and no sharp line can be drawn between them. Individuation may appear at *any* period in the phylogeny of a eumeristic aggregate and synthesize its units. On the other hand, individuation is more or less completely dominant *throughout* the history of a dysmeristic aggregate, and is gradually broken down as a more and more complete analysis of the primary unit into new units is effected. It will be observed, however, that in dysmerogenesis, the *form* which individuation tends to preserve is that of the primary unit (notably the case in leeches as compared with the ameristic flukes), whereas when we have eumerogenesis followed by synthesis the resulting form-individuality is something absolutely new. Thus, using the terms eumeromorph and dysmeromorph, we have—(1) synthesized eumeromorph simulates normal dysmeromorph; (2) analysized dysmeromorph simulates normal eumeromorph.

Whether the fixed hydriform colonies of the *Hydrozoa*, with their more or less complete medusiform buds, and further, the floating colonies of *Siphonophora*, with their polymorphous units, are to be regarded as synthesized eumeromorphs or as dysmeromorphs, more or less analysed, is perhaps still open to discussion. The former view (that adopted here) is that held by Allman (*Monograph of the Tubularian Hydroids*, 1874), by Leuckart (1851), by Gegenbaur (*Grundriss*, 1874), by Claus (*Grundzüge der Zoologie*, 1876), and by the Hertwigs (*Organismus der Medusen*, 1878). On the other hand, Huxley (*Oceanic Hydrozoa*, 1856), formerly Gegenbaur (*Zur Lehre der Generations-Wechsel*, 1854), and, more recently, Ed. Van Beneden ("De la distinction originelle du testicule et de l'ovaire," *Bull. Acad. Roy. Belg.*, 1874) have held that the medusiform person is a generative wart which has gradually assumed the characters of a bud, and that the various phases presented by it in different genera are so many more or less successful strivings after complete assumption of the hydra-form (from which the medusa-form is thus secondarily derived). Similarly the variously modified units of the siphonophorous colony have been regarded as the organs of a parent unit which have each more or less completely acquired the form of that parent unit, or, in other words, the colonies in question have been held to be dysmeromorphs. Recently ascertained facts as to the polymorphism of *Hydrocorallinæ*, but more especially the demonstration of the identity of structure of the medusæ of the Scyphomedusan and Hydromedusan groups, and, further, the mode of development of the *Scyphomedusæ* from the scyphistoma and the relations of the generative products to the enteric cavity, combine to render the view that the polymorphous and dimorphous colonies of *Hydrozoa* are synthesized eumeromorphs more probable, in the judgment of the present writer, than that which would explain them as dysmeromorphs.

The term "merogenesis," and its subordinate terms, "eumerogenesis, dysmerogenesis," &c., are applicable to units of the first order, namely, cells, as well as to the "persons" which are built up by them. Ordinary cell-division is an example of eumerogenesis; free-formation of nuclei, as in the fertilized ovum of Arthropods, is dysmerogenesis. A syncytium is usually a synthesized eumeromorph, but may be a dysmeromorph.

Definition of the Hydrozoa.—The *Hydrozoa* are *Cœlentera nematophora*, distinguished from the fellow-group *Anthozoa* (the name applied to *Actinozoa* when the *Ctenophora* are removed from them) by not possessing the latter's constant and sharp differentiation of the arch-enteric cavity into axial digestive and periaxial septate portions, usually by a simpler form of nematocyst, and generally by lower histological differentiation.[1]

The following is a brief summary of the chief characters of the larger divisions of the *Hydrozoa*:—

Sub-class I. SCYPHOMEDUSÆ.—These are *Hydrozoa* which in the adult condition always have four or eight interradial groups of gastral filaments ("phacellæ" of Haeckel) (figs. 16 (6), 23, and 26). The genitalia (ovaria and spermaria) are developed from endoderm, and are always interradial (in the four radii formed after the first four). The hydra-form is not a "hydroid," but a short polyp with broad hypostome—the "scyphistoma," which gives rise to medusa-forms by transverse fission (strobilation), or itself develops genitalia (*Lucernariæ*). Combined visual and auditory organs in the form of modified tentacles (tentaculocysts) to the number of four, eight, or more occur on the edge of the disc (except in *Lucernariæ*, where they are represented by the "colleto-cystophors"). The medusa-form in some cases develops from the egg without the intermediate scyphistoma-stage (*Pelagia*, *Charybdæa*?). The edge of its disc is provided with lappets, which cover the sensorial tentaculocysts (hence *Steganophthalmia* of Forbes), and is not provided with a velum (hence "*Acraspeda*" of Gegenbaur), excepting the rudimentary velum of *Aurelia* (fig. 31) and the well-developed vascular velum (pseudo-velum) of *Charybdæa* (fig. 21). There is no continuous marginal nerve-ring (except in *Charybdæa*), but several separate marginal nerve centres (hence *Toponeura* of Eimer). The

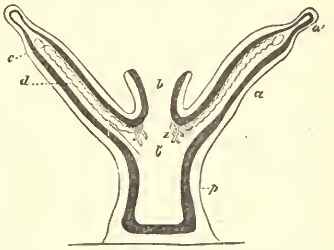

FIG. 19.—Diagrammatic vertical section of a *Lucernaria* in the plane of an interradius. *a*, one of the interradial angles of the disc, giving rise at *a'* to two groups of tentacles adradial in position; *b*, axial enteric cavity; *c*, endoderm; *d*, band-like genital gland (ovary or testis), adradial in position, and attached to the interradial septum which runs along the angular process of the disc, to which the letters *c*, *d* point; *p*, aboral region or "foot"; *z*, the interradial gastral filaments or phacellæ. (After Allman.)

[1] Quite recently the Hertwigs (*Jenaische Zeitschr.*, bd. vi., new series, 1879) have insisted that in the *Hydromedusæ* the genitalia (both ova and testes) are developed from the ectoderm, whilst in the *Scyphomedusæ* and in the *Anthozoa* they develop from the endoderm. On this account they propose to abandon the grouping into *Hydrozoa* and *Anthozoa* of *Cœlentera nematophora*, and suggest two groups, the *Ectocarpeæ* and the *Endocarpeæ*—the former equivalent to *Hydromedusæ*, the latter embracing *Scyphomedusæ* and *Anthozoa*. The *Anthozoa* exhibit a further predominance of the endoderm in its extensive origination in them of muscular fibre, which but rarely and in small quantity develops from endoderm in the *Hydromedusæ* or in the *Scyphomedusæ*. The Hertwigs base their generalization on their own studies of medusæ, but they have ignored the observations of Van Beneden on *Hydractinia* and of Ciamician on various Tubularians, in which the origin of either sperm or ova from endoderm is established. Recently Fraipont has repeated an observation of Van Beneden's on *Campanularia*, and shown conclusively that the ova in that form arise from endoderm. Weismann (*Zoologischer Anzeiger*, May 1880) shows the same for *Plumularidæ* and *Sertularidæ*; the reader is referred to his paper.

diblastula in all cases, as yet observed, is formed by invagination, the blastopore closing up (Balfour).

Fig. 20.

Fig 21.

Fig. 22.

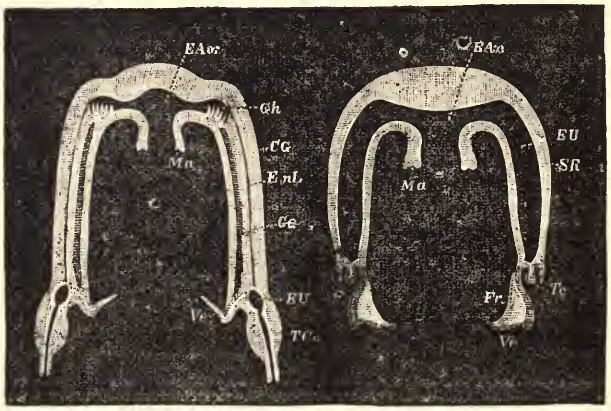

Fig. 23.

Fig. 20.—*Charybdæa marsupialis* (natural size, after Claus). The four annulated tentacles are seen depending from the four lappets placed at the four corners of the quadrangular umbrella. These are interradial. Two of the four perradial enteric pouches of the umbrella, representing radiating canals, are seen of a pale tint. *Fg*, gastral filaments (interradial); *R*, the modified perradial tentacles forming tentaculocysts; *G*, corner ridge facing the observer and dividing adjacent pouches of the umbrella; *GF*, position of one of the genital bands.

Fig. 21.—View of the margin of the umbrella of *Charybdæa marsupialis* (natural size, after Claus). At the four corners are seen the lappets which support the long tentacles, and in the middle of each of the four sides is seen a tentaculocyst. *Vel*, the vascular velum or pseudo-velum, with its branched vessels.

Fig. 22.—Horizontal section through the umbrella and manubrium of *Charybdæa marsupialis* (modified from Claus). *Ma*, manubrium; *SR*, side ridge (perradial); *CR*, corner ridges, separated by *CG*, the interradial corner groove; *Ge*, the genital lamellæ in section, projecting from the interradial angles on each side into *UE*, the enteric pouches of the umbrella; *SU*, the sub-umbrella space.

Fig. 23.—Vertical sections of *Charybdæa marsupialis*, to the left in the plane of an interradius, to the right in the plane of a perradius. *Ma*, manubrium; *EAx*, axial enteron; *Gh*, gastral filaments (*phacellæ*); *CG*, corner groove; *SR*, side ridge; *EnL*, endoderm lamella (line of concrescence of the walls of the enteric cavity of the umbrella, whereby its single chamber is broken up into four pouches); *Ge*, line of attachment of a genital band; *EU*, enteric pouch of the umbrella, in the left-hand figure, points to the cavity uniting neighbouring pouches near the margin of the umbrella and giving origin to *TCa*, the tentacular canal; *Ve*, velum; *Fr*, frenum of the velum; *Tc*, tentaculocyst.

The binary division of the *Hydrozoa* was established by Eschscholtz (*System der Acalephen*, 1829) whose *Discophoræ phanerocarpæ* correspond to the *Scyphomedusæ*, whilst his *Discophoræ cryptocarpæ* represent the *Hydromedusæ*. The terms point to distinctions which are not valid. In 1853 Kölliker used the term *Discophora* for the *Scyphomedusæ* alone, an illegitimate limitation of the term which was followed by Louis Agassiz in 1860. Nicholson has used the term in the reverse sense for a heterogeneous assemblage of those medusæ not classified by Huxley as *Lucernaridæ*, nor as yet recognized as derived from hydroid trophosomes. This use of the term adds to the existing confusion, and renders its abandonment necessary. The term *Discomedusæ* was used for the *Scyphomedusæ* by Haeckel in his *Generelle Morphologie* (excluding *Charybdæa*)—whilst Carus (*Handbuch*, 1867) confines the term "*Medusæ*" to them alone, which is objectionable, since it belongs as justly to the *Hydromedusæ*. Forbes's term for them, *Steganophthalmia*, indicates a true characteristic, failing only in the *Lucernariæ*, but its complementary term *Gymnophthalmia* is inaccurate. Similarly the terms *Acraspeda* and its complement *Craspedota* are inacceptable. Eimer has proposed to use the terms *Toponeura* and *Cycloneura* for the two divisions—but *Charybdæa* appears to break down this division as so many others. The old term *Acalephæ*, which is retained by Gegenbaur in its proper sense for all the *Cœlentera nematophora*, is used as the designation of the *Scyphomedusæ* alone by Claus (*Grundzüge der Zool.*, 1878), which cannot fail to produce confusion. The term *Lucernaridæ*, proposed so long ago as 1856 by Huxley (*Med. Times and Gazette*), most truly indicates the relationships of these organisms which he was the first to recognize, but it seems desirable to restrict this term to the limited order in which *Lucernaria* is placed, and to employ for the larger group—*Scyphomedusæ*—a term which is the true complement of the convenient name assigned to the other division of *Hydrozoa*, viz., *Hydromedusæ*.[1]

Order 1. *Lucernariæ*,—*Scyphomedusæ* devoid of tentaculocysts, with the aboral pole of the body produced into an adhesive disc by which the organism (which possesses the power of swimming by contraction of the circular muscular zone of the hypostome) usually affixes itself. The enteric cavity is divided into four perradial chambers by four delicate interradial[2] septa. The genitalia are developed as four-paired ridges at the sides of the interradial septa on the oral wall of the chambers (fig. 19). No reproduction by fission nor "alternation of generations" is known in the group. At the edges of the disc capitate tentacles are developed in eight adradial[2] groups; between these are modified tentacles in some genera,—the marginal anchors or colleto-cystophors. The canal system which has sometimes been described in them is a product of erroneous observation. A very few genera and species of this order are known. They may be justly called the cœnotype of the medusæ (James Clark), and their relationship to the free swimming forms may be compared, as was done by L. Agassiz, to the relationship of the stalked Crinoids to such forms as *Comatula*. Three species are not uncommon on the British coasts.

By Milne Edwards the animals forming this group were termed *Podactinaria* and associated with the *Anthozoa*. By Leuckart they were termed *Calycozoa*; it is only of late that the closeness of their relationship to the *Scyphomedusæ* has been fully recognized, though long since insisted on by Huxley and by James Clark. Haeckel in his new system of the medusæ (*Sitzungsber. der Jenaische Gesellschaft für Medicin und Naturwiss.*, July 26, 1878) adopts for them the term *Scyphomedusæ* in allusion to their permanently maintaining the distinctive features of the scyphistoma larval form of the *Acraspedæ*, the term which he adopts from Gegenbaur for our *Scyphomedusæ*.

Order 2. *Discomedusæ*.—These are *Scyphomedusæ* developing as sexual medusiform persons by transverse fission from a scyphistoma, or else directly from the egg. They have eight tentaculocysts, four perradial, four interradial, and sometimes accessory ones (adradial). Four or eight genital lobes (ovaria or spermaria or hermaphrodite) are developed from the endoderm forming the oral floor of the central region of the enteric cavity, which is produced into a corresponding number of pouches. The mouth is either a simple opening at the termination of a rudimentary manubrium (sub-order *Cubostomæ*), or it is provided with four or eight arm-like processes (sub-orders *Semostomæ* and *Rhizostomæ*). In the sub-order *Rhizostomæ* (fig. 24, *a*), the

[1] *Scyphomedusæ* (σκύφος, a cup) are medusæ which are related by strobilation to *Scyphistoma*,—a wide-mouthed polyp with four gastral ridges. *Hydromedusæ* are medusæ related to a *Hydra*,—a narrower polyp, devoid of gastral ridges,—by lateral gemmation.

[2] For use of these terms see paragraphs on *Aurelia* below.

edges of the oral opening fuse together at an early age and leave several sucker-like secondary mouths, which were formerly mistaken for independent persons. The central enteric chamber is continued through the disc by a complicated often reticulate system of radiating canals, which excavate the endoderm lamella.

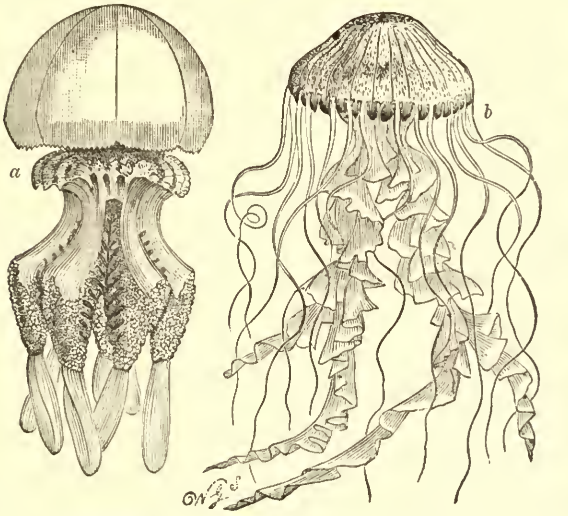

FIG. 24.—*Scyphomedusæ.* a, *Rhizostoma pulmo*; b, *Chrysaora hyosceua*

In the *Semostomæ* and *Rhizostomæ* (not in the *Cubostomæ*) four remarkable (respiratory) sub-genital pits (fig. 28) are hollowed out in the gelatinous substance of the sub-umbrella (oral face of the umbrella). These do not communicate, as

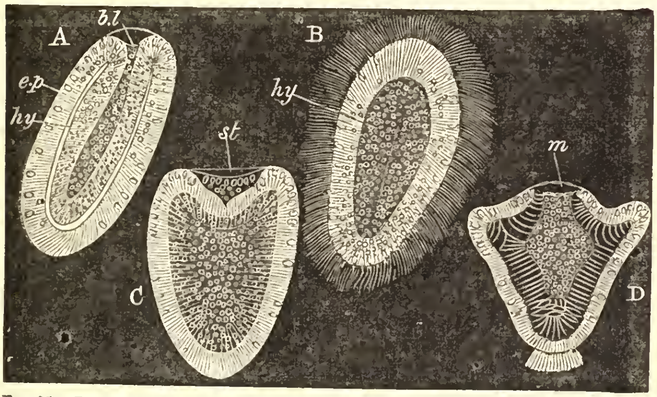

FIG. 25.—Four stages in the development of *Chrysaora*. A, Diblastula stage; B, stage after closure of blastopore; C, fixed larva with commencing stomodæum or oral ingrowth; D, fixed larva with mouth, short tentacles, &c.; *ep*, ectoderm; *hy*, endoderm; *st*, stomodæum; *m*, mouth; *bl*, blastopore. (From Balfour, after Claus.)

has been erroneously supposed, with the genital organs, the products of which normally are evacuated by the mouth. In the Tetragamelian *Rhizostomæ* these pits remain distinct from one another as in *Semostomæ*, but in the Monogamelian *Rhizostomæ* they unite to form one continuous sub-genital cavity placed between the wall of the enteric cavity and the polystomous oral disc. The common English forms, *Aurelia*, *Chrysaora*, and *Cyanæa*, are types of the *Semostomæ*, the somewhat less common *Rhizostoma* of the Monogamelian *Rhizostomæ*, whilst *Nausithoe* and *Discomedusa* represent the simple *Cubostomæ*.

The writer has adopted the term used by Haeckel for this order, and is indebted to his preliminary notices of a large work on the *Medusæ*, now in the press, for outlines of the classification and definitions which have been introduced with modifications in relation to these and the other *Medusæ*. The term *Discophora* is used by Claus (*Grundzüge*) for the *Discomedusæ*. It is quite clear from the varied and inconsistent use by different authors of that term, and also of the terms *Acalephæ* and *Medusæ*, that they must be ejected altogether from use in systematic treatises.

The structure of the common *Aurelia aurita* and its development have recently formed the subject of investigation by Claus, Eimer, and others. As the current accounts

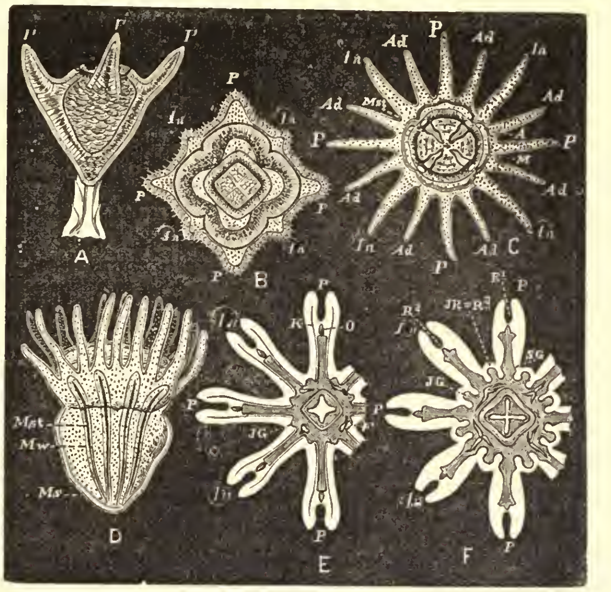

FIG. 26.—Later development of *Chrysaora* and *Aurelia* (after Claus). A, Scyphistoma of *Chrysaora*, with four perradial tentacles and horny basal perisarc. B, Oral surface of later stage of scyphistoma of *Aurelia*, with commencement of four interradial tentacles. The quadrangular mouth is seen in the centre; the outline of the stomach wall, seen by transparency around it, is nipped in four places interradially to form the four gastric ridges. C, Oral surface of a sixteen-tentacled scyphistoma of *Aurelia*. The four gastric interradial ridges are seen through the mouth. D, First constriction of the *Aurelia* scyphistoma to form the pile of ephyræ or young medusæ (see fig. 27). The single ephyra carries the sixteen scyphistoma tentacles, which will atrophy and disappear. The four longitudinal gastric ridges are seen by transparency. E, Young ephyra just liberated, showing the eight bifurcate arms of the disc and the interradial single gastral filaments. F, Ephyra developing into a medusa by the growth of the adradial regions. The gastral filaments have increased to three in each of the four sets. *A*, margin of the mouth; *Ad*, adradial radius; *F*, gastral filament; *In*, interradial radius; *JG*, adradial gastral canal; $JR=R^3$, adradial lobe of the disc; *K*, lappet of a perradial arm; *M*, stomach wall; *Mst*, muscle of the gastral ridge; *Mw*, gastral ridge; *Ms*, mesoderm; *O*, tentaculocyst; *P*, perradial radius; R^2, interradial radius; R^3, adradial radius; *SG*, commencement of lateral vessel.

in text-books are very inadequate, a short sketch of the morphology of that form is appended here.

From the egg, according to the researches of Claus (whose figures, here reproduced, refer more especially to the closely allied genus *Chrysaora*, up to the completion of the scyphistoma), a single-cell-layered blastula develops which forms a diblastula by invagination (fig. 25, A, B, C). The orifice of invagination closes up, and the ciliated "planula" (as this stage used to be termed in all *Cœlentera*), after swimming around for a time, fixes itself, probably by the blastoporal pole. The true mouth then forms by inruption at the opposite pole. Two tentacles now grow out near the mouth opposite to one another (fig. 25, D), and are followed by two more (fig. 26), these indicating the four primary radii of the body which pass through the angles of the four-sided mouth, and are termed *perradial*. Meanwhile the aboral pole narrows and forms a distinct stalk, which in *Chrysaora* secretes a horny perisarc (fig. 25,

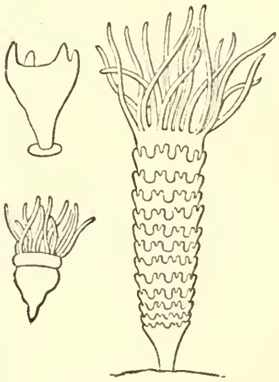

FIG. 27.—Development of *Aurelia*. Above to left, young scyphistoma with four perradial tentacles. Below to left, scyphistoma with sixteen tentacles and first constriction. To the right, strobila condition of the scyphistoma, consisting of thirteen metameric segments; the uppermost still possesses the sixteen tentacles of the scyphistoma; the remainder have no tentacles, but are ephyræ, each with eight bifid arms (processes of the disc). Each segment when detached becomes an ephyra, such as that drawn in fig. 26, E, F. (From Gegenbaur.)

D). Four new tentacles, those of the intermediate or secondary radii, now appear between the first four, and are termed *interradial*. At the same time four longitudinal ridges grow forward on the wall of the enteric cavity (fig. 26). These interradial ridges have sometimes

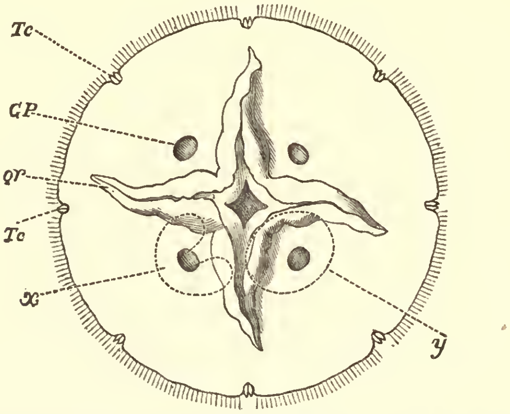

FIG. 28.—Surface view of the sub-umbrella or oral aspect of *Aurelia aurita*, to show the position of the openings of the sub-genital pits, *GP*. In the centre is the mouth, with four perradial arms corresponding to its angles (compare fig. 26). The four sub-genital pits are seen to be interradial. *x* indicates the outline of the roof (aboral limit) of a sub-genital pit; *y*, the outline of its floor or oral limit, in which is the opening (compare 6 of fig. 16).

been erroneously described as containing each a longitudinal canal connected with a circular canal at the base of the tentacles. They are in reality solid, as is the margin of the hypostome from which the tentacles spring. It is in connexion with these four ridges that the gastral filaments will subsequently appear, as also the genital organs either along their middle line or adradially to them. The ridges correspond to the mesenteries of the *Anthozoa*. Eight additional tentacles placed one on each side of the perradial tentacles (or of the interradial, according as we may choose to regard the matter) next appear, and are distinguished as *adradial*. All the tentacles reaching an equal size, we obtain the appearance seen in fig. 26, when the young scyphistoma is looked at from above. Looked at from the side, with its wide hypostome and short vertical axis, the scyphistoma differs widely from an ordinary hydra-form, and approaches the medusa-form, to which its four longitudinal gastral ridges further assimilate it. The little creature is now about an eighth of an inch in height; in other genera, but not in *Chrysaora*, it may now multiply by the production of a few buds from its fixed basal disc. After nourishing itself for a period, and increasing to four or five times the size just noted, the vertical axis elongates and a series of transverse constrictions appear on the surface, marking off the body of the scyphistoma into a series of discs (figs. 26 and 27), each of which by the development

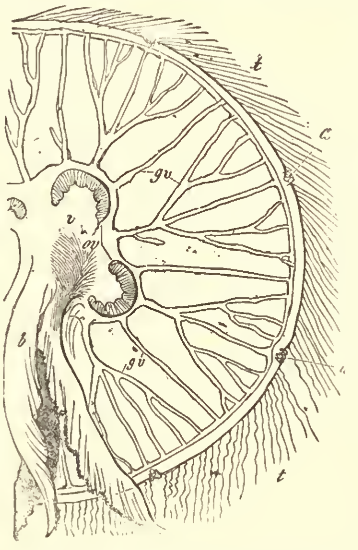

FIG. 29.—Half of the lower surface of *Aurelia aurita*. The transparent tissues allow the enteric cavities and canals to be seen through them. *a*, marginal lappets hiding tentaculocysts; *b*, oral arms; *v*, axial or gastric portion of the enteric cavity; *gv*, radiating and anastomosing canals of the enteric system; *ov*, ovaries. The gastral filaments near to these are not drawn. (From Gegenbaur.)

of tentacles and completion of the constriction will become a separate medusa (in its young state called "ephyra"). The tentacles of the *Aurelia* and the structure of the margin of its hypostome are very different from those of the scyphistoma. They are exhibited in their earliest condition (when the *Aurelia*-medusa is first liberated from its attachment and is an ephyra) in fig. 26, E, F. The margin of the hypostome is drawn out into eight arms (which are not to be confused with tentacles); the end of each arm is bifid, carrying a pair of lappets—the marginal lappets which persist in the adult (see figs. 30 and 31). Between the lappets is placed a short and peculiar tentacle, the tentaculocyst or sense-organ. The eight arms of the disc and their tentaculocysts are perradial and interradial. As the organism grows, a set of eight adradial tentacles appear in the notches between the eight arms, but never attain any relatively large size in *Aurelia*. The asteroid arm-bearing

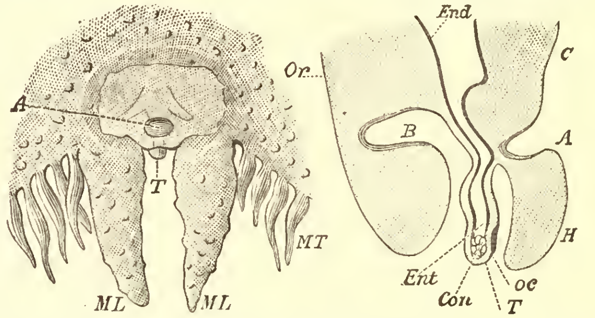

FIG. 30.—Tentaculocyst and marginal lappets of *Aurelia aurita*. In the left-hand figure—*ML*, marginal lappets; *T*, tentaculocyst; *A*, superior or aboral olfactory pit; *MT*, marginal tentacles of the disc. The view is from the aboral surface, magnified about 50 diameters. In the right-hand figure—*A*, superior or aboral olfactory pit; *B*, inferior or adoral olfactory pit; *H*, bridge between the two marginal lappets forming the hood; *T*, tentaculocyst; *End*, endoderm; *Ent*, canal of the enteric system continued into the tentaculocyst; *Con*, endodermal concretion (auditory); *oc*, ectodermal pigment (ocellus). The drawing represents a section, taken in a radial vertical plane so as to pass through the long axis of the tentaculocyst. (After Eimer.)

character of the margin of the disc is soon obliterated by the relative growth of the intermediate adradial areas, which become quite filled up, so that in the adult the tentaculocyst is carried in a notch instead of on a prominence, and is concealed by the two lappets (figs. 28 and 30). The margin of the disc between adjacent pairs of lappets gives rise to a fold which grows inwards (toward the mouth) during an early stage (fig. 31), and numerous small tentacles (the fringe) appear along the margin of the disc, which soon equal in size the first adradial tentacle. The ingrowing fold is the velum or "pseudo-velum," and never increases in size, so that in the adult it is not observable. The tentacles also remain very small and fine in *Aurelia*, forming a continuous fringe along the edge of the disc, interrupted only by the eight notches for the tentaculocysts (fig. 29).

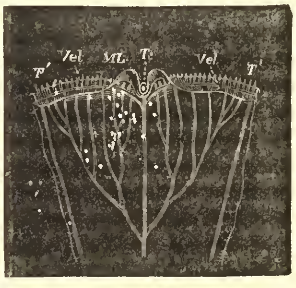

FIG. 31.—Part of the margin of the disc of a young *Aurelia*, to show the rudimentary velum, *Vel*, extending from the marginal lappets, *ML*, on either side; *T'*, the small tentacles fringing the disc.

The sixteen tentacles of the scyphistoma are necessarily attached to the most anterior of the pile of medusæ; they atrophy, but to what extent they may be metamorphosed to form the parts of the ephyra or young medusa has not been determined. The scyphistoma, having given rise to its pile of ephyræ, may (in some genera, *Aurelia*?) redevelop its own kind of tentacles below the constriction marking off the last ephyra. Hence scyphistoma tentacles appear sometimes at the top and sometimes at the bottom of the pile, which has led to diverse accounts of the mode of development of the ephyræ.

Whilst changes are going on in the configuration of the margin of the disc of an ephyra on its way to the perfect form of the adult *Aurelia*, the enteric cavity has also undergone most important changes. Foremost in importance is the development of a single gastral filament on each of the four gastral ridges which necessarily are present in the transverse slice (so to call it) of a scyphistoma, which becomes an ephyra (fig. 26). These rapidly increase in number as the ephyra grows. Further, the enteric cavity at first follows the outline of the ephyra, sending a process into each arm, but then by adhesion of its walls is converted into a four-lobed central chamber, a marginal canal, and an endoderm lamella. A system of canals, the arrangement of which is seen in figs. 29 and 31, subsequently opens out again certain lines and tracts of the conjoined endoderm walls.

In the adult *Aurelia* we find the mouth surrounded by four large arm-like perradial processes (figs. 25 and 29) (not tentacles), and leading through a short manubrium into a flattened four-lobed chamber, the lobes being interradial, and having on their oral floor numerous gastral filaments (rich in thread cells) (6 in fig. 16). Each pouch or lobe gives off a canal, which runs towards the circular canal at the margin of the disc, but breaks up into three or four secondary canals on its way. Between the pouches come off eight other "radiating" canals (adradial), which do not branch, but go straight to the circular canal.

The oral floor of the concavity of each lobe of the enteric cavity is occupied by a horse-shoe-shaped frill (fig. 29, *ov*), either testis or ovary (the sexes being in separate individuals). The open arms of the horse-shoe are turned towards the centre of the disc, and the folds of the genital frill are so deep as to show themselves on the outer ectodermal wall of the disc. Here, however, there is a very remarkable arrangement, which has rarely, if ever, been correctly described and figured in our common *Aurelia*. The gelatinous substance of the disc is hollowed out on that part of the oral face corresponding to the position of the genital frills, so as to form four separate extensive pits or chambers. Each of these sub-genital pits has in *Aurelia* a small round opening on the oral face of the disc (fig. 28, GP), but is otherwise entirely closed, having no communication with the genital tissues, from which it is separated by a delicate layer of ectoderm (6 in fig. 16). The pits probably serve to admit water for respiratory purposes into close proximity with the genital tissues.

The whole enteric surface, including canals, is ciliated, whilst the ectoderm is not ciliated, but provided with groups of nematocysts.

The tentaculocyst in the adult *Aurelia* is relatively an extremely minute body, completely hidden by the two large marginal lappets (fig. 30, T). Above it (that is, on the aboral surface, as the *Aurelia* swims) is a deep pit (A), Schäfer's fovea nervosa superior, sunk in a sort of bridge which connects the two lappets and overhangs the tentaculocyst. A similar pit (the fovea inferior) exists on the oral surface. These have been recognized by Claus, Eimer, and the Hertwigs as olfactory organs. The tentaculocyst is seen in section in fig. 30 (right-hand figure), which exhibits its central cavity continuous with the enteric cavity, its ectodermal pigment spot (eye), and its endodermal mass of concretions (auditory organ).

The chief muscular mass of *Aurelia*, except that of the oral arms, is a circular zone on the oral face of the disc. The muscular fibres are not distinct cells, but transversely-striated processes of the epidermic cells (epidermo-muscular cells) (fig. 9). In the "arms" of other medusæ, and presumably of *Aurelia*, the muscular fibre is formed by independent nucleated cells (fig. 9).

The nerve-epithelium from the olfactory pits of *Aurelia* is drawn in fig. 14. Starting from this and from the cells of the tentaculocysts are nerve-fibres, which spread themselves on the surface of the circular muscular zone in the neighbourhood of the tentaculocysts, and these are connected each and separately with large isolated nerve-ganglion cells (fig. 15). The nerve-fibre is continued beyond the cell, and in some instances has been traced into a broadened expansion lying on a muscular fibre (Schäfer). The nerve-ganglion cells lie very superficially immediately below the flat epithelium of the body surface and between it and its muscular processes.

The ova and spermatozoa of *Aurelia* develop in the genital frills from endoderm cells in separate individuals. They pass to the exterior through the mouth.

Order 3. *Conomedusæ*,—*Scyphomedusæ* with only four tentaculocysts, and these perradial. A broad velum (so-called pseudo-velum) of complete circular form is present, differing from that of the *Hydromedusæ* in the fact that it is penetrated by canals of the enteric system (*Charybdæa*). The whole umbrella is bell-shaped. The genital organs are four pairs of lamelliform ridges (fig. 22) which are attached to the four narrow interradial septa that divide the large enteric cavity of the umbrella into four perradial gastro-canal pouches. The lamelliform genital glands hang freely in these pouches. At the edge of the umbrella are four interradial lappet-like prolongations of the gelatinous substance of the disc, which support each a long tentacle (fig. 20). The nerve-ring is complete, like that of the *Hydromedusæ*.

There is now no doubt that *Charybdæa*, which has been placed in each of the two large divisions of the *Hydrozoa*, must be classed with the *Scyphomedusæ*. The recent investigations of Claus (*Arbeiten aus dem Zool. Institut zu Wien*, Bd. i. Hft. ii., 1878), as well as those of Haeckel and Fritz Müller, lead to this conclusion. The term *Conomedusæ* is adopted from Haeckel, who places here, besides *Charybdæa* and *Tamoya*, other forms, a fuller description of which may be expected in his forthcoming *System der Medusen*. In many respects—its quadrangular form, its marginal lappets, its broad enteric pouches in place of fine canals, its vascular velum, and its highly complicated tentaculocysts (fig. 13, B)—*Charybdæa* is peculiar. The simplicity of the enteric system and the arrangement of the genital glands brings it near to *Lucernaria*. The existence of four interradial groups of gastral filaments, and the disposition of the paired genital glands at the sides of the interradial septa, determine its position to be among the *Scyphomedusæ*. Its development is not known. Figs. 20 to 23 illustrate the structure of *Charybdæa*.

Order 4. *Peromedusæ*,—*Scyphomedusæ* with four interradial tentaculocysts. The enteric system consists of three divisions,—an aboral main stomach with four interradial gastral ridges and filament groups; a mid-stomach, which communicates by means of four perradial slits with a very large ring-sinus (occuping two-thirds of the umbrella); and thirdly, an oral portion or pharynx, with four wide perradial pouches. The genital organs are four pairs of sausage-shaped interradial ridges lying on the oral floor of the ring-sinus.

This is a new group founded by Haeckel, of which we have at present no further details.

Sub-class II. HYDROMEDUSÆ.—These are *Hydrozoa* devoid of gastral filaments; the sexual persons are always medusiform, the genital glands are developed sometimes from ectodermal cells, sometimes from endoderm, and are always perradial (in the radii of the first order). The medusiform persons always possess a muscular non-vascular velum (hence *Craspedota*) and a complete nerve-ring (hence *Cycloneura* of Eimer). The marginal sense-organs are either ocelli or otocysts or tentaculocysts. The diblastula, in all cases as yet observed, is formed by delamination (Balfour). The sexual medusiform persons may develop directly from the egg, but more usually the egg gives rise to a hydriform person—the hydroid—which differs from a scyphistoma in its elongate vertical axis, the indefinite number (often also position) of its tentacles, and its frequent formation of a colony of large size by lateral budding. By lateral budding (not by

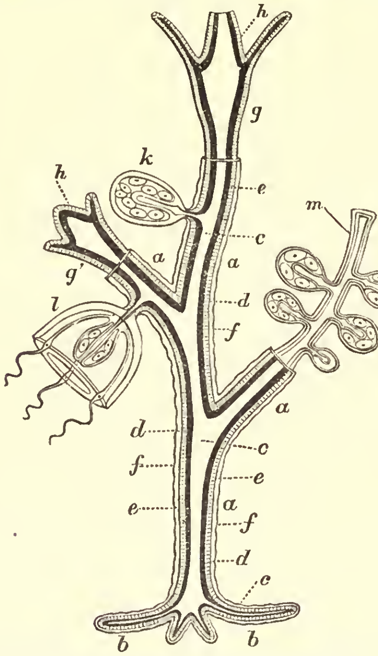

Fig. 32.—Diagram showing possible modifications of persons of a gymnoblastic *Hydromedusa*. *a*, hydrocaulus (stem); *b*, hydrorhiza (root); *c*, enteric cavity; *d*, endoderm; *e*, ectoderm; *f*, perisarc (horny case); *g*, hydranth (hydriform person) expanded; *g′*, hydranth (hydriform person) contracted; *h*, hypostome, bearing mouth at its extremity; *k*, sacciform gonophor (sporosac) springing from the hydrocaulus; *k′*, sporosac springing from *m*, a modified hydriform person (blastostyle): the genitalia are seen surrounding the spadix or manubrium; *l*, medusiform person or medusa; *m*, blastostyle. (After Allman.)

metameric fission) medusiform persons which alone develop sexual glands are produced on the hydriform colonies;

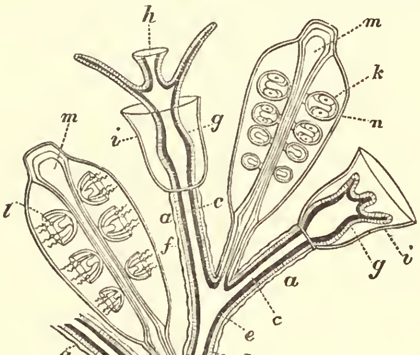

Fig. 33.—Diagram showing possible modifications of the persons of a Calyptoblastic *Hydromedusa*. Letters *a* to *h* same as in fig. 32. *i*, the horny cup or hydrotheca of the hydriform persons; *l*, medusiform person springing from *m*, a modified hydriform person (blastostyle); *n*, the horny case or gonangium enclosing the blastostyle and its buds. This and the hydrotheca *i* give origin to the name *Calyptoblastea*. (After Allman.)

these may separate from the colony, or may be retained in a more or less degenerate form adherent to it, as generative buds or warts.

The medusiform persons of this group are the *Discophoræ cryptocarpæ* of Eschscholtz, the *Craspedota* of Gegenbaur (1854), and the *Hydromedusida* of Kölliker (1853)—the last two authors at that time separating the hydriform persons as *Hydroidea*. Louis Agassiz (1860) includes both sets of persons under the term

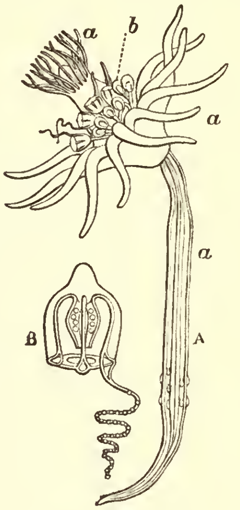

Fig. 34.

Fig. 35.—Diagram of *Tubularia indivisa*. A single hydriform person *a* bearing a stalk carrying numerous degenerate medusiform persons or sporosacs *b*. (After Allman.)

Hydroida (together with *Lucernaria*), which also is the term adopted by Allman in his beautiful monograph (1871–74). J. V. Carus, amending the limitations given by Carl Vogt, was the first to use the term *Hydromedusæ* in the sense here adopted (*Handbuch der Zoologie*, 1863), and it is now employed in the same sense by Gegenbaur (*Elements of Comparative Anatomy*, London, 1878), namely, to embrace both the cryptocarpous medusæ of Eschscholtz and the

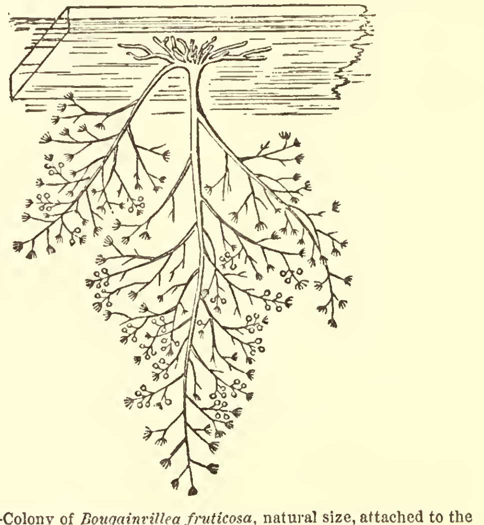

Fig. 36.—Colony of *Bougainvillea fruticosa*, natural size, attached to the underside of a piece of floating timber. (After Allman.)

hydroids related to them. The term *Hydromedusæ* is used unwisely by Claus (*Grundzüge d. Z.*) for the whole group of *Hydrozoa*. It has been the practice of some authors to give a double classification of the group—one based on the characters of the medusiform persons, the other on that of the hydriform persons. In the present article a double name will in some cases be assigned to a group—but the attempt is made to bring both sets of persons under one system.

Order 1. *Gymnoblastea-Anthomedusæ*.—These are *Hydromedusæ* which all, as far as is known, pass through a hydriform phase, but in which the medusiform persons may either reach full development or exhibit the extremest degeneration (*Hydra*). The ectoderm of the hydriform persons may secrete a horny tubular protective case (perisarc), but this does not form cups for the reception of the tentacular crown nor cases enclosing groups of medusiform buds (gonangia). The fully-developed medusiform

FIG. 37.—Portion of colony of *Bougainvillea* (*Endendrium*) *fruticosa* (*Anthomedusæ-calyptoblastea*) more magnified. (From Lubbock, after Allman.)

persons never possess otocysts nor tentaculocysts, but always ocelli at the base of the tentacles. The latter are usually four or six, corresponding to the same number of simple radial enteric canals, but may be more numerous or reduced to one or to two; rarely they are branched (*Cladonema*).

(After Allman.)

FIG. 40.—Diagram of a colony of *Dicoryne*, showing three forms of persons *a*, normal hydriform person; *b*, modified bud-bearing hydriform person (blastostyle); *c*, degenerate medusiform persons (sporosacs). (After Allman.)

The sexual glands are placed in the wall of the manubrium, either equally distributed all round it or in four separate perradial groups, which are often divided into eight adradial groups by the perradial longitudinal muscles.

This is a very well defined group, since the *Gymnoblastea* of Allman, based on the characters of the hydriform persons—also known as *Tubulariæ* and *Gymnotoka*—correspond exactly with the *Anthomedusæ* of Haeckel's new system. *Hydra* is included here, though placed in a separate order by Allman. Some of the leading forms of hydriform and medusiform persons are given in the cuts (figs. 34 to 42). The greatest range in the amount of degeneration of the medusiform persons is seen even in genera of the same family—*e.g.*, *Turris* and *Clava*—the former producing free medusæ, the latter sessile sporosacs. The *Oceanidæ* of Gegenbaur (excluding the *Williadæ*, which Haeckel assigns to the next group) correspond on the whole to the medusa-forms of this order.

FIG. 42.—*Hydra viridis*. *ov*, ovary; *te*, testis.

Order 2. *Calyptoblastea-Leptomedusæ*.—These are *Hydromedusæ* of which the hydriform phase is known in a large number of cases, whilst of others only the medusa-forms are known; none are *known* to develop directly from the egg to the medusa-form. As in the preceding group, the medusiform persons may reach full development or

FIG. 43.—Diagram of a colony of *Campanularia*, showing four forms of persons. A, portion of a fixed colony; *a*, hydriform person; *b*, bud-bearing hydriform person (blastostyle); B, free-swimming colony, being a sexless medusiform person (blastochеme of Allman), with modified medusiform persons budding from its radiating canals, as sporosacs. (After Allman.)

FIG. 44.—Medusiform person (*Lizzia*), one of the *Anthomedusæ*, detached from a hydroid colony of the family *Endendridæ*. Ocelli are seen at the base of the tentacles, and two medusiform buds on the sides of the manubrium. (After Allman.)

exhibit themselves as degenerate sexual sacs on the hydriform colonies. The ectoderm of the hydra-forms always secretes a perisarc which forms a cup-like protection (hydrotheca) to the tentacle-crown, and which also encloses the group of medusa-buds in peculiar horny cases (gonangia). The fully-developed medusiform persons (fig. 47) either have no otocysts, but only ocelli (*Ocellatæ*), or they have otocysts (fig. 11) (ectodermal sacs), four, eight, or over a hundred, not homologous with tentacles, and sometimes in addition ocelli (*Vesiculatæ*). The radial enteric canals are usually four or eight in number, but may be more numerous, whilst the marginal tentacles of the disc are either few or

very numerous. The genital glands always are placed in the course of the radial canals of the disc (not in the manubrium), and stand out as groups of wart-like processes on the sub-umbrellar surface (fig. 43). Their mode of discharge is uncertain.

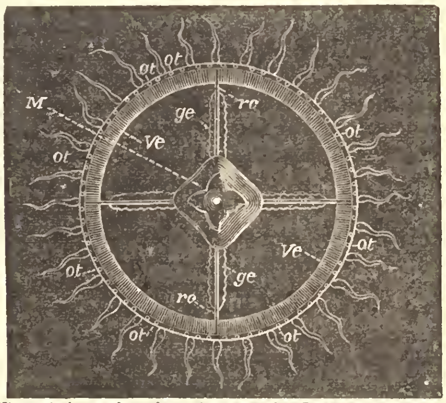

Fig. 47.—View of the oral surface of one of the *Leptomedusæ* (*Irene pellucida*, Haeckel), to show the numerous tentacles and the otocysts. *ge*, genital glands; *M*, manubrium; *ot*, otocysts; *rc*, the four radiating canals; *Ve*, the velum.

The *Calyptoblastea* of Allman, *Skenotoka* of Carus, and *Campanulariæ* of authors form a well-marked group of hydroids which, when they give rise to free medusæ, give rise to those termed *Leptomedusæ* by Haeckel, corresponding to the *Thaumantiadæ* and *Eucopidæ* of Gegenbaur's system. The calyptoblastic hydroid *Leptoscyphus*, which, according to Allman, gives rise to a *Lizzia*-like medusa (*Anthomedusæ*), is the only recorded exception to this correspondence. The *Æquoridæ* and other medusæ of similar structure have not been traced into connexion with any hydriform trophosome, but we are not justified therefore in concluding that they develop directly from the egg without hydriform phase. The chief point distinguishing the *Leptomedusæ* as a lot from the *Anthomedusæ* is the development of the generative bodies in the radial canals. This position is similar to that occupied by the same organs in *Trachomedusæ* and *Scyphomedusæ*. Allman, however, considers the genital glands of the *Leptomedusæ*, not as mere glands like those of *Aurelia* or *Charybdæa*, but as a series of buds—a generation of aborted medusæ or sporosacs. In consequence he terms the medusa of the *Leptomedusæ* a blastocheme (or bud-producer), as distinguished from a gonocheme (or genital-producer). In support of this view, Allman (*Monograph*, 1874) adduces the various remarkable cases of production of buds by medusæ which have been recorded (fig. 44, 45, 46), and, further, the very striking similarity between the structure of a lobe of the genital gland of *Obelia* and a sporosac such as we find in *Hydractinia*. It seems necessary to accept Allman's view on this matter, unless we are prepared to abandon the homology of sporosacs with medusæ in the case of hydriform persons.

The colonies of hydriform persons of the present group differ *inter se* according to the arrangement of the cups or hydrothecæ. In *Plumularidæ* they are sessile, and all on one side of a branch; in *Sertularidæ* they are sessile, and alternately placed on either side; in *Campanularidæ* each cup is raised on a pedicel or stalk. The medusiform persons sometimes remain abortive and sessile in their gonangia.

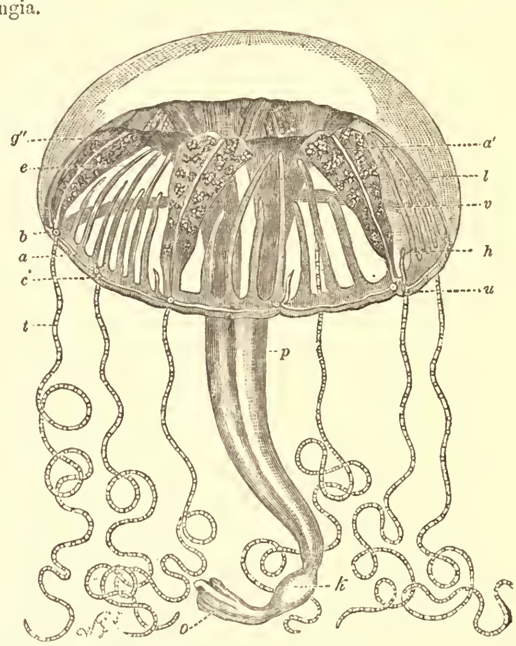

Fig. 48.—*Carmarina* (*Geryonia*) *hastata*, one of the *Trachomedusæ*. (After Haeckel.) *a*, nerve-ring; *a'*, radial nerve; *b*, tentaculocyst; *c*, circular canal; *e*, radiating canal; *g''*, ovary; *h*, peronia or cartilaginous process ascending from the cartilaginous margin of the disc centripetally in the outer surface of the jelly-like disc; six of these are perradial, six interradial, corresponding to the twelve solid larval tentacles, resembling those of *Cunina*; *k*, dilatation (stomach) of the manubrium; *l*, jelly of the disc; *p*, manubrium; *t*, tentacle (hollow and tertiary, *i.e.*, preceded by six perradial and six interradial solid larval tentacles); *u*, cartilaginous margin of the disc covered by thread-cells; *v*, velum.

Order 3. *Trachomedusæ*,—*Hydromedusæ* which have as sense-organs tentaculocysts. The otoliths (fig. 12) are

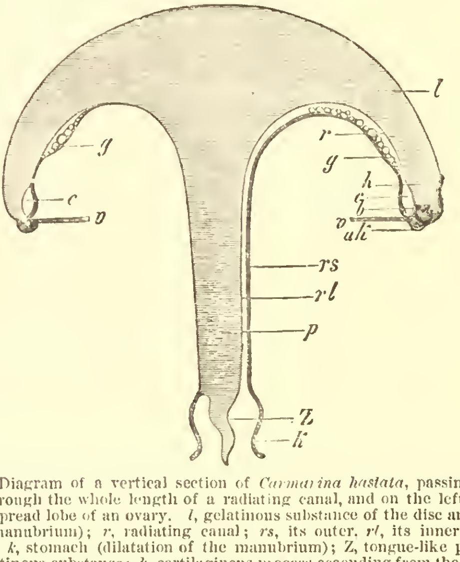

Fig. 49.—Diagram of a vertical section of *Carmarina hastata*, passing on the right through the whole length of a radiating canal, and on the left through the outspread lobe of an ovary. *l*, gelatinous substance of the disc and gastric stalk (manubrium); *r*, radiating canal; *rs*, its outer, *rl*, its inner wall; *g*, ovaries; *k*, stomach (dilatation of the manubrium); Z, tongue-like process of the gelatinous substance; *h*, cartilaginous process ascending from the marginal ring at the site of a tentaculocyst; *c*, circular canal; *b*, tentaculocyst; *v*, velum; *uk*, cartilaginous marginal ring. (From Gegenbaur.)

formed by endodermic cells as in *Scyphomedusæ*, and ocelli may or may not be present on the tentaculocyst.

The genital glands have the form of wide outgrowths or lamelliform enlargements in the course of the radial canals (figs. 48, 49). No hydriform phase is known in any member of this group, and one at least (*Geryonia*) has been observed to develop from the egg directly into the medusa-form.

Order 4. *Narcomedusæ.*—These have the same characters as the *Trachomedusæ*, excepting that the genital glands are in the wall of the manubrium or in pocket-like radial outgrowths thereof (figs. 50 and 51). Further, the marginal tentacles of the disc possess peculiar "roots," which can be traced upwards into the gelatinous substance of the body. No hydriform phase has been observed in this group, whilst *Ægina* and *Æginopsis* have been shown to develop directly from the egg to the medusa-form.

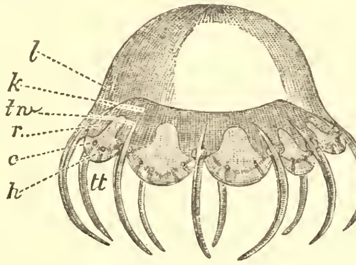

FIG. 50.—*Cunina rhododactyla*, one of the *Narcomedusæ*. *c*, circular canal; *h*, "otoporpæ" (ear-rivets) or centripetal process of the marginal cartilaginous ring connected with tentaculocyst; *k*, stomach; *l*, jelly of the disc; *r*, radiating canal (pouch of stomach); *tt*, tentacles; *tw*, tentacle root. (After Haeckel.) The lappets of the margin of the disc, separated by deep notches, above which (nearer the aboral pole) the tentacles project from the disc (not marginal therefore), are characteristic of many *Narcomedusæ* and *Trachomedusæ*. Cartilaginous strands (the mantle rivets or peroniæ) connect the tentacle root with the solid marginal ring.

The two orders *Trachomedusæ* and *Narcomedusæ* are established by Haeckel in his new "system" for the peculiar forms classed by Carus as *Haplomorpha*, and by Allman as *Monopsea*. These latter names have reference to the fact that no hydriform phase is *known* to occur in the life-history of these organisms, a fact which is not peculiar to them, and, if it should prove to be not universal amongst them, would by no means invalidate their claim to a distinct position on the grounds afforded by the characters above given. They are remarkable for a certain hardness and stiffness of the gelatinous substance of the disc, or at any rate of the cellular axis of the tentacles, on account of which the orders are contrasted by Haeckel as *Trachylinæ* with *Anthomedusæ* and *Leptomedusæ*, which are

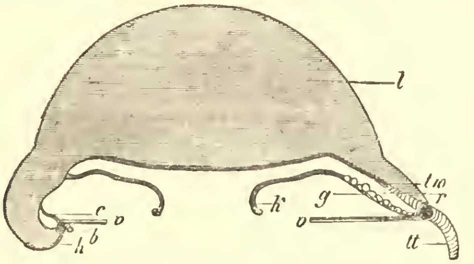

FIG. 51.—Diagram of a vertical section through a young *Cunina rhododactyla*, passing on the right side through a radiating pouch. *b*, tentaculocyst; *c*, circular canal; *g*, ovary; *h*, marginal cartilage and connecting process springing from a tentaculocyst (otoporpa); *k*, stomach; *l*, jelly of the disc; *r*, radiating canal or pouch; *tt*, tentacle (solid, cartilaginous); *tw*, tentacle root; *v*, velum. (From Gegenbaur.)

termed *Leptolinæ*; a curious parallelism as to the position of the genitalia exists between *Anthomedusæ* and *Narcomedusæ* on the one hand and *Leptomedusæ* and *Trachomedusæ*, on the other. The orders present a very high degree of development, both in coarser and histological differentiation. At one time it was supposed, in accordance with Haeckel's observations, that *Geryonia* (*Carmarina*, fig. 48), one of the *Trachomedusæ*, gave rise by buds from its enteric walls to young *Cuninæ* (*Narcomedusæ*, fig. 50), but this has been explained by the observations of Franz Schulze and of Uljanin as due to parasitism, young *Cuninæ* in the condition of ciliated *Planulæ* entering the mouth and enteric chamber of the *Carmarina*. The same explanation probably applies (Claus) to the supposed internal buds of *Cunina* observed by Gegenbaur, Fritz Müller, and Metschnikow. The process is sufficiently remarkable according to the last observer, for the first generation of buds produce a second generation by external gemmation, before attaining the characters of the parent *Cunina*. The anatomy of these forms is fully given in Haeckel's memoirs in the *Jenaische Zeitschrift*, vols. i. and ii., 1864–66; also further details as to *Carmarina* are given in Eimer's *Medusen*, 1878.

Order 5. *Hydrocorallinæ.*—These are *Hydromedusæ* in which the hydriform phase forms large colonies, presenting a copious calcareous deposit in the ectodermal tissue (cœnosteum of Moseley), leaving only the hydranths or tentacular region free from such hardening. The medusiform persons are, at present, only known in the degenerate form of sporosacs, which occupy cavities (ampullæ of Moseley) in the hardened base of the colony (*Stylasteridæ*). No such cavities have been detected in others (*Milleporidæ*), which may, therefore, give rise to complete medusiform persons.

FIG. 52.—Portion of the calcareous corallum of *Millepora nodosa*, showing the cyclical arrangement of the pores occupied by the "persons" or hydranths. Twice the natural size. (From Moseley.)

In all a marked polymorphism has been observed (fig. 53), consisting in the differentiation of longer tentacle-like persons (dactylozooids) and shorter mouth-bearing persons (gastrozooids). The persons of both kinds are either scattered irregularly or the dactylozooids are arranged around the gastrozooids in cyclosystems of greater or less definiteness, or in distinct rows (fig. 55). The position of these two kinds of hydriform persons is marked by definite groups of pits (cyclosystems) in the dried calcareous skeleton of the colonies, which simulate the calycles of the stony corals (*Anthozoa*).

FIG. 53.—Enlarged view of the surface of a living *Millepora*, showing five dactylozooids surrounding a central gastrozooid. (From Moseley.)

Louis Agassiz was the first to recognize the true nature of the *Milleporidæ*, and his imperfect observations have been fully confirmed and greatly extended by Mr Moseley (*Phil. Trans.*, 1878) who added the *Stylasteridæ* previously regarded as *Anthozoa* to the category of calcigenous hydroids, and founded the order of *Hydrocorallinæ*. The *Stylasteridæ* differ from the *Milleporidæ* in possessing a calcified axial style at the base of the dilated portion of each gastrozooid, and further in the ascertained development of sporosacs, and in the greater complication of their cyclosystems. These forms are abundant in tropical seas, and contribute with the *Anthozoa* and Corallines to the formation of coral reefs. *Allopora* and *Stylaster* occur off the Norwegian coast. The woodcuts illustrating the structure of this group are borrowed from Mr Moseley's *Notes of a Naturalist on the "Challenger."*

The nearest allies of the *Hydrocorallinæ* are such polymorphic *Gymnoblastea* as *Hydractinia* (fig. 39); the definite division of labour and the polymorphism in the former, together with their calcigenous peculiarity, entitle them to rank as a distinct order.

Order 6. *Siphonophora.*—These are *Hydromedusæ* in which hydriform persons alone (*Velella*) or hydriform persons and sterile medusiform persons are united, under many special modifications of form, to constitute floating colonies of very definite shape and constitution. In addition to these are developed medusiform sexual persons which usually are sporosacs and only exceptionally attain full development so as to be liberated from the colony as free-swimming medusæ (*Velella*, as *Chrysomitra*; *Physalia*, only liberating female medusæ). The medusiform persons, where sufficiently developed, exhibit the velum characteristic of *Hydromedusæ*; the larger mouth-bearing hydriform persons, which are sometimes the only representatives of their kind, are remarkable for differentiation into four regions,—a proboscis, a stomach, a basal ring, and a short stalk on which the *single* tentacle of great length is situated (fig. 56, *f*). In the sub-order *Physophoridæ* (fig. 57, C) the persons are united by a short or long and spiral stem, terminated at one end by a flask-like air-sac (pneumatocyst); below the air-sac a biserial or multiserial range of swimming-bells (nectocalyces = medusæ with suppression of manubrium, tentacles, and sense-organs) are placed. Covering pieces (hydrophyllia, reduced medusæ) and dactylozooids are affixed to the succeeding region of the stem, and alternate in definite order with the mouth-bearing hydriform persons (polyps or nutritive persons) and generative medusiform persons. In the sub-order *Physalidæ* the stem is converted into an air-sac, enormously enlarged, and the necto-

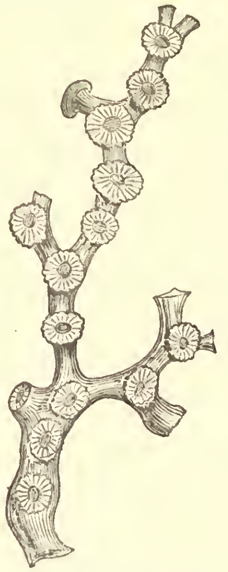

Fig. 54.—Portion of the corallum of *Astylus subviridis* (one of the *Stylasteridæ*), showing cyclosystems placed at intervals on the branches, each with a central gastropore and zone of slit-like dactylopores. (After Moseley.)

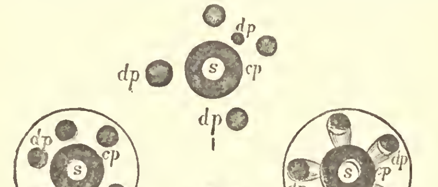

Fig. 55.—Diagrams illustrating the successive stages in the development of the cyclosystems of the *Stylasteridæ*. 1, *Sporadopora dichotoma*. 2, 3, *Allopora nobilis*. 4, *Allopora profunda*. 5, *Allopora miniacea*. 6, *Astylus subviridis*. 7, *Distichopora coccinea*. *s*, style; *dp*, dactylopore; *gp*, gastropore; *b*, in fig. 6, inner horseshoe-shaped mouth of gastropore. (After Moseley.)

calyces and hydrophyllia are absent. In the sub-order *Calycophoridæ* the air-sac is not developed, the nectocalyces are in a biserial group, or reduced to two or to one. Dactylozooids are wanting. The modified persons (appendages, Huxley) arise from the stem in groups, and can be withdrawn into the cavity of a swimming-bell (fig. 57, B). Each group consists of a nutritive person, with long tentacle, of generative medusoids, and usually also an umbrella-shaped or funnel-like covering piece. The latter separate in some *Diphyidæ*, and lead an independent life as *Eudoxiæ*.

In the suborder *Discoidæ* the stem is converted into a flattened disc with a system of canalicular cavities. Above this lies the air sac, a flattened reservoir of cartilaginous consistence. The hydriform persons depend from the disc, centrally a large nutritive person surrounded by smaller similar persons carrying at their bases the generative medusoids; near the edge of the disc are dactylozooids. The medusoids develop into complete medusiform persons, and develop the genital products after liberation from the colony, when they are known as *Chrysomitra*.

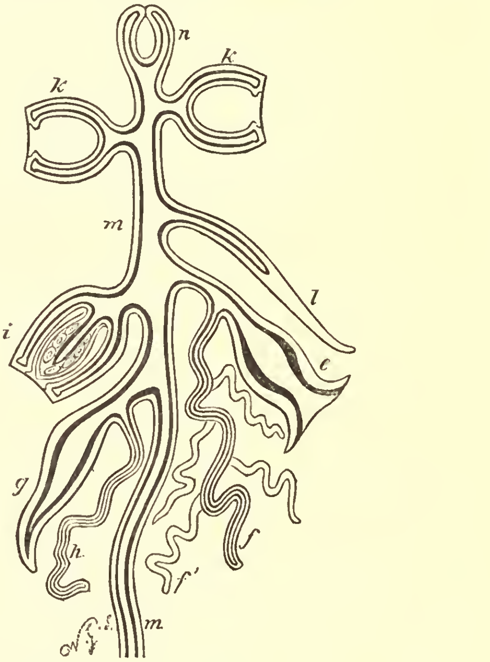

Fig. 56.—Diagram showing possible modifications of medusiform and hydriform persons of a colony of *Siphonophora*. *n*, pneumatocyst; *k*, nectocalyces (swimming bells); *l*, hydrophyllium (covering-piece); *i*, generative medusiform person; *g*, dactylozooid with attached tentacle, *h*; *e*, nutritive hydriform person, with branched grappling tentacle, *f*; *m*, stem. The thick black line represents endoderm, the thinner line ectoderm. (After Allman.)

The *Siphonophora* alone, amongst the colonies formed by *Hydrozoa*, exhibit a high degree of division of labour and consequent individuation. The mode of origin of such colonies has been discussed above. The locomotive habit, as contrasted with the sessile habit of other colonies, is no doubt correlated with the sharply defined individuality which they attain (compare *Cristatella* among *Polyzoa*). *Velella* and *Physalia* are occasionally seen on the southern and western shores of England, but as a rule the *Siphonophora* are met with only in the open ocean and in the Mediterranean. By some authorities the *Siphonophora* are assigned a distinct position among the *Hydrozoa*, side by side with the *Hydromedusæ* and *Scyphomedusæ*; their interpretation as floating colonies of *Hydromedusæ*, an interpretation necessitated by the structure of their medusiform persons, forbids their separation from that group.

Fossil Hydrozoa.—The researches of Moseley have necessitated a redistribution of the group of *Anthozoa* known as the *Tabulata*. Among these appear to be a few *Hydrocoralline*, which occur in the fossil state. The Palæozoic forms known as graptolites are by some authors assigned to the *Hydrozoa*, but the grounds for placing them in this position are very slight, owing to the imperfect nature of the remains. A discussion of the small amount of structure which they present would be out of place here.

Remarkable *Scyphomedusæ* have been obtained from the Solenhofen slates (Jurassic); excepting these, no noteworthy extinct *Hydrozoa* are known (see Haeckel in *Zeitsch. wiss.*

Zool., vols. xv., xix., and *Jenaische Zeitsch.*, vol. viii., 1874).

Relationship of the Ctenophora to the Hydrozoa.—The remarkable medusa-form recently described by Haeckel (*Sitzungsber. Jenaische Gesellsch.*, 1878) as *Ctenaria ctenophora*, and classed by him amongst the *Anthomedusæ*, seems to furnish a very direct transition from the structure of a medusa to that of such a ctenophor as *Cydippe* (*Pleurobrachia*). The woodcut and appended explanation (fig. 58) copied from Haeckel's memoir will render the relations of the two forms clear. *Ctenaria* has the margin of its disc narrowed so as to give the organism a spherical form. The approximated margins bound an orifice leading to the sub-umbrella space. This orifice corresponds to the so-called mouth of a *Cydippe*. Further, *Ctenaria* has two, and only two, long-fringed tentacles, like those of *Cydippe*, and each springing from a pocket as in that genus, and on the surface of its spheroidal umbrella eight rows of differentiated ectodermal cells, which though not ciliated correspond closely in position with the eight ctenophoral ambulacra of *Cydippe*. The disposition of the enteric canal-system of *Ctenaria* is, as shown in the cut, also transitional in the direction of *Cydippe*. Apart from the existence of *Ctenaria*, the homologies suggested by Haeckel between *Hydromedusæ* and *Ctenophora* are such as to commend themselves very strongly to acceptance. (E. R. L.)

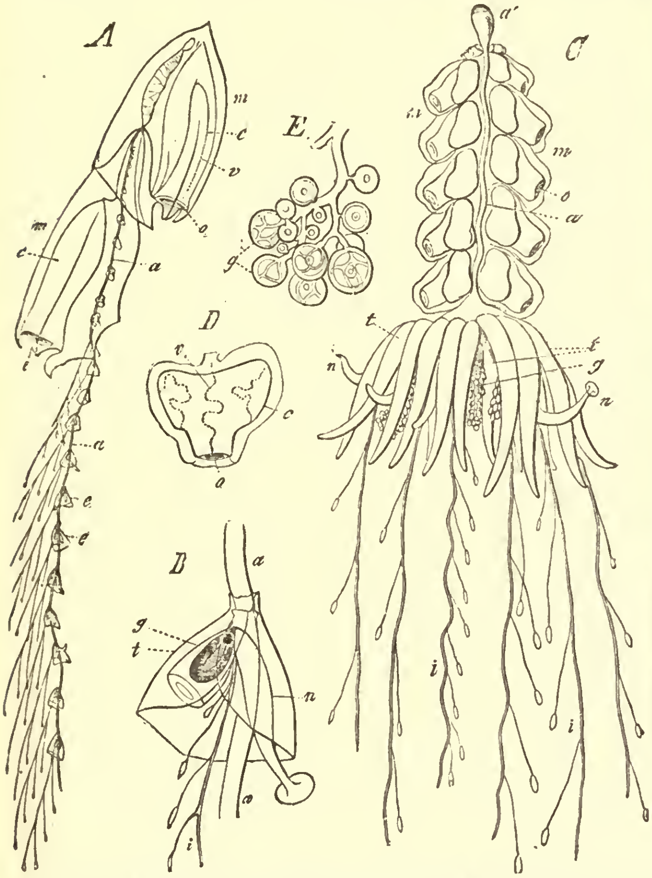

FIG 57.—Floating colonies of *Siphonophora*. *A*, *Diphyes campanulata*. *B*, A group of appendages from the stem of the same *Diphyes*. *C*, *Physophora hydrostatica*. *D*, Separate nectocalyx of the same. *E*, Cluster of female sporosacs (aborted medusæ) of *Agalma sarsii*. *a*, stem or axis of the colony; *a'*, pneumatocyst (air-bladder); *m*, nectocalyx; *c*, sub-umbrellar cavity of nectocalyx; *v*, radiating canals of the umbrella of the nectocalyx; *o*, orifice formed by the margin of the umbrella; *t*, hydrophyllia in *B*, dactylozooids in *C*; *n*, stomach; *i*, tentacles; *g*, sporosacs. (From Gegenbaur.)

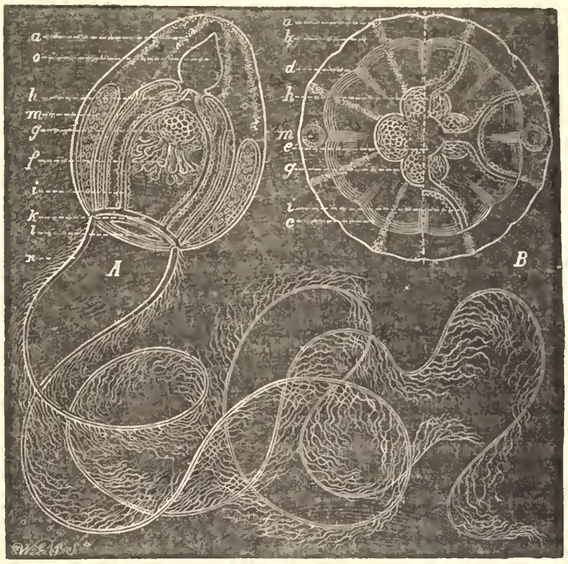

FIG. 58.—*Ctenaria Ctenophora* (Haeckel), one of the *Anthomedusæ*, connecting that group with the *Ctenophora*. *A*, lateral view of the entire medusa; *B*, two horizontal views, that to the left representing the surface of the aboral hemisphere, that to the right a section passing nearly equatorially. *a*, the eight (ciliated?) rows of thread-cells, adradial in position, and corresponding to the eight ctenophoral zones of *Pleurobrachia*; *b*, jelly of the umbrella; *c*, circular muscle of the sub-umbrella; *d*, longitudinal muscles of the sub-umbrella; *e*, stomachal dilatation of the enteric cavity; *f*, the sixteen oral tentacles; *g*, the four perradial generative glands in the stomach wall (manubrium); *h*, the four perradial primary radiating canals; *i*, the eight adradial bifurcations of the preceding; *k*, ring canal in the margin of the umbrella; *l*, velum; *m*, the two lateral tentacle pouches; *n*, the two lateral unilaterally fringed tentacles; *o*, the apical cavity (infundibulum) above the stomach. The canal system, with its four primary and eight secondary rami agrees in *Ctenaria* and *Pleurobrachia*. The mouth of the latter is homologous with the margin of the umbrella of the former. The mouth of *Ctenaria* is homologous with the junction of the so-called funnel of *Pleurobrachia* with its so-called digestive cavity. This last is the homologue of the sub-umbrellar cavity of *Ctenaria*. The apical opening or openings of the funnel of *Ctenophora* is paralleled, by the stalk canal of medusæ, whilst the agreement between the tentacles and their pouches in *Ctenaria* and *Pleurobrachia* is complete.

HYDRUNTUM. See OTRANTO.

HYÈRES, a town of France, in the department of Var and arrondissement of Toulon, about 3 miles from the coast of the Mediterranean. It is connected by a branch line with the railway from Toulon to Cannes, and by diligences with the neighbouring towns. The town proper is situated on the south-eastern side of a steep hill (650 feet high) which forms one of the last buttresses of the Maurettes, a group of picturesque hills covered with olive, pine, and cork trees, and underwood of myrtles and other shrubs. In front, towards the south and south-east, a fertile plain, once famous for its orange groves, and now mainly occupied by vineyards and farms, stretches to the sea, while towards the south-west, across a narrow valley, rises a cluster of low but well-clad hills. The older part of the town, still on its eastern and northern sides surrounded by its ancient and dilapidated wall, is a labyrinth of steep dirty streets; but the new quarters which have grown up at the foot of the hill have handsome boulevards and villas, many of them with beautiful gardens full of semi-tropical plants. Of best note among the objects of interest at Hyères are the house (Rue Rabaton, No. 7) where Massillon was born; the cathedral or church of St Louis, a low building of the 12th century (restored in 1840), which belonged to the Cordeliers; and the ancient castle, crowning the highest part of the hill. The Place des Palmiers takes its name from the seven palm trees planted there in 1834. On the plain between the town and the sea are large nurseries, an excellent jardin d'acclimatation, and the famed kitchen gardens which supply Paris with early fruits and vegetables and with roses in winter. There are extensive salt-beds on the peninsula of

Giens, which juts due south into the Mediterranean, where salt is made by the exposure of the sea-water to the sun. Up to the 14th century Hyères was a larger and more important town than Toulon; and in the 16th century it became famous as a winter resort. Catherine de' Medici at one time thought of making it the seat of a royal residence. At present the more brilliant social attractions of some of the neighbouring watering-places of the Riviera divert the more fashionable visitors from Hyères. In climate it differs little from its more favoured compeers. From the east and north-east winds it is completely sheltered, but it lies open to the ravages of the mistral. The population in 1872 was returned at 5881 for the town and 11,212 for the commune; in 1876 the corresponding figures were 6797 and 12,289. The islands of Hyères (the Stœchades—αἱ Στοιχάδες νῆσοι—of the classical geographers), otherwise called Les Îles d'Or, lie to the east of the peninsula of Giens, and form a protection to the roads of Hyères, one of the great rendezvous of the French fleets. The principal islands are Porquerolles, which rises to a height of 600 feet, Port-cros, and Titan. The population is scanty. A marquisate of the Îles d'Or was created by Francis I.

See Alphonse Denis, *Promenades pittoresques à Hyères*, 1842; Eugène Farenc, *Les récits du touriste Provençal*, 1859; Aufauvre, *Hyères et sa vallée*, 1862; Joanne, *Hyères et Toulon*, 1870; Lenthéric, *La Provence maritime*, 1880.

HYGIENE is the science, PRACTICAL HYGIENE the art, of preserving health. The name has been adopted from the French, from which language it has also been introduced into most other tongues; it is derived from the Greek ὑγίεια or ὑγεία, health. Writings on health are among the oldest in the world, for the subject has engaged the attention of the profoundest thinkers and the most renowned leaders of men. We have only to point to the elaborate directions in the Mosaic laws for the preservation of health through scrupulous attention to cleanliness, the isolation of the sick, and extreme care in the use of wholesome articles of food and drink. Throughout the whole of their history the Jews enjoyed a remarkable immunity from epidemic disease, the most of the instances in which such disease occurred being represented as those in which they departed from the law and doubtless relaxed the wholesome vigilance enjoined by it. In mediæval and modern history they have often, even down to our own time, been spared the ravages of epidemics, when their Christian neighbours were perishing around them. Ignorant superstition often gave rise to the idea that they had poisoned the wells, and they fell victims to the fanaticism of the times. It is highly probable that the periodical cleansing of their dwellings, involved in the thorough search for the leaven which preceded the yearly passover (*Mishna*, Pesachim, i. 11), had a notable influence in preventing that continuous deposition of organic matter, which is no doubt one most powerful factor in the production of zymotic disease. On the other hand, the filthy habits of the Christian populations offered a premium to plagues of every kind; for there is no parallel in ancient history to the terrible invasions of disease which from time to time ravaged Europe down to quite recent times.

It is the province of hygiene to seek out and determine the causes of disease, and to formulate rules for their prevention and removal. It may thus be called also preventive medicine, although this term does not quite express all that must be included. The progress of hygiene, such as it was, rested for many ages upon an empirical basis, and indeed to a large extent this is still the case. The subject has, however, in later times at least, been studied to considerable advantage, although much remains to be done. Two centuries ago the mortality of London was 80 per 1000—at the present day it is under 23. A century ago ships could barely keep the sea for scurvy, whilst jails and hospitals were in many cases the hotbeds of fatal disease; now those conditions are rectified, or at least the means of rectifying them are known. Thirty years ago the English troops at home died at the rate of 20 per 1000—now their death-rate is less than one-half of this. A knowledge of the causes and modes of propagation of disease being necessary in order to provide rules for its prevention, it is obvious that hygiene must be largely dependent upon the advances made in pathology and ætiology; hence the impossibility of any very marked progress in former times, by reason of the imperfection of the collateral sciences, and the want of the appliances more recently made available for inquiries of such a difficult and recondite character. Within this century, however, and especially within the last forty or fifty years, it has been possible to follow out the subject on a more strictly scientific basis, and so to lay a foundation, at least, on which to build a structure, which may one day entitle hygiene to a place among the more exact sciences.

The special subjects which hygiene embraces are the following:—I. Those which concern the surroundings of man; such as meteorological conditions, roughly included under the head of climate; the site or soil on which his dwelling is placed; the character, materials, and arrangement of his dwelling; the air he breathes; the cleansing of his dwelling, and the arrangements for the removal therefrom of excreta and other effete matters.

II. Those which concern the personal care of health; such as the food he eats and the water and other beverages he drinks; clothing; work and exercise; personal cleanliness; special habits, such as the use of tobacco, narcotics, &c.; control of sexual and other passions.

III. Certain points not directly included in the above; such as the management of infancy; the prevention of disease; the hygiene of the sick-chamber; and the disposal of the dead.

It is obvious that it is impossible to draw any hard and fast line in these divisions, and that they must constantly run into and overlap each other. Such a division, however, gives a general idea of the scope of the science, and a brief consideration of the different sections will enable us to furnish a slight sketch of the nature of the subject.

1. *Meteorological* or (so-called) *climatic* conditions. Here temperature and humidity are the two points that obviously present themselves for consideration, but it is very difficult indeed to separate their influence from those of soil or site. It is also certain that much that has been attributed to climate is really due to other causes. It may be laid down as a general principle that, if moderate care be taken, man may preserve his health in almost any part of the world, although it must be admitted that in some places, such as hot and moist climates, disease causes appear to be more easily called into action than under colder or drier conditions. Some diseases, such as yellow fever, appear to require a certain temperature for their development and propagation; others, such as enteric (commonly called "typhoid") fever, appear to exist indiscriminately under any meteorological conditions; others, such as cholera, although undoubtedly originating in hot and moist countries, appear capable of being propagated in most parts of the world. In some cases great heat and dryness arrest disease, as used to be observed in Egypt, where the plague was commonly said to cease after St John's day. During the hot harmattan wind of the west coast of Africa small-pox is arrested, and successful vaccination becomes impossible. To the sick or delicate, meteorological conditions are of great importance, but this part of the subject belongs more to the treatment of disease than to general hygiene. To the healthy, meteorological conditions, however much they may affect personal comfort, are of comparatively little moment as

regards health, so long as reasonable care is observed. In a healthy body an adaptation to circumstances rapidly takes place, and an equilibrium is soon established. Thus, it used to be supposed that great heat increased the temperature of the body, but later observations have shown this to be erroneous, and that the balance is soon re-established by the process of transpiration;—should this, however, be arrested, then a rise of temperature may take place, and disease of a febrile character be established.

2. The *soil* or *site* of the dwelling is, however, of greater moment, and much that has been attributed to climate has been more truly due to locality. Soils are generally divided into moist and dry, permeable and impermeable, and again subdivided according to formation, composition, slope, &c. Healthy soils are those which are dry and permeable, or which have such a slope as renders drainage easy; on the other hand, soils which are flat, moist, and impermeable are generally unhealthy. Soils containing much organic matter are to be avoided, such as alluvial soils generally, as well as all marshy districts. The air in soils is generally more or less impure, hence the unadvisability of occupying dwellings below the ground level or situated immediately on its surface. The water in the soil is a question of great importance, apart from the mere moisture. At varying distances from the surface, but everywhere, there exists a great subterranean lake or sea, known as the *ground-water* or *water-table*, which is constantly in motion, both vertically and horizontally. Its horizontal movement is towards the nearest water-course or towards the sea; its vertical movement is determined by rainfall chiefly. Much importance has been attached to it, and the following points may be considered as accepted by most hygienists :—(1) a permanently high ground-water, that is, within 5 feet of the surface, is bad, while a permanently low ground-water, that is, more than 15 feet from the surface, is good; and (2) violent fluctuations are bad, even with an average low ground-water; a comparatively high ground-water with moderate and slow fluctuations may be healthy. According to the school of Pettenkofer, it is the ground-water which determines the spread of certain forms of disease, such as cholera and enteric fever. A previously high level, succeeded by a fall, with a certain height of temperature in the soil-air, is the condition believed by them to be the one most favourable for disease production. Healthy soils are the granites, metamorphic rocks, clay-slate, limestone, sandstone, chalk, gravel, and sand; unhealthy are—clay, sand and gravel with clay subsoil, alluvial soil, and marsh-lands, with the exception of peatlands. Among the unhealthy soils ought also to be included all "made" soils, particularly those that are formed so often in towns from rubbish of all sorts. Such soils ought not to be occupied as building sites for at least two years.

3. The sanitation of *dwellings* involves numerous points. The site has been considered in the previous section, but the importance of excluding soil emanations must be insisted upon. The placing of a dwelling in any spot of ground tends to exert an extractive force upon the soil, because the air of the dwelling is almost always warmer than the external air, and there is therefore a constant danger of sucking up the more or less impure soil-air into the dwelling. Not only is this a recognized source of disease, but fatal cases of direct poisoning have sometimes resulted, as when coal-gas has escaped into the soil below or near a dwelling. An impervious foundation is therefore necessary, although this precaution is too often neglected, even in high-class dwellings. Houses ought to be so arranged that they may receive plenty of light, not merely for work or convenience, but as a matter of health. Sunlight, for full health, is as necessary as air, and this is now so strongly recognized in America that in many of the hospitals in that country rooms are provided where patients may take a "sun-bath."

The materials of which houses are built are various. Wooden dwellings have advantages, but there is always the danger of fire. Brick or stone is most commonly used, but very good dwellings may be made of concrete or even of mud. Probably the best material is good, sound, well-burnt brick. Dryness must be secured by means of damp-proof courses along the foundations, hollow walls, and cementing or slate-hanging externally. Non-absorbent surfaces internally are important, although some writers, such as Pettenkofer, &c., have been inclined to attribute the unhealthiness of dwellings to the impermeability of the walls obstructing air change. But where air can pass, organic matter can lodge and become a source of danger. It is better, therefore, to have non-absorbent surfaces as much as possible, and to provide for ventilation in other ways. Paint that can be washed is therefore better than paper; if the latter is used it had better be glazed. Care should be taken to scrape off all old papers beneath, as they and the paste used with them tend to decompose and become injurious to health. Ceilings ought to be impervious as well as walls, and floors ought to be made of well-fitting seasoned wood, caulked, and oiled or varnished so as to make them water-tight.

Proper cubic space is a matter of great importance, for upon it depends the renewal of air. The air of an air-space can seldom be changed oftener than three times an hour, hence the space ought to be large enough to allow of such rate of change providing enough of air for respiratory purposes. The furniture of rooms, especially sleeping rooms, ought not to be too massive; whilst curtains and hangings too often form traps for dust and organic matter.

The warming of houses is important, and is generally badly and wastefully done. The open fire-place has great advantages, but it is in many cases insufficient. Where any general system is employed it is better to warm the air in the room itself, as by pipes conveying hot water or steam, than to warm it before delivery. Overheated rooms are a source of ill-health. For sitting-rooms 60° to 65° is quite enough; for a study or work-room 60° is sufficient, even in some cases less than this. A sleeping-room need never be above 60°, often with advantage below it. Fresh air ought not to be sacrificed to temperature, except under extreme circumstances. Dwellings should not be occupied for some time after building, till they are thoroughly dry. Rheumatism, chest diseases, &c., are very apt to arise from neglect of this precaution.

Scrupulous attention to cleanliness is necessary in dwellings, and there is wisdom in their periodical vacation for a certain time, so as to let them lie fallow, as it were, and interrupt the continuity of deposit of organic matter. Dwellings ought to be scattered over as wide an area as possible, for statistics show that sickness and death-rate are often inversely proportional to the amount of area per head occupied by a community. The area per head in London is estimated at double that of Paris and many other cities, whilst at the same time its death-rate is smaller than that of any other large city in Europe.

4. *Air* is the prime necessity of life. Food or water may be abstained from for a considerable time, and we may thus have an opportunity of replacing either should we doubt its purity or wholesomeness, but the atmosphere around us we must breathe or die. Hence the paramount necessity for having it pure. But, although this is apparently so obvious, attention to its importance has been very generally omitted. Air consists of a mechanical mixture of oxygen and nitrogen, in the proportion of nearly 21 per cent. of the former to 79 of the latter, with small quantities in addition of carbonic acid, moisture, organic matter,

&c. By respiration and combustion air becomes vitiated, the oxygen diminishing and the carbonic acid and organic and suspended matter increasing. Within certain limits the amount of carbonic acid is in itself immaterial to health, but it is important as a measure of the amount of organic matter, which is really the dangerous impurity. Air vitiated by respiration is also much more dangerous than when the carbonic acid is partly the result of combustion. It is now pretty generally admitted that air cannot be considered as really good and fit for respiration in which the respiratory impurity reckoned as carbonic acid much exceeds two parts in 10,000 by volume. On the other hand, if air can be kept down to this point, the condition may be looked upon as satisfactory. The amount of impurity given off by living beings varies of course with size, weight, age, sex, and work, but it may be allowed that under ordinary circumstances it amounts to about six cubic feet of carbonic acid per head in ten hours during repose. This requires an hourly supply per head of 3000 cubic feet of fresh air for its dilution, and this amount should be largely increased during work or in sickness (see HOSPITAL). The diseases which have been shown to arise from the effects of vitiated air are widely prevalent, including such as consumption and other forms of scrofulous disorders, bronchitis and pneumonia, sore throat, &c. Crowded and ill-ventilated places also tend to increase the virulence and the rapidity of spread of the various communicable diseases.

5. *Cleansing*, including the removal of slops, excreta, &c., forms one of the most important and also most difficult of questions. The main principle is that all should be immediately and effectually removed from the house and its neighbourhood, and that there should be no possibility of reflux of foul air from drain or cesspool. The system of water-carriage is certainly the cleanest and most convenient, especially among large communities, but other systems find advocates. In villages and isolated houses the earth system and other dry methods have many advantages. The question of the disposal of sewage is a very large one, into which it is impossible to enter here. Hitherto all or almost all the material has been wasted by being poured into rivers or the sea, the streams being thus polluted and the shores rendered offensive. The object to be aimed at is to utilize a product of undoubted fertilizing influence, without endangering the health of the community. The diseases to be apprehended from imperfect methods of sewage removal are enteric fever, cholera, diphtheria, sore throat, and an aggravation of most other diseases, especially those of an eruptive character. Ashpits ought to be especially attended to, their neglect being attended with much danger.

6. *Water-supply*, although included under the head of food and beverages, merits special consideration, so important is its relation to health, both directly as a drink and indirectly with reference to its many other uses. It is required for drinking, cooking, the cleansing of person, clothes, and dwelling, and the flushing of closets, sewers, and drains. The hygienic requirements are that water should be good in quality and sufficient in quantity. Good water should be clear, colourless, quite free from suspended matter, of a good lustre, and should have a pleasant sparkling taste, the latter qualities being due to the carbonic acid and atmospheric air dissolved in it. In its chemical composition it ought to be as free as possible from organic matter. The evidence in favour of communication of disease by means of drinking water is now very extensive, and we may cite diarrhœa, dysentery, ague, enteric fever, and cholera as among the diseases which may be conveyed through this channel. Numerous parasites also find their way into the human body by this means. Hard water is objectionable for cooking and washing, nor can it be recommended for drinking, although some insist upon a certain amount of hardness being essential. In the case of water being impure, boiling, distilling, or filtering may be resorted to. The two former are the most efficacious, but the last has advantages of convenience if properly carried out. Charcoal filters, if properly cleansed, or renewed sufficiently often, are useful, but it is better to have a material that purifies without risking any deterioration of the water itself. Such filters as the spongy iron and the carferal effect this. All filters, however, require the medium to be cleansed or renewed periodically. In a house the chief dangers are from dirty cisterns and from pipes being connected with drains and closets. All supply should be on the constant system, and no pipe supplying a closet should be resorted to for drinking purposes. All overflow pipes should deliver in the open air. The quantity of water required per head may be stated at a minimum of 12 to 16 gallons per diem where there is no general system of drainage, and about 25 gallons with drainage. In towns more than this is necessary, and from 30 to 50 gallons are desirable. In sickness generally double the amount is necessary that is required in health. The source of the water ought to be pure,—springs, deep wells, and upland surface water being the best. Shallow wells and rivers to which sewage gains access are most to be avoided.

7. For *food* and *beverages* the reader is referred to the article DIETETICS.

8. *Work and Exercise.*—The kinds of work performed by man are of course very various, but they may be reduced more or less to a uniform standard, which is usually reckoned as so many tons (or pounds) raised through one foot, or, tersely, as foot-tons or ton-feet. A fair day's work is generally taken at 300 foot-tons, a laborious day's work at 450, and the maximum to be expected, except under very special conditions, at 600. For this work a certain time should be allowed, as the strain increases (almost in a geometrical ratio) with the velocity. Usually speaking 50 foot-tons an hour is a fair amount, and this ratio is equal to a walk of three miles for an average man. The amount for mental work has not been accurately calculated, but it may be safely assumed that a man of sedentary occupation ought to take exercise of a physical kind varying from 50 to 100 foot-tons per diem. In all cases his food ought to be proportioned to his work, for it is now recognized that man is a machine, whose work depends upon the energy derived from the food he eats.

9. *Clothing and Personal Cleanliness.*—Clothing should fulfil the functions of preserving warmth in cold weather, providing covering without being too oppressive in hot weather, keeping out wet in wet weather, and yet allowing sufficient transpiration for health. At the same time it ought to admit of frequent change and cleansing. Dr Parkes has pointed out that it is probably due in some measure to cleaner habits with reference to clothing that the diminution of typhus fever should have been so marked in recent times. Personal cleanliness is also a matter of great importance, a daily general bath being advisable for every one. For animals as well as human beings it has been shown that cleanliness is conducive to improved appetite and general health. Filth is one of the prime factors in the production and propagation of most of the devastating plagues known to mankind.

10. *Prevention of Disease.*—This is a large question, on which we can only briefly touch. Much depends upon our knowledge of ætiology or the remote causes of disease. The best rule for preventing disease is to follow out carefully the principles of general hygiene, laid down with reference to pure air, pure water, proper food, cleanliness, &c. Some diseases may be more specially provided against, such as paroxysmal fevers by the use of quinine, and small-pox by vaccination, but for the great majority of diseases

no such special preventive is known. Some diseases, such as typhus fever and plague, are successfully combated by scattering the population over a large area and inducing the freest ventilation, and to all diseases this plan may be applied with more or less effect. In those diseases which are known to be communicable, such as scarlet fever, isolation of the patients is an effectual means of arresting the spread; but the poisons of others, such as measles and hooping-cough, are so subtle that isolation can only be looked upon as a measure of doubtful success. Much stress has been laid upon *disinfection* as a means of preventing disease, and if properly carried out it has some efficacy. But it is a mistake to place too implicit reliance upon it as ordinarily practised. In dealing with clothing, bedding, &c., the best method is the application of heat, at or above the boiling-point of water, which may be done by means of dry heat, superheated steam, or boiling water. In fumigating places, burning sulphur or the vapour of chlorine or nitrous acid is used, but to be effectual the air must be rendered for the time irrespirable. The solid and liquid disinfectants (so-called) are chloride of lime, the permanganates, carbolic acid, and a great many similar substances, many of which have been made the subjects of patents. A large number of them are merely deodorants. It may be stated generally that disinfectants are useful as adjuncts to other hygienic measures, but that they cannot replace them, except to a small extent, and in a very imperfect way.

11. *Disposal of the Dead.*—The most frequent plan is interment in the earth, but it may well be a question if this be the best plan; it has certainly led to much evil when carried out near habitations. Two other plans have been suggested, viz., burial at sea (suggested by the late Dr Parkes) and cremation. The former is hardly likely to be resorted to, but the latter would be effectual in preventing the evil consequences of ordinary interment. At the same time the danger that it might too effectually conceal much secret crime has to be taken into account.

Bibliography.—E. A. Parkes, *Manual of Practical Hygiene*, edited by F. de Chaumont; G. Wilson, *Handbook of Hygiene*; A. Buck, *Hygiene and Public Health*, New York; Michel Lévy, *Traité d'Hygiène Publique et Privée*; Von Pappenheim, *Handbuch der Sanitäts-Polizei*; Roth and Lex, *Handbuch der Militärische Gesundheitspflege*; and numerous works and monographs on special departments. (F. DE C.)

HYGINUS, Caius Julius, a native of Spain, and the freedman of Augustus, by whom he was made chief of the Palatine library. He is said to have fallen into great poverty in his old age, and to have been supported by one C. Licinius. He was a voluminous author, and his works included topographical and biographical treatises, commentaries on Cinna and on Virgil, and disquisitions on agriculture, bee-keeping, and the military art. All of these are lost. But there have come down under his name two school treatises on mythology, which have produced much discussion. They are entitled (1) *Fabularum Liber*, containing 277 mythological legends, and valuable for the use made of the Greek tragedians; and (2) *Poeticon Astronomicon Libri IV.*, an astronomical treatise of little value. Both are abridgments; both are by the same hand; but from the "tyro-like mistakes" in both they have been thought unworthy of the librarian of Augustus. It is not, however, impossible that they are early compositions of his, written before he had gained full command of the Latin language. A suggestion has also been made (Bursian in Fleckeisen's *Jahrbuch*, xciii. p. 773) that a work of Hyginus, named *Genealogiæ*, was abridged by a grammarian of the latter half of the 2d century, who appended a treatise on the whole mythology arranged according to mythological views. This text-book, retaining the name of Hyginus, would be used in the schools, and would be from time to time altered and augmented. But in these, as in the many other opinions that have been advanced, there is nothing beyond conjecture.

HYGINUS (surnamed Gromaticus, from *gruma*, a surveyor's measuring rod), a writer on land surveying and castrametation, who flourished in the reign of Trajan (98–117 A.D.). There survive fragments of a comprehensive treatise *De munitionibus castrorum* or *De castrametatione*, and of a work *De limitibus constituendis*, which may be found in Lachmann's edition of the works of the Roman Gromatics (1848), i. 108–134.

HYGROMETRY. In the British Islands all are familiar with the arid character of the east winds of spring, and not a few are only too painfully aware of the discomfort experienced while under their influence; and all are likewise familiar with the opposite state of the atmosphere, most frequently and unmistakably occurring also with east winds, when every object feels damp and clammy to the touch, and horses on the streets are seen each with a steaming cloud of dense mist around it. In certain other climates, such as are met with in India and South Africa, these effects are greatly intensified, so that on the one hand the ivory scales of thermometers, quill pens, and other objects curl up, articles of furniture open at the joints and split up, and the grass which covers the soil is reduced to a state of tinder; and on the other hand, everything becomes so permeated with moisture that, even in the interior of houses, furniture, books, and wearing apparel become sodden with wet. These different effects depend on the states of the air as regards the quantity of aqueous vapour diffused through it taken in connexion with the temperature, these varying from the completest possible saturation of the air, which is of occasional occurrence in the rainy season of some tropical climates, to that extreme desiccation of the air which sometimes happens in Great Britain in spring, but more completely and frequently in such dry summer climates as that of the Punjaub.

A large number of substances, such as sugar, flour, and bread, possess the property of absorbing moisture, and most gases, as well as air, absorb and retain aqueous vapour. The term *hygrometry* is employed to signify the measurement of the degree of dampness of substances, and to denote the processes by which their humidity is ascertained. The term, however, may be considered as restricted to the humidity of the atmosphere, owing to the paramount importance of that branch of the subject, and the slight and unsatisfactory knowledge we yet possess of the laws of hygrometry of other substances.

All organic substances contain pores for the conveyance of their juices, and are influenced by the accession of moisture, some of them very markedly so. Every species of wood is liable to these hygrometric changes, the amount of contraction and expansion being much greater across the grain of the wood than lengthways. Hence the panels of doors are fitted into grooves so as to allow of shrinkage, for, if secured at the edges, the panels must inevitably split. The hair of animals is also eminently hygrometric, curling and uncurling as the air becomes drier or moister, and it is because of the peculiar sensations accompanying these hygrometric changes that the cries and behaviour of many of the lower animals furnish valuable prognostications of weather changes. Similarly many manufactured objects, such as paper, cordage, &c., vary in weight, bulk, form, and elasticity with the varying degrees of humidity of the air, and other interesting prognostics have been drawn from these hygrometric changes.

In the earlier stages of the investigation of the hygrometry of the air, the hygrometric properties of several substances were made use of as instruments of observation. Of these may be named the twisted Indian grass (*Oobeena*

Hooloo), employed by Captain Kater on account of its remarkable property of twisting and untwisting according to the dampness of the air; a slip of whalebone cut across the fibres, used by De Luc; and the hygrometer of Saussure, which was formed of a hair from which the oily matter had been previously removed, and which stretches when moist and contracts when dry. Experience has, however, shown that none of these hygrometers are satisfactory instruments, seeing they give inconsistent results, and are liable when in use to great and uncertain changes. Hence, while they serve to give the roughest idea of the state of the air as regards moisture, they have fallen into disuse as accurate instruments of observation of the hygrometry of the atmosphere. But in the intensely cold climates of Russia and Siberia, the hair hygrometer still continues to be used as an instrument of observation; and when we consider the tediousness and difficulty of making hygrometric observations with the hygrometer in most general use when the temperature of the air descends below the freezing-point of water, the hair hygrometer should perhaps be considered as good an instrument as is available to put into the hands of ordinary observers in times of low temperature.

The most accurate hygrometers are those which are constructed, not as the above, on the principle of absorption of vapour, but on the principles of condensation or evaporation. The well-known fact that the temperature of a wet body is lower than that of a dry one when under the same atmospheric conditions was applied by Sir John Leslie to measure the humidity of the air. Leslie's hygrometer (fig. 1), which is an adaptation of his differential thermometer, is formed by uniting two tubes having a ball blown on the end of each, into which some coloured sulphuric ether has been previously introduced. When both bulbs are at the same temperature, the fluid stands at the zero of the scale, but when one of them is covered with wetted paper or muslin the instrument shows the depression of temperature of the wetted bulb. In order to ascertain the quantity of moisture corresponding to the reading of a Leslie's hygrometer, we must deduct from the total quantity of moisture which the air of the temperature at the time of observation is capable of holding the deficiency due to the degree of cooling shown by the hygrometer.

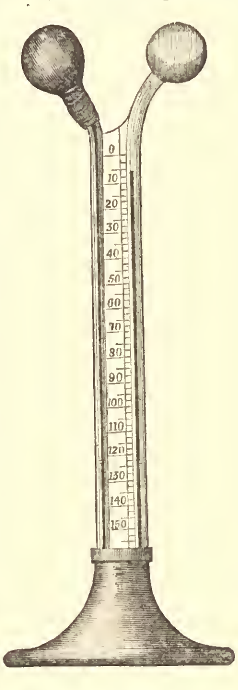

Fig. 1.—Leslie's Hygrometer.

As no air is ever absolutely dry, but contains more or less moisture, it is evident that if any mass of air be cooled sufficiently it may be made to deposit its moisture. A familiar example of the condensation of vapour is seen in the formation of dew on a tumbler filled with cold water and brought into a warm room. This dew is caused by the deposition of moisture from the air in contact with the cold surface of the glass, which is cooled down below the point of saturation. The temperature of the glass at the instant dew begins to form on its surface is termed the dew-point, which corresponds with the point of saturation of the air.

Daniell's and Regnault's hygrometers are constructed on the principle of this simple phenomenon, various contrivances being used for lowering the temperature quickly to any point that may be desired, and for observing with requisite precision the temperature at which the dew begins to form. In both cases ether is employed to lower the temperature.

Daniell's hygrometer consists of a glass tube bent at right angles at two points with a bulb at each extremity, one bulb being of black and the other of clear glass, the latter covered with muslin. The liquid within the bulbs is ether, which at the time of being sealed is made to boil for the purpose of expelling the air. If the temperature of the two bulbs be made to differ from each other, all the ether is transferred from the warmer to the colder bulb. In making an observation the whole of the ether is first transferred to the black bulb, and ether is then dropped on the muslin covering outside the clear bulb. This ether quickly evaporates, and in doing so rapidly lowers the temperature of the clear bulb so that the ether inside the black bulb distils over into the clear bulb. The result is a lowering of the temperature of the black bulb, and, as soon as this falls to the temperature of the dew-point of the air where the experiment is conducted, a ring of vapour begins to be formed outside the black bulb, more or less dulling its surface. At this instant a thermometer placed inside the tube with its bulb immersed in the ether filling the black bulb is read, and the reading gives the dew-point of the air at the time.

Regnault's hygrometer is a little more complicated than Daniell's, but its indications are much more trustworthy. It consists (fig. 2) of a glass tube or capsule A, having on the bottom and a little way up a highly polished silver surface, and closed by a cork with two holes. Through one of these holes the stem of a thermometer B passes, having its bulb at the bottom of the silvered capsule, while through the other hole passes a narrow metallic tube C, one end of which opens close to the bottom of the capsule, and the other end may, if desired, be connected with an aspirator or air-pump. In making an observation as much ether is introduced into the capsule A as will cover the bulb of the thermometer, and then by transmitting air through the tube C the ether vapour is withdrawn from the capsule A through another tube D. By this means the temperature of the ether is very rapidly reduced, and since the whole mass of the ether is agitated by the air-bubbles which rise through it from the bottom of the capsule, the cooling of the ether is equal throughout. The thermometer is then read quickly, but to ensure an accuracy to the tenth of a degree a second and a third experiment, conducted more slowly, should be made. As showing the rapidity with which observations can be made with this hygrometer, Henry F. Blanford on one occasion made six observations in six minutes in the dry climate of Secunderabad, when the temperature of the air was 93°, the dew-point 51°, and the relative humidity consequently 24°. The temperature of the air at the time of observation may be ascertained in the usual way, or by means of the thermometer E, if care be taken that its temperature is unaffected by the proximity of the person of the observer.

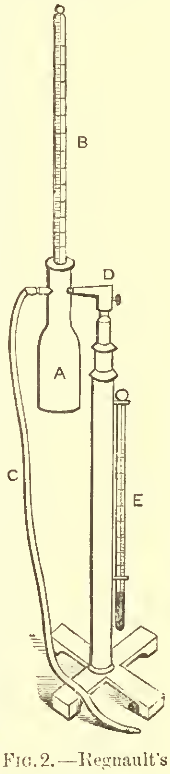

Fig. 2.—Regnault's Hygrometer.

Owing to the expense and great trouble attending the use of hygrometers which give the dew-point directly by condensation, another hygrometer has come into extensive use by which the dew-point is determined indirectly by evaporation. This is August's hygrometer, sometimes called

Mason's hygrometer, but more generally known as the dry and wet bulb hygrometer, which has the strong recommendation of being self-acting, and requiring only the readings of the two thermometers in making air observations. This hygrometer (fig. 3) consists of two thermometers *a* and *b* similar to each other in all respects except that one of them has a piece of muslin tied closely over the surface of its bulb *c*, and kept constantly wet by a few threads of cotton which connect it with the water in the vessel *d*. The water then which rises from the vessel by capillary attraction spreads over the muslin, and evaporates from its surface with more or less rapidity according to the dryness or moistness of the air; and the greater the dryness of the air the greater is the difference between the observed readings of the dry and the wet thermometers.

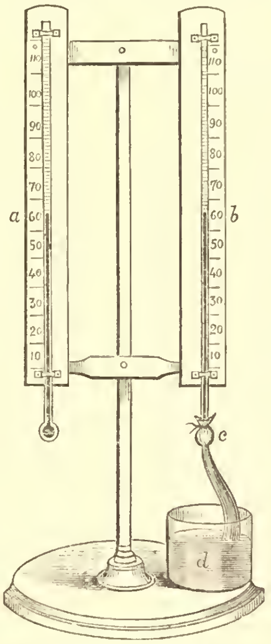

Fig. 3.—Dry and Wet Bulb Hygrometer.

The formula for deducing the hygrometric state of the air from these two observations has been investigated by Professor Apjohn (*Trans. Roy. Irish Acad.*, vol. xvii.), and has been already described (see Atmosphere, vol. iii. p. 32). As it is very troublesome to go through the calculations for each fresh observation, tables have been prepared which give the dew-point by inspection. The best of these tables in English measures are those of Glaisher, fifth edition, constructed empirically from direct experiments carried on at Greenwich, combined with Regnault's last revised tables relating to aqueous vapour. There can be but one opinion as to the great service rendered to meteorology by Glaisher in the preparation of these tables, which give results approximately correct for high and moderate humidities and for situations at no great height above the sea; in other words, they may be regarded as accurate for at least such conditions as are presented by the climates of the British Islands. They are, however, insufficient, owing to the comparatively large errors attending their use, for the reduction of observations made in elevated situations and in such arid states of the atmosphere as are of frequent occurrence in India and South Africa. The preparation of such tables remains still a serious desideratum in meteorology; and another desideratum equally important is the introduction of a simple, handy, and accurate method of observing the hygrometry of the air when its temperature descends below the freezing-point of water, some method which would involve only a minimum of manipulative skill and trouble in making an observation. See Atmosphere. (A. B.)

HYMEN, or Hymenæus, was originally the name of the song sung at marriages among the Greeks. As usual the name gradually produced the idea of an actual person whose adventures gave rise to the custom of this song. He occurs often in association with Linus and Ialemus, who represent similar personifications, and is generally called a son of Apollo and a Muse. In Attic legend he was a beautiful youth who, being in love with a girl, followed her in a procession to Eleusis disguised as a woman, and saved the whole band from pirates. As reward he obtained the girl in marriage, and his happy married life caused him ever afterwards to be invoked in marriage songs. At other times the tale is of an opposite character; Hymen was unfortunate either by dying on his marriage day or in some other way, and he was invoked to propitiate him and avert a similar fate. He occurs often in the train of Aphrodite, along with Eros, Himerus, Pothus, &c. According to Orphic legend he was restored to life by Asclepius.

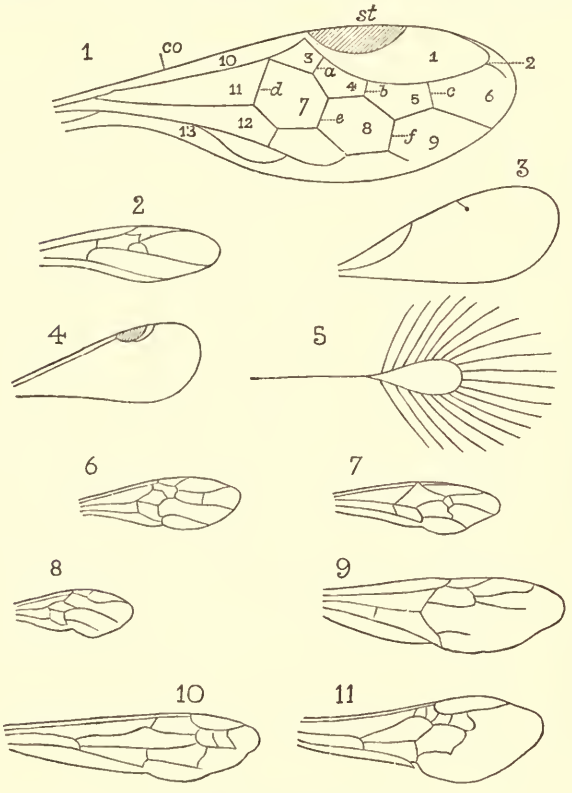
HYMENOPTERA (the *Piezata* of Fabricius, *Hautflüger* or *Aderflüger* in German), an order of *Insecta* (so named from their wings being joined, as hereafter described) containing the insects commonly called bees, wasps, ants, ichneumons, gall-flies, saw-flies, and others less known which have received no English names. The main characteristics of the order are these:—the possession of four wings, of which the anterior are always larger than the posterior, always of the same texture, and mostly with nervures arranged in regular patterns; a dense hard skin, smooth, shining, or very hairy; a mouth always provided with mandibles adapted for biting, though the other mouth parts may be so modified as to serve for mastication, or for the sucking, or rather lapping, of liquids. The female is provided with an anal instrument connected with oviposition, and sometimes serving for defence, in which case it is in communication with a poison gland. They undergo a regular transformation, and have larvæ provided with legs on the thorax and abdomen, or on the former part only, or (as is more often the case) entirely footless.

General characteristics.

The wings have few nervures, and may be even entirely devoid of them; when present they proceed from the base of the wing, or from the costa (the part which bounds the wing in front) towards the apex, which they may or may not reach. Connected with the lateral nervures are others (recurrent nervures) which unite them together, and form in this way regular cellules. The first two lateral nervures (those nearest the top) are the most important, and are called the "marginal" and "submarginal" respectively. The cellules which they form by means of the cross or recurrent nervures are called the "marginal" and "submarginal cellules." Not unfrequently there is, towards the apical third of the costa, a thickened spot (considered by some to act as a counterpoise when the insect is flying) termed the "stigma" or "pterostigma." It is not always present, however, and when present may be very small, or, as in *Pachylostica*, very large and projecting. In a similar way the hind wing may contain lateral and cross nervures, but they are fewer in number and in importance, and may be entirely absent, although present in the larger pair. The arrangement of the nervures in the *Hymenoptera* undergoes, in the various families, great diversity; and, what is of great importance in classification, their form, in the different families, and even genera, is, within certain limits, remarkably constant. On this account great attention has been paid to them; and each nervure and cellule has received a distinct name. The use of the nervures and cellules does not lead to the formation of artificial groups; for we find that the existence of a particular arrangement of the nervures in a hymenopterous insect denotes the presence of other characters. Each family indeed has its own form of wing, as will be seen from the accompanying figures. The relative value, however, of the neuration in classification is not always the same. It is of much greater importance, for instance, with saw-flies than with bees. The wings are usually shorter than the body, and may be so short as to be useless for flight; they may be even entirely absent. Apterous species are found in almost all the families. In most cases it is the females only which are thus deprived of the power of flight. But the opposite of this may exist; as, for instance, with a curious species of *Chalcididæ* which lives in the nest of bees as a parasite. With ants, again, the neuters are always wingless; and the females lose their wings when they commence the formation of a colony. It is worthy of remark, too, that some *Chalci-*

Wings.

didæ and *Oxyura*, which are normally winged, occasionally appear in an apterous or semi-apterous condition. On the anterior margin of the hind wings are placed a number of very minute hooks, which fit into a thickened rim on the posterior margin of the front wings, so that the two become united, and strike the air as one whole. The wings are usually transparent, and, in certain arrangements of the light, are seen to be highly iridescent. Occasionally they are coloured in patches, or are entirely black or blue; in the latter case, they are not unfrequently of a thickish texture and have a metallic lustre, as, *e.g.*, in *Hylotoma*. The smaller forms (*Chalcididæ* and *Oxyura*) have few or no nervures. Some of these have the wings deeply fringed;



Wings of Hymenoptera.

1. Tenthredinidæ (*Hylotoma*)—1, marginal; 2, appendicular; 3, 4, 5, 6, submarginal; 7. 8, 9, discoidal; 10, costal; 11, 12, branchial; and 13, lanceolate cellules; *a*, *b*, *c*, submarginal nervures; *d*, basal nervures; *e*, *f*, recurrent nervures; *st*, stigma; {*co*, costa. 2. Cynipidæ (*Cynips*). 3. Chalcididæ (*Perilampus*). 4. Oxyura (*Codrus*). 5. Oxyura (*Mymar*). 6. Braconidæ (*Bracon*). 7. Ichneumonidæ (*Trogus*). 8. Chrysididæ (*Cleptes*). 9. Formicidæ (*Formica*). 10. Diploptera (*Vespa*). 11. Anthophilia (*Apathus*).

and *Mymar* and *Flabrinus* have the wings as it were cleft and stalked; that is to say, there is a long, thin stalk projecting from the thorax for a certain distance; then it dilates into a number of deeply fringed branches (see fig. 5).

Head. The head is seldom broader than the thorax. It is usually of a more or less globular shape, but may be much flattened and long. The compound eyes are placed along the sides, while the simple eyes, or ocelli, are arranged in a triangle on the vertex. Certain ants and *Chalcididæ* are blind. Others have eyes, but want the ocelli. The mouth organs are, except with bees, adapted solely for mastication or for prehension; while, in addition to performing these functions, wasps use them for building up or digging out their nests in the ground or wood. Some worker ants and other aculeates (especially males) have the mandibles enormously developed. *Blastophaga*, an insect found in figs, has a curious mandible, remarkable, not in itself, but by having attached to it an appendage whose use is supposed to be to clean away the juice of the fig from the mouth. The maxilla and labium are provided with jointed palpi. The number of joints in the maxillary palpi is usually five, but may be more or less than that; the labial palpi are two- to four-jointed. It is with bees that the mouth parts (and especially the ligula) have their greatest development and specialization. With them the various parts (except the mandibles) are elongated to form a sucking tube, by means of which they lap up the nectar of flowers.

The form of the antennæ is very variable. They may Anten have three (*Hylotoma*) to sixty joints (ichneumons); may be very long and thin as in ichneumons, or scarcely projecting beyond the head as in *Perga*; of uniform thickness, or distinctly clavate as in *Cimbex*; bare, or very hairy. Then they often differ very much in the males. *Lophyrus* (*Tenthredinidæ*) and many *Chalcididæ* have them pectinated in various degrees; they are deeply forked in *Schizocera*; and many others have them covered with long hair, although they are quite bare in the other sex. In some families the number of joints varies very much, but most *Aculeata* have the same number, namely, 13 in the male and 12 in the female. These appendages serve as sense organs, especially for the discovery of food, and, in the male, for finding the female. At any rate an ichneumon (for instance) when searching for a larva in which to lay its eggs (and this has especially been noticed with those which oviposit in concealed larvæ) keeps them in a state of continuous trembling motion, and males have also been observed to do the same when searching for the females.

The three divisions of the thorax—pro-, meso-, and meta- Thora thorax—have pretty much the same relative proportions in all the families. The prothorax is small. The upper part is strongly articulated to the mesothorax, while the lower is freer; and it is by means of this lower part that the head is united to the thorax. The metathorax is very large, as might be expected, from its having to take such an important part in flight. As for the scutellum it varies more than any other portion of the thorax. Mostly it is flat, or at least only slightly raised above the mesonotum; but in the smaller groups (*Oxyura*, *Chalcididæ*, *Cynipidæ*) its form is sometimes very curious. In *Ægilips* (*Cynipidæ*) and *Agriotypes* (*Ichneumonidæ*) it is produced into a sharp more or less curved spine; in *Eucœla* it is cup-shaped, that is to say, it is raised up, and has the centre hollow. It undergoes, however, its greatest development with some *Chalcididæ*. In *Chirocerus*, for example, it is lengthened so much that it reaches the middle of the abdomen. The metathorax is never very large, nor does it exhibit any marked peculiarities.

The legs show the same manifold diversity in form that Legs. we found to exist with the other appendages. The basal parts—the coxæ and trochanters—are not usually of any size, except in the lower tribes, *e.g.*, *Chalcididæ*. In classification the trochanters are of value, for we find with the *Aculeata* they are joined to the femora by a single joint, whereas in all the other *Hymenoptera* there are two joints. Hence the bees, wasps, &c., form the division *Monotrocha*; and the ichneumons, saw-flies, &c., are denominated *Ditrocha*. Some *Chalcididæ* have the femora greatly thickened, and toothed on the under side;[1] but as a rule it does not show any striking peculiarity unless it be with some male insects. As might be expected from their more intimate connexion with the habits of the insects, the tibiæ and tarsi vary according to the uses they are put to, apart from locomotion. With bees (at least with the non-parasitic species) they are employed to carry the pollen necessary for the nourishment of the young; for this purpose they are

[1] The enormous development of the hind femora in *Chalcis* and *Leucaspis* does not appear to give these insects extra leaping power. Other *Chalcididæ* which have not thickened femora can leap considerable distances.

provided with hairs, or the apex of the tibiæ and base of the tarsi are flattened out to form a plate on which the pollen is stored for its easier and more economical conveyance to the hive. They are richly spined in the sand-wasps, and are thus useful to the animals in digging out the nests which they form in the earth. At the base of the tibiæ are placed two spurs (calcaria), which, however, may be absent. Finally the tarsi are provided with plate-like processes termed patellæ, which may be very largely developed, especially with males; and the front pair may terminate in large jointed raptorial claws, as is the case with *Chelogynus* (*Oxyura*).

men. The abdomen may be united to the metathorax in two ways: it may be joined to it by its entire width, or by a narrow pedicle only. In the former case the thorax and abdomen form as it were one whole, so that the body has the appearance of being composed of only two parts; whereas in the other section the three divisions, head, thorax, and abdomen, are clearly separated, or specialized. It is only the *Siricidæ* and *Tenthredinidæ* which have the abdomen united by the whole width. Thus the order becomes divided into two well-marked divisions, one represented by the *Tenthredinidæ* (having the abdomen sessile) and the other by the *Aculeata*, *Ichneumonidæ* (having it appendiculated). The abdomen shows little variation in structure or form in the *Tenthredinidæ*; but does so to a large extent with the others. Usually more or less globular and rounded, and not of any great length compared to the head and thorax, it is often very much compressed and sabre-like, as in *Ophion*, or very long and thread-like as in *Pelecinus*; then it may be joined to the thorax in such a way as to be semi-sessile, or by a very long, thin, thread-like pedicle (*Pelopæus*, many *Chalcididæ*, and *Cynipidæ*). Between these two extremes there are all gradations, the form of the abdomen depending on the habits of the insect, upon its manner of self-defence or of oviposition. As regards the number of the segments, it varies. It is 8 with the *Tenthredinidæ* and with the *Siricidæ*, but in other groups it is less. Through one or other of the basal segments being greatly developed, and the terminal ones correspondingly reduced in size, some groups appear to have only 3 or 4 (*Chrysididæ*). The *Aculeata* have always the same number, namely, 7 in the males and 6 in the females. Some bees (*Cœlioxys*) and *Chrysididæ* have the abdomen armed with spines or teeth at the apex.

pro-ctive ans. The male and female organs are situated at the end of the abdomen. They are rarely conspicuous externally with the males; but in some females they are of great length, and may indeed exceed considerably the length of the body. However different in the various groups of *Hymenoptera* the organs connected with the laying of the eggs may be, they are fundamentally constructed on the same plan in all of them, no matter how different they may appear or how various the ways in which they may be used. A typical ovipositor in the *Hymenoptera* may be described as being composed of three bristle-like organs,—one placed above, and the others below. This upper bristle is channelled throughout, and has (when in use) the others pressed to it in such a way that the three together form a narrow tube, through which the egg passes. The two lower bristles are toothed at the lower end. These three parts are enclosed between a couple of two-jointed valves, situated at their base, which serve them as supports. Thus the ovipositor consists of five different parts. It exists under two forms. In the bees and wasps (*Aculeata*) it takes the form of a sting, or weapon of defence; and it is connected with a gland secreting a poison (the principal constituent being formic acid) which the insect injects by means of the sting into any thing that attacks it. Besides this defensive (or offensive) use to which it is put, it is employed by the sand-wasps to benumb the larvæ and other insects or spiders with which they store their nests for the use of their young, in such a way that they remain to all intents and purposes lifeless, yet still keeping fresh, until such time as the wasp-larvæ escape from the eggs and are ready to feed on them. In the rest of the order—with ichneumons, saw-flies, &c.—it is not used as an instrument of defence (some ichneumons, indeed, will attempt to pierce the hand with it when caught, but they are never able to do any harm); it is simply an instrument for laying the eggs, and is not connected with a poison gland, or at any rate with a gland secreting a poison similar to that of a wasp. A poison gland exists, for instance, with saw-flies, but its purpose and also the manner of its use are different from what they are in the case of the aculeates. Its function is to act on the plant in which the eggs are laid,—either to raise galls in which the larvæ will find food and shelter, or to prevent the hole made by the ovipositor for the reception of the egg from closing in on the egg, and thereby crushing it; for we find that eggs laid, for example, on leaves are not closely pressed by the substance of the leaf, but have a more or less open space surrounding them.

From the observations of Kraepelin on the development of the ovipositor, it seems clear that the grooved central bristle and the two basal sheaths arise in the larva from papillæ situated on the under side of the ninth abdominal segment, while the two lateral (or rather lower) bristles have their origin in similar papillæ on the eighth. It would appear also highly probable that the parts are true appendages of the abdominal segments, rather than modified portions of the body walls.

The ovipositor is either hidden (as is mostly the case) or may be exserted to a greater or less extent. Its length varies with the habits of the species; that is to say, the longer it is, the deeper, in wood, or in any other substance, does the larva, on which the ichneumon is a parasite, live. Species with long ovipositors occur in all the parasitic families, except the *Oxyura* and *Chrysididæ*. With the last-mentioned family it is tubular. It is strangely modified with the saw-flies. With them it forms a veritable sawing apparatus (hence the name of these insects), being broad, plate-like, and toothed in various ways and degrees according to the habits of the insects; according as the eggs are laid in leaves or in bark it is slender and thin or broad and thick. In the pupa state *Hymenoptera* with long ovipositors have them curled up on, and closely pressed to, the back. It is a curious circumstance that this embryonic condition of the ovipositor is retained in the perfect state by a few forms, as, *e.g.*, *Leucaspis*.

As remarked at the beginning of this article, the *Hymenoptera* go through a regular metamorphosis—appearing in four distinct forms. The egg is generally longer than it is broad, and rounded at both ends. The skin is always thin, never sculptured, and rarely coloured; the only instance of colour in any of their eggs known to the writer being in those of certain saw-flies which are more or less greenish, and this colour may have been imbibed from the leaf. Many parasitic species (*Ophion*, *Cynips*, *Mymar*) have pedunculated eggs,—eggs provided with a long pedicle or stalk, by means of which they are attached to the plant or insect, as the case may be. A *Tryphon*, for example, attaches her stalked eggs to the larva's skin; it hangs by the stalk; and when the young tryphon-larva's development in the egg is matured it leaves it by the lower end, and then proceeds to bore its way into the inside of its victim. A curious phenomenon has been observed to take place in hymenopterous eggs shortly after being laid; it is that they swell up (perhaps by imbibing moisture, although this cannot be the sole cause of the swelling) to double or more than double the size they were when laid. The number of eggs laid by a female varies of course with the species. Colonial species lay the greatest number; but with them the eggs are not laid all at once, as is the case with solitary species. Some social forms lay comparatively few eggs, while, on the other hand, many saw-flies and ichneumons must lay some hundreds. Solitary bees and wasps do not lay many; but it must be remembered that the storing of food and the building and digging of the nest are works of labour and time. Metamorphoses. The egg.

The larvæ. The larvæ are of two sorts. Those of species with a petiolated abdomen are white, footless grubs, incapable of any extended motion; nor is this necessary, for they have not to seek their food, which is provided for them by their mothers,—either collected and stored up for them in nests made by the female, as with bees and wasps, or by the eggs being placed in the bodies of other insects on which they live as parasites, or in galls upheaved on plants. It is, however, of interest to note that, while the larva after leaving the egg shows no trace of legs, yet they were present when it was in the egg. This shows clearly that the legs were lost through disuse. And this view is confirmed by the fact that the larvæ of the lowest division of the *Hymenoptera*, those with a sessile abdomen, have jointed thoracic legs, and often abdominal legs as well, while they, for the most part, lead a free existence. In the lowest group of this division, the *Siricidæ*, as well as in those *Tenthredinidæ* most nearly allied to them, the larvæ have only the thoracic or true legs. They live either boring in wood, as *Sirex*, or in stems of plants, as *Cephus*, or in leaves rolled together by silken threads, as *Lyda*. Except *Lyda*, *Cephus*, and *Xyela*, all the saw-fly larvæ have the usual thoracic and a variable number of false or abdominal legs, which are in fact merely prolongations of the ventral surface of the body, as with many phytophagous *Coleoptera*; nor have they anything like the claspers of lepidopterous caterpillars. With their similar habits and the presence of these ventral legs, saw-fly larvæ have a considerable resemblance to the caterpillars of *Lepidoptera*, but they may be known from them in two ways,—by always having more than five pairs of ventral legs (eight in *Cimbex*, seven in *Nematus*, and six in some *Hylotomides*), and never having more than two ocelli—one on each side of the head—instead of six on each side as in *Lepidoptera*. As with lepidopterous caterpillars, green is the prevailing colour of saw-fly larvæ. They agree with them, too, in their general habits: they live on the leaves of various plants, devouring them in different ways, roll down leaves, raise galls, and mine leaves. It is interesting to note further that, as with lepidopterous caterpillars, larvæ which are innoxious and eaten by birds are either entirely green, or green with black, pink, or white stripes along the sides and back, while noxious larvæ—those with bad smells or secretions which render them unpalatable to birds—have bright contrasting colours with irregular markings, tubercles, &c., and they feed exposed, so that they may be readily seen and avoided. Some hymenopterous larvæ before becoming pupæ moult a certain number of times. According to Packard, a *Bombus* casts off its skin ten times; *Tenthredinidæ* do it five times; but many (all parasitic, and most aculeates) do not moult until they become pupæ; nor do they empty the contents of the stomach till then. The period during which a hymenopteron remains in the larva state is seldom long; it may be eight or nine days, or a month or two, but this depends on the season of the year; for many larvæ, which have not been able to reach maturity in the autumn, remain in the same condition until the following spring, when they pupate. In order that this period may be passed in quietness, a cocoon is usually spun by the larva. For this purpose it is provided with a spinning apparatus, and a gland for secreting the silk required for the construction of the cocoon. With the *Aculeata* it is thin and almost transparent; it is of a firmer consistency with ichneumons, and is often coloured black, brown, or grey. *Microgaster* and other *Braconidæ* spin their cocoons in company, and often around the dead body of the larva which they have devoured. They may be placed together without any regularity, or closely pressed in regularly arranged rows like the cells in a hive. Some ichneumons suspend their cocoons from twigs, &c., by means of a silken thread. Generally the cocoon is single, but certain saw-flies (*e.g.*, *Cimbex*) spin double ones,—a thin inner one (which may be separated from the outer one by a considerable space) placed inside an outer, harder, and more tenacious covering. A cocoon, however, is not always spun. *Cynipidæ* never spin one, nor apparently do *Chalcididæ* nor some ants, *e.g.*, *Myrmica*. The empty skin of the caterpillar which they have devoured is utilized by some ichneumons instead of a cocoon; galls serve the same purpose with others; while *Emphytus* and other *Tenthredinidæ* bore into pithy stems, where they pass into pupæ without any other protection. Finally, others make a cell in the earth for the same purpose.

The pupa. The pupa resembles very closely the perfect insect, save that the wings are not developed, although visible as pad-like structures along the sides. The legs and antennæ are laid along the front of the body, enclosed in thin pellicles. In certain *Chalcididæ* (*Eulophus*) the pupa is of that form called "coarctate"; that is to say, the entire body is enveloped in a case which conceals its form, and this case is hard and of some thickness, instead of being a mere thin transparent skin. When the insect leaves this pupal covering the latter retains its form intact. Most pupæ are white. Many saw-fly pupæ are green, with orange spots on the abdomen. A few *Braconidæ* (*Apanteles*) have orange-coloured pupæ.

In the pupa state *Hymenoptera* remain but a short time,—as a rule, not more than seven to ten days. They are not entirely quiescent in this condition, but have considerable power of motion, especially if exposed to the light, or disturbed in any way. As the insect gradually reaches maturity, the pupa becomes more or less black,—at first on the back of the thorax, then on the abdomen and limbs. When maturity is gained, the insect splits the pellicles which so closely envelop its body; the limbs are freed; the wings spread out and lose their flabby consistency; the nervures become hard and firm; the insect moves about, ejects from the anus a coloured liquid, and enters on its new mode of existence.

The sexes. Hymenopterous insects procreate by the union of the two sexes. This takes place usually in the sunshine. Sometimes the connexion does not last more than a few seconds, and is not preceded by any preliminary courting. On the other hand many bees remain united for hours, and the genital parts of the male get torn and ruptured, so that it dies immediately after. Some species of *Chalcididæ* have been observed coquetting together for more than an hour before uniting. Generally copulation takes place on the ground; but a few forms pair on the wing. The male *Anthophora*, for instance, carries the female with him into the air for the marriage flight. This is the reason why the male *Anthophora* is larger than the female, instead of being smaller, as is usually the case.

While, as has been said, *Hymenoptera* reproduce by the union of the two sexes, yet parthenogenesis or virgin reproduction is of not uncommon occurrence, and has been observed in all the families whose development for more than one generation can be traced with sufficient facility and accuracy. We meet with this phenomenon under (broadly speaking) two or three phases. Many females, if they cannot get access to males, will readily lay eggs, which are fertile and give issue to larvæ; but these larvæ, when they reach maturity, yield invariably males. Any one can test this for himself with the too common gooseberry grub, *Nematus ribesii*. The same thing occurs with wasps, ants, and bees. With saw-flies, again, there are some species whose males are quite unknown, although the species have been caught and bred from the larvæ in hundreds, *e.g.*, *Eriocampa ovata*. Others have males, but they are extremely rare, *e.g.*, *Nematus gallicola*. It has been shown, too, that the species just mentioned and some others (*Phyllotoma nemorata*, *Pœcilosoma pulveratum*, &c.) with males unknown readily lay fertile eggs. The queen bee can lay eggs which will produce males or females, by opening or closing the spermatic sac, and letting the eggs come in contact or not with the spermatic fluid. In the former case females will be the result, in the latter males. Worker bees, wasps, and ants deposit eggs which produce, however, only males. A still more curious phenomenon in connexion with the reproduction of some gall-insects (*Cynipidæ*) requires to be mentioned. In early spring will be found on oak leaves and flowers soft, juicy, greenish, globular pea-shaped galls. Out of these come in summer the gall-flies represented by both sexes. In the autumn (also on oak leaves) are found those curious flat brownish galls commonly called "oak spangles," which by many are taken for fungi, and have indeed been described as such. These "spangle galls" retain very much the same form during the autumn and winter; then in March they swell up and become juicy, and a larva makes its appearance; this soon becomes a pupa and finally a fly, but only in one sex, the female. It was long supposed that these two insects had no relationship with each other, that they belonged in fact to two distinct genera, for not only did the galls differ, but the insects themselves differed in the form of the body, the wings, &c. But it has recently been shown by Dr Adler that the two are forms of the same species, that there is an alternation of a spring bisexual form, with an autumnal unisexual one.

A dimorphism of another kind exists among the social bees, wasps, and ants. An ordinary colony of these insects consists of three sorts of individuals. There is the large female which founded the colony; then there are the workers or neuters, undeveloped females on whom the work of the colony depends; and, lastly, there are the males. It is with ants that the workers are most profoundly modified. They are wingless, and there may be in a colony several sorts, each kind performing different duties, and having the body modified in accordance with the work it has to do. Those which act as soldiers (when a special kind is set apart for this work), for instance, have the mandibles enormously developed; another set may secrete honey for the benefit of the others, &c.

...g of ...rder ...an.

The *Hymenoptera* must be regarded as one of the most beneficial and useful to man of the insect orders. The produce of the hive bee—wax and honey—has been employed by man since the earliest ages, and forms an extensive article of commerce. The curious structures raised by *Cynipidæ* on the oaks of eastern Europe—galls—have long been used in the manufacture of ink. But, whatever the bee may have done in contributing to our luxuries, and the gall-fly in rendering easier the advance of knowledge, these are small benefits compared to the indirect advantages we derive from the labours of the parasitic species through the havoc they make among the insects which devour the produce of our fields and gardens, and too often destroy the labours of the farmer and gardener. When we remember that there are vast numbers of insects which destroy plants; that many of these are so minute and obscure in their mode of life as to escape ordinary observation, save when the injury is done; and that others appear in enormous numbers,—it becomes evident that an insect which causes the death of a single caterpillar does good service, since that caterpillar would have (if left undisturbed) given, in all probability, origin to an imago which might give birth to hundreds of others. It is this which the ichneumons do,—they destroy the larvæ of plant-devouring insects. Another division of *Hymenoptera* does equally good service. It has been shown by modern researches that without the aid of bees many flowers would never yield seed. Many plants cannot fertilize themselves, so that if bees did not carry the pollen from one plant to another, and thus effect fertilization, no seed would be produced. The red clover, for instance, would never produce seed if it were not for the humble bees fertilizing it in their visits in search of honey. It must, however, be confessed that some *Hymenoptera* do very considerable damage to vegetation, especially saw-flies and ants. Of injurious saw-flies the most destructive are *Eriocampa adumbrata*, on fruit trees; *Nematus ribesii*, which is so destructive to the gooseberry and red currant; *Athalia spinarum*, at one time so destructive to the turnip (probably when it first took to feeding on it); and *Cephus*, in the stems of corn. The damage done by ants in Europe is small; but in the tropics the leaf-cutting ants do enormous damage by cutting down the leaves of trees (especially cultivated ones), which they convey into their nests, where they are used (according to Belt) to rear fungi upon which the ants feed.

...atic ...ies.

The *Hymenoptera* are almost exclusively dwellers on land, and are essentially sun-loving insects. Two or three only live an aquatic or quasi-aquatic mode of life. Sir John Lubbock discovered two minute species of *Oxyura* (*Polynema*) which descend into the water for the purpose of depositing their eggs in the eggs of aquatic insects. They use the wings as oars to swim in the water, and can remain in it for two hours. An ichneumon (*Agriotypes*) has long been known to live as a parasite in the bodies of caddis-worms; and it has been observed to go down into the water to find the worms, which are said, when infested by the ichneumons, to anchor themselves by means of a silken thread.

...ssion ...ound.

Many *Hymenoptera* give origin to sounds. The humming of bees is one of the most familiar and delightful of country sounds. It is not yet quite clearly understood how it is caused, but there is evidence enough to show that the buzzing originates by the air impinging against the lips of the metathoracic and abdominal stigmas; although it is possible, too, that the rapid vibration of the wings (224 per second with the *Bombus muscorum* and 440 with the honey bee) may also have something to do with the production of sound, for a bee can give out differently pitched notes according to its mood, as it is pleased or angry. Besides the buzzing sounds, a few other species chirp by means of the abdominal segments. *Mutilla* stridulates by drawing in and out the raised striated surface of the third under the edge of the elongated second segment. The workers of *Myrmica* stridulate in pretty much the same way.

Internal anatomy.

The internal anatomy of the *Hymenoptera* presents some interesting features. Their organs of secretion are numerous. The poison is secreted in two long ramose tubes; and from them it goes into a sac situated near the base of the sting. Wax is made in some of the abdominal segments.[1] The salivary glands in the hive bee (worker) are very large and complicated. They are three in number, two (an upper and a lower) placed in the head, and the other in the front region of the thorax. Each gland is different, and has excretory ducts of its own. In the queen bee these are not nearly so much developed as in the worker, and they are even less in the drones. Many saw-fly larvæ secrete fluids for purposes of defence. Some species of *Tenthredo* secrete a blackish liquid, which they eject from the mouth; *Perga* throws out a gummy matter from the same orifice, and *Cimbex* an acid liquid from lateral pores. Then there are the silk-secreting glands which most larvæ possess. The urinary vessels are always present, and may be as many as 150. According to Von Siebold, the aculeates have a long intestine and a stomach with many convolutions, while they are short in the terebrant forms. The tracheæ are well developed. Many dilatations are given off from the main stems, a pair at the base of the abdomen being exceptionally large. In connexion with the female organs of generation, it is worthy of remark that sebaceous glands and a copulatory pouch are absent in the *Aculeata*, although present in the other section. The ovaries are two in number, and consist of a number (it may be as many as a hundred) of distinct many-chambered tubes. Each tube in *Athalia*, for instance, contains 7 eggs, and, as there are 18 of such tubes in each ovary, there will be thus 250 eggs in all. In *Platygaster* the ovary is of a very exceptional nature, inasmuch as the egg tube is a close sac, so that it is burst when the egg is laid.

Specialties in development.

The most noteworthy and exceptional features in the developmental history of the *Hymenoptera* are those shown by some very minute species of *Oxyura*, which live in the bodies of *Diptera* (*Cecidomyia*), and in the eggs of beetles and dragon-flies. After the eggs of *Platygaster* have undergone segmentation, and the embryo has been formed, there leaves the egg a larva of a very unusual form. It is broad and rounded at the head, but contracted towards the tail, which terminates in four spined, bristle-like appendages, so that the larva has a considerable resemblance to a copepod. It is provided with a mouth and hook-like mandibles, by the aid of which it anchors itself inside the body of its host (the larva of a *Cecidomyia*); there are a rudimentary stomach and antennæ, but no trace of nerves, tracheæ, or organs of circulation. Soon it changes its form: the tail with its bristles is thrown off; it becomes shaped somewhat like a hen's egg; the nervous, circulatory, and reproductive organs become visible, while the alimentary organs show an advance in structure. This second

[1] The wax is secreted on the ventral surface of the hive bee, but on the dorsal surface with the stingless bee of America (*Melipona*).

larva is succeeded by a third, which differs from it in being longer and thinner, while the various organs have reached a further stage of advancement in complexity of structure. The after course of its development does not differ from that of other *Hymenoptera*. *Polynema* and *Mymar* (egg-parasites) go through somewhat similar changes in their early embryonic life.

Classification.

Classification.—As regards the classification of the *Hymenoptera*, the order divides itself naturally into two great divisions, as has been already indicated. The *Aculeata* form a division distinguished alike by the form of the sting, with its connected poison-bag, and by the trochanter being joined to the femur by a single joint. The other division (that usually called *Terebrantia* or *Ditrocha*) has a double joint to the trochanter, and the ovipositor is never used as a weapon of offence.

The *Ditrocha* are again divided into two sections, well distinguished by the form of the abdomen, by the larva, and by habits: the one (the *Securifera*) has the abdomen sessile, the larvæ have legs, and they are phytophagous; while the other (the *Spiculifera*) has the abdomen petiolated, the larvæ are apodal, and they are (except part of the *Cynipidæ*) animal feeders. The *Securifera* are further distinguished from all others by the form of the ovipositor, which forms either a short "saw," as in the *Tenthredinidæ*, or a stout exserted "borer," as in the *Siricidæ*; and they have another peculiarity in having at the bottom of the anterior wing a cellule, termed the "lanceolate cellule" (see fig. 1, above), which is found in no other family, and is of great use in classification. The *Securifera* embraces the families *Tenthredinidæ* and *Siricidæ* (by some *Cephus* is made into a third family, while by others it is placed among the *Tenthredinidæ*, owing to its agreeing with the saw-flies in the form of the thorax and ovipositor, and by others with the *Siricidæ*, because it has only one spine in the anterior leg, while the saw-flies have two). The species of *Siricidæ* are few in number, and have a very wide distribution. They are larger than any *Tenthredinidæ*, and are indeed among the giants of the order. All live in wood, especially in *Coniferæ*, and have occasionally done great damage to the forests in Germany. As they are easily imported along with timber, they very often make their appearance in out-of-the-way places and frighten ignorant people, although, of course, they are perfectly harmless.

The *Spiculifera* contain the families *Cynipidæ*, *Chalcididæ*, *Proctotrypidæ*, *Evanidæ*, *Braconidæ*, and *Ichneumonidæ*.

The *Cynipidæ*, or gall-flies, are small insects, rarely exceeding two lines in length. The antennæ are straight, inserted in the middle of the face; the joints are variously shaped, and do not exceed 16 in number. The thorax is large; the scutellum always forms a conspicuous object, and its form is very varied. The abdomen is much compressed, especially with the males; curled up over the apical segments is the long thin bristle-like ovipositor. A few species are apterous. There is always a radial cellule in the anterior wing, but few nervures and there is never a stigma. What distinguishes the *Cynipidæ* more especially is their habit of raising galls on plants to serve as food and lodgings for their young.[1] These galls have the most diversified shapes, and are raised on all parts of a plant—the buds, leaves, roots, flowers, and fruit all being used by the gall insects. A gall may serve to shelter a solitary larva, or it may be so large as to contain many hundreds. The oak is the principal tree used by the *Cynipidæ*; next is the rose, upon which is found the well-known "bedeguar gall" of *Rhodites rosæ*, once used medicinally; the maple, poppy, bramble, hawkweed, and some other plants have likewise their galls. All *Cynipidæ*, however, are not gall-makers. One group deposit their eggs in the galls raised by the true gall-makers, when they are soft and young, and the larva of the cuckoo-fly lives on the gall at the expense of the legitimate owner, which is killed by the more energetic intruder. Another group contains pure animal feeders, parasites which live at the expense of other insects (especially plant lice).

Closely allied to the *Cynipidæ* is the family *Chalcididæ*, an immense tribe of very minute insects with brilliant metallic green bodies. Their wings have few nervures, and they never form closed cellules, but a stigma is always present. The antennæ are always elbowed; they have never more than 13 joints, and may have as few as 6. With the males they are sometimes flabellate, or covered with tufts of hair. Generally the ovipositor is short and concealed, but it may be exserted and much longer than the entire body. In either case it issues from the lower side of the belly. Apterous and semi-apterous species are not uncommon. In habits the *Chalcididæ* are very diversified. They are parasites on insects of all orders and in all stages. While no definite line can be drawn, yet particular groups in the mass confine their attacks to certain families of insects. Thus *Leucaspis* and *Chalcis* are attached to bees and other nest-building aculeates, the long-tailed *Torymides* to oak and other galls, the *Encrytides* to *Homoptera* (*Coccus* especially). Species of *Isosoma* appear to be herbivorous, and one in America is destructive to corn, by raising gall-like structures at the joints and thus causing the plant to wither. Giraud has likewise described *Isosoma* to be a vegetable feeder, at any rate during a considerable portion of its life, as well as another species (*Aulogymnus aceris*) which lives in galls on the maple. Those curious forms, *Sycophaga* and *Blastophaga*, which live in figs, appear undoubtedly to feed on their seeds.

The species of *Proctotrypidæ* (called also *Oxyura*), unlike those of the *Chalcididæ*, are dull-coloured insects, usually entirely black, or at best relieved by brown or red. They are distinguished from the last family by the non-elbowed antennæ, which are 8- to 13-jointed. The wings in the smaller forms may be without nervures, while in the higher they are much more developed than in the *Chalcididæ*. The edges of the wings are deeply fringed with some species; and other species have dense patches of hair on the thorax and abdomen. One group bears raptorial claws on the front tarsi; and, in connexion with this structure, it is worthy of notice that the late A. H. Haliday observed one species to kill and deposit in an empty straw a caterpillar, apparently for the purpose of laying its eggs in it; so that in habits it approximates to the fossorial *Hymenoptera*, which some of them undoubtedly do in structure. The *Oxyura* are parasites. Some are attached to gall insects, others to aphides, while *Diptera* and eggs of insects of all orders afford nourishment to many.

The insects usually called "ichneumons" belong to two families —the *Ichneumonidæ* and *Braconidæ*. Both are readily distinguished from the families already mentioned by the wings being well provided with nervures, which form regular cellules, by the greater number of joints in the antennæ, and generally by their much greater size. The only radical distinctions between the groups are that the *Ichneumonidæ* have two recurrent nervures, and a little joint in front of the second antennal joint, whereas this is absent in the *Braconidæ*, which have besides only one recurrent nervure. In habits there is no broad distinction between them. They are parasites on insects of all orders. The *Evanidæ* are a small and somewhat heterogeneous assemblage of insects, which do not agree very well in their structure; but the typical species may be known by the abdomen being inserted in the middle or above the middle of the metathorax. As far as is known the family are parasitic on cockroaches, and appear to be not very numerous in species.

In some respects the *Chrysididæ* are intermediate between the *Aculeata* and the *Terebrantia*, for they have the single-jointed trochanter of the former, while in the structure of the ovipositor, in having the antennæ 13-jointed in both sexes, as well as in habit, they agree with the latter. They are exceedingly brilliant insects; their bodies are metallic, with shining green, purple, or golden hues. The abdomen hangs as it were from the thorax, and is somewhat concave on the under side. It can be bent under the thorax, so that the insect can roll itself up into a ball, which is its way of protecting itself when attacked—its hard metallic coat of mail being impregnable against the mandibles of other insects. These insects differ from other terebrant *Hymenoptera* in the structure of the abdomen, for it has never more than four segments visible in the female and five in the male, while the ichneumons have always more. The terminal segments form a tube, which is used in oviposition. In habits the *Chrysididæ* do not differ from the ichneumons, being parasites. They prey principally on bees and wasps, whose nests they enter when the owners are absent, and should they be discovered their hard skin saves them from serious injury. Indeed the only portions of their bodies which can be mutilated are the wings. St Fargeau observed a bee do this to a chrysis; she bit off the four wings, but did not thereby save her young, for as soon as the bee left, the now wingless parasite crawled into the nest and laid her eggs therein.

As has been stated, the *Aculeata* are distinguished from all other *Hymenoptera* by having a sting, a single-jointed trochanter, and the antennæ with 12 joints in the female and 13 in the male. They differ, too, in habits from the *Terebrantia*, for, although many of them are parasites, their parasitism is unlike that of the ichneumons. Parasitic *Aculeata* earn their bread differently: they enter the nests of other aculeate species and lay their eggs in the food stored up there for the benefit of the young of the builder, which are starved or destroyed by the more vigorous larva of the parasite. In order to carry out their ends with greater ease, some parasites mimic the forms of the species upon which they prey. Thus *Apathus rupestris* is coloured exactly like *Bombus lapidarius*, its host. On the other hand the species of *Nomada*, an extensive genus of parasitic bees, do not resemble in the least the bees on which they prey; they have instead gaudily coloured, hairless bodies. One of the most interesting chapters in the history of the *Aculeata* is their nest building. The nests are built in all sorts of places and of all kinds of materials.

[1] There is a radical distinction between the gall-making *Cynipidæ* and the gall-making saw-flies. The latter feed on the gall itself, so that in course of time it becomes reduced to a mere bladder; and the gall is fully formed before the larva leaves the egg. On the other hand, the development of *Cynips* and the growth of the gall go on at the same time,—the reason of this being that it feeds only on the juice of the gall, which hardens and dries very soon after it makes its appearance, so that necessarily the larva has to feed up rapidly. After the gall has dried the larva occupies a cell of harder matter than the rest of the gall, not much larger than its own bulk.

Many, like *Andrena*, dig in light soils a burrow, consisting of a narrow passage going down some inches, and having at each side of it at intervals cells in which the food is stored. Wood is used by others to form somewhat similar cells, which may be lined with pieces of leaves or flowers. The stems of brambles are utilized by a large number of species of bees and fossorial *Hymenoptera*. *Osmia* uses empty shells for its habitation. Then others build up nests. *Chalicodoma* and other bees, with many wasps, construct cells by cementing together bits of mud and clay. Social wasps form their large nests of paper made of masticated wood; humble bees and the hive bee do so by a secretion called wax. Some ants build up from the ground, of leaves, &c., nests shaped like a hay-stack, which in size they may almost equal. An Indian species builds, at the ends of branches of trees, large nests of dead and living leaves matted together with a white web. Finally, the thorns of *Acacia* are hollowed out by others to serve as a residence.

The *Aculeata* may be divided into five families—the *Formicidæ*, or ants, *Mutillidæ* (commonly called "solitary ants"), *Fossores* (sand-wasps, &c.), *Diploptera*, or true wasps, and *Anthophila*, or bees. The ants are, as a rule, social insects, and their workers differ from those of wasps and bees in being always wingless.[1] What morphologically more especially distinguishes ants from other aculeates is the structure of the abdomen, which at the base (on the peduncle or petiole) is provided either with a flattened plate-like projection or with two nodes. In the former case, there is, as in *Formica*, only a rudimentary sting, while in the latter there is an efficient one, as in *Myrmica*; but there are exceptions to both rules. A few ants are solitary and parasitic in habits, and in this case the female is wingless. Closely allied to the ants are the *Mutillidæ* (by some authors the two are placed in one group, *Heterogyna*), which, however, differ from them in being solitary, in having neither a scale nor node, while the tibiæ are spined, and the tarsi ciliated. It is only the males which are winged, and they have the abdomen spined and curved at the apex. They are brightly coloured insects, and are very numerous in species. So far as is known they are parasites on humble bees. The group of *Fossores* is a very extensive one. Their habits are very interesting and varied even in the same genus. They are carnivorous, storing up (after having benumbed but not killed) caterpillars, beetles, flies, aphides, &c., in cells formed or dug out of wood or of bramble stems, in the ground, or built up of mud or sand. Some build no nests, and store up no food for their young, but live, cuckoo fashion, on other *Fossores* or bees. In general structure the *Diploptera* do not differ essentially from the *Fossores*; but they may be readily known from them by the wings being folded longitudinally in repose, while the eyes are reniform and reach to or near to the base of the mandibles. They differ too from the *Fossores* in some of them being social, as is the case with *Polistes* and *Vespa*. In habits the solitary wasps agree more or less with the *Fossores*. While the above-mentioned tribes are carnivorous, the bees, on the other hand, are entirely vegetable feeders, living on the pollen or nectar of flowers. As might be expected, we find with them certain peculiarities of structure in connexion with their habits. The great business of a bee is the storing up of food, for its own use or (and more especially) for that of its young. To do this to the best advantage certain parts of the body are adapted for the carrying home of pollen. This is done more especially on the legs. The basal joint of the tarsus is, for this purpose, flattened and compressed, and covered (at least on the inner side) with hair. This then, is a character which distinguishes them from all other aculeates. The least specialized bees carry home the pollen loose, but *Apis* mixes it into a paste in the field. To serve the same end the mouth parts are profoundly modified for the lapping of nectar. Many bees are parasites on other bees. These want the pollen collecting apparatus, and many of them have bright-coloured hairless bodies, as already remarked.

[Distribu-] The earliest *Hymenoptera* known belong to the upper Oolitic formation; but, as they are *Apidæ*, it is certain that the order must have appeared much earlier in time than that. At the present day, representatives of the order are found in all parts of the world, even as far north as 78° to 83° N. lat., where *Bombi* and ichneumons were found by the naturalists attached to the Arctic expedition of 1875–76. Many genera in all the families have a very wide distribution, *e.g.*, *Ophion* and *Pimpla* among the ichneumons, *Odynerus* with the wasps, *Megachile* with bees. Humble bees and saw-flies are characteristic of temperate, if not northern, latitudes; *Mutilla* of warm regions, although it also appears in arctic regions. *Vespa* is more limited in its range than the solitary wasps (*Odynerus*, &c.), being absent from Africa, Australia, and South America. Many individual species have a very extensive range. This has been brought about in some cases by the aid of man. In this way many pests have been carried over the globe, *e.g.*, *Nematus ribesii*, the gooseberry grub, which is now spreading over the American gardens; *Eriocampa adumbrata*, the slug worm of British fruit trees, has reached New Zealand; while, among ants, the house ant of Madeira (*Pheidole pusilla*) is now cosmopolitan. Many species are common to the Palæarctic and Nearctic regions, *e.g.*, *Megachile centuncularis*, *Vespa vulgaris*, *Hemichroa rufa*. Others have a wider geographical range. The ant *Solenopsis geminata*, for instance, is found in India, the Eastern Archipelago, South America, and the Hawaiian Islands. *Hylotoma pagana*, again, occurs in the Southern States of America, and all over Europe, and extends to India and Japan.

There being no complete list of *Hymenoptera*, it is not easy to give the number of described species, but probably it is not much over 17,000. The actual number, however, must be very much greater; probably it will be found to reach 70,000 or 80,000; for in those countries where anything like the same attention has been paid to them as to beetles they are nearly as numerous; and in no country have they received so much attention as *Coleoptera*. As regards the number of British species, there are recorded in the catalogues published by the Entomological Society of London, in 1871–2, 378 *Aculeata*, 1654 *Ichneumonidæ* and *Braconidæ*, and 325 *Oxyura*; while 325 saw-flies were catalogued in 1878—in all about 2700. Besides these there are about 150 *Cynipidæ*, and upwards of 1200 *Chalcididæ* have been described by Francis Walker; but that number may safely be reduced to 600 or 700. Number of species.

H Y M N S

1. *Classical Hymnody.*

THE word "hymn" (ὕμνος) was employed by the ancient Greeks to signify a song or poem composed in honour of gods, heroes, or famous men, or to be recited on some joyful, mournful, or solemn occasion. Polymnia was the name of their lyric muse. Homer makes Alcinous entertain Odysseus with a "hymn" of the minstrel Demodocus, on the capture of Troy by the wooden horse. The *Works and Days* of Hesiod begins with an invocation to the Muses to address hymns to Zeus, and in his *Theogonia* he speaks of them as singing or inspiring "hymns" to all the divinities, and of the bard as "their servant, hymning the glories of men of old, and of the gods of Olympus." Pindar calls by this name odes, like his own, in praise of conquerors at the public games of Greece. The Athenian dramatists (Euripides most frequently) use the word and its cognate verbs in a similar manner; they also describe by them metrical oracles and apophthegms, martial, festal, and hymenæal songs, dirges, and lamentations or incantations of woe.

[1] The wings, however, may be distinguished in the pupæ of the neuters, thus showing clearly that they have been lost through disuse.

Hellenic hymns, according to this conception of them, have come down to us, some from a very early and others from a late period of Greek classical literature. Those which passed by the name of Homer were already old in the time of Thucydides. They are mythological poems (several of them long), in hexameter verse,—some very interesting. That to Apollo contains a traditionary history of the origin and progress of the Delphic worship; those on Hermes and on Dionysus are marked by much liveliness and poetical fancy. Hymns of a like general character, but of less interest (though these also embody some fine poetical traditions of the Greek mythology, such as the story of Tiresias, and that of the wanderings of Leto), were written in the 3d century before Christ, by Callimachus of Cyrene. Cleanthes, the successor of Zeno, composed (also in hexameters) an "excellent and devout hymn" (as it is justly called by Cudworth, in his *Intellectual System*) to Zeus, which is preserved in the *Eclogæ* of Stobæus, and from which Aratus borrowed the words, "For we are also His offspring," quoted by St Paul at Athens. The so-called Orphic hymns, in hexameter verse, styled τελεταί, or hymns of initiation into the "mysteries" of the Hellenic religion, are productions of the Alexandrian school,—as to which learned men are not agreed whether they are earlier or later than the Christian era.

The Romans did not adopt the word "hymn;" nor have we many Latin poems of the classical age to which it can properly be applied. There are, however, a few,—such as the simple and graceful "Dianæ sumus in fide" ("Dian's votaries are we") of Catullus, and "Dianam teneræ dicite virgines" ("Sing to Dian, gentle maidens") of Horace,—which approach much more nearly than anything Hellenic to the form and character of modern hymnody.

2. *Hebrew Hymnody.*

For the origin and idea of Christian hymnody we must look, not to Gentile, but to Hebrew sources. St Augustine's definition of a hymn, generally accepted by Christian antiquity, may be summed up in the words, "praise to God with song" ("cum cantico"). Bede understood the "canticum" as properly requiring metre; though he thought that what in its original language was a true hymn might retain that character in an unmetrical translation. Modern use has enlarged the definition: Roman Catholic writers extend it to the praises of saints; and the word now comprehends rhythmical prose as well as verse, and prayer and spiritual meditation as well as praise.

The modern distinction between psalms and hymns is arbitrary (see PSALMS). The former word was used by the LXX. as a generic designation, probably because it implied an accompaniment by the psaltery (said by Eusebius to have been of very ancient use in the East) or other instruments. The cognate verb "psallere" has been constantly applied to hymns, both in the Eastern and in the Western Church; and the same compositions which they described generically as "psalms" were also called by the LXX. "odes" (*i.e.*, songs) and "hymns." The latter word occurs, *e.g.*, in Ps. lxxii. 20 ("the hymns of David the son of Jesse"), in Ps. lxv. 1, and also in the Greek titles of the 6th, 54th, 55th, 67th, and 76th (this numbering of the psalms being that of the English version, not of the LXX.). The 44th chapter of Ecclesiasticus, "Let us now praise famous men," &c., is entitled in the Greek πατέρων ὕμνος, "The Fathers' Hymn." Bede speaks of the whole book of Psalms as called "liber hymnorum," by the universal consent of Hebrews, Greeks, and Latins.

In the New Testament we find our Lord and His apostles singing a hymn (ὑμνήσαντες ἐξῆλθον), after the institution of the Lord's Supper; St Paul and Silas doing the same (ὕμνουν τὸν θεόν) in their prison at Philippi; St James recommending psalm-singing (ψαλλέτω), and St Paul "psalms and hymns and spiritual songs" (ψαλμοῖς καὶ ὕμνοις καὶ ᾠδαῖς πνευματικαῖς). St Paul also, in the 14th chapter of the first epistle to the Corinthians, speaks of singing (ψαλῶ), and of every man's psalm (ἕκαστος ὑμῶν ψαλμὸν ἔχει), in a context which plainly has reference to the assemblies of the Corinthian Christians for common worship. All the words thus used were applied by the LXX. to the Davidical psalms; it is therefore possible that these only may be intended, in the different places to which we have referred. But there are in St Paul's epistles several passages (Eph. v. 14; 1 Tim. iii. 16; 1 Tim. vi. 15, 16; 2 Tim. ii. 11, 12) which have so much of the form and character of later Oriental hymnody as to have been supposed by Michaelis and others to be extracts from original hymns of the Apostolic age. Two of them are apparently introduced as quotations, though not found elsewhere in the Scriptures. A third has not only rhythm, but rhyme. The thanksgiving prayer of the assembled disciples, recorded in Acts iv., is both in substance and in manner poetical; and in the canticles, "Magnificat," "Benedictus," &c., which manifestly followed the form and style of Hebrew poetry, hymns or songs, proper for liturgical use, have always been recognized by the church.

3. *Eastern Church Hymnody.*

The hymn of our Lord, the precepts of the apostles, the angelic song at the nativity, and "Benedicite omnia opera," are referred to in a curious metrical prologue to the hymnary of the Mozarabic Breviary, as precedents for the practice of the Western Church. In this respect, however, the Western Church followed the Eastern, in which hymnody prevailed from the earliest times.

The peu

Philo describes the "Therapeutæ" of the neighbourhood of Alexandria as composers of original hymns, which (as well as old) were sung at their great religious festivals,—the people listening in silence till they came to the closing strains, or refrains, at the end of a hymn or stanza (the "acroteleutia" and "ephymnia"), in which all, women as well as men, heartily joined. These songs, he says, were in various metres (for which he uses a number of technical terms); some were choral, some not; and they were divided into variously constructed strophes or stanzas.

Eusebius, who thought that the Therapeutæ were communities of Christians, says that the Christian practice of his own day was in exact accordance with this description. Gibbon considered it to be proved, by modern criticism, that the Therapeutæ were not Christians, but Essene Jews; but he recognized in their customs "a very lively image of primitive discipline;" and he states that the Christian religion was embraced by great numbers of them, and that they were probably, by degrees, absorbed into the church, and became the fathers of the Egyptian ascetics. Apollos, "born at Alexandria," may possibly have been one of them.

Ant pho sing

The practice, not only of singing hymns, but of singing them antiphonally, appears, from the well-known letter of Pliny to Trajan, to have been established in the Bithynian churches at the beginning of the 2d century. They were accustomed "stato die ante lucem convenire, carmenque Christo, quasi Deo, dicere *secum invicem*." This agrees well, in point of time, with the tradition recorded by the historian Socrates, that Ignatius (who suffered martyrdom about 107 A.D.) was led by a vision or dream of angels singing hymns in that manner to the Holy Trinity to introduce antiphonal singing into the church of Antioch, from which it quickly spread to other churches. There seems to be an allusion to choral singing in the epistle of Ignatius himself to the Romans, where he exhorts them, "χορὸς γενόμενοι" ("having formed themselves into a choir"), to "sing praise to the Father in Christ Jesus." A statement of Theodoret has sometimes been supposed to refer the origin of antiphonal singing to a much later date; but this seems to relate only to the singing of Old Testament Psalms (τὴν Δαυιδικὴν μελῳδίαν), the alternate chanting of which, by a choir divided into two parts, was (according to that statement) first introduced into the church of Antioch by two monks famous in the history of their time, Flavianus and Diodorus, under the emperor Constantius II.

Other evidence of the use of hymns in the 2d century is contained in a fragment of Caius, preserved by Eusebius, which refers to "all the psalms and odes written by faithful brethren from the beginning," as "hymning Christ, the Word of God, as God." Tertullian also, in his description of the "Agapæ," or love-feasts, of his day, says that, after washing hands and bringing in lights, each man was invited to come forward and sing to God's praise something either taken from the Scriptures or of his own composition ("ut quisque de Sacris Scripturis vel proprio ingenio potest"). Bishop Bull believed one of those primitive compositions to be the hymn appended by Clement of Alexandria to his *Pædagogus*; and Archbishop Ussher considered the ancient morning and evening hymns, of which the use was enjoined by the *Apostolical Constitutions*, and which are also mentioned in the "Tract on Virginity" printed with the works of St Athanasius, and in St Basil's treatise upon the Holy Spirit, to belong to the same family. Clement's hymn, in a short anapæstic metre, beginning στόμιον πώλων ἀδαῶν (or, according to some editions, βασιλεῦ ἁγίων, λόγε πανδαμάτωρ—translated by Mr Chatfield, "O Thou, the King of saints, all-conquering Word"), is rapid, spirited, and well-adapted for singing. The Greek "Morning Hymn" (which, as divided into verses by Archbishop Ussher in his treatise *De Symbolis*, has a majestic rhythm, resembling a choric or dithyrambic strophe) is the original form of "Gloria in Excelsis," still said or sung, with some variations, in all branches of the church which have not relinquished the use of liturgies. The Latin form of this hymn (of which that in the English communion office is an exact translation) is said, by Bede and other ancient writers, to have been brought into use at Rome by Pope Telesphorus, as early as the time of the emperor Hadrian. A third, the Vesper or "Lamp-lighting" hymn ("φῶς ἱλαρὸν ἁγίας δόξης,"—translated by Canon Bright "Light of Gladness, Beam Divine"), holds its place to this day in the services of the Greek rite. In the 3d century Origen seems to have had in his mind the words of some other hymns or hymn of like character, when he says (in his treatise *Against Celsus*); "We glorify in hymns God and His only begotten Son; as do also the Sun, the Moon, the Stars, and all the host of heaven. All these, in one Divine chorus, with the just among men, glorify in hymns God who is over all, and His only begotten Son." So highly were these compositions esteemed in the Syrian churches that the council which deposed Paul of Samosata from the see of Antioch in the time of Aurelian justified that act, in its synodical letter to the bishops of Rome and Alexandria, on this ground (among others) that he had prohibited the use of hymns of that kind, by uninspired writers, addressed to Christ.

After the conversion of Constantine, the progress of hymnody became closely connected with church controversies. There had been in Edessa, at the end of the 2d or early in the 3d century, a Gnostic writer of conspicuous ability, named Bardesanes, who was succeeded, as the head of his sect or school, by his son Harmonius. Both father and son wrote hymns, and set them to agreeable melodies, which acquired, and in the 4th century still retained, much local popularity. Ephraem Syrus, the first voluminous hymn writer whose works remain to us, thinking that the same melodies might be made useful to the faith, if adapted to more orthodox words, composed to them a large number of hymns in the Syriac language, principally in tetrasyllabic, pentasyllabic, and heptasyllabic metres, divided into strophes of from 4 to 12, 16, and even 20 lines each. When a strophe contained five lines, the fifth was generally an "ephymnium," detached in sense, and consisting of a prayer, invocation, doxology, or the like, to be sung antiphonally, either in full chorus or by a separate part of the choir. The *Syriac Chrestomathy* of Hahn (published at Leipsic in 1825), and the third volume of Daniel's *Thesaurus Hymnologicus*, contain specimens of these hymns. Some of them have been translated into (unmetrical) English by the Rev. Henry Burgess (*Select Metrical Hymns of Ephrem Syrus*, &c., 1853). A considerable number of those so translated are on subjects connected with death, resurrection, judgment, &c., and display not only Christian faith and hope, but much simplicity and tenderness of natural feeling. Theodoret speaks of the spiritual songs of Ephraem as very sweet and profitable, and as adding much, in his (Theodoret's) time, to the brightness of the commemorations of martyrs in the Syrian Church.

The Greek hymnody contemporary with Ephraem followed, with some licence, classical models. One of its favourite metres was the Anacreontic; but it also made use of the short anapæstic, Ionic, iambic, and other lyrical measures, as well as the hexameter and pentameter. Its principal authors were Methodius, bishop of Tyre (who died about 311 A.D.), Synesius, who became bishop of Ptolemais in Cyrenaica in 410, and Gregory Nazianzen, for a short time (380–381) patriarch of Constantinople. The merits of these writers have been perhaps too much depreciated by the admirers of the later Greek "Melodists." They have found an able English translator in the Rev. Allen Chatfield (*Songs and Hymns of Earliest Greek Christian Poets*, &c., London, 1876). Among the most striking of their works are μνώεο Χριστέ ("Lord Jesus, think of me"), by Synesius; σὲ τὸν ἄφθιτον μονάρχην ("O Thou, the One Supreme") and τί σοι θέλεις γενέσθαι ("O soul of mine, repining"), by Gregory; also ἄνωθεν παρθένοι ("The Bridegroom cometh"), by Methodius. There continued to be Greek metrical hymn writers, in a similar style, till a much later date. Sophronius, patriarch of Jerusalem in the 7th century, wrote seven Anacreontic hymns; and St John Damascene, one of the most copious of the second school of "Melodists," was also the author of some long compositions in trimeter iambics.

Period of Arian controversy.

An important development of hymnody at Constantinople arose out of the Arian controversy. Early in the 4th century Athanasius had rebuked, not only the doctrine of Arius, but the light character of certain hymns by which he endeavoured to make that doctrine popular. When, towards the close of that century (398), St John Chrysostom was raised to the metropolitan see, the Arians, who were still numerous at Constantinople, had no places of worship within the walls; but they were in the habit of coming into the city at sunset on Saturdays, Sundays, and the greater festivals, and congregating in the porticoes and other places of public resort, where they sung, all night through, antiphonal songs, with "acroteleutia" (closing strains, or refrains), expressive of Arian doctrine, often accompanied by taunts and insults to the orthodox. Chrysostom was apprehensive that this music might draw some of the simpler church people to the Arian side; he therefore organized, in opposition to it, under the patronage and at the cost of Eudoxia, the empress of Arcadius (then his friend), a system of nightly processional hymn-singing, with silver crosses, wax-lights, and other circumstances of ceremonial pomp. Riots followed, with bloodshed on both sides, and with some personal injury to the empress's chief eunuch, who seems to have officiated as conductor or director of the church musicians. This led to the suppression, by an imperial edict, of all public Arian singing; while in the church the practice of nocturnal hymn-singing on certain solemn occasions, thus first introduced, remained an established institution.

Greek system of hymnody.

It is not improbable that some rudiments of the peculiar system of hymnody which now prevails throughout the Greek communion, and whose affinities are rather to the Hebrew and Syriac than to the classical forms, may have existed in the church of Constantinople, even at that time. Anatolius, patriarch of Constantinople in the middle of the 5th century, was the precursor of that system; but the reputation of being its proper founder belongs to Romanus, of whom little more is known than that he wrote hymns still extant, and lived towards the end of that century. The importance of that system in the services of the Greek church may be understood from the fact that the late Dr Neale computed four-fifths of the whole space (about 5000 pages) contained in the different service-books of that church to be occupied by hymnody, all in a language or dialect which has ceased to be anywhere spoken.

The system has a peculiar technical terminology, in which the words "troparion," "ode," "canon," and "hirmus" (εἱρμός) chiefly require explanation.

The *troparion* is the unit of the system, being a strophe or stanza, seen, when analysed, to be divisible into verses or clauses, with regulated cæsuras, but printed in the books as a single prose sentence, without marking any divisions. The following (turned into English, from a "canon" by John Mauropus) may be taken as an example:—"The never-sleeping Guardian, | the patron of my soul, | the guide of my life, | allotted me by God, | I hymn thee, Divine Angel | of Almighty God." Dr Neale and most other writers regard all these "troparia" as rhythmical or modulated prose. Cardinal J. B. Pitra, on the other hand, who in 1867 and 1876 published two learned works on this subject, maintains that they are really metrical, and governed by definite rules of prosody, of which he lays down sixteen. According to him, each "troparion" contains from three to thirty-three verses; each verse varies from two to thirteen syllables, often in a continuous series, uniform, alternate, or reciprocal, the metre being always syllabic, and depending, not on the quantity of vowels or the position of consonants, but on an harmonic series of accents.

In various parts of the services solitary troparia are sung, under various names, "contacion," "œcos," "cathisma," &c., which mark distinctions either in their character or in their use.

An *ode* is a song or hymn compounded of several similar "troparia,"—usually three, four, or five. To these is always prefixed a typical or standard "troparion," called the *hirmus*, by which the syllabic measure, the periodic series of accents, and in fact the whole structure and rhythm of the stanzas which follow it are regulated. Each succeeding "troparion" in the same "ode" contains the same number of verses, and of syllables in each verse, and similar accents on the same or equivalent syllables. The "hirmus" may either form the first stanza of the "ode" itself, or (as is more frequently the case) may be taken from some other piece; and, when so taken, it is often indicated by initial words only, without being printed at length. It is generally printed within commas, after the proper rubric of the "ode." A hymn in irregular "stichera" or stanzas, without a "hirmus," is called "idiomelon." A system of three or four odes is "triodion" or "tetraodion."

A *canon* is a system of eight (theoretically nine) connected odes, the second being always suppressed. Various pauses, relieved by the interposition of other short chants or readings, occur during the singing of a whole "canon." The final "troparion" in each ode of the series is not unfrequently detached in sense (like the "ephymnia" of Ephraem Syrus), particularly when it is in the (very common) form of a "theotokion," or ascription of praise to the mother of our Lord, and when it is a recurring refrain or burden.

There were two principal periods of Greek hymnography constructed on these principles,—the first that of Romanus and his followers, extending over the 6th and 7th centuries, the second that of the schools which arose during the Iconoclastic controversy in the 8th century, and which continued for some centuries afterwards, until the art itself died out.

The works of the writers of the former period were collected in *Tropologia*, or church hymn-books, which were held in high esteem till the 10th century, when they ceased to be regarded as church-books, and so fell into neglect. They are now preserved only in a very small number of manuscripts. From three of these, belonging to public libraries at Moscow, Turin, and Rome, Cardinal Pitra has lately printed, in his *Analecta*, a number of interesting examples, the existence of which appears to have been unknown to the late learned Dr Neale, and which, in the cardinal's estimation, are in many respects superior to the "canons," &c., of the present Greek service-books, from which all Dr Neale's translations (except some from Anatolius) are taken. Cardinal Pitra's selections include twenty-nine works by Romanus, and some by Sergius, and nine other known, as well as some unknown, authors. He describes them as having generally a more dramatic character than the "melodies" of the later period, and a much more animated style; and he supposes that they may have been originally sung with dramatic accompaniments, by way of substitution for the theatrical performances of Pagan times. As an instance of their peculiar character, he mentions a Christmas or Epiphany hymn by Romanus, in twenty-five long strophes, in which there is, first, an account of the Nativity and its accompanying wonders, and then a dialogue between the wise men, the Virgin mother, and Joseph. The magi arrive, are admitted, describe the moral and religious condition of Persia and the East, and the cause and adventures of their journey, and then offer their gifts. The Virgin intercedes for them with her Son, instructs them in some parts of Jewish history, and ends with a prayer for the salvation of the world.

The controversies and persecutions of the 8th and succeeding centuries turned the thoughts of the "melodists" of the great monasteries of the Studium at Constantinople and St Saba in Palestine and their followers, and those of the adherents of the Greek rite in Sicily and South Italy (who suffered much from the Saracens and the Normans), into a less picturesque but more strictly theological course; and the influence of those controversies, in which the final success of the cause of "Icons" was largely due to the hymns, as well as to the courage and sufferings, of these confessors, was probably the cause of their supplanting, as they did, the works of the older school. Cardinal Pitra gives them the praise of having discovered a graver and more solemn style of chant, and of having done much to fix the dogmatic theology of their church upon its present lines of near approach to the Roman.

Among the "melodists" of this latter Greek school there were many saints of the Greek church, several patriarchs, and two emperors,—Leo the Philosopher, and Constantine Porphyrogenitus, his son. Their greatest poets were Theodore and Joseph of the Studium, and Cosmas and John (called Damascene) of St Saba. Dr Neale has translated into English verse several selected portions, or centoes, from the works of these and others, together with four selections from earlier works by Anatolius. Some of his translations,—particularly "The day is past and over," from Anatolius, and "Christian, dost thou see them," from Andrew of Crete, have been adopted into hymn-books used in many English churches; and the hymn "Art thou weary," &c., which is rather founded upon than translated from one by Stephen the Sabaite, has obtained still more general popularity.

The older learning on the subject of Greek hymnody and church music is collected in a dissertation prefixed to the second volume for June of the Bollandists' *Acta Sanctorum*; the more recent in Cardinal Pitra's *Hymnographie de l'Eglise Grecque* (Rome, 1867), and *Analecta Sacra*, &c. (Paris, 1876), in the *Anthologia Græca Carminum Christianorum* (Leipsic, 1871), and in Dr Daniel's *Thesaurus Hymnologicus*. There is also an able paper on Cardinal Pitra's works, by M. E. Miller, in the *Journal des Savants* for 1876.

4. *Western Church Hymnody.*

It was not till the 4th century that Greek hymnody was imitated in the West, where its introduction was due to two great lights of the Latin Church,—St Hilary of Poitiers and St Ambrose of Milan.

ry. Hilary was banished from his see of Poitiers in 356, and was absent from it for about four years, which he spent in Asia Minor, taking part during that time in one of the councils of the Eastern Church. He thus had full opportunity of becoming acquainted with the Greek church music of that day; and he wrote (as St Jerome, who was thirty years old when he died, and who was well acquainted with his acts and writings, and spent some time in or near his diocese, informs us) a "book of hymns," to one of which Jerome particularly refers, in the preface to the second book of his own commentary on the epistle to the Galatians. Isidore, archbishop of Seville, who presided over the fourth council of Toledo, in his book on the offices of the church, speaks of Hilary as the first Latin hymn-writer; that council itself, in its 13th canon, and the prologue to the Mozarabic hymnary (which is little more than a versification of the canon), associate his name, in this respect, with that of Ambrose. A tradition, ancient and widely spread, ascribed to him the authorship of the remarkable "Hymnum dicat turba fratrum, hymnum cantus personet" ("Band of brethren, raise the hymn, let your song the hymn resound"), which is a succinct narrative, in hymnal form, of the whole gospel history; and is perhaps the earliest example of a strictly didactic hymn. Both Bede and Hincmar much admired this composition, though the former does not mention, in connexion with it, the name of Hilary. The private use of hymns of such a character by Christians in the West may probably have preceded their ecclesiastical use; for Jerome says that in his day those who went into the fields might hear "the ploughman at his hallelujahs, the mower at his hymns, and the vine-dresser singing David's psalms." Besides this, seven shorter metrical hymns attributed to Hilary are still extant.

ose. Of the part taken by Ambrose, not long after Hilary's death, in bringing the use of hymns into the church of Milan, we have a contemporary account from his convert, St Augustine. Justina, mother of the emperor Valentinian, favoured the Arians, and desired to remove Ambrose from his see. The "devout people," of whom Augustine's mother Monica was one, combined to protect him, and kept guard in the church. "Then," says Augustine, "it was first appointed that, after the manner of the Eastern churches, hymns and psalms should be sung, lest the people should grow weary and faint through sorrow; which custom has ever since been retained, and has been followed by almost all congregations in other parts of the world." He describes himself as moved to tears by the sweetness of these "hymns and canticles":—"The voices flowed into my ears; the truth distilled into my heart; I overflowed with devout affections, and was happy." To this time, according to an uncertain but not improbable tradition which ascribed the composition of the "Te Deum" to Ambrose, and connected it with the conversion of Augustine, is to be referred the commencement of the use in the church of that sublime unmetrical hymn.

It is not, however, to be assumed that the hymnody thus introduced by Ambrose was from the first used according to the precise order and method of the later Western ritual. To bring it into (substantially) that order and method appears to have been the work of St Benedict. Walafridus Strabo, the earliest ecclesiastical writer on this subject (who lived at the beginning of the 9th century), says that Benedict, on the constitution of the religious order known by his name (about 530), appointed the Ambrosian hymns to be regularly sung in his offices for the canonical hours. Hence probably originated the practice of the Italian churches, and of others which followed their example, to sing certain hymns (Ambrosian, or by the early successors of the Ambrosian school) daily throughout the week, at "Vespers," "Lauds," and "Nocturns," and on some days at "Compline" also—varying them with the different ecclesiastical seasons and festivals, commemorations of saints and martyrs, and other special offices. Different dioceses and religious houses had their own peculiarities of ritual, including such hymns as were approved by their several bishops or ecclesiastical superiors, varying in detail, but all following the same general method. The national rituals, which were first reduced into a form substantially like that which has since prevailed, were probably those of Lombardy and of Spain, now known as the "Ambrosian" and the "Mozarabic." That of Spain was settled in the 7th century by Leander and Isidore, brothers, successively archbishops of Seville. It contained a copious hymnary, the original form of which may be regarded as canonically approved by the fourth council of Toledo (633). By the 13th canon of that council, an opinion (which even then found advocates) against the use in churches of any hymns not taken from the Scriptures,—apparently the same opinion which had been held by Paul of Samosata,—was censured; and it was ordered that such hymns should be used in the Spanish as well as in the Gallican churches, the penalty of excommunication being denounced against all who might presume to reject them.

The hymns of which the use was thus established and authorized were those which entered into the daily and other offices of the church, afterwards collected in the "Breviaries;" in which the hymns "proper" for "the week," and for "the season," continued for many centuries, with very few exceptions, to be derived from the earliest epoch of Latin Church poetry,—reckoning that epoch as extending from Hilary and Ambrose to the end of the pontificate of Gregory the Great. The "Ambrosian" music, to which those hymns were generally sung down to the time of Gregory, was more popular and congregational than the "Gregorian," which then came into use, and afterwards prevailed. In the service of the mass it was not the general practice, before the invention of sequences in the 9th century, to sing any hymns, except some from the Scriptures esteemed canonical, such as the "Song of the Three Children" ("Benedicite omnia opera"). But to this rule there were, according to Walafridus Strabo, some occasional exceptions; particularly in the case of Paulinus, patriarch of Aquileia under Charlemagne, himself a hymn-writer, who frequently used hymns, composed by himself or others, in the eucharistic office, especially in private masses.

Some of the hymns called "Ambrosian" (nearly 100 in number) are beyond all question by Ambrose himself, and the rest probably belong to his time or to the following century. Ambrosian hymns. Four, those beginning "Æterne rerum conditor" ("Dread Framer of the earth and sky"), "Deus Creator omnium" ("Maker of all things, glorious God"), "Veni Redemptor Gentium" ("Redeemer of the nations, come"), and "Jam surgit hora tertia" ("Christ at this hour was crucified"), are quoted as works of Ambrose by Augustine. These, and others by the hand of the same master, have the qualities most valuable in hymns intended for congregational use. They are short and complete in themselves; easy, and at the same time elevated in their expression and rhythm; terse and masculine in thought and language; and (though sometimes criticized as deficient in theological precision) simple, pure, and not technical in their rendering of the great facts and doctrines of Christianity, which they present in an objective and not a subjective manner. They have exercised a powerful influence, direct or indirect, upon many of the best works of the same kind in all succeeding generations. With the Ambrosian hymns are properly classed those of Hilary, and the contemporary works of Pope Damasus (who wrote two hymns in commemoration of saints), and of Prudentius, from whose *Cathemerina* ("Daily Devotions") and *Peristephana* ("Crown-songs for Martyrs"), all poems of considerable, some of great length, —about twenty-eight hymns, found in various Breviaries, were derived. Prudentius was a layman, a native of Saragossa, and it was in the Spanish ritual that his hymns were most largely used. In the Mozarabic Breviary almost the whole of one of his finest poems (from which most churches took one part only, beginning "Corde natus ex parentis") was appointed to be sung between Easter and Ascension-Day, being divided into eight or nine hymns; and on some of the commemorations of Spanish saints long poems from his *Peristephana* were recited or sung at large. He is entitled to a high rank among Christian poets, many of the hymns taken from his works being full of fervour and sweetness, and by no means deficient in dignity or strength.

5th and 6th centuries.

These writers were followed in the 5th and early in the 6th century by the priest Sedulius, whose reputation perhaps exceeded his merit; Elpis, a noble Roman lady, wife of the philosophic statesman Boetius; Pope Gelasius; and Ennodius, bishop of Pavia. Sedulius and Elpis wrote very little from which hymns could be extracted; but the small number taken from their compositions obtained wide popularity, and have since held their ground. Gelasius was of no great account as a hymn-writer; and the works of Ennodius appear to have been known only in Italy and Spain. The latter part of the 6th century produced Pope Gregory the Great, and Venantius Fortunatus, an Italian poet, the friend of Gregory, and the favourite of Radegunda, queen of the Franks, who died (609) bishop of Poitiers. Eleven hymns of Gregory, and twelve or thirteen (mostly taken from longer poems) by Fortunatus, came into general use in the Italian, Gallican, and British churches. Those of Gregory are in a style hardly distinguishable from the Ambrosian; those of Fortunatus are graceful, and sometimes vigorous. He does not, however, deserve the praise given to him by Dr Neale, of having struck out a new path in Latin hymnody. On the contrary, he may more justly be described as a disciple of the school of Prudentius, and as having affected the classical style, at least as much as any of his predecessors.

The poets of this primitive epoch, which closed with the 6th century, wrote in the old classical metres, and made use of a considerable variety of them—anapæstic, anacreontic, hendecasyllabic, asclepiad, hexameters and pentameters, and others. Gregory and some of the Ambrosian authors occasionally wrote in sapphics; but the most frequent measure was the iambic dimeter, and, next to that, the trochaic. The full alcaic stanza does not appear to have been used for church purposes before the 16th century, though some of its elements were. In the greater number of these works, a general intention to conform to the rules of Roman prosody is manifest; but even those writers (like Prudentius) in whom that conformity was most decided allowed themselves much liberty of deviation from it. Other works, including some of the very earliest, and some of conspicuous merit, were of the kind described by Bede as not metrical but "rhythmical,"—*i.e.* (as he explains the term "rhythm"), "modulated to the ear in imitation of different metres." It would be more correct to call them metrical—(*e.g.*, still trochaic or iambic, &c., but, according to new laws of syllabic quantity, depending entirely on accent, and not on the power of vowels or the position of consonants,—laws by which the future prosody of all modern European nations was to be governed. There are also, in the hymns of the primitive period (even in those of Ambrose), anticipations,—irregular indeed and inconstant, but certainly not accidental,—of another great innovation, destined to receive important developments, that of assonance or rhyme, in the final letters or syllables of verses. Archbishop Trench, in the introduction to his *Sacred Latin Poetry*, has traced the whole course of the transition from the ancient to the modern forms of versification, ascribing it to natural and necessary causes, which made such changes needful for the due development of the new forms of spiritual and intellectual life, consequent upon the conversion of the Latin speaking nations to Christianity.

6th century downward.

From the 6th century downwards we see this transformation making continual progress, each nation of Western Christendom adding, from time to time, to the earlier hymns in its service-books others of more recent and frequently of local origin. For these additions, the commemorations of saints, &c., as to which the devotion of one place often differed from that of another, offered especial opportunities. This process, while it promoted the development of a mediæval as distinct from the primitive style, led also to much deterioration in the quality of hymns, of which, perhaps, some of the strongest examples may be found in a volume published in 1865 by the Irish Archæological Society from a manuscript in the library of Trinity College, Dublin. It contains a number of hymns by Irish saints of the 6th, 7th, and 8th centuries,—in several instances fully rhymed, and in one mixing Erse and Latin barbarously together, as was not uncommon, at a much later date, in semi-vernacular hymns of other countries. The Mozarabic Breviary, and the collection of hymns used in the Anglo-Saxon churches, published in 1851 by the Surtees Society (chiefly from a Benedictine MS. in the college library of Durham, supplemented by other MSS. in the British Museum), supply many further illustrations of the same decline of taste:—such sapphics, *e.g.*, as the "Festum insigne prodiit coruscum" of Isidore, and the "O veneranda Trinitas laudanda" of the Anglo-Saxon books. The early mediæval period, however, from the time of Gregory the Great to that of Hildebrand, was far from deficient in the production of good hymns, wherever learning flourished. Bede in England, and Paul "the Deacon,"—the author of a fairly classical sapphic ode on St John the Baptist,—in Italy, were successful followers of the Ambrosian and Gregorian styles. Eleven metrical hymns are attributed to Bede by Cassander; and there are also in one of Bede's works (*Collectanea et Flores*) two rhythmical hymns of considerable length on the Day of Judgment, with the refrains "In tremendo die" and "Attende homo," both irregularly rhymed, and, in parts, not unworthy of comparison with the "Dies Iræ." Paulinus, patriarch of Aquileia, contemporary with Paul, wrote rhythmical trimeter iambics in a manner peculiar to himself. Theodulph, bishop of Orleans (793–835), author of the famous processional hymn for Palm Sunday in hexameters and pentameters, "Gloria, laus, et honor tibi sit, Rex Christe Redemptor" ("Glory and honour and laud be to Thee, King Christ the Redeemer"), and Hrabanus Maurus, archbishop of Mainz (847–856), the pupil of Alcuin, and the most learned theologian of his day, enriched the church with some excellent works. Among the anonymous hymns of the same period there are three of great beauty, of which the influence may be traced in most, if not all, of the "New Jerusalem" hymns of later generations, including those of Germany and Great Britain:—"Urbs beata Hierusalem" ("Blessed city, heavenly Salem"); "Alleluia piis edite laudibus" ("Alleluias sound ye in strains of holy praise,"—called, from its burden, "Alleluia perenne"); and "Alleluia dulce carmen" ("Alleluia, song of sweetness"), which, being found in Anglo-Saxon hymnaries certainly older than the Conquest, cannot be of the late date assigned to it, in his *Mediæval Hymns and Sequences*, by Dr Neale. These were followed by the "Chorus novæ Hierusalem" ("Ye Choirs of New Jerusalem") of Fulbert, bishop of Chartres (1007–1028). This group of hymns is remarkable for an attractive union of melody, imagination, poetical colouring, and faith. It represents, perhaps, the best and highest type of the middle school, between the severe Ambrosian simplicity and the florid luxuriance of later times.

Veni Creator. Another celebrated hymn, which belongs to the first mediæval period, is the "Veni Creator Spiritus" ("Come, Holy Ghost, our souls inspire"). The earliest recorded occasion of its use is that of a translation (898) of the relics of St Marcellus, mentioned in the *Annals* of the Benedictine order. It has since been constantly sung throughout Western Christendom (as versions of it still are in the Church of England), as part of the appointed offices for the coronation of kings, the consecration and ordination of bishops and priests, the assembling of synods, and other great ecclesiastical solemnities. It has been attributed—probably in consequence of certain corruptions in the text of Ekkehard's *Life of Notker* (a work of the 13th century)—to Charlemagne. Ekkehard wrote in the Benedictine monastery of St Gall, to which Notker belonged, with full access to its records; and an ignorant interpolator, regardless of chronology, added, at some later date, the word "Great" to the name of "the emperor Charles," wherever it was mentioned in that work. The biographer relates that Notker,—a man of a gentle contemplative nature, observant of all around him, and accustomed to find spiritual and poetical suggestions in common sights and sounds,—was moved by the sound of a mill-wheel to compose his "sequence" on the Holy Spirit, "Sancti Spiritus adsit nobis gratia" ("Present with us ever be the Holy Spirit's grace"); and that, when finished, he sent it as a present to "the emperor Charles," who in return sent him back, "by the same messenger," the hymn "Veni Creator," which (says Ekkehard), the same "Spirit had inspired him to write" ("Sibi idem Spiritus inspiraverat"). If this story is to be credited,—and, from its circumstantial and almost dramatic character, it has an air of truth,—the author of "Veni Creator" was not Charlemagne, but his grandson Charles the Bald, who succeeded to the royal crown in 840, about the time when Notker was born, and to the imperial in 875. Notker himself long survived that emperor, and died in 912.

Sequences. The invention of "sequences" by Notker may be regarded as the beginning of the later mediæval epoch of Latin hymnody. In the eucharistic service, in which (as has been stated) hymns were not generally used, it had been the practice, except at certain seasons, to sing "laud," or "Alleluia," between the epistle and the gospel, and to fill up what would otherwise have been a long pause, by extending the cadence upon the two final vowels of the "Alleluia" into a protracted strain of music. It occurred to Notker that, while preserving the spirit of that part of the service, the monotony of the interval might be relieved by introducing at that point a chant of praise specially composed for the purpose. With that view he produced the peculiar species of rhythmical composition which obtained the name of "sequentia" (probably from following after the close of the "Alleluia"), and also that of "prosa," because its structure was originally irregular and unmetrical, resembling in this respect the Greek "troparia," and the "Te Deum," "Benedicite," and canticles. That it was in some measure suggested by the forms of the later Greek hymnody seems probable, both from the intercourse (at that time frequent) between the Eastern and Western churches, and from the application by Ekkehard, in his biography and elsewhere (*e.g.*, in Lyndwood's *Provinciale*), of some technical terms, borrowed from the Greek terminology, to works of Notker and his school and to books containing them.

Dr Neale, in a learned dissertation prefixed to his collection of sequences from mediæval Missals, and enlarged in a Latin letter to Dr Daniel (printed in the fifth volume of Daniel's *Thesaurus*), has investigated the laws of cæsura and modulation which are discoverable in these works. Those first brought into use were sent by their author to Nicholas I., pope from 858 to 867, who authorized their use, and that of others composed after the same model by other brethren of St Gall, in all churches of the West.

Although the sequences of Notker and his school, which then rapidly passed into most German, French, and British Missals, were not metrical, the art of "assonance" was much practised in them. Many of those in the Sarum and French Missals have every verse, and even every clause or division of a verse, ending with the same vowel "a,"—perhaps with some reference to the terminal letter of "Alleluia." Artifices such as these naturally led the way to the adaptation of the same kind of composition to regular metre and fully developed rhyme. Dr Neale's full and large collection, and the second volume of Dr Daniel's *Thesaurus*, contain numerous examples, both of the "proses," properly so called, of the Notkerian type, and of those of the later school, which (from the religious house to which its chief writer belonged) has been called "Victorine." Most Missals appear to have contained some of both kinds. In the majority of those from which Dr Neale's specimens are taken, the metrical kind largely prevailed; but in some (*e.g.*, those of Sarum and Liége) the greater number were Notkerian.

Of the sequence on the Holy Ghost, sent by Notker (according to Ekkehard) to Charles the Bald, Dr Neale says that it "was in use all over Europe, even in those countries, like Italy and Spain, which usually rejected sequences"; and that, "in the Missal of Palencia, the priest was ordered to hold a white dove in his hands, while intoning the first syllables, and then to let it go." Another of the most remarkable of Notker's sequences, beginning "Media in vita" ("In the midst of life we are in death"), is said to have been suggested to him while observing some workmen engaged in the construction of a bridge over a torrent near his monastery. Miss Winkworth states that this was long used as a battle-song, until the custom was forbidden, on account of its being supposed to exercise a magical influence. A translation of it ("Mitten wir im Leben sind") is one of Luther's funeral hymns; and all but the opening sentence of that part of the burial service of the Church of England which is directed to be "said or sung" at the grave, "while the corpse is made ready to be laid into the earth," is taken from it.

The "Golden Sequence," "Veni, sancte Spiritus" ("Holy Spirit, Lord of Light"), is an early example of the transition of sequences from a simply rhythmical to a metrical form. Archbishop Trench, who esteems it "the loveliest of all the hymns in the whole circle of Latin sacred poetry," is inclined to give credit to a tradition which ascribes its authorship to Robert II., king of France, son of Hugh Capet (997–1031). Others have assigned to it a later date,—some attributing it to Pope Innocent III., and some to Stephen Langton, archbishop of Canterbury. Many translations, in German, English, and other languages, attest its merit. Berengarius of Tours, St Bernard of Clairvaux, and Abelard, in the 11th century and early in the 12th, followed in the same track; and the art of the Victorine school was carried to its greatest perfection by Adam of St Victor (who died between 1173 and 1194),—"the most fertile, and" (in the concurrent judgment of Archbishop Trench and Dr Neale) "the greatest of the Latin hymnographers of the Middle Ages." The archbishop's selection contains many excellent specimens of his works.

But the two most widely celebrated of all this class of compositions,—works which have exercised the talents of the greatest musical composers, and of innumerable translators in almost all languages,—are the "Dies Iræ" ("That day of wrath, that dreadful day"), by Thomas de Celano, the companion and biographer of St Francis of Assisi (who died in 1226), and the "Stabat Mater dolorosa" ("By the cross sad vigil keeping") of Jacopone or Jacobus de Benedictis, a Franciscan humorist and reformer, who was persecuted by Pope Boniface VIII. for his satires on the prelacy of the time, and died very old in 1306. Besides these, the 13th century produced the famous sequence "Lauda Sion Salvatorem" ("Sion, lift

Dies Iræ. Stabat Mater.

thy voice and sing"), and the four other well-known sacramental hymns of St Thomas Aquinas, viz., "Pange lingua gloriosi corporis mysterium" ("Sing, my tongue, the Saviour's glory"), "Verbum supernum prodiens" ("The Word, descending from above"—not to be confounded with the Ambrosian hymn from which it borrowed the first line), "Sacris solemniis juncta sint gaudia" ("Let us with hearts renewed our grateful homage pay"), and "Adoro Te devote, latens Deitas" ("O Godhead hid, devoutly I adore Thee"),—a group of remarkable compositions, written by him for the then new festival of Corpus Christi, of which he induced Pope Urban IV. (1261–1265) to decree the observance. In these (of which all but "Adoro Te devote," &c., passed rapidly into Breviaries and Missals) the doctrine of transubstantiation is set forth with a wonderful degree of scholastic precision; and they exercised, probably, a not unimportant influence upon the general reception of that dogma. They are undoubtedly works of genius, powerful in thought, feeling, and expression.

Aquinas.

Mediæval hymns.

These and other mediæval hymn-writers of the 12th and 13th centuries may be described, generally, as poet-schoolmen. Their tone is contemplative, didactic, theological; they are especially fertile and ingenious in the field of mystical interpretation. Two great monasteries in the East had, in the 8th and 9th centuries, been the principal centres of Greek hymnology; and, in the West, three monasteries,—St Gall, near Constance (which was long the especial seat of German religious literature), Cluny in Burgundy, and St Victor, near Paris,—obtained a similar distinction. St Gall produced, besides Notker, several distinguished sequence writers, probably his pupils,—Hartmann, Hermann, and Gottschalk,—to the last of whom Dr Neale ascribes the "Alleluiatic Sequence" ("Cantemus cuncti melodum nunc Alleluia"), well known in England through his translation, "The strain upraise of joy and praise." The chief poets of Cluny were two of its abbots, Odo (who died in 947) and Peter the Venerable (1122–1156), and one of Peter's monks, Bernard of Morlaix, who wrote the remarkable poem on "Contempt of the World" in about 3000 long rolling "leonine-dactylic" verses, from parts of which Dr Neale's popular hymns, "Jerusalem the golden," &c., are taken. The abbey of St Victor, besides Adam and his follower Pistor, was destined afterwards to produce the most popular church poet of the 17th century.

There were other distinguished Latin hymn-writers of the later mediæval period besides those already mentioned. The name of St Bernard of Clairvaux cannot be passed over with the mere mention of the fact that he was the author of some metrical sequences. He was, in truth, the father, in Latin hymnody, of that warm and passionate form of devotion which some may consider to apply too freely to Divine Objects the language of human affection, but which has, nevertheless, been popular with many devout persons, in Protestant as well as Roman Catholic churches. Spee, "Angelus," Madame Guyon, Bishop Ken, Count Zinzendorf, and Frederick William Faber may be regarded as disciples in this school. Many hymns, in various languages, have been founded upon St Bernard's "Jesu dulcis memoria" ("Jesu, the very thought of Thee"), "(Jesu dulcedo cordium" ("Jesu, Thou joy of loving hearts"), and "Jesu Rex admirabilis" ("O Jesu, King most wonderful"), —three portions of one poem, nearly 200 lines long. Cardinal Damiani, the friend of Pope Gregory VII., Marbode (bishop of Rennes) in the 11th, Hildebert (archbishop of Tours) in the 12th, and Cardinal Bonaventura in the 13th centuries, are other eminent men, who added poetical fame, as hymnographers, to high public distinction.

Bernard of Clairvaux.

Before the time of the Reformation, the multiplication of sequences (often as unedifying in matter as unpoetical in style) had done much to degrade the common conception of hymnody. In some parts of France, Portugal, Sardinia, and Bohemia, their use in the vernacular language had been allowed. In Germany also there were vernacular sequences as early as the 12th century, specimens of which may be seen in the third chapter of Miss Winkworth's *Christian Singers of Germany*. Scoffing parodies upon sequences are said to have been among the means used in Scotland to discredit the old church services. After the 15th century they were discouraged at Rome. They retained for a time some of their old popularity among German Protestants, and were only gradually relinquished in France. A new "prose," in honour of St Maxentia, is among the compositions of Jean Baptiste Santeul; and Dr Daniel's second volume closes with one written in 1855 upon the dogma of the Immaculate Conception.

Romai vision hymns

The taste of the Renaissance was offended by all deviations from classical prosody and Latinity. Pope Leo X. directed the whole body of the hymns in use at Rome to be reformed; and a volume of "new ecclesiastical hymns," prepared by Ferreri, a scholar of Vicenza, to whom Leo had committed that task, appeared in 1523, with the sanction of a later pope, Clement VII. The next step was to revise the whole Roman Breviary. That undertaking, after passing through several stages under different popes (particularly Pius V. and Clement VIII.), was at last brought to a conclusion by Urban VIII., in 1631. From this revised Breviary a large number of mediæval hymns, both of the earlier and the later periods, were excluded; and in their places many new hymns, including some by Pope Urban himself, and some by Cardinal Bellarmine and another cardinal (Silvius Antonianus) were introduced. The hymns of the primitive epoch, from Hilary to Gregory the Great, for the most part retained their places (especially in the offices for every day of the week); and there remained altogether from seventy to eighty of earlier date than the 11th century. Those, however, which were so retained were freely altered, and by no means generally improved. The revisers appointed by Pope Urban (three learned Jesuits,—Strada, Gallucci, and Petrucci), professed to have made "as few changes as possible" in the works of Ambrose, Gregory, Prudentius, Sedulius, Fortunatus, and other "poets of great name." But some changes, even in those works, were made with considerable boldness; and the pope, in the "constitution" by which his new book was promulgated, boasted that, "with the exception of a very small number ('perpaucis'), which were either prose or merely rhythmical, all the hymns had been made conformable to the laws of prosody and Latinity, those which could not be corrected by any milder method being entirely rewritten." The latter fate befel, among others, the beautiful "Urbs beata Hierusalem," which now assumed the form (to many, perhaps, better known), of "Cœlestis urbs Jerusalem." Of the "very few" which were spared, the chief were "Ave maris stella" ("Gentle star of ocean"), "Dies Iræ," "Stabat Mater dolorosa," the hymns of Thomas Aquinas, two of St Bernard, and one Ambrosian hymn, "Jesu nostra Redemptio" ("O Jesu, our Redemption"), which approaches nearer than others to the tone of St Bernard. A then recent hymn of St Francis Xavier, with scarcely enough merit of any kind to atone for its neglect of prosody, "O Deus, ego amo Te" ("O God, I love Thee, not because"), was at the same time introduced without change. This hymnary of Pope Urban VIII. is now in general use throughout the Roman Communion.

Paris revisi

The Parisian hymnary underwent three revisions—the first in 1527, when a new "Psaltery with hymns" was issued. In this such changes only were made as the revisers thought justifiable upon the principle of correcting supposed corruptions of the original text. Of these, the transposition, "Urbs Jerusalem beata," instead of "Urbs beata Hierusalem," may be taken as a typical example. The next revision was in 1670–1680, under Cardinal Péréfixe, preceptor of Louis XIV., and Francis Harlay, successively archbishops of Paris, who employed for this purpose Claude Santeul, of the monastery of St Magloire, and, through him, obtained the assistance of other French scholars, including his more celebrated brother, Jean Baptiste Santeul, of the abbey of St Victor,—better known as "Santolius Victorinus." The third and final revision was completed in 1735, under the primacy of Cardinal Archbishop de Vintimille, who engaged for it the services of Charles Coffin, then rector of the university of Paris. Many old hymns were omitted in Archbishop Harlay's Breviary, and a large number of new compositions, by the Santeuls and others, was introduced. It still, however, retained in their old places (without further changes than had been made in 1527) about seventy of earlier date than the 11th century,—including thirty-one Ambrosian, one by Hilary, eight by Prudentius, seven by Fortunatus, three by Paul the Deacon, two each by Sedulius, Elpis, Gregory, and Hrabanus Maurus, "Veni Creator," and "Urbs Jerusalem beata." Most of these disappeared in 1735, although Cardinal Vintimille, in his preface, professed to have still admitted the old hymns, except when the new were better —("veteribus hymnis locus datus est, nisi quibus, ob sententiarum vim, elegantiam verborum, et teneriores pietatis sensus, recentiores anteponi satius visum est"). The number of the new was, at the same time, very largely increased. Only twenty-one more ancient than the 16th century remained, of which those belonging to the primitive epoch were but eight, viz., four Ambrosian, two by Fortunatus, and one each by Prudentius and Gregory. The number of Jean Baptiste Santeul's hymns (who had died in 1697) rose to eighty-nine; those by Coffin,—including some old hymns, *e.g.*, "Jam lucis orto sidere" ("Once more the sun is beaming bright"), which he substantially re-wrote,—were eighty-three; those of other modern French writers, ninety-seven. Whatever opinion may be entertained of the principles on which these Roman and Parisian revisions proceeded, it would be unjust to deny very high praise as hymn-writers to several of their poets, especially to Coffin and Jean Baptiste Santeul. The noble hymn by Coffin, beginning—

"O luce qui mortalibus Lates inaccessa, Deus, Præsente quo sancti tremunt Nubuntque vultus angeli,"	"O Thou who in the light dost dwell, To mortals unapproachable, Where angels veil them from Thy rays, And tremble as they gaze,"

and several others of his works, breathe the true Ambrosian spirit; and though Santeul (generally esteemed the better poet of the two) delighted in alcaics, and did not greatly affect the primitive manner, there can be no question as to the excellence of such hymns as his "Fumant Sabæis templa vaporibus" ("Sweet incense breathes around"), "Stupete gentes, fit Deus hostia" ("Tremble, ye Gentile lands"), "Hymnis dum resonat curia cœlitum" ("Ye in the house of heavenly morn"), and "Templi sacratas pande, Sion, fores" ("O Sion, open wide thy gates"). It is a striking testimony to the merits of those writers that such accomplished translators as the Rev. Isaac Williams and the Rev. John Chandler appear (from the title page of the latter, and the prefaces of both) to have supposed their hymns to be "ancient" and "primitive." Among the other authors associated with them, perhaps the first place is due to the Abbé Besnault, of Sens, who contributed to the book of 1735 the "Urbs beata vera pacis Visio Jerusalem," in the opinion of Dr Neale "much superior" to the "Cœlestis urbs Jerusalem" of the Roman Breviary. This stood side by side with the "Urbs Jerusalem beata" of 1527 (in the office for the dedication of churches) till 1822, when the older form was at last finally excluded by Archbishop de Quelen.

The Parisian Breviary of 1735 remained in use till the national French service-books were superseded (as they have lately been, generally, if not universally) by the Roman. Almost all French dioceses followed, not indeed the Breviary, but the example, of Paris; and before the end of the 18th century the ancient Latin hymnody was all but banished from France.

odern tin mns. In some parts of Germany, after the Reformation, Latin hymns continued to be used even by Protestants. This was the case at Halberstadt until quite a recent date. In England, a few are still occasionally used in the older universities and colleges. Some, also, have been composed in both countries since the Reformation. The "Carmina Lyrica" of John Jacob Balde, a native of Alsace, and a Jesuit priest in Bavaria, have received high commendation from very eminent German critics, particularly Herder and Augustus Schlegel. Some of the Latin hymns of William Alard, a Protestant refugee from Belgium, and pastor in Holstein (1572–1645), have been thought worthy of a place in Archbishop Trench's selection. Two by W. Petersen (printed at the end of Haberkorn's supplement to Jacobi's *Psalmodia Germanica*) are good in different ways,—one, "Jesu dulcis amor meus" ("Jesus, Thee my soul doth love"), being a gentle melody of spiritual devotion, and the other, entitled *Spes Sionis*, violently controversial against Rome. An English hymn of the 17th century, in the Ambrosian style, "Te Deum Patrem colimus" ("Almighty, Father, just and good"), is sung on every May-Day morning by the choristers of Magdalen College, Oxford, from the top of the tower of their chapel; and another in the style of the Renaissance, of about the same date, "Te de profundis, summe Rex" ("Thee from the depths, Almighty King"), is, or until lately was, sung as part of a grace by the scholars of Winchester College.

ithori- s. The principal ancient authorities on Latin hymnody are the 25th chapter ("De hymnis et cantilenis et incrementis eorum") of the treatise of Walafridus Strabo, and a treatise of the 14th century ("De Psalterio observando"), by Radulphus, dean of Tongres in the Netherlands. Next to those are the first book of Clichtovens's *Elucidatorium Ecclesiasticum* (Paris, 1556); the chapter on Ambrosian and other hymns in the works of George Cassander (Paris, 1616); the *Psalterium*, &c., in the second volume of the works of Cardinal J. M. Thomasius (Rome, 1747); and the treatise "De Hymnis Ecclesiasticis," prefixed to the *Hymnodia Hispanica* of Faustinus Arevalus (Rome, 1786). The present century, more especially within the last fifty years, has added much to the stores of learning accessible on this subject. In Germany, Rambach's *Christian Anthology*; Mone's *Hymni Latini medii Ævi;* Daniel's *Thesaurus Hymnologicus*; and Mohnike's *Hymnologische Forschungen*;—and in England, Archbishop Trench's *Sacred Latin Poetry*; Dr Neale's two collections of *Latin Hymns and Sequences* (Oxford, 1851 and 1852), and his *Essays on Liturgiology and Church History*; the Oxford collection of Hymns from the Roman, Sarum, York, and other Breviaries (1838); the *Psalter*, &c., according to Sarum use, of Mr J. D. Chambers (1852); and the two volumes already referred to of Anglo-Saxon and Irish hymns, published in 1851 and 1865 by the Surtees Society and the Irish Archæological Society, have left little to be added by any future labourers in this field. The same period has also produced numerous English translations of Latin hymns, many of which are good and interesting, though perhaps few of the translators have overcome the inherent difficulties of their task sufficiently either to represent the characteristic merits of the originals, or to add to our vernacular hymns many adaptations really well-suited for popular use. The most important are—Mr Isaac Williams's *Hymns from the Parisian Breviary* (1839), and Mr Chandler's *Hymns of the Primitive Church* (1837); Bishop Mant's volume of 1837, and the Rev. Edward Caswall's *Lyra Catholica* (1849), both from the Roman Breviary; the versions of Mr Chambers, in his Sarum *Psalter*, &c.; Dr Neale's *Mediæval Hymns and Sequences* (1862), with his versions, separately published, of some other works; and *Hymns of the Latin Church*, translated by David T. Morgan, with the originals appended (privately printed in 1871). The first lines, in English, given in this article, are generally adopted from some of these.

5. *German Hymnody.*

Luther was a proficient in and a lover of music. He desired (as he says in the preface to his hymn-book of 1545) that this "beautiful ornament" might "in a right manner serve the great Creator and His Christian people." The persecuted Bohemian or Hussite Church, then settled on the borders of Moravia under the name of "United Brethren" (which their descendants still retain), had sent to him, on a mission in 1522, Michael Weiss, who not long afterwards published a number of German translations from old Bohemian hymns (known as those of the "Bohemian Brethren"), with some of his own. These Luther highly approved and recommended. He himself, in 1522, published a small volume of eight hymns, which was enlarged to 63 in 1527, and to 125 in 1545. He had formed what he called a "house choir" of musical friends, to select such old and popular tunes (whether secular or ecclesiastical) as might be found suitable, and to compose new melodies, for church use. His fellow labourers in this field (besides Weiss) were Justus Jonas, his own especial colleague; Paul Eber, the disciple and friend of Melanchthon; John Walther, choirmaster successively to several German princes, and professor of arts, &c., at Wittenberg; Nicholas Decius, who from a monk became a Protestant teacher in Brunswick, and translated the "Gloria in Excelsis," &c.; and Paul Speratus, chaplain to Duke Albert of Prussia in 1525. Some of their works are still popular in Germany. Weiss's "Funeral Hymn," "Nun lasst uns den Leib begraben" ("Now lay we calmly in the grave"); Eber's "Herr Jesu Christ, wahr Mensch und Gott" ("Lord Jesus Christ, true Man and God"), and "Wenn wir in höchsten Nöthen sein" ("When in the hour of utmost need"); Walther's "New Heavens and new Earth" ("Now fain my joyous heart would sing"); Decius's "To God on high be thanks and praise;" and Speratus's "Salvation now has come for all," are among those which at the time produced the greatest effect, and are still best remembered. Luther.

Luther's own hymns, thirty-seven in number (of which about twelve are translations or adaptations from Latin originals), are for the principal Christian seasons; on the sacraments, the church, grace, death, &c; and paraphrases of seven psalms, of a passage in Isaiah, and of the Lord's Prayer, Ten Commandments, Creed, Litany, and "Te Deum." There is also a very touching and stirring song on the martyrdom of two youths by fire at Brussels, in 1523–24. Homely and sometimes rugged in form, and for the most part objective in tone, they are full of fire, manly simplicity, and strong faith. Three rise above the rest. One for Christmas, "Vom Himmel hoch da komm ich her" ("From Heaven above to earth I come"), has a reverent tenderness, the influence of which may be traced in many later productions on the same subject. That on salvation through Christ, of a didactic character, "Nun freuet euch, lieben Christen g'mein" ("Dear Christian people, now rejoice"), is said to have made many conversions, and to have been once taken up by a large congregation to silence a Roman Catholic preacher in the cathedral of Frankfort. Pre-eminent above all is the celebrated paraphrase of the 46th Psalm: "Ein' feste Burg ist unser Gott" ("A sure stronghold our God is He"),—"the production" (as Ranke says) "of the moment in which Luther, engaged in a conflict with a world of foes, sought strength in the consciousness that he was defending a divine cause which could never perish." Carlyle compares it to "a sound of Alpine avalanches, or the first murmur of earthquakes." Heine called it "the Marseillaise of the Reformation."

Luther spent several years in teaching his people at Wittenberg to sing these hymns, which soon spread over Germany. Without adopting the hyperbolical saying of Coleridge, that "Luther did as much for the Reformation by his hymns as by his translation of the Bible," it may truly be affirmed that, among the secondary means by which the success of the Reformation was promoted, none was more powerful. They were sung everywhere,—in the streets and fields as well as the churches, in the workshop and the palace, "by children in the cottage and by martyrs on the scaffold." It was by them that a congregational character was given to the new Protestant worship. This success they owed partly to their metrical structure, which, though sometimes complex, was recommended to the people by its ease and variety; and partly to the tunes and melodies (many of them already well known and popular) to which they were set. They were used as direct instruments of teaching, and were therefore, in a large measure, didactic and theological; and it may be partly owing to this cause that German hymnody came to deviate, so soon and so generally as it did, from the simple idea expressed in the ancient Augustinian definition, and to comprehend large classes of compositions which, in most other countries, would be thought hardly suitable for church use.

Followers of Luther. The principal hymn-writers of the Lutheran school, in the latter part of the 16th century, were Selnecker, Nicholas Hermann, and Hans Sachs, the shoemaker of Nuremberg, also known in other branches of literature. All these wrote some good hymns. They were succeeded by men of another sort, to whom Cunz gives the name of "master-singers," as having raised both the poetical and the musical standard of German hymnody:—Ringwaldt, Helmbold, Pappus, Schalling, Rutilius, and Weingartner. The principal topics of their hymns (as if with some foretaste of the calamities which were soon to follow) were the vanity of earthly things, resignation to the Divine will, and preparation for death and judgment. The well-known English hymn, "Great God, what do I see and hear," is founded upon one by Ringwaldt. Of a quite different character were two of great beauty and universal popularity, composed by Philip Nicolai, a Westphalian pastor, during a pestilence in 1597, and published by him, with fine chorales, two years afterwards. One of these (the "Sleepers wake! a voice is calling," of Mendelssohn's oratorio, *St Paul*) belongs to the family of Advent or New Jerusalem hymns. The other, a "Song of the believing soul concerning the Heavenly Bridegroom" ("Wie schön leucht't uns der Morgenstern,"—"O morning Star, how fair and bright"), became the favourite marriage hymn of Germany.

The hymns produced during the Thirty Years' War are characteristic of that unhappy time, which (as Miss Winkworth says) "caused religious men to look away from this world," and made their songs more and more expressive of personal feelings. In point of refinement and graces of style, the hymn-writers of this period excelled their predecessors. Their taste was chiefly formed by the influence of Martin Opitz, the founder of what has been called the "first Silesian school" of German poetry, who died comparatively young in 1639, and who, though not of any great original genius, exercised much power as a critic. Some of the best of these works were by men who wrote little. In the famous battle-song of Gustavus Adolphus, published (1631) after the victory of Leipsic, for the use of his army, "Verzage nicht du Häuflein klein" ("Fear not, O little flock, the foe"), we have almost certainly a composition of the hero-king himself, the versification corrected by his chaplain Fabricius, and the music composed by Altenburg, whose name has been given to the hymn. This, with Luther's paraphrase of the 67th Psalm, was sung by Gustavus and his soldiers before the fatal battle of Lützen. Two very fine hymns, one of prayer for deliverance and peace, the other of trust in God under calamities, were written about the same time by Löwenstern, a saddler's son, poet, musician, and statesman, who was ennobled after the peace by the emperor Ferdinand III. Martin Rinckhart, in 1636, wrote the "Chorus of God's faithful children" ("Nun danket alle Gott,"—"Now thank we all our God"), introduced by Mendelssohn in his "Lobgesang," which has been called the "Te Deum" of Germany, being usually sung on occasions of public thanksgiving. Weissel, in 1635, composed a beautiful Advent hymn ("Lift up your heads, ye mighty gates"), and Meyfart, professor of theology at Erfurt, in 1642, a fine adaptation of the ancient "Urbs beata Hierusalem." The hymn of trust in Providence by Neumarck, librarian to that duke of Weimar who was a distinguished general in the war ("Wer nur den lieben Gott lässt walten"—"Leave God to order all thy ways"), is scarcely, if at all, inferior to that of Paul Gerhardt on the same theme. Paul Flemming, a great traveller and lover of nature, who died young in 1639, also wrote excellent compositions, coloured by the same tone of feeling; and some, of great merit, were composed, soon after the close of the war, by Louisa Henrietta, electress of Brandenburg, granddaughter of the famous Admiral Coligny, and mother of the first king of Prussia. With these may be classed (though of later date) a few striking hymns of faith and prayer under mental anxiety, by Anton Ulrich, duke of Brunswick, whose nominal conversion to Romanism cast a shade over the close of a life otherwise conscientious and honourable. Period of Thirty Years' War.

Heermann. The most copious, and in their day most esteemed, hymn-writers of this first half of the 17th century, were Heermann and Rist. Heermann, a pastor in Silesia, the theatre (in a peculiar degree) of war and persecution, experienced in his own person a very large share of the miseries of the time, and several times narrowly escaped a violent death. His *Devoti Musica Cordis*, published in 1630, reflects the feelings natural under such circumstances. With a correct style and good versification, his tone is subjective, and the burden of his hymns is not praise, but prayer. Among his works (which enter largely into most German hymn-books), two of the best are the "Song of Tears," and the "Song of Comfort," translated by Miss Winkworth in her *Christian Singers of Germany*. Rist published about 600 hymns, "pressed out of him," as he said, "by the cross." He was a pastor, and son of a pastor, in Holstein, and lived after the peace to enjoy many years of prosperity, being appointed poet-laureate to the emperor, and finally ennobled. The bulk of his hymns, like those of other copious writers, are of inferior quality; but some, particularly those for Advent, Epiphany, Easter Eve, and on Angels, are very Rist.

good. They are more objective than those of Heermann, and written, upon the whole, in a more manly spirit. Next to Heermann and Rist in fertility of production, and
.ch. above them in poetical genius, was Simon Dach, professor of poetry at Königsberg, who died in 1659. Miss Winkworth ranks him high among German poets, "for the sweetness of form and depth of tender contemplative emotion to be found in his verses."

The fame of all these writers was eclipsed in the latter part of the same century by three of the greatest hymnographers whom Germany has produced,—Paul Gerhardt (1604–1676), John Franck (1618–1677), and John Scheffler (1624–1677), the founder of the "second Silesian
hardt. school," who assumed the name of "Angelus." Gerhardt is by universal consent the prince of Lutheran poets. His compositions (which may be compared, in many respects, to those of the *Christian Year*) are lyric poems, of considerable length, rather than hymns, though many hymns have been taken from them. They are, with few exceptions, subjective, and speak the language of individual experience. They occupy a middle ground between the masculine simplicity of the old Lutheran style and the highly wrought religious emotion of the later Pietists, towards whom they (on the whole) incline. Being nearly all excellent, it is not easy to distinguish among the 123 those which are entitled to the highest praise. Two, which were written one during the war and the other after the conclusion of peace, "Zeuch ein zu deinen Thoren" ("Come to Thy temple here on earth"), and "Gottlob, nun ist erschollen," ("Thank God, it hath resounded"), are historically interesting. Of the rest, one is well known and highly appreciated in England through Wesley's translation, "Commit thou all thy ways," &c.; and the Evening and Spring-tide hymns ("Now all the woods are sleeping," and "Go forth, my heart, and seek delight") show an exquisite feeling for nature; while nothing can be more tender and pathetic than "Du bist zwar mein und bleibest mein" ("Thou'rt mine, yes, still thou art mine own"), on the
nck. death of his son. Franck, who was burgomaster of Guben in Lusatia, has been considered by some second only to Gerhardt. If so, it is with a great distance between them. His approach to the later Pietists is closer than that of Gerhardt. His hymns were published, under the title of *Spiritual Zion*, in 1674, some of them being founded on Ambrosian and other Latin originals. Miss Winkworth gives them the praise of a condensed and polished style and fervid and impassioned thought. It was after his
effler. conversion to Romanism that Scheffler adopted the name of "Angelus," and published (1657) his hymns, under a fantastic title, and with a still more fantastic preface. Their key-note is divine love; they are enthusiastic, intense, exuberant in their sweetness, like those of St Bernard among mediæval poets. An adaptation of one of them, by Wesley, "Thee will I love, my Strength, my Tower," is familiar to English readers. Those for the first Sunday after Epiphany, Sexagesima Sunday, and Trinity Sunday, in *Lyra Germanica*, are good examples of his excellences, with few of his defects. His hymns are generally so free from the expression, or even the indirect suggestion, of Roman Catholic doctrine, that it has been supposed they were written before his conversion, though published afterwards. The evangelical churches of Germany found no difficulty in admitting them to that prominent place in their services which they have ever since retained.

tists. Towards the end of the 17th century, a new religious school arose, to which the name of "Pietists" was given, and of which Philip Jacob Spener was esteemed the founder. He and his pupils and successors, August Hermann Francke and Anastasius Freylinghausen, all wrote hymns. Spener's hymns are not remarkable, and Francke's are not numerous. Freylinghausen was their chief singer: his rhythm is lively, his music florid; but, though his book attained extraordinary popularity, he was surpassed in solid merit by other less fertile writers of the same school. The "Auf hinauf zu deiner Freude" ("Up, yes, upward to thy gladness") of Schade may recall to an English reader a hymn by Seagrave, and more than one by Lyte; the "Malabarian hymn" (as it was called by Jacobi) of Schütz, "All glory to the Sovereign Good," has been popular in England as well as Germany; and one of the most exquisite strains of pious resignation ever written is "Whate'er my God ordains is right," by Rodigast.

Joachim Neander, a schoolmaster at Düsseldorf, and a Neander. friend of Spener and Schütz (who died before the full development of the "Pietistic" school), was the first man of eminence in the "Reformed" or Calvinistic Church who imitated Lutheran hymnody. This he did, while suffering persecution from the elders of his own church for some other religious practices, which he had also learnt from Spener's example. As a poet, he is sometimes deficient in art; but there is feeling, warmth, and sweetness in many of his "Bundeslieder" or "Songs of the Covenant," and they obtained general favour, both in the Reformed and in Lutheran congregations. The Summer Hymn ("O Thou true God alone") and that on the Glory of God in Creation ("Lo, heaven and earth and sea and air") are instances of his best style.

With the "Pietists" may be classed Schmolke and Dessler, representatives of the "Orthodox" division of Spener's school; Hiller, their leading poet in South Germany; Arnold and Tersteegen, who were practically independent of ecclesiastical organization, though connected, one with the "Orthodox" and the other with the "Reformed" churches; and Louis Count Zinzendorf. Schmolke, a Schmoll… pastor in Silesia, called the Silesian Rist (1672–1737), was perhaps the most voluminous of all German hymnwriters. He wrote 1188 religious poems and hymns, a large proportion of which do not rise above mediocrity. His style, if less refined, is also less subjective and more simple than that of most of his contemporaries. Among his best and most attractive works (which, indeed, it would be difficult to praise too highly) are the "Hosianna David's Sohn," for Palm Sunday,—much resembling a shorter hymn by Jeremy Taylor; and the Ascension, Whitsuntide, and Sabbath hymns,—"Heavenward doth our journey tend," "Come deck our feast to-day," and "Light of light, enlighten me." Dessler was a greater poet than Schmolke. Dessler. Few hymns, of the subjective kind, are better than his "I will not let Thee go, Thou Help in time of need;" "O Friend of souls, how well is me;" and "Now the pearly gates unfold," &c. Hiller was a pastor in Würtemberg Hiller. (1699–1769), who, falling into ill-health during the latter part of his ministry, published a *Casket of Spiritual Songs*, in a didactic vein, with more taste than power, but (as Miss Winkworth says) in a tone of "deep, thoughtful, practical piety." They were so well-adapted to the wants of his people that to this day Hiller's *Casket* is prized, next to their Bibles, by the peasantry of Würtemberg; and the numerous emigrants from that part of Germany to America and other foreign countries generally take it with them wherever they go. Arnold, a professor at Giessen, and Arnold. afterwards a pastor in Brandenburg, was a man of strong will, uncompromising character, and austere views of life, intolerant and controversial towards those whose doctrine or practice he disapproved, and more indifferent to separatism and sectarianism than the "Orthodox" generally thought right. His hymns, like those of our own Toplady (whom in these respects he resembled), unite with considerable strength more gentleness and breadth of sympathy than might be expected from a man of such a character.

Tersteegen. Tersteegen (1697–1769), who never formally separated himself from the "Reformed" communion, in which he was brought up, but whose sympathies were with the Moravians and Count Zinzendorf, was, of all the more copious German hymn-writers after Luther, perhaps the most remarkable man. Pietist, mystic, and missionary, he was also a great religious poet. His 111 hymns were published in 1731, in a volume called *The Spiritual Flower-garden.* They are intensely individual, meditative, and subjective. Wesley's adaptations of two—"Lo! God is here; let us adore," and "Thou hidden Love of God, whose source"—are well known. Among those translated by Miss Winkworth, "O God, O spirit, Light of all that live," and "Come, brethren, let us go," are specimens which exhibit favourably his manner and power. Miss Cox speaks of him as "a gentle heaven-inspired soul, whose hymns are the reflexion of a heavenly, happy life, his mind being full of a child-like simplicity;" and his own poem on the child-character, which Miss Winkworth has appropriately connected with Innocents' day ("Dear Soul, couldst thou become a child")—one of his best compositions, exquisitely conceived and expressed—shows that this was in truth the ideal which he sought to realize. **Zinzendorf.** The hymns of Zinzendorf are often disfigured by excess in the application of the language and imagery of human affections to Divine Objects; and this blemish is also found in many later Moravian hymns. But one hymn, at least, of Zinzendorf may be mentioned with unqualified praise, as uniting the merits of force, simplicity, and brevity,—"Jesu, geh voran" ("Jesus, lead the way"), which is taught to most children of religious parents in Germany. Wesley's "Jesus, Thy blood and righteousness" is a translation from Zinzendorf.

The transition from Tersteegen and Zinzendorf to Gellert and Klopstock marks strongly the reaction against Pietism which took place towards the middle of the 18th century. **Gellert.** The *Spiritual Odes and Songs* of C. F. Gellert were published in 1757, and are said to have been received with an enthusiasm almost like that which "greeted Luther's hymns on their first appearance." It is a proof of the moderation both of the author and of his times that they were largely used, not only by Protestant congregations, but in those German Roman Catholic churches in which vernacular services had been established through the influence of the emperor Joseph II. They became the model which was followed by most succeeding hymn-writers, and exceeded all others in popularity till the close of the century, when a new wave of thought was generated by the movement which produced the French Revolution. Since that time they have been, perhaps, too much depreciated. They are, indeed, cold and didactic, as compared with Scheffler or Tersteegen; but there is nevertheless in them a spirit of genuine practical piety; and, if not marked by genius, they are pure in taste, and often terse, vigorous, and graceful.

Klopstock. Klopstock, the author of the *Messiah*, cannot be considered great as a hymn-writer, though his "Sabbath Hymn" (of which there is a version in *Hymns from the Land of Luther*) is simple and good. Generally his hymns (ten are translated in Mr Sheppard's *Foreign Sacred Lyre*) are artificial and much too elaborate.

Of the "romantic" school, which came in with the French Revolution, the two leading writers are Frederick von Hardenberg, called "Novalis," and Frederick de la Motte Fouqué, the celebrated author of *Undine* and *Sintram*,—both romance-writers, as well as poets. **Novalis.** The genius of Novalis was early lost to the world; he died in 1802, just thirty years old. Some of his hymns are very beautiful; but even in such works as "Though all to Thee were faithless," and "If only He is mine," there is a feeling of insulation and of despondency as to good in the actual world, which was perhaps inseparable from his ecclesiastical idealism. **Fouqué.** Fouqué survived till 1843. In his hymns there is the same deep flow of feeling, richness of imagery, and charm of expression, which distinguishes his prose works. The two missionary hymns—"Thou, solemn Ocean, rollest to the strand," and "In our sails all soft and sweetly,"—and the exquisite composition which finds its motive in the gospel narrative of blind Bartimeus, "Was du vor tausend Jahren" (finely translated both by Miss Winkworth and by Miss Cox), are among the best examples.

The later German hymn-writers of the present century are numerous, and belong, generally, to the revived "Pietistic" school. Some of the best, *e.g.*, Arndt, Albertini, Krummacher, and especially Spitta, have produced works **Spitta.** not unworthy of the fame of their nation. Mr Massie, the able translator of Spitta's *Psaltery and Harp* (published at Leipsic in 1833), speaks of it as having "obtained for him in Germany a popularity only second to that of Paul Gerhardt." Such praise is hyperbolical; posterity alone can adjust the relative places of the writers of this and of former generations. In Spitta's poems (for such they generally are, rather than hymns) the subjective and meditative tone is tempered, not ungracefully, with a didactic element; and they are not, like some contemporary hymns, disfigured by exaggerated sentiment, or by a too florid and rhetorical style.

Authorities. The best and fullest modern collection of choice German hymns is that of Baron von Bunsen, in his *Versuch eines allgemeinen Gesang- und Gebetbuchs* of 1833, unfortunately not reprinted after the first edition. This contains about 900 hymns. In his later *Allgemeines evangelisches Gesang- und Gebetbuch* of 1846 the number was reduced to 440. Many other authors, besides those who have been here mentioned, are represented in these collections, and also in the excellent English translations contained in the *Lyra Germanica* of Miss Winkworth; Miss Cox's *Sacred Hymns from the German*; Miss Fry's *Hymns of the Reformation*; Miss Dunn's *Hymns from the German*; the Misses Borthwick's *Hymns from the Land of Luther*; and the Rev. Arthur T. Russell's *Hymns for the Church of England.* In Cunz's *Geschichte des deutschen Kirchenliedes* (Leipsic, 1855), the number of German hymn-writers named considerably exceeds 300. Besides the volumes of mixed translations from different authors just enumerated (of which the earliest is that of Miss Cox, 1841), translations of Luther's hymns were published by Mr John Hunt, of Preston, in 1853, and by Mr Massie, of Eccleston, in 1854. The *Lyra Domestica* of Mr Massie (which appeared in 1860) contains his translations from Spitta. A much earlier series of English versions of ninety-three mixed German hymns was published in 1722, 1725, and 1732, by John Christian Jacobi, under the patronage of Caroline, queen of George II. To this collection, entitled *Psalmodia Germanica*, a supplement, containing thirty-one more, and also two Latin hymns by Petersen, was added by John Haberkorn in 1765, with a dedication to the mother of George III. Some of these are now sung (though not without considerable alteration) in English churches.

Much of the historical and critical information contained in the foregoing account of German hymnody has been taken from Miss Winkworth's book, entitled *Christian Singers of Germany* (Macmillan, 1869); and to her also we are in most instances indebted for our English renderings of the first lines of hymns. The principal German authorities on the subject, Wackernagel's *Das Deutsche Kirchenlied*, Koch's *Geschichte des Kirchenliedes u Kirchengesanges*, &c., are mentioned in her preface; to which may be added the work already mentioned of F. A. Cunz.

6. *British Hymnody.*

After the Reformation, the development of hymnody was retarded, in both parts of Great Britain, by the example and influence of Geneva. Archbishop Cranmer appears at one time to have been disposed to follow Luther's course, and to present to the people, in an English dress, some at least of the hymns of the ancient church. In a letter to King Henry VIII. (7th October 1544), among some new "processions" which he had himself translated into English, he mentions the Easter hymn, "Salve, festa dies, toto memorabilis ævo" ("Hail, glad day, to be joyfully kept through all generations"), of Fortunatus. In the two "Primers" of 1535 (by Marshall) and of 1539 (by Bishop Hilsey of Rochester, published by order of the vicar-general Cromwell) there had been several rude English hymns, none of them taken from ancient sources. King Henry's "Primer" of 1545 (commanded by his injunction of the 6th May 1545 to be used throughout his dominions) was formed on the model of the daily offices of the Breviary; and it contains English metrical translations from some of the best-known Ambrosian and other early hymns. But in the succeeding reign different views prevailed. A new direction had been given to the taste of the "Reformed" congregations in France and Switzerland by the French metrical translation of the Old Testament Psalms, which appeared about 1540. This was the joint work of Clement Marot, valet or groom of the chamber to Francis I., and Theodore Beza, then a mere youth, fresh from his studies under Wolmar at Orleans.

Marot's Psalms.

Marot's Psalms were dedicated to the French king and the ladies of France, and, being set to popular airs, became fashionable. They were sung by Francis himself, the queen, the princesses, and the courtiers, upon all sorts of secular occasions, and also, more seriously and religiously, by the citizens and the common people. They were soon perceived to be a power on the side of the Reformation. Calvin, who had settled at Geneva in the year of Marot's return to Paris, was then organizing his ecclesiastical system. He rejected the hymnody of the Breviaries and Missals, and fell back upon the idea, anciently held by Paul of Samosata, and condemned by the fourth council of Toledo, that whatever was sung in churches ought to be taken out of the Scriptures. Marot's Psalter, appearing thus opportunely, was introduced into his new system of worship, and appended to his catechism. On the other hand, it was interdicted by the Roman Catholic priesthood. Thus it became a badge to the one party of the "Reformed" profession, and to the other of heresy.

Sternhold and Hopkins.

The example thus set produced in England the translation commonly known as the "Old Version" of the Psalms. It was begun by Thomas Sternhold, whose position in the household of Henry VIII., and afterwards of Edward VI., was similar to that of Marot with Francis I., and whose services to the former of those kings were rewarded by a substantial legacy under his will. Sternhold published versions of thirty-seven Psalms in 1549, with a dedication to King Edward, and died soon afterwards. A second edition appeared in 1551, with seven more Psalms added, by John Hopkins, a Suffolk clergyman. The work was continued during Queen Mary's reign by British refugees at Geneva, the chief of whom were William Whittingham (afterwards dean of Durham), who succeeded John Knox as minister of the English congregation there, and William Kethe (or Keith), said by Strype to have been a Scotchman. They published at Geneva in 1556 a service-book, containing fifty-one English metrical Psalms, which number was increased, in later editions, to eighty-seven. On the accession of Queen Elizabeth, this Genevan Psalmody was at once brought into use in England,—first (according to a letter of Bishop Jewell to Peter Martyr, dated 5th March 1560) in one London church, from which it quickly spread to others both in London and in other cities. Jewell describes the effect produced by large congregations, of as many as 6000 persons, young and old, women and children, singing it after the sermons at St Paul's Cross,—adding, "Id sacrificos et diabolum ægre habet; vident enim sacras conciones hoc pacto profundius descendere in hominum animos." The first edition of the completed "Old Version" (containing forty Psalms by Sternhold, sixty-seven by Hopkins, fifteen by Whittingham, six by Kethe, and the rest by Thomas Norton, a barrister, Robert Wisdom, John Mardley, and Thomas Churchyard) appeared in 1562.

In the meantime, the Books of Common Prayer, &c., of 1549, 1552, and 1559 had been successively established as law by the Acts of Uniformity of Edward VI. and Queen Elizabeth. In these no provision was made for the use of any metrical psalm or hymn on any occasion whatever, except at the consecration of bishops and the ordination of priests, in which offices (first added in 1552) an English version of "Veni Creator" (the longer of the two now in use) was appointed to be "said or sung." The canticles, "Te Deum," "Benedicite," &c., the Nicene and Athanasian Creeds, the "Gloria in Excelsis," and some other parts of the communion and other special offices were also directed to be "said or sung;" and, by general rubrics, the chanting of the whole service was allowed.

The silence, however, of the rubrics in these books as to any other singing was not meant to exclude the use of psalms not expressly appointed, when they could be used without interfering with the prescribed order of any service. It was expressly provided by King Edward's First Act of Uniformity (by later Acts made applicable to the later books) that it should be lawful "for all men, as well in churches, chapels, oratories, or other places, to use openly any psalms or prayers taken out of the Bible, at any due time, not letting or omitting thereby the service, or any part thereof, mentioned in the book." And Queen Elizabeth, by one of the injunctions issued in the first year of her reign, declared her desire that the provision made, "in divers collegiate and also some parish churches, for singing in the church, so as to promote the laudable service of music," should continue. After allowing the use of "a modest and distinct song in all parts of the common prayers of the church, so that the same may be as plainly understanded as if it were read without singing," the injunction proceeded thus—"And yet, nevertheless, for the comforting of such that delight in music, it may be permitted that in the beginning or in the end of the Common Prayer, either at morning or evening, there may be sung an hymn, or such like song to the praise of Almighty God, in the best sort of melody and music that may be conveniently devised, having respect that the sentence" (*i.e.*, sense) "of hymn may be understanded and perceived."

The "Old Version," when published (by John Daye, for the Stationers' Company, "cum gratia et privilegio Regiæ Majestatis"), bore upon the face of it that it was "newly set forth, and allowed to be sung of the people in churches, before and after morning and evening prayer, as also before and after the sermon." The question of its authority has been at different times much debated, chiefly by Heylin and Thomas Warton on one side (both of whom disliked and disparaged it), and by Bishop Beveridge and the Rev. H. J. Todd on the other. Heylin says, it was "permitted rather than allowed," which seems to be a distinction without much difference. "Allowance," which is all that the book claimed for itself, is authorization by way of permission, not of commandment. Its publication in that form could hardly have been licensed, nor could it have passed into use as it did without question, throughout the churches of England, unless it had been "allowed" by some authority then esteemed to be sufficient. Whether that authority was royal or ecclesiastical does not appear, nor (considering the proviso in King Edward's Act of Uniformity, and Queen Elizabeth's injunctions) is it very important. No inference can justly be drawn from the inability of inquirers, in Heylin's time or since, to discover any public record bearing upon this subject, many public documents of that period having been lost.

In this book, as published in 1562, and for many years afterwards, there were (besides the versified Psalms) eleven metrical versions of the "Te Deum," canticles, Lord's Prayer, &c., &c. (the best of which is that of the "Benedicite"); and also "Da pacem, Domine," a hymn suitable to the times, rendered into English from Luther; two original hymns of praise, to be sung before Morning and Evening Prayer; two penitential hymns (one of them the "Humble Lamentation of a Sinner"); and a hymn of faith, beginning, "Lord, in Thee is all my trust." In these respects, and also in the tunes which accompanied the words (stated by Dr Burney, in his *History of Music*, to be German, and not French), there was a departure from the Genevan platform. Some of these hymns, and some of the psalms also (*e.g.*, those by Robert Wisdom, being alternative versions), were omitted at a later period; and many alterations and supposed amendments were from time to time made by unknown hands in the Psalms which remained, so that the text, as now printed, is in many places different from that of 1562.

Scotch Psalms. In Scotland, the General Assembly of the kirk caused to be printed at Edinburgh in 1564, and enjoined the use of, a book entitled *The Form of Prayers and Ministry of the Sacraments used in the English Church at Geneva, approved and received by the Church of Scotland; whereto, besides that was in the former books, are also added sundry other prayers, with the whole Psalms of David in English metre.* This contained all the Psalms of the "Old Version" by Sternhold, Whittingham, and Kethe, but only thirty-seven of those by Hopkins, and none by any of the other English translators. Instead of those omitted, it had nineteen more by Kethe and Whittingham; one by John Pulleyn (one of the Genevan refugees, who became Archdeacon of Colchester); six by Robert Pont, Knox's son-in-law, who was a minister of the kirk, and also a lord of session; and fifteen signed with the initials I. C., supposed to be John Craig.

So matters continued in both churches until the Rebellion. During the interval, King James I. conceived the project of himself making a new version of the Psalms, and appears to have translated thirty-one of them,—the correction of which, together with the translation of the rest, he entrusted to Sir William Alexander, afterwards earl of Stirling. Sir William having completed his task, King Charles the First (after having it examined and approved by several archbishops and bishops of England, Scotland, and Ireland) caused it to be printed in 1631 at the Oxford University Press, as the work of King James; and, by an order under the royal sign manual, recommended its use in all churches of his dominions. In 1634 he enjoined the Privy Council of Scotland not to suffer any other Psalms, "of any edition whatever," to be printed in or imported into that kingdom. In 1636 it was republished, and was attached to the famous Scottish Service-book, with which the troubles began in 1637. It need hardly be added that the king did not succeed in bringing this Psalter into use in either kingdom.

When the Long Parliament undertook, in 1642, the task of altering the liturgy, its attention was at the same time directed to psalmody. It had to judge between two rival translations of the Psalms—one by Francis Rouse, a member of the House of Commons, afterwards one of Cromwell's councillors, and finally provost of Eton; the other by William Barton, a clergyman of Leicester. The House of Lords favoured Barton, the House of Commons Rouse, who had made much use of the labours of Sir William Alexander. Both versions were printed by order of parliament, and were referred for consideration to the Westminster Assembly. They decided in favour of Rouse. His version, as finally amended, was published in 1646, under an order of the House of Commons dated 14th November 1645. In the following year it was recommended by the parliament to the General Assembly at Edinburgh, who appointed a committee, with large powers, to prepare a revised Psalter, recommending to their consideration not only Rouse's book but that of 1564, and two other versions (by Zachary Boyd, and Sir William Mure of Rowallan), then lately executed in Scotland. The result of the labours of this committee was the "Paraphrase" of the Psalms, which, in 1649–1650, by the concurrent authority of the General Assembly and the committee of estates, was ordered to be exclusively used throughout the church of Scotland. Some use was made in the preparation of this book of the versions to which the attention of the revisers had been directed, and also of Barton's; but its basis was that of Rouse. It was received in Scotland with great favour, which it has ever since retained; and it is fairly entitled to the praise of striking a tolerable medium between the rude homeliness of the "Old," and the artificial modernism of the "New" English versions—perhaps as great a success as was possible for such an undertaking. Sir Walter Scott is said to have dissuaded any attempt to alter it, and to have pronounced it, "with all its acknowledged occasional harshness, so beautiful, that any alterations must eventually prove only so many blemishes." No further step towards any authorized hymnody was taken by the kirk of Scotland till the following century.

In England, two changes bearing on church hymnody were made upon the revision of the Prayer-book after the Restoration, in 1661–1662. One was the addition, in the offices for consecrating bishops and ordaining priests, of the shorter version of "Veni Creator" ("Come, Holy Ghost, our souls inspire"), as an alternative form. The other, and more important, was the insertion of the rubric after the third Collect, at Morning and Evening Prayer: "In quires and places where they sing, here followeth the Anthem." By this rubric synodical and parliamentary authority was given for the interruption, at that point, of the prescribed order of the service by singing an anthem, the choice of which was left to the discretion of the minister. Those actually used, under this authority, were for some time only unmetrical passages of Scripture, set to music by Blow, Purcell, and other composers, of the same kind with the anthems still generally sung in cathedral and collegiate churches. But the word "anthem" had no technical signification which could be an obstacle to the use under this rubric of metrical hymns.

Tate and Brady. The "New Version" of the Psalms, by Dr Nicholas Brady and the poet-laureate Nahum Tate (both Irishmen), appeared in 1696, under the sanction of an order in council of William III., "allowing and permitting" its use "in all such churches, chapels, and congregations as should think fit to receive it." Dr Compton, bishop of London, recommended it to his diocese. No hymns were then appended to it; but the authors added a "Supplement" in 1703, which received an exactly similar sanction from an order in council of Queen Anne. In that Supplement there were several new versions of the canticles, &c., and of the "Veni Creator;" a variation of the old "Humble Lamentation of a Sinner;" six hymns for Christmas, Easter, and Holy Communion (all versions or paraphrases of Scripture), which are still usually printed at the end of the Prayer-books containing the new version; and a hymn "On the Divine use of Music,"—all accompanied by tunes. The authors also reprinted, with very good taste, the excellent version of the "Benedicite" which appeared in the book of 1562. Of the hymns in this "Supplement," one ("While shepherds watched their flocks by night") greatly exceeded the rest in merit. It has been ascribed to Tate, but it has a character of simplicity unlike the rest of his works.

Old and new versions compared. The relative merits of the "Old" and "New" versions have been very variously estimated. Competent judges have given the old the praise, which certainly cannot be accorded to the new, of fidelity to the Hebrew. In both, it must be admitted, that those parts which have poetical merit are few and far between; but a reverent taste is likely to be more offended by the frequent sacrifice, in the new, of depth of tone and accuracy of sense to a fluent commonplace correctness of versification and diction, than by any excessive homeliness in the old. In both, however, some Psalms, or portions of Psalms, are well enough rendered to entitle them to a permanent place in our hymn-books,—especially the 8th, and parts of the 18th Psalm, by Sternhold; the 57th, 84th, and 100th, by Hopkins; the 23d, 34th, and 36th, and part of the 148th, by Tate and Brady.

The judgment which a fastidious critic might be disposed to pass upon both these books may perhaps be considerably mitigated by comparing them with the works of other labourers in the same field, of whom Mr Holland, in his interesting volumes entitled *Psalmists of Great Britain*, enumerates above 150. Some of them have been real poets—the celebrated earl of Surrey, Sir Philip Sidney and his sister the countess of Pembroke, George Sandys, George Wither, John Milton, and John Keble. In their versions, as might be expected, there are occasional gleams of power and beauty, exceeding anything to be found in Sternhold and Hopkins, or Tate and Brady; but even in the best these are rare, and chiefly occur where the strict idea of translation has been most widely departed from. In all of them, as a rule, the life and spirit, which in prose versions of the Psalms are so wonderfully preserved, have disappeared. The conclusion practically suggested by so many failures is that the difficulties of metrical translation, always great, are in this case insuperable; and that, while the Psalms (like other parts of Scripture) are abundantly suggestive of motive and material for hymnographers, it is by assimilation and adaptation, and not by any attempt to transform their exact sense into modern poetry, that they may be best used for this purpose.

The order in council of 1703 is the latest act of any public authority by which an express sanction has been given to the use of psalms or hymns in the Church of England. At the end, indeed, of many modern Prayer-books, there will be found, besides some of the hymns sanctioned by that order in council, or of those contained in the book of 1562, a Sacramental and a Christmas hymn by Doddridge; a Christmas hymn (varied by Martin Madan) from Charles Wesley; an Easter hymn of the 18th century, beginning "Jesus Christ has risen to day;" and abridgments of Bishop Ken's Morning and Evening Hymns. These additions first began to be made in or about 1791, in London editions of the Prayer-book and Psalter, at the mere will and pleasure (so far as appears) of the printers. They have no sort of authority.

[Eng]lish [con]gre[gati]onal [hy]m[nody]. In the state of authority, opinion, and practice disclosed by the preceding narrative may be found the true explanation of the fact that, in the country of Chaucer, Spenser, Shakespeare, and Milton, and notwithstanding the example of Germany, no native congregational hymnody worthy of the name arose till after the commencement of the 18th century. Yet there was no want of appreciation of the power and value of congregational church music. Milton could write, before 1645,—

"There let the pealing organ blow
To the full-voiced quire below
In service high, and anthems clear,
As may with sweetness through mine ear
Dissolve me into ecstasies,
And bring all Heaven before mine eyes."

Thomas Mace, in his *Music's Monument* (1676), thus described the effect of psalm-singing before sermons, by the congregation in York Minster on Sundays, during the siege of 1644: "When that vast concording unity of the whole congregational chorus came thundering in, even so as it made the very ground shake under us, oh, the unutterable ravishing soul's delight! in the which I was so transported and wrapt up in high contemplations that there was no room left in my whole man, body, soul, and spirit, for anything below divine and heavenly raptures; nor could there possibly be anything to which that very singing might be truly compared, except the right apprehension or conceiving of that glorious and miraculous quire, recorded in the Scriptures at the dedication of the Temple." Nor was there any want of men well-qualified, and by the turn of their minds predisposed, to shine in this branch of literature. Some (like Sandys, Boyd, and Barton) devoted themselves altogether to paraphrases of other Scriptures as well as the Psalms. Others (like George Herbert, and Francis and John Quarles) moralized, meditated, soliloquized, and allegorized in verse. Without reckoning these, there were a few, even before the Restoration, who came very near to the ideal of hymnody.

Wedderburn. First in time is the Scottish poet John Wedderburn, who translated several of Luther's hymns, and in his *Compendious Book of Godly and Spiritual Songs* added others of his own (or his brothers') composition. Some of these poems, published before 1560, are of uncommon excellence, uniting ease and melody of rhythm, and structural skill, with grace of expression, and simplicity, warmth, and reality of religious feeling. Those entitled "Give me thy heart," "Go, heart," and "Leave me not" (which will be found in a collection of 1860 called *Sacred Songs of Scotland*), require little, beyond the change of some archaisms of language, to adapt them for church or domestic use at the present day.

Next come the two hymns of "The New Jerusalem," by an English Roman Catholic priest signing himself F. B. P. (supposed by the late Mr Sedgwick to be "Francis Baker, Presbyter"), and by another Scottish poet, David Dickson, of which the history is given by Dr Bonar in his edition of Dickson's work. This (Dickson's), which begins "O mother dear, Jerusalem," and has long been popular in Scotland, is a variation and amplification (by the addition of a large number of new stanzas) of the English original, beginning "Jerusalem, my happy home," written in Queen Elizabeth's time, and printed (as appears by a copy in the British Museum) about 1616, when Dickson was still young. Both have an easy natural flow, and a simple happy rendering of the beautiful Scriptural imagery upon the subject, with a spirit of primitive devotion uncorrupted by mediæval peculiarities. The English hymn (of which some stanzas are now often sung in churches) is the true parent of the several shorter forms,—all of more than common merit,—which, in modern hymn-books, begin with the same first line, but afterwards deviate from the original. Kindred to these is the very fine and faithful translation, by Drummond of Hawthornden (who was Dickson's contemporary), of the ancient "Urbs beata Hierusalem" ("Jerusalem, that place divine"). Other ancient hymns (two of Thomas Aquinas, and the "Dies Iræ") were also well translated, in 1646, by Crashaw, after he had become a Roman Catholic, and had been deprived by the parliament of his fellowship at Cambridge. Dickson.

Conspicuous among the sacred poets of the first two Stuart reigns in England is the name of George Wither, an accomplished layman, of strong church principles, whose fate it was to be opposed and slighted while he was a staunch churchman and Royalist, and afterwards to be driven into the parliamentary and Puritan ranks; for which cause, probably, recognition was denied to his genius as a poet by Dryden, Swift, and Pope. He had almost fallen into oblivion, when attention was recalled to his merits by the more discerning criticisms of Charles Lamb and Southey; and, when his *Hallelujah* was republished in 1857 by Mr Farr, only two copies of it were known to exist, one in the British Museum, and another which had been in Mr Heber's library. His *Hymns and Songs of the Church* appeared in 1622–1623, under a patent of King James I., by which they were declared "worthy and profitable to be inserted, in convenient manner and due place, into every English Psalm-book to metre." This patent was opposed, as inconsistent with their privilege to print the "singing-psalms," by the Stationers' Company, to Wither's great mortification and loss. His *Hallelujah* (in which some of the former *Hymns and Songs* were repeated) followed, after several intermediate publications of a different kind, in 1641. The *Hymns and Songs* were set to music by Orlando Gibbons, and those in both books were written to be sung, though for the most part privately, there being no evidence that the author contemplated the use of any of them in churches. They included, however, hymns for every day in the week (founded, as those contributed nearly a century afterwards by Coffin to the Parisian Breviary also were, upon the successive works of the days of creation); hymns for all Wither.

the church seasons and festivals, including saints' days; hymns for various public occasions; and hymns of prayer, meditation, and instruction, for a great number of different sorts and conditions of men and women, in a variety of the circumstances incident to human life,—being at once a "Christian Year" and a manual of practical piety. Many of them rise to a very high point of excellence,—particularly the "general invitation to praise God" ("Come, O come, in pious lays"), with which *Hallelujah* opens; the Thanksgivings for Peace and for Victory, the Coronation Hymn, a Christmas, an Epiphany, and an Easter Hymn, and one for St Bartholomew's day (Hymns 1, 74, 75, and 84 in part i., and 26, 29, 36, and 54 in part ii., of *Hallelujah*). All these are properly entitled to the designation of hymns, which can hardly be conceded to some others, of singular beauty, viz., the Cradle-song ("Sleep, baby, sleep, what ails my dear"), the Anniversary Marriage Song ("Lord, living here are we"), the Perambulation Song ("Lord, it hath pleasèd Thee to say"), the Song for Lovers ("Come, sweet heart, come, let us prove"), the Song for the Happily Married ("Since they in singing take delight"), and that for a Shepherd ("Renownèd men their herds to keep")—(Nos. 50 in the first part, 17 and 24 in the second, and 20, 21, and 41 in the third). There is also in the second part a fine song (No 59), full of historical as well as poetical interest, upon the evil times in which the poet lived, beginning—

> "Now are the times, these are the days,
> Which will those men approve
> Who take delight in honest ways
> And pious courses love;
> Now to the world it will appear
> That innocence of heart
> Will keep us far more free from fear
> Than helmet, shield, or dart."

Wither wrote, generally, in a pure nervous English idiom, and preferred the reputation of "rusticity" (an epithet applied to him even by Baxter) to the tricks and artifices of poetical style which were then in favour. It may be partly on that account that he has been better appreciated by posterity than by his contemporaries.

Cosin. Cosin, afterwards bishop of Durham, published in 1627 a volume of "Private Devotions," for the canonical hours and other occasions. In this there are seven or eight hymns of considerable merit,—among them a very good version of the Ambrosian "Jam lucis orto sidere," and the shorter version of the "Veni Creator," which was introduced after the Restoration into the consecration and ordination services of the Church of England.

Milton. The hymns of Milton (on the Nativity, Passion, Circumcision, and "at a Solemn Music"), written about 1629, in his early manhood, were probably not intended for singing; but they are odes full of characteristic beauty and power.

Jeremy Taylor. During the Commonwealth, in 1654, Jeremy Taylor published, at the end of his *Golden Grove*, twenty-one hymns, described by himself as "celebrating the mysteries and chief festivals of the year, according to the manner of the ancient church, fitted to the fancy and devotion of the younger and pious persons, apt for memory, and to be joined to their other prayers." Of these, his accomplished editor, Bishop Heber, justly says:—

> "They are in themselves, and on their own account, very interesting compositions. Their metre, indeed, which is that species of spurious Pindaric which was fashionable with his contemporaries, is an obstacle, and must always have been one, to their introduction into public or private psalmody; and the mixture of that alloy of conceits and quibbles which was an equally frequent and still greater defilement of some of the finest poetry of the 17th century will materially diminish their effect as devotional or descriptive odes. Yet, with all these faults, they are powerful, affecting, and often harmonious; there are many passages of which Cowley need not have been ashamed, and some which remind us, not disadvantageously, of the corresponding productions of Milton."

He mentions particularly the Advent hymn ("Lord, come away"), part of the hymn "On Heaven," and (as "more regular in metre, and in words more applicable to public devotion") the "Prayer for Charity" ("Full of mercy, full of love").

Restoration period. The epoch of the Restoration produced in 1664 Samuel Crossman's *Young Man's Calling*, with a few "Divine Meditations" in verse attached to it; in 1668 John Austin's *Devotions in the Ancient Way of Offices, with psalms, hymns, and prayers for every day in the week and every holyday in the year*; and in 1681 Richard Baxter's *Poetical Fragments.* In these books there are altogether seven or eight hymns, the whole or parts of which are extremely good:—Crossman's "New Jerusalem" ("Sweet place, sweet place alone"), one of the best of that class, and "My life's a shade, my days;" Austin's "Hark, my soul, how everything," "Fain would my thoughts fly up to Thee," "Lord, now the time returns," "Wake all my hopes, lift up your eyes;" and Baxter's "My whole, though broken heart, O Lord," and "Ye holy angels bright." Austin's *Offices* (he was a Roman Catholic) seem to have attracted much attention. Theophilus Dorrington, in 1686, and afterwards Hickes, the non-juror, published variations of them under the title of *Reformed Devotions*; and the Wesleys, in their earliest hymn-book, adopted hymns from them, with little alteration. These writers were followed by John Mason in 1683, and Thomas Shepherd in 1692,—the former, a country clergyman, much esteemed by Baxter and other Nonconformists; the latter himself a Nonconformist, who finally emigrated to America. Between these two men there was a close alliance, Shepherd's *Penitential Cries* being published as an addition to the *Spiritual Songs* of Mason. Their hymns came into early use in several Nonconformist congregations; but, with the exception of one by Mason ("There is a stream which issues forth"), they are not suitable for public singing. In those of Mason there is often a very fine vein of poetry; and later authors have, by extracts or centoes from different parts of his works (where they were not disfigured by his general quaintness), constructed several hymns of more than average excellence.

Three other eminent names of the 17th century remain to be mentioned, John Dryden, Bishop Ken, and Bishop Simon Patrick; with which may be associated that of Addison, though he wrote in the 18th century.

Dryden. Dryden's translation of "Veni Creator" (a cold and laboured performance) is to be met with in many hymnbooks. Abridgments of Ken's Morning and Evening Hymns are in all. These, with the Midnight Hymn (not inferior to them), first appeared in 1697, appended to the third edition of the author's *Manual of Prayers for Winchester Scholars.* Between these and a large number of other hymns (on the Attributes of God, and for the Festivals of the Church) published by Bishop Ken after 1703 the contrast is remarkable. The universal acceptance of the Morning and Evening Hymns is due to their transparent simplicity, warm but not overstrained devotion, and extremely popular style. Those afterwards published have no such qualities. They are mystical, florid, stiff, didactic, and seldom poetical, and deserve the neglect into which they have fallen. Bishop Patrick's hymns were chiefly translations from the Latin, most of them from Prudentius. The best is a version of "Alleluia dulce carmen." Of the five attributed to Addison, not more than three are adapted to public singing; one ("The spacious firmament on high") is a very perfect and finished composition, taking rank among the best hymns in the English language.[1]

[1] The authorship of this and of one other, "When all Thy mercies, O my God," has been made a subject of controversy,—being claimed

From the preface to Simon Browne's hymns, published in 1720, we learn that down to the time of Dr Watts the only hymns known to be "in common use, either in private families or in Christian assemblies," were those of Barton, Mason, and Shepherd, together with "an attempt to turn some of Mr Herbert's poems into common metre," and a few sacramental hymns by authors now forgotten, named Vincent, Boyse, and (Joseph) Stennett. Of the 1410 authors of original British hymns enumerated in Mr Sedgwick's catalogue, published in 1863, 1213 are of later date than 1707; and, if any correct enumeration could be made of the total number of hymns of all kinds published in Great Britain before and after that date, the proportion subsequent to 1707 would be very much larger.

The English Independents, as represented by Dr Watts, have a just claim to be considered the real founders of modern English hymnody. Watts was the first to understand the nature of the want, and, by the publication of his *Hymns* in 1707–1709, and *Psalms* (not translations, but hymns founded on psalms) in 1719, he led the way in providing for it. His immediate followers were Simon Browne and Doddridge. Later in the 18th century, Hart, Gibbons, Grigg, and Mrs Barbauld (the two first Independents, the two last Presbyterians), and Miss Steele, Medley, Samuel Stennett, Ryland, Beddome, and Swaine (all Baptists), succeeded to them.

Among these writers (most of whom produced some hymns of merit, and several are extremely voluminous), Watts and Doddridge are pre-eminent. It has been the fashion with some to disparage Watts, as if he had never risen above the level of his *Hymns for Little Children.* No doubt his taste is often faulty, and his style very unequal, but, looking to the good, and disregarding the large quantity of inferior matter, it is probable that more hymns which approach to a very high standard of excellence, and are at the same time suitable for congregational use, may be found in his works than in those of any other English writer. Such are "When I survey the wondrous cross," "Jesus shall reign where'er the sun" (and also another adaptation of the same 72d Psalm), "Before Jehovah's awful throne" (which first line, however, is not his, but Wesley's), "Joy to the world, the Lord is come," "My soul, repeat His praise," "Why do we mourn departing friends," "There is a land of pure delight," "Our God, our help in ages past," "Up to the hills I lift mine eyes," and many more. It is true that in some of these cases dross is found in the original poems mixed with gold; but the process of separation, by selection without change, is not difficult. As long as pure nervous English, unaffected fervour, strong simplicity, and liquid yet manly sweetness are admitted to be characteristics of a good hymn, works such as these must command admiration.

Doddridge is, generally, much more laboured and artificial; but his place also as a hymn-writer ought to be determined, not by his failures, but by his successes, of which the number is not inconsiderable. In his better works he is distinguished by a graceful and pointed, sometimes even a noble style. His "Hark, the glad sound, the Saviour comes" (which is, indeed, his masterpiece), is as sweet, vigorous, and perfect a composition as can anywhere be found. Two other hymns, "How gentle God's commands," and that which, in a form slightly varied, became the "O God of Bethel, by whose hand," of the Scottish "Paraphrases," well represent his softer manner.

Of the other followers in the school of Watts, Miss Steele (1780) is the most popular and perhaps the best. Her hymn beginning "Far from these narrow scenes of night" deserves high praise, even by the side of other good performances on the same subject. Miss Steele.

The influence of Watts was felt in Scotland, and among the first whom it reached there was Ralph Erskine. This seems to have been after the publication of Erskine's *Gospel Sonnets*, which appeared in 1732, five years before he joined his brother Ebenezer in the Secession Church. The *Gospel Sonnets* became (as some have said) a "people's classic"; but there is in them very little which belongs to the category of hymnody. More than nineteen-twentieths of this very curious book are occupied with what are, in fact, theological treatises and catechisms, mystical meditations on Christ as a Bridegroom or Husband, and spiritual enigmas, paradoxes, and antithetical conceits, versified, it is true, but of a quality of which such lines as— Ralph Erskine.

> "Faith 's certain by fiducial acts,
> Sense by its evidential facts,"

may be taken as a sample. The grains of poetry scattered through this large mass of Calvinistic divinity are very few; yet in one short passage of seven stanzas ("O send me down a draught of love"), the fire burns with a brightness so remarkable as to justify a strong feeling of regret that the gift which this writer evidently had in him was not more often cultivated. Another passage, not so well sustained, but of considerable beauty (part of the last piece under the title "The Believer's Soliloquy"), became afterwards, in the hands of Berridge, the foundation of a very striking hymn ("O happy saints, who walk in light").

After his secession, Ralph Erskine published two paraphrases of the "Song of Solomon," and a number of other "Scripture songs," paraphrased, in like manner, from the Old and New Testaments. In these the influence of Watts became very apparent, not only by a change in the writer's general style, but by the direct appropriation of no small quantity of matter from Dr Watts's hymns, with variations which were not always improvements. His paraphrases of 1 Cor. i. 24, Gal. vi. 14, Heb. vi. 17–19, Rev. v. 11, 12, vii. 10–17, and xii. 7–12 are little else than Watts transformed. One of these (Rev. vii. 10–17) is interesting as a variation and improvement, intermediate between the original and the form which it ultimately assumed as the 66th "Paraphrase" of the Church of Scotland, of Watts's "What happy men or angels these," and "These glorious minds, how bright they shine." No one can compare it with its ultimate product, "How bright these glorious spirits shine," without perceiving that Cameron followed Erskine, and only added finish and grace to his work,—both excelling Watts, in this instance, in simplicity as well as in conciseness.

Of the contributions to the authorized "Paraphrases" (with the settlement of which committees of the General Assembly of the Church of Scotland were occupied from 1745 or earlier till 1781), the most noteworthy (besides the two already mentioned) were those of John Morrison and those claimed for Michael Bruce. The obligations of these "Paraphrases" to English hymnody, already traced in some instances (to which may be added the adoption from Addison of three out of the five "hymns" appended Scottish Paraphrases.

---

for Andrew Marvell (who died in 1678), in the preface to Captain Thomson's edition (1776) of Marvell's *Works.* But this claim does not appear to be substantiated. The editor did not give his readers the means of judging as to the real age, character, or value of a manuscript to which he referred; he did not say that these portions of it were in Marvell's handwriting; he did not even himself include them among Marvell's poems, as published in the body of his edition; and he advanced a like claim on like grounds to two other poems, in very different styles, which had been published as their own by Tickell and Mallet. It is certain that all the five hymns were first made public in 1712, in papers contributed by Addison to the *Spectator* (Nos. 441, 453, 465, 489, 513), in which they were introduced in a way which might have been expected if they were by the hand which wrote those papers, but which would have been improbable, and unworthy of Addison, if they were unpublished works of a writer of so much genius, and such note in his day, as Marvell. They are all printed as Addison's in Dr Johnson's edition of the *British Poets.*

to them), are perceptible in the vividness and force with which these writers, while adhering with a severe simplicity to the sense of the passages of Scripture which they undertook to render, fulfilled the conception of a good original hymn. Morrison's "The race that long in darkness pined" and "Come, let us to the Lord our God," and Bruce's "Where high the heavenly temple stands" (if this was really his), are well entitled to that praise. The advocates of Bruce in the controversy, not yet closed, as to the poems said to have been entrusted by him to John Logan, and published by Logan in his own name, also claim for him the credit of having varied the paraphrase "Behold, the mountain of the Lord," from its original form, as printed by the committee of the General Assembly in 1745, by some excellent touches.

Methodist hymns.

Attention must now be directed to the hymns produced by the "Methodist" movement, which began about 1738, and which afterwards became divided, between those esteemed Arminian, under John Wesley, those who adhered to the Moravians, when the original alliance between that body and the founders of Methodism was dissolved, and the Calvinists, of whom Whitfield (himself no poet) was the leader, and Selina, countess of Huntingdon, the patroness. Each of these sections had its own hymn-writers, some of whom did, and others did not, secede from the Church of England. The Wesleyans had Charles Wesley, Seagrave, Olivers, and Bakewell; the Moravians, Cennick and Hammond (with whom, perhaps, may be classed John Byrom, who imbibed the mystical ideas of some of the German schools); the Calvinists, Toplady, Berridge, William Williams, Madan, Batty, Haweis, Rowland Hill, John Newton, and Cowper.

Charles Wesley.

Among all these writers, the palm undoubtedly belongs to Charles Wesley. In the first volume of hymns published by the two brothers are several good translations from the German, believed to be by John Wesley, who, although he translated and adapted, is not supposed to have written any original hymns; and the influence of German hymnody, particularly of the works of Paul Gerhardt, Scheffler, Tersteegen, and Zinzendorf, may be traced in a large proportion of Charles Wesley's works. He is more subjective and meditative than Watts and his school; there is a didactic turn, even in his most objective pieces (as, for example, in his Christmas and Easter hymns); most of his works are supplicatory, and his faults are connected with the same habit of mind. He is apt to repeat the same thoughts, and to lose force by redundancy—he runs sometimes even to a tedious length; his hymns are not always symmetrically constructed, or well balanced and finished off. But he has great truth, depth, and variety of feeling; his diction is manly, and always to the point; never florid, though sometimes passionate and not free from exaggeration; often vivid and picturesque. Of his spirited style there are few better examples than "O for a thousand tongues to sing," "Blow ye the trumpet, blow," "Rejoice, the Lord is King," and "Come, let us join our friends above;" of his more tender vein, "Happy soul, thy days are ended;" and of his fervid contemplative style (without going beyond hymns fit for general use), "O Thou who camest from above," "Forth in thy name, O Lord, I go," and "Eternal Beam of Light Divine." With those whose taste is for hymns in which warm religious feelings are warmly and demonstratively expressed, "Jesus, lover of my soul," is as popular as any of these.

Olivers.

Of the other Wesleyan hymn-writers, Olivers (originally a Welsh shoemaker, afterwards a preacher) is the most remarkable. He is the author of only two works, both odes, in a stately metre, and from their length unfit for congregational singing, but one of them, "The God of Abraham praise," an ode of singular power and beauty.

The Moravian Methodists produced few hymns now available for general use. The best are Cennick's "Children of the heavenly King," and Hammond's "Awake and sing the song of Moses and the Lamb," the former of which (abridged), and the latter as varied by Madan, are found in many hymn-books, and are deservedly esteemed. Byrom, whose name we have thought it convenient to connect with these, though he did not belong to the Moravian community, was the author of a Christmas hymn ("Christians awake, salute the happy morn") which enjoys great popularity in the county (Lancashire) of which he was a native; and also of a short subjective hymn, very fine both in feeling and in expression, "My spirit longeth for Thee within my troubled breast."

The contributions of the Calvinistic Methodists to English hymnody are of greater extent and value. Few writers of hymns had higher gifts than Augustus Montague Toplady, author of "Rock of Ages," by some esteemed the finest in the English language. He was a man of ardent temperament, enthusiastic zeal, strong convictions, and great energy of character. "He had," says one of his biographers, "the courage of a lion, but his frame was brittle as glass." Between him and John Wesley there was a violent opposition of opinion, and much acrimonious controversy; but the same fervour and zeal which made him an intemperate theologian gave warmth, richness, and spirituality to his hymns. In some of them (particularly those which, like "Deathless principle, arise," are meditations after the German manner, and not without direct obligation to German originals) the setting is somewhat too artificial; but his art is never inconsistent with a genuine flow of real feeling. Others (*e.g.*, "When languor and disease invade," and "Your harps, ye trembling saints") fail to sustain to the end the beauty with which they began, and would have been better for abridgment. But in all these, and in most of his other works, there is great force and sweetness, both of thought and language, and an easy and harmonious versification.

Berridge, Williams, and Rowland Hill (all men remarkable for eccentricity, activity, and the devotion of their lives to the special work of missionary preaching), though not the authors of many good hymns, composed, or adapted from earlier compositions, some of great merit. One of Berridge, adapted from Erskine, has been already mentioned; another, adapted from Watts, is "Jesus, cast a look on me." Williams, a Welshman (who wrote "Guide me, O Thou great Jehovah"), was especially an apostle of Calvinistic Methodism in his own country, and his hymns are still much used in the principality. Rowland Hill wrote the popular hymn beginning "Exalted high at God's right hand."

If, however, the number as well as the quality of good hymns available for general use is to be regarded, the authors of the "Olney Hymns" are entitled to be placed at the head of all the writers of this Calvinistic school. The greater number of the Olney Hymns are, no doubt, homely and didactic; but to the best of them (and they are no inconsiderable proportion) the tenderness of Cowper and the manliness of Newton give the interest of contrast, as well as that of sustained reality. If Newton carried to some excess the sound principle laid down by him, that "perspicuity, simplicity, and ease should be chiefly attended to, and the imagery and colouring of poetry, if admitted at all, should be indulged very sparingly and with great judgment," if he is often dry and colloquial, he rises at other times into "soul-animating strains," such as "Glorious things of thee are spoken, Zion, city of our God;" and sometimes (as in "Approach, my soul, the mercy seat") rivals Cowper himself in depth of feeling. Cowper's hymns in this book are, almost without exception, worthy of his name. Among them are "Hark, my soul, it is the Lord," "There is a fountain filled with blood," "Far from the world, O Lord, I flee," "God moves in a mysterious way," and "Sometimes a light surprises." Some, perhaps, even of these, and others of equal excellence (such as "O for a closer walk with God"), speak the language of a special experience, which, in Cowper's case, was only too real, but which could not (without a degree of unreality not desirable in exercises of public worship) be applied to themselves by all ordinary Christians.

...ury ...ns. During the first quarter of the present century there were not many indications of the tendency, which afterwards became manifest, to enlarge the boundaries of British hymnody. A few, indeed, of Bishop Heber's hymns, and

...rant. those of Sir Robert Grant (which, though offending rather too much against John Newton's canon, are well known and popular), appeared between 1811 and 1816, in the *Christian*

...dler. *Observer*. In John Bowdler's *Remains*, published soon after his death in 1815, there are a few more of the same, perhaps too scholarlike, character. But the chief hymn-writers of that period were two clergymen of the Established Church —one in Ireland, Thomas Kelly, and the other in England, William Hurn—who both became Nonconformists, and the Moravian poet, James Montgomery, a native of Scotland.

K...y. Kelly was the son of an Irish judge, and in 1804 published a small volume of ninety-six hymns, which grew in successive editions till, in the last before his death in 1854, they amounted to 765. There is (as might be expected) in this great number a large preponderance of the didactic and commonplace. But not a few very excellent hymns may be gathered from them. Simple and natural, without the vivacity and terseness of Watts or the severity of Newton, Kelly has some points in common with both those writers, and he is less subjective than most of the "Methodist" school. His hymns beginning "Lo! He comes, let all adore Him," and "Through the day Thy love hath spared us," have a rich melodious movement; and another, "We sing the praise of Him who died," is distinguished by a calm subdued power, rising gradually from a rather low to a very high key.

H...n. Hurn published in 1813 a volume of 370 hymns, which were increased after his secession to 420. There is little in them which deserves to be saved from oblivion; but one at least, "There is a river deep and broad," may bear comparison with the best of those which have been produced upon the same (and it is rather a favourite) theme.

M...go...ry. The *Psalms and Hymns* of James Montgomery were published in 1822 and 1825, though written earlier. More cultivated and artistic than Kelly, he is less simple and natural. The number of his valuable contributions to our hymnals is, upon the whole, considerable; and, though it may be doubted whether he ever attains to the first rank, all must acknowledge that he stands high in the second. His "Hail to the Lord's Anointed," "Songs of praise the angels sang," and "Mercy alone can meet my case" are among his most successful efforts.

...ions of ...ys. During this first quarter of the present century, the collections of miscellaneous hymns for congregational use, of which the example was set by the Wesleys, Whitfield, Toplady, and Lady Huntingdon, had greatly multiplied; and with them the practice (for which, indeed, too many precedents existed in the history of Latin and German hymnody) of every collector altering the compositions of other men without scruple, to suit his own doctrine or taste; with the effect, too generally, of patching and disfiguring, spoiling, and emasculating the works so altered, substituting neutral tints for natural colouring, and a dead for a living sense. In the Church of England, the use of these collections had become frequent in churches and chapels (principally in cities and towns) where the sentiments of the clergy approximated to those of the Nonconformists. In rural parishes, when the clergy were not of the "Evangelical" school, they were generally held in disfavour; for which (even if doctrinal prepossessions had not entered into the question) the great want of taste and judgment often manifested in their compilation, and perhaps also the prevailing mediocrity of the bulk of the original compositions from which most of them were derived, would be enough to account. In addition to this, the idea that no hymns ought to be used in any services of the Church of England (except prose anthems after the third Collect), without express royal or ecclesiastical authority, continued down to that time largely to prevail among churchmen of the higher school.

Heber, Milman, Keble. Two publications, which appeared almost simultaneously in 1827,—Bishop Heber's *Hymns*, with a few added by Dean Milman, and Keble's *Christian Year* (not a hymn-book, but one from which several admirable hymns have been taken, and the well-spring of many streams of thought and feeling by which good hymns have since been produced), —introduced a new epoch, breaking down the barrier as to hymnody which had till then existed between the different theological schools of the Church of England. In

Mant. this movement Bishop Mant was also one of the first to cooperate. It soon received a great additional impulse from the increased attention which, about the same time, began to be paid to ancient hymnody, and from the publication in 1833 of Bunsen's *Gesangbuch*. Among its earliest fruits was the *Lyra Apostolica*, containing hymns, sonnets, and other devotional poems, most of them originally contributed by some of the leading authors of the *Tracts for the Times* to the "British Magazine"; the finest of which is the pathetic "Lead, kindly Light, amid th' encircling gloom," by John Henry (now Cardinal) Newman,—well known, and universally admired. Newman. From that time hymns and hymn-writers rapidly multiplied in the Church of England, and in Scotland also, and their number is still on the increase. Nearly 600 authors, whose publications were later than 1827, are enumerated in Mr Sedgwick's catalogue of 1863, and many more have since appeared. Works, critical and historical, upon the subject of hymns, have also multiplied; and collections for church use have become innumerable,— several of the various religious denominations, and many of the leading ecclesiastical and religious societies, having issued hymn-books of their own, in addition to those compiled for particular dioceses, churches, and chapels, and to books (like *Hymns Ancient and Modern*) which have become popular without any sanction from authority. In these more recent collections, an improved standard of taste has become generally apparent. There is a larger and more liberal admission of good hymns from all sources than might have been expected from the jealousy, so often felt by churches, parties, and denominations, of everything which does not bear their own mint-mark; a considerable (perhaps too large) use of translations, especially from the Latin; and an increased (though not as yet sufficient) scrupulousness about tampering with the text of other men's works. To mention all the authors of good hymns since the commencement of this new epoch would be impossible; but probably no names could be chosen more fairly representative of its characteristic merits, and perhaps also of some of its defects, than those of Josiah Conder and James Edmeston among English Nonconformists; Henry Francis Lyte and Charlotte Elliott among evangelicals in the Church of England; John Mason Neale and Bishop Christopher Wordsworth among English churchmen of the higher school; and, in Scotland, Dr Horatius Bonar. Criticism, in this place, of the works of these and other living or recent authors, or of those of Heber and Keble, which are on everybody's lips, and in everybody's hands, would be at once premature and superfluous.

Ameri-can hymns.

What has been said of British hymnody during the last fifty years is equally true of American. The American hymn-writers belong to the same schools, and have been affected by the same influences. Some of them enjoy a just reputation on both sides of the Atlantic. Among those best known are Bishop Doane, Dr Muhlenberg, and Mr Thomas Hastings; and it is difficult to praise too highly such works as the Christmas hymn, "It came upon the midnight clear," by Mr Edmund H. Sears; the Ascension hymn, "Thou, who didst stoop below," by Mrs S. E. Miles; and two by Dr Ray Palmer, "My faith looks up to Thee, Thou Lamb of Calvary," and "Jesus, Thou joy of loving hearts," the latter of which is the best among several good English versions of "Jesu, dulcedo cordium."

Among the authorities of which use has been made in the foregoing account of British Hymnody are the Appendix on Scottish Psalmody in Mr Laing's edition of Baillie's *Letters and Journals*; Mr Holland's *Psalmists of Britain* (1843); Mr Josiah Miller's *Our Hymns, their Authors and Origin* (1866); Mr John Gadsby's *Memoirs of the Principal Hymn-writers*, &c. (3d ed., 1861); the "Annotations" of the Rev. Louis Coutier Biggs to *Hymns Ancient and Modern* (1867); and the late Mr Daniel Sedgwick's *Comprehensive Index of Names of original Authors of Hymns*, &c. (2d ed., 1863). Mr Sedgwick's name cannot be mentioned without special honour, as one of the most painstaking, sympathetic, and accurate of all modern students of British hymns.

7. *Conclusion.*

The object aimed at in this article has been to trace the general history of the principal schools of ancient and modern hymnody, and especially the history of its use in the Christian church. For this purpose it has not been thought necessary to give any account of the hymns of Racine, Madame Guyon, and others, who can hardly be classed with any school, nor of the works of Cæsar Malan and other quite modern hymn-writers of the Reformed churches in Switzerland and France.

On a general view of the whole subject, hymnody is seen to have been a not inconsiderable factor in religious worship. It has been sometimes employed to disseminate and popularize particular views, but its spirit and influence has been Catholic, on the whole. It has embodied the faith, trust, and hope, and no small part of the inward experience, of generation after generation of men, in many different countries and climates, of many different nations, and in many varieties of circumstances and condition. Coloured, indeed, by these differences, and also by the various modes in which the same truths have been apprehended by different minds (and sometimes reflecting partial and imperfect conceptions of them, and errors with which they have been associated in particular churches, times, and places), its testimony is, nevertheless, generally the same. It has upon it a stamp of genuineness which cannot be mistaken. It bears witness to the force of a central attraction more powerful than all causes of difference, which binds together times ancient and modern, nations of various race and language, churchmen and nonconformists, churches reformed and unreformed; to a true fundamental unity among good Christians; and to a substantial identity in their moral and spiritual experience. (s.)

HYPATIA (Ὑπατία or Ὑπάτεια), mathematician, philosopher, and finally one of the martyrs of paganism, was the daughter and disciple of the mathematician and philosopher Theon,[1] and was born in Alexandria not earlier than 350 A.D.[2] After a long period of study (partly, perhaps, in Athens) she became a distinguished lecturer on philosophy in her native town, and ultimately became the recognized head of the Neo-Platonic school there (*c.* 400). The fascination of her great eloquence (she is said on more than one occasion to have proved an effective advocate in the courts of law), and the charm of a rare modesty and beauty, combined with her remarkable intellectual gifts to attract to her class-room a large number of disciples, over some of whom her influence was very great. Among these was Synesius, who afterwards (*c.* 410) became bishop of Ptolemais, several of whose letters addressed to her (τῇ φιλοσόφῳ), full of chivalrous admiration and reverence, are still extant (*Epp.* 10, 15, 16, 33, 80, 124, 153). In the conflicts between the various elements of Alexandrian society which took place shortly after the accession of Cyril to the patriarchate in 412, she became closely identified as counsellor and friend with the prefect Orestes, and in the same degree made herself an object of fear and hatred to the Nitrian monks and the fanatical Christian mob, by whom she was ultimately murdered under circumstances of revolting barbarity (Lent, 415). Socrates has related how she was torn from her chariot, dragged to the Cæsareum (then a Christian church), stripped naked, cut to pieces with oyster shells (ὀστράκοις ἀνεῖλον), and finally burnt piecemeal. Most prominent among the actual perpetrators of the crime was one Peter, a reader; but there seems little reason to doubt Theodoret's assertion of Cyril's real complicity.

Hypatia, according to Suidas, was the author of commentaries on the mathematician Diophantus and on the *Conics* of Apollonius of Perga, and also of an astronomical canon. None of these works have come down to our time; but their titles, combined with expressions in the letters of Synesius, who consulted her about the construction of an astrolabe, would seem to indicate that she devoted herself specially to astronomy and mechanics. Of her philosophical opinions nothing is known, except that they shared the general eclectic features of the Alexandrian Neo-Platonism. A Latin letter to Cyril on behalf of Nestorius, which has sometimes been attributed to her, is undoubtedly spurious. It can be read in Baluze. The story of Hypatia appears in a considerably disguised yet still recognizable form in the legend of St Catherine as recorded in the Roman *Breviary* (Nov. 25), and still more fully in the *Martyrologies* (see Jameson, *Sacred and Legendary Art*, p. 467 *sqq.*).

The chief source for the little we know about Hypatia is the account given by Socrates (*H. E.*, vii. 15). The article in Suidas, which Gibbon has characterized as "curious and original," must be received with some caution. It is on his authority that the somewhat doubtful statement is made that she was the wife of Isidorus the philosopher. She is the subject of an epigram by Palladas in the *Anthology* (ix. 400; ed. Jacobs). See Menage, *Hist. Mul. Phil.*, p. 52; Fabricius, *Bibl. Gr.*, ix. 187 *sqq.*; Wernsdorf, *op. cit.*; and the exhaustive monograph of Hoche in *Philologus*, xv. 435 *sqq.* (1860). An anonymous work entitled *Hypatia, or the history of a most beautiful, most virtuous, most learned, and every way accomplished lady, who was torn to pieces by the clergy of Alexandria to gratify the pride, emulation, and cruelty of their archbishop Cyril, commonly but undeservedly styled Saint Cyril*, was published in London in 1720. The history of Hypatia has also been made the basis of an attractive historical romance by Charles Kingsley (1853).

HYPERIDES (Ὑπερείδης), one of the ten Attic orators, was son of Glaucippus, of a noble family of the tribe Ægeis and the deme Collytus. He was probably younger than Lycurgus (born about 396 B.C.) and older than Demosthenes (born about 385 B.C.). Having studied under Isocrates, he began life as a writer of speeches for the courts, and in 360 B.C. he prosecuted Autocles, a general charged with treason in Thrace. From the end of the Sacred War, 346–

[1] For some account of whom see Suidas; compare Fabricius, *Bibl. Gr.*, ix. 178 *sqq.* (1804). He observed an eclipse in 365.

[2] The date assigned by Wernsdorf (*Diss. Acad. IV. de Hypatia*, Wittenberg, 1747). Hoche (*Philologus*, xv.) gives 370.

324 B.C., Hyperides supported Demosthenes in the struggle against Macedon; but in the affair of Harpalus he was one of the ten public prosecutors of Demosthenes, and on the exile of his former leader he became the head of the patriotic party (see DEMOSTHENES). He was the chief promoter of the Lamian War against Antipater and Craterus. After the decisive defeat of Crannon, 322 B.C., Hyperides with the other orators demanded by Antipater was condemned to death by the subdued Athenians, but fled to Ægina and thence into sanctuary in the temple of Demeter at Hermione. Antipater's emissaries dragged him forth to be put to death at Athens. Hyperides was an ardent pursuer of "the beautiful," which in his time generally meant pleasure and luxury. His temper was easy-going and humorous; and hence, though in his development of the periodic sentence he followed Isocrates, the essential tendencies of his style are those of Lysias, whom he surpassed, however, in the richness of his vocabulary and in the variety of his powers. His diction was plain and forcible, though he occasionally indulged in long compound words probably borrowed from the Middle Comedy, with which, and with the everyday life of his time, he was in full sympathy. His composition was simple. He was specially distinguished for subtlety of expression, grace, and wit, as well as for tact in approaching his case and handling his subject matter. Professor Jebb sums up the criticism of Longinus in the phrase—"Hyperides was the Sheridan of Athens." Of his lost speeches we should perhaps regret most the Δηλιακός, on the presidency of the Delian temple claimed by Athens and Delos, which was adjudged by the Amphictyons to Athens.

The extant works of Hyperides are—1, Fragment of the ἀπολογία ὑπὲρ Λυκόφρονος, *Pro Lycophrone*, delivered before 349 B.C., incidentally interesting as throwing light on the order of marriage processions and other details of Athenian life, and on the Athenian government of Lemnos; 2, Ὑπὲρ Εὐξενίππου εἰσαγγελίας ἀπολογία πρὸς Πολύευκτον, *Pro Euxenippo*, about 330 B.C., nearly perfect (a *locus classicus* on εἰσαγγελίαι); 3, fragments of the Κατὰ Δημοσθένους, *In Demosthenem*, see above; 4, a considerable portion of the λόγος ἐπιτάφιος, *Oratio Funebris*, over Leosthenes and his comrades who fell in the Lamian war, 322 B.C., after Antiphilus's victory over Leonnatus at Melitea. This is an elevated panegyric in the style of Isocrates, but in invention and sentiment the best specimen we have of epideictic oratory. Of the epilogue a portion is preserved by Stobæus only. The MSS. are papyri—those of the first two speeches found by Joseph Arden, January 1847, that of the third speech by A. C. Harris, 1847, of the last by the Rev. H. Stobart, 1856, all at Thebes in Egypt. They are among the oldest extant MSS., dating within the limits 300 B.C. and 300 A.D.

Schwarz, on the speech for Euxenippus, published at Moscow, 1875.

HYPERTROPHY (from ὑπέρ, over, and τροφή, nourishment), a term in medicine employed to designate an abnormal increase in bulk of one or more of the organs or component tissues of the body. In its strict sense this term can only be applied where the increase affects the natural textures of a part, and is not applicable where the enlargement is due to the presence of some extraneous morbid formation. Hypertrophy of a part may manifest itself either by simply an increase in the size of its constituents, or by this combined with an increase in their number (hyperplasia). In many instances both are associated.

The conditions giving rise to hypertrophy are the reverse of those already described as producing ATROPHY (*q.v.*). They are concisely stated by Sir James Paget as being chiefly or only three, namely:—(1) the increased exercise of a part in its healthy functions; (2) an increased accumulation in the blood of the particular materials which a part appropriates to its nutrition or in secretion; and (3) an increased afflux of healthy blood.

Illustrations are furnished of the first of these conditions by the high development of muscular tissue under habitual active exercise; of the second in the case of obesity, which is an hypertrophy of the fatty tissues, the elements of which are furnished by the blood; and of the third in the occasional overgrowth of hair in the neighbourhood of parts which are the seat of inflammation. Obviously therefore, in many instances, hypertrophy cannot be regarded as a deviation from health, but rather on the contrary as indicative of a high degree of nutrition and physical power. Even in those cases where it is found associated with disease, it is often produced as a salutary effort of nature to compensate for obstructions or other difficulties which have arisen in the system, and thus to ward off evil consequences. No better example of this can be seen than in the case of certain forms of heart disease, where from defect at some of the natural orifices of that organ the onward flow of the blood is interfered with, and would soon give rise to serious embarrassment to the circulation, were it not that behind the seat of obstruction the heart gradually becomes hypertrophied, and thus acquires greater propelling power to overcome the resistance in front. Again, it has been noticed, in the case of certain double organs such as the kidneys, that when one has been destroyed by disease the other has become hypertrophied to such a degree as enables it to discharge the functions of both.

Hypertrophy may, however, in certain circumstances constitute a disease, as in GOITRE and ELEPHANTIASIS (*q.v.*), and also in the case of certain tumours and growths (such as cutaneous excrescences, fatty tumours, mucous polypi, &c.), which are simply enlargements of normal textures. Hypertrophy does not in all cases involve an increase in bulk; for, just as in atrophy there may be no diminution in the size of the affected organ, so in hypertrophy there may be no increase. This is apt to be the case where certain only of the elements of an organ undergo increase, while the others remain unaffected or are actually atrophied by the pressure of the hypertrophied tissue, as is seen in the disease known as cirrhosis of the liver.

A spurious sort of hypertrophy is observed in the rare disease to which M. Duchenne has applied the name of *pseudo-hypertrophic paralysis*. This ailment, which appears to be confined to children, consists essentially of a progressive loss of power accompanied with a remarkable enlargement of certain muscles or groups of muscles, more rarely of the whole muscular system. This increase of bulk is, however, not a true hypertrophy, but rather an excessive development of connective tissue in the substance of the muscles, the proper texture of which tends in consequence to undergo atrophy or degeneration. The appearance presented by a child suffering from this disease is striking. The attitude and gait are remarkably altered, the child standing with shoulders thrown back, small of the back deeply curved inwards, and legs wide apart, while walking is accompanied with a peculiar swinging or rocking movement. The calves of the legs, the buttocks, the muscles of the back, and occasionally other muscles, are seen to be unduly enlarged, and contrast strangely with the general feebleness. The progress of the disease is marked by increasing failure of locomotory power, and ultimately by complete paralysis of the limbs. The malady is little amenable to treatment, and, although often prolonged for years, generally proves fatal before the period of maturity.

HYPOCHONDRIASIS (synonyms—the spleen, the vapours). As the name implies (from τὸ ὑποχόνδριον, τὰ ὑποχόνδρια, the soft part of the body immediately under the χόνδρος or cartilage of the breast-bone), hypochondriasis and its symptoms were referred by the ancients, and indeed by physicians down to the time of Cullen, to diseases or derangements of one or more of the abdominal viscera. Cullen classified it amongst nervous diseases, and Falret more fully described it as a morbid condition of the nervous system characterized by depression of feeling and false beliefs as to an impaired state of the health. The subjects of hypochondriasis are for the most part members of families in which hereditary predisposition to degradation of the nervous system is strong, or those who have suffered from morbid influences affecting this system during the earlier years of life. It may be dependent on depressing disease affecting the general system, but under such circumstances it is generally so complicated with the symptoms of hysteria as to render differentiation difficult (see HYSTERIA). Hypochondriasis is often handed down from one generation to another in its individual form, but it is also not unfrequently to be met with in an individual as the sole manifestation in him of a family tendency to insanity. In its most common form it is manifested by simple false belief as to the state of the health, the intellect being otherwise unaffected. We may instance the "vapourish" woman or the "splenetic" as terms society has applied to its milder manifestations. Such persons are constantly asserting a weak state of health although no palpable cause can be discovered. In its more definite phases pain or uneasy sensations are referred by the patient to some particular region, generally the abdomen, the heart, or the head. That these are subjective is apparent from the fact that the general health is good: all the functions of the various systems are duly performed; the patient eats and sleeps well; and, when any circumstance temporarily overrides the false belief, he is happy and comfortable. No appeal to the reason is of any avail, and the hypochondriac idea so dominates his existence as to render him unable to perform the ordinary duties of life. In its most aggravated form hypochondriasis amounts to actual insanity, delusions arising as to the existence of living creatures in the intestines or brain, or to the effect that the body is materially changed, *e.g.*, into glass, wood, &c. (see INSANITY). The symptoms of this condition may be remittent; they may even disappear for years, and only return on the advent of some exciting cause. Suicide is occasionally committed in order to escape from the constant misery. As there is nothing to treat, medication is of no avail, and recovery can only be looked for by placing the patient under such morally hygienic conditions as may help to take his mind off himself. More generally he lives through the attack rather than is cured of it.

See Cullen, *Clinical Lectures*, pp. 39–57 (London, 1777); Georget, *De la Phys. du Syst. Nerv.* (Paris, 1819); Reynolds, *System of Medicine*, vol. ii. p. 293 (London, 1868); Griesinger, *Mental Pathology and Therapeutics* (1867); Niemeyer, *Practical Medicine* (1871).

HYPOTHEC (*Hypotheca*), in Roman law, is the most advanced form of the contract of pledge. A specific thing may be given absolutely to a creditor on the understanding that it is to be given back when the creditor's debt is paid; or the property in the thing may be assigned to the creditor while the debtor is allowed to remain in possession, the creditor as owner being able to take possession if his debt is not discharged. Here we have the kind of security known as pledge and mortgage respectively. In the *hypotheca*, the property does not pass to the creditor, nor does he get possession, but he acquires a preferential right to have his debt paid out of the hypothecated property; that is, he can sell it and pay himself out of the proceeds, or in default of a purchaser he can become the owner himself. The name and the principle have passed into the law of Scotland, which distinguishes between conventional hypothecs, as *bottomry* and *respondentia*, and tacit hypothecs established by law. Of the latter the most important is the landlord's hypothec for rent (corresponding to distress in the law of England), which extends over the produce of the land and the cattle and sheep fed on it, and over stock and horses used in husbandry. The law of agricultural hypothec has long caused much discontent in Scotland; its operation was restricted by 30 & 31 Vict. c. 42, and finally by 43 Vict. c. 12 it has been enacted that the "landlord's right of hypothec for the rent of land, including the rent of any buildings thereon, exceeding two acres in extent, let for agriculture or pasture, shall cease and determine." As a set off the landlord is to have the same rights and remedies against a tenant when six months' rent or twelve months' rent is due and unpaid as he had formerly against a tenant when twelve months' rent or two years' rent respectively was due and unpaid.

HYRAX, a genus of diminutive plantigrade mammals, the position of which in the mammalian series has, owing to their apparent affinity with several widely different groups, given rise to considerable controversy. Approaching the hare in their external appearance and habits, the rhinoceros in their molar teeth and much of their skeleton, the hippopotamus in the form of their lower incisors, and the sloth in the great number of their dorsal vertebræ, they were at first classed with the rodents, and afterwards, by Cuvier, with the pachyderms, where they remained until, on the breaking up of that most heterogeneous of groups,

Cape Hyrax.

Professor Huxley established the order *Hyracoidea* for their reception. They are small, rabbit-like creatures, the largest not exceeding 18 inches in length, covered with a thick soft fur with numerous bristles interspersed. Their ears and legs are short; the tail is represented only by a small tubercle; and their toes, of which they have four on each foot in front and three behind, are, with the exception of the inner one on each hind foot, provided with flat hoof-like nails. They have twenty-one pairs of ribs—a larger number than is possessed by any other mammals except the sloths, which have twenty-three pairs. They are gregarious animals, dwelling in colonies in the crevices of rocks and in the caverns which abound in the hilly regions they frequent, and feeding on grass and other herbage, on roots, fruits, and the tender shoots of plants. There are, according to Dr Gray, thirteen species of *Hyrax*, many of which are, however, regarded by other authorities as merely varieties. They are all confined to the African continent with the exception of the Syrian hyrax or daman (*Hyrax syriacus*), whose range extends from Abyssinia into Arabia, Syria, and Palestine. This species is generally regarded as the "shaphan," rendered "conies" in the English Bible, which "are but a feeble folk, yet make their houses in the rocks" (Prov. xxx. 26). They measure about a foot in length and 11 inches in height, and are of a greyish-brown colour above, fulvous on the flanks, and white beneath. They are active little creatures, darting in and out of their rocky shelters with remarkable agility. Bruce, who observed their habits in Abyssinia, states that large numbers of them were frequently to be seen sitting on great stones at the mouths of caves, basking in the sunshine, or enjoying the coolness of the summer evening. Of timid and gentle disposition, they can be readily tamed, although when roughly handled at first they are said to bite severely. The Cape hyrax (*Hyrax capensis*) or "badger" (dasse; Dutch, Das; German, Dachs) is the largest known species, measuring about 18 inches in length. It frequents situations similar to those occupied by the Syrian form, and is exceedingly shy, peeping out of its rocky hiding places with a circumspection which is by no means uncalled for, as it forms a favourite food of lions, hyænas, and the larger birds of prey. The latter, it is said, may often be seen perched, for hours, like statues on the rocks, watching their opportunity to dart upon the luckless "badger." To guard against such surprises, they are said, when feeding, to place one of their number, usually an old male, as a sentinel, whose shrill prolonged cry gives timely notice of approaching danger. Like the "conies," they are readily tamed, and seem capable of considerable attachment, although their natural timidity and suspicion cause them to hide themselves on the appearance of a stranger. There are two species of hyrax, one in the south and the other in the west of Africa, which are said to be arboreal in their habits, making their abode in the holes of trees. Dr Gray has placed these in a separate genus—*Dendrohyrax*. The island of Fernando Po possesses a species peculiar to itself, while the genus is entirely wanting in Madagascar. No fossil remains of the hyrax have yet been found.

HYRCANIA, a province of Asia, south of the Caspian Sea, and bounded on the E. by the river Oxus. It was, however, a wide and indefinite tract, the extent of which is variously conceived. Its chief city is called Tape by Strabo, Zadracarta by Arrian. The latter is evidently the same as Carta, mentioned by Strabo as an important city. Some parts of the country were fertile, but the general idea prevalent among the classical writers is that it was a rude region of forests full of dangerous wild animals. Little is known of the history of the country, as it seldom came into connexion with the better known races. Xenophon says it was subdued by the Assyrians; Curtius says that 6000 Hyrcanians were in the army of the last Persian king Darius. Two towns named Hyrcania are mentioned, one in the country of Hyrcania, the other in Lydia. The latter is said to have derived its name from a colony of Hyrcanians, transported thither by the Persians.

HYRCANUS (Ὑρκανός), a Greek surname, of unknown origin, borne by several Jews of the Maccabæan period.

John Hyrcanus I., high priest of the Jews from 135 to 105 B.C., was the youngest son of Simon Maccabæus. In 137 B.C. he, along with his brother Judas, commanded the force which repelled the invasion of Judæa led by Cendebeus the general of Antiochus VII. (Sidetes). On the assassination of his father and two elder brothers by Ptolemy, governor of Jericho, his brother-in-law, in February 135, he succeeded to the high priesthood and the supreme authority in Judæa. While still engaged in the struggle with Ptolemy, he was attacked by Antiochus with a large army (134), and compelled to shut himself up in Jerusalem; after a severe siege peace was at last secured only on condition of a Jewish disarmament, and the payment of an indemnity and an annual tribute, for which hostages were taken. In 129 he accompanied Antiochus as a vassal prince on his ill-fated Parthian expedition; returning, however, to Judæa before winter, he escaped the final disaster. By the judicious mission of an embassy to Rome he now obtained confirmation of the alliance which his father had previously made with the growing western power; at the same time he availed himself of the weakened state of the Syrian monarchy under Demetrius II. to overrun Samaria, and also to invade Idumæa, which he completely subdued, compelling its inhabitants to receive circumcision and accept the Jewish faith. After a long period of rest he directed his arms against the town of Samaria, which, in spite of the intervention of Antiochus, his sons Antigonus and Aristobulus ultimately took, and by his orders razed to the ground (*c.* 109 B.C.). He died in 105, and was succeeded by Aristobulus, the eldest of his five sons. The external policy of Hyrcanus was marked by considerable energy and tact, and, aided as it was by favouring circumstances, was so successful as to leave the Jewish nation in a position of independence and of influence such as it had not known since the days of Solomon. During its later years his reign was much disturbed, however, by the contentions for ascendency which arose between the Pharisees and Sadducees, the two rival sects or parties which then for the first time (under those names at least) came into prominence. Josephus has related the curious circumstances under which he ultimately transferred his personal support from the former to the latter.

John Hyrcanus II., high priest from 78 to 40 B.C., was the eldest son of Alexander Jannæus by his wife Alexandra, and was thus a grandson of the preceding. When his father died in 78, he was by his mother forthwith appointed high priest, and on her death in 69 he claimed the succession to the supreme civil authority also; but, after a brief and troubled reign of three months, he was compelled to abdicate both kingly and priestly dignities in favour of his more energetic and ambitious younger brother Aristobulus II. In 63 it suited the policy of Pompey that he should be restored to the high priesthood, with some semblance of supreme command, but of much of this semblance even he was soon again deprived by the arrangement of the proconsul Gabinius, according to which Palestine was in 57 B.C. divided into five separate circles (σύνοδοι, συνέδρια). For services rendered to Cæsar after the battle of Pharsalia, he was again rewarded with the sovereignty (προστασία τοῦ ἔθνους, Jos., *Ant.*, xx. 10) in 47 B.C., Antipater of Idumæa, however, being at the same time made procurator of Judæa. In 41 B.C. he was practically superseded by Antony's appointment of Herod and Phasael to be tetrarchs of Judæa; and in the following year he was taken prisoner by the Parthians, deprived of his ears that he might be permanently disqualified for priestly office, and carried to Babylon. He was permitted in 33 B.C. to return to Jerusalem, where on a charge of treasonable correspondence with Malchus, king of Arabia, he was put to death in 30 B.C.

See Josephus (*Ant.*, xiii. 8–10; xiv. 5–13; *Bell. Jud.*, i. 2; i. 8–13), upon whose narrative all the modern accounts, as, *e.g.*, those by Ewald, Grätz, and Hitzig in their *Histories*, are based.

HYSSOP (*Hyssopus officinalis*), a garden herb belonging to the natural order *Labiatæ*, cultivated for use in domestic medicine. It is a small perennial plant about 2 feet high, with slender, quadrangular, woody stems; narrowly elliptical, pointed, entire, dotted leaves, about 1 inch long and ⅓ inch wide, growing in pairs on the stem; and long terminal, erect, half-verticillate, leafy spikes of small violet-blue flowers, which are in blossom from June to September. Two varieties of the plant occur in gardens, one having variegated leaves and the other reddish flowers. The leaves have a warm, aromatic, bitter taste, and are believed to owe their properties to a volatile oil which is present in the proportion of $\frac{1}{4}$ to $\frac{1}{2}$ per cent. Hyssop is a native of the south of Europe, its range extending eastward to Siberia; it was introduced into England by Gerard in the year 1596. A strong tea made of the leaves, and sweetened with honey, was formerly used in pulmonary and catarrhal affections, and externally as an application to bruises and indolent swellings.

The Hedge Hyssop (*Gratiola officinalis*) belongs to the natural order *Scrophulariaceæ*, and is a native of marshy lands in the south of Europe, whence it was introduced into Britain nearly 300 years ago. Like *Hyssopus officinalis*, it has smooth opposite entire leaves, but the stems are cylindrical, the leaves twice the size, and the flowers solitary in the axils of the leaves and having a yellowish-red veined tube and bluish-white limb, while the capsules are oval and many-seeded. The herb has a bitter, nauseous taste, but is almost odourless. In small quantities it acts as a purgative, diuretic, and emetic when taken internally. It was formerly official in the Edinburgh Pharmacopœia, being esteemed as a remedy for dropsical and scrofulous affections. It has also been given in the form of wine for hypochondriasis. It is said to have formed the basis of a celebrated nostrum for gout, called *Eau médicinale*, and in former times was called *Gratia Dei*, on account of its medicinal properties. When growing in abundance, as it does in some damp pastures in Switzerland, it becomes dangerous to cattle. *G. peruviana* is known to possess similar properties.

The hyssop (*'ezob*) of Scripture (Ex. xii. 22; Lev. xiv. 4, 6; Numb. xix. 6, 18; 1 Kings v. 13 (iv. 33); Ps. li. 9 (7); John xix. 29), a wall-growing plant adapted for sprinkling purposes, has long been the subject of learned disputation, the only point on which all have agreed being that it is not to be identified with the *Hyssopus officinalis*, which is not a native of Palestine. No less than eighteen plants have been supposed by various authors to answer the conditions, and Celsius has devoted more than forty pages to the discussion of their several claims. By Tristram (*Oxford Bible for Teachers*, 1880) and others the caper plant (*Capparis spinosa*) is supposed to be meant; but, apart from other difficulties, this identification is open to the objection that the caper seems to be, at least in one passage (Eccl. xii. 5), otherwise designated (*'abiyyônah*). Thenius (on 1 Kings v. 13) suggests *Orthotrichum saxatile*. The most probable opinion would seem to be that found in Maimonides and many later writers, according to which the Hebrew *'ezob* is to be identified with the Arabic *sa'atar*, now understood to be *Satureja Thymus*, a plant of very frequent occurrence in Syria and Palestine, with which *Thymus Serpyllum*, or Wild Thyme, and *Satureja Thymbra* are closely allied. Its smell, taste, and medicinal properties are similar to those of *H. officinalis*. In Morocco the *sa'atar* of the Arabs is *Origanum compactum*, Benth.; and it appears probable, as suggested by Mr W. Carruthers, that several plants of the genera *Thymus*, *Origanum*, and others nearly allied in form and habit, and found in similar localities, were used under the name of hyssop.

See Gerard, *Herball*, p. 578–582; Stillé and Maisch, *National Dispensatory*, p. 7512; Carruthers, in *Bible Educator*, vol. iv. p. 226–27; Thomson, *The Land and the Book*, p. 112; J. Smith, *Bible Plants*, p. 214; Furrer, art. "Ysop," in Schenkel's *Bibel-Lexicon*, vol. v.

HYSTERIA, a term applied to a disordered condition of the nervous system, the anatomical seat and nature of which are unknown to medical science, but of which the symptoms consist in well-marked and very varied disturbances of nerve function. By the ancients and by modern physicians down to the time of Sydenham its symptoms were supposed to be due to disturbances of the uterus (ὑστέρα, whence the name), but it is now universally recognized that they are dependent on a variety of causes with which that organ has no necessary connexion. The causes of hysteria may be divided into the predisposing, such as hereditary predisposition to nervous degeneration, sex, age, occupation, and national idiosyncracy; and the immediate, such as mental and physical exhaustion, fright, and other emotional influences, pregnancy, the puerperal condition, diseases of the uterus and its appendages, and the depressing influence of injury or general disease. Each and all of these causes may act and react in any given case; in fact, it is nearly always impossible to assign a particular cause in a particular instance. Perhaps, taken over all, hereditary predisposition to nerve-instability may be asserted as the most prolific cause. It is often noticed in families in which this instability exists that hysteria presents itself to a greater or less extent in a considerable number of its members as the sole indication of the diathesis. As regards age the condition is apt to appear at the evolutional periods of life—puberty, pregnancy, and the climacteric—without any further assignable cause except that first spoken of. It is very frequent in girls between the ages of twelve and fifteen, and in women on the cessation of the menstrual flow. It is much more common in the female than the male,—in the proportion of 20 to 1,—which circumstance points to the important influence of the uterus in causation, but definitely places hysteria in the category of nervous diseases. It has been asserted that certain races are more liable to the disease than others—that for instance the Latins and the Slavs are more prone to it than other inhabitants of Europe. This, however, is doubtful; in the more excitable races we find on the whole a greater tendency to hysterical excitement, in those whose national characteristic is calm and impassionateness a tendency to hysterical depression; and it is probable that the greater prominence of the symptoms in the former may have masked the more subtle yet not less important manifestations of the disease presented in the latter. Occupation, or be it rather said want of occupation, is a prolific cause. This is noticeable in all classes of society: in the higher the idle luxurious woman concentrates herself upon herself, and the frivolity of her existence helps to aggravate the evil which may be innate in her constitution; in the lower classes the disease is not so prevalent except among women who live a vicious and excited life. The experience of prison authorities shows not only that women of the criminal classes are individually liable to the hysterical paroxysm, but that it is very apt to assume an epidemic form amongst them. There is no proof that any particular legitimate occupation tends to its development. The depressing effects of almost any disease may be directly productive of hysteria, more especially those accompanied by pain and loss of sleep. There can be little doubt, however, that disease of the uterus and its appendages has a greater tendency towards its production than disease of any other system. At the same time, hysteria seems to follow more frequently on the less severe than on the graver forms of uterine complaints.

In point of duration hysteria may be transient or chronic. In the first phase it consists of an explosion of emotionalism, generally the result of mental excitement, to which the popular term "hysterics" is applied. Such attacks are generally preceded and accompanied by a sensation of a lump in the throat (the "globus hystericus"), a flow of limpid urine, violent outbursts of alternate laughter and weeping, and sometimes even convulsion. In the chronic condition we find an extraordinary complexity of symptoms, both physical and mental. These are continuous, constituting the "status hystericus," and paroxysmal. The physical symptoms are extremely diverse: there may be a pseudo-paralysis, the patient lying palsied wholly or partially, or there may be rigidity of one or more limbs, in either case the symptom persisting for weeks or months or even years; there may be flushing or pallor of the face, an increase or decrease of temperature. Perversions of sensation are frequent symptoms; these consist in complaint of pain, generally of a local character: a common instance is the sensation of a nail being driven through the vertex of the head ("clavus hystericus"), or of increased sensibility of particular parts. On the other hand loss of sensation may be complained of, or, as occasionally happens, hyperæsthesia and anæsthesia may be stated by an individual to exist in different parts of the body. The region of the spine is a very frequent seat of hysterical pain. Pain, more especially when referred to a joint, is apt to be accompanied by swelling. Both the motor and the sensory symptoms are in every instance out of all proportion to any assignable cause, and for the most part disappear suddenly, leaving the patient in perfect health. It is to such cases that the wonderful cures effected by quacks and charlatans may be referred. The mental symptoms have not the same tendency to pass away suddenly. They may be spoken of as interparoxysmal and paroxysmal. The chief characteristics of the former are extreme emotionalism combined with a curious obstructiveness, a desire to be an object of importance, and a constant craving for sympathy. This is sought to be procured at an immense sacrifice of personal comfort, and to this may be referred a very large proportion of the motor and sensory symptoms above spoken of. The paroxysmal condition does not materially differ from the transient hysteric attack, except that convulsion is more common and more violent. The special senses of taste, sight, and hearing may be affected, sometimes temporarily obliterated. Hysteria may pass into absolute insanity.

Treatment consists in attention to the general health, and to such special symptoms as may arise, notably those connected with the function of menstruation. The submission of the patient to the best moral influences is of no mean importance. But it may be admitted that the results are generally unsatisfactory so far as medication is concerned, as the cure is usually spontaneous or dependent on some sudden mental influence.

See Ziemssen's *Cyclopedia of the Practice of Medicine*, vol. xiv.; Reynolds's *System of Medicine*, vol. ii. (J. B. T.)

HYSTERO-EPILEPSY, a nervous disease of women, occurring during the fertile period of life, first observed and described by Professor Charcot of Paris. As yet it has been rarely observed in Great Britain. Its phenomena are very extraordinary, and serious doubts have been entertained by eminent authorities as to their substantiality, it being asserted that they are merely manifestations of ordinary hysteria, intensified by a process of education. But these doubts are being rapidly dissipated by the observations of competent observers. The disease is of a paroxysmal nature, and its symptoms may be divided into inter-paroxysmal and paroxysmal. The former consist of extreme sensitiveness over the region of one or (less frequently) both ovaries, and loss of tactile sensibility and complete insensibility to pain in one lateral half of the body, the side on which ovarian tenderness exists. Sight is sometimes implicated, manifested by a peculiar form of colour-blindness. Perhaps the most remarkable phenomenon presented in this disease is that all these impairments of sensation may be shifted to the other side of the body on the application of magnets and plates of metals, the originally affected side regaining sensibility so long as the opposite one is insensible. In some cases the symptoms are permanently bilateral. The paroxysm consists in violent general convulsion, epileptiform in character, which is at once checked by pressure over the tender ovary. The mental faculties are generally weakened, and the disease is for the most part incurable. (See Charcot, *Lectures on Diseases of the Nervous System*, New Sydenham Soc., 1877.)

HYTHE, a municipal and parliamentary borough of Kent, England, and one of the original Cinque Ports, is beautifully situated at the foot of a steep cliff near the eastern extremity of Romney Marsh, about half a mile from the sea, on a branch line of the South-Eastern Railway, 66 miles E.S.E. of London, 16 S.W. of Dover, and 5 W. of Folkestone. It consists principally of one long handsome street running parallel with the shore. On the slope of the hill above the town stands the fine old church of St Leonard, partly Late Norman and partly Early English, with a tower rebuilt about 1750. In a vault under the chancel there is a collection of human skulls and bones supposed to be the remains of ancient Britons and Saxons slain in a battle which took place near Hythe in 456. Of late the church has been undergoing restoration at a considerable cost, and it is proposed to complete the chancel, which was originally left unfinished. At Lympne there are the remains of a Roman *castrum*, and excavations made some years ago brought to light many interesting remains of the old Roman town, the *Portus Lemanus*. The site of the *castrum* is now occupied by the fine old castellated mansion of Studfall Castle, at one time the residence of the archdeacons of Canterbury, but at present used as a farm-house. Norman portions of the Lympne church originally built by Archbishop Lanfranc are still standing; and a small distance east from it is Shipway or Shepway Cross, where the great assemblies relating to the Cinque Ports used to be held until they were removed to Romney. Several bronze implements and weapons were discovered near Hythe in 1873, during the excavation of the railway line from Hythe to Sandgate. A mile north from Hythe is Saltwood Castle, of very ancient origin, but rebuilt in the time of Richard II. Hythe possesses a guild hall founded in 1794, and two hospitals, that of St Bartholomew founded by Haimo, bishop of Rochester, in 1336, and that of St John, of still greater antiquity but unknown date, and founded originally for the reception of lepers. A Government school of musketry, in which instructors of musketry for the army are trained, was established in 1854; and the Shorncliffe military camp is within 2½ miles of the town. On account of its pleasant situation and its picturesque and interesting neighbourhood, Hythe has become a favourite watering-place. Baths were erected in 1854 at a cost of £2000, and the sea wall and parade has lately been extended eastwards to Sandgate, the total length being 3 miles. From the town to the sea-shore there is a stately avenue of wych elms. The area of the municipal borough is 1744 acres, and of the parliamentary borough 3571 acres. The population of the municipal borough in 1871 was 3383, and of the parliamentary borough 24,078. The latter includes the municipal borough of Folkestone.

Hythe occurs in old documents as Hethe, and in Domesday Book as Hede. The word is derived from the Saxon *Hyth*, meaning a harbour. The present town of Hythe rose to importance after the decay of West Hythe by the withdrawal of the sea, West Hythe having previously succeeded to the *Portus Lemanus*, whose decay had been due to a like cause. Since the reign of Elizabeth the harbour has been choked up with sand. It is a theory of some writers that the landing place of Julius Cæsar on his first invasion of Britain was in the vicinity of Lympne. Anciently Hythe, with the parish of West Hythe, was within a "hundred" of its own. Along with Saltwood it was given in 1026 by Halfdan, a Saxon thane, to Christ Church in Canterbury; and it was afterwards held for knight's service by Earl Godwine. According to Leland, it at one time had a fine abbey and four parish churches. It succeeded to the ancient privileges which West Hythe enjoyed as a Cinque Port, its quota being 5 ships, 105 men, and 5 boys. When Earl Godwine ravaged the coast of Kent in 1052 he took several ships from the harbour of Hythe. In 1293 the inhabitants with great valour repulsed the attacks of the seamen of a French man-of-war who had disembarked in the harbour and were beginning to plunder the town. In the reign of Richard II. a great conflagration destroyed 200 of the houses and 5 of the ships in the harbour. Hythe and Saltwood were given by Archbishop Cranmer to Henry VIII. in lieu of other estates, and they continued vested in the crown until the 17th year of Elizabeth, when the town received a charter of incorporation. It is now governed by 4 aldermen and 12 councillors, one of whom is mayor. From the 42d year of Edward III. it possessed the privilege of returning two members to parliament, but since 1832 it has returned only one.

I

I is one of those symbols which the Greeks employed differently from the Phœnicians. In Phœnician it denoted the palatal semi-vowel *y*, called in Hebrew *yodh*. The Greeks disliked this sound, and it vanished at an early time out of their language. Consequently they needed no symbol to represent it, and could use the Phœnician symbol to denote that for which the Phœnician alphabet gave them no help, namely, the vowel *i*. The symbol, however, had not at that time its present simple form, as may be seen by reference to the table at the end of the article ALPHABET. It was made up of several lines, and so it appears in the oldest Greek inscriptions, *e.g.*, in those of Thera, about the 40th Olympiad, in which it is not unlike the later form of sigma (Σ). In the old Corinthian alphabet it sometimes has this form; sometimes the angles to the left are rounded, so that it resembles an *e*. Generally, however, we find it in Greek simplified into the single straight line with which we are familiar. It has no other form in the Latin alphabet. In the last century before Christ, the Romans sometimes lengthened the symbol to denote the long vowel, so that it reached above the top of the line, while the short vowel was expressed by a line of the usual length. This took the place of the older method by which the symbol was doubled to denote the long vowel; as *aa, ee, ii*. But it never became universal, nor was the lengthened symbol always put to the same use; for about the same time we find it used to denote the *y* sound in words like *Maia, cuius*, where the Romans rightly thought it expedient to have a distinct mark for the semi-vowel. But this also was not permanent.

The value of the symbol is generally constant in all European languages, ancient or modern, with the exception of English. It is the vowel sound produced by raising the front of the tongue towards the palate, as high as it can be raised without touching. The lips are not rounded; by rounding them, when the tongue is in this position, we should produce the sound of the French *u* or the German *ü*. The vowel may, however, be either open or close, and in either of these cases it may be short or long. Therefore we have four variations, of which, however, probably not more than two are found in any spoken language:—(1) the short open *i*, heard in English "sin"; (2) the long open *ī*, which is not one of our spoken sounds, but can be produced in singing; (3) the short close *i*, which again is not English, but is the Italian short *i*; (4) the long close *i*, which is the Italian long *i*, and is also common in English; but we denote the sound, not by *ī*, but by *ee*, as in "seen." It is generally supposed that the sound of *ee* stands to that of *i* in English as a long vowel to the corresponding short; but this is not so; there is a difference in quality as well; *ee* denotes (as has been just explained) a close vowel, whereas *i* is open. It is true that in ordinary English the open vowel *i* only occurs short, and the close vowel long, therefore the confusion is natural. A Scotchman, however, finds no difficulty in pronouncing "seen" short.

It is practically necessary in English to denote the simple long *i* sound by *ee*, because the English language has habitually altered the simple sound into a diphthong, and has retained for that diphthong the original spelling *i*. Thus in words like "pride," "mine," "fire," &c., the vowel had once in England the same sound as it has on the Continent; but now it is sounded as the diphthong *ai*, though the spelling has not been changed. It appears from Mr Alexander J. Ellis's investigations into the history of English pronunciation that *i* had become a diphthong in the 16th century; but the exact date of the change must remain uncertain. There can be little doubt that its nature has been correctly explained by the same philologist. It consists in pronouncing the long vowel without sufficiently raising the tongue at the beginning of the sound; hence the sound is at first too open, and is modified into the proper *i* sound before it is terminated. Changes of this sort are natural in long vowels, because there is time to vary the original sound, either as a refinement, or, more probably, through mere inattention and laziness.

IAMBLICHUS, the chief representative of Syrian Neo-Platonism, is only imperfectly known to us in the events of his life and the details of his creed. We learn, however, from Suidas, and from his biographer Eunapius, that he was born at Chalcis in Cœle-Syria, the scion of a rich and illustrious family, that he studied under Anatolius and afterwards under Porphyry, the pupil of Plotinus, that he himself gathered together a large number of disciples of different nations with whom he lived on terms of genial friendship, that he wrote "various philosophical books," and that he died during the reign of Constantine,—according to Fabricius, before 333 A.D. His residence (probably) at his native town of Chalcis was varied by a yearly visit with his pupils to the baths of Gadara. Of the books referred to by Suidas only a fraction has been preserved. His commentaries on Plato and Aristotle, and works on the Chaldæan theology and on the soul, are lost. For our knowledge of his system we are indebted partly to the fragments of these writings preserved by Stobæus and others, and to the notices of his successors, especially Proclus, partly to his five extant books, the sections of a great work on the Pythagorean philosophy. Besides these, Proclus (412–485) seems to have ascribed to him[1] the authorship of the celebrated book *On the Egyptian Mysteries* (so-called), and although its differences in style and in some points of doctrine from the writings just mentioned make it improbable that the work was by Iamblichus himself, it certainly emanated from his school, and in its systematic attempt to give a speculative justification of the polytheistic cultus of the day, marks the turning-point in the history of thought at which Iamblichus stood.

As a speculative theory Neo-Platonism had received its highest development from Plotinus. The modifications introduced by Iamblichus were the elaboration in greater detail of its formal divisions, the more systematic application of the Pythagorean number-symbolism, and chiefly, under the influence of Oriental systems, the thorough-going mythic interpretation of what the previous philosophy had still regarded as notional. It is on the last account, probably, that Iamblichus was looked upon with such extravagant veneration. As a philosopher he had learning indeed, but little originality. But by using what he had to throw a haze of philosophy over the popular superstition, he acquired his fame. By his contemporaries he was accredited with miraculous powers (which he, however, disclaimed), and by his followers in the decline of Greek philosophy, and his admirers on its revival in the 15th and 16th centuries, his name was scarcely mentioned without the epithet "divine" or "most divine," while, not content with the more modest eulogy of Eunapius that he was inferior to Porphyry only in style, the emperor Julian regarded him as not even

[1] Besides the anonymous testimony prefixed to an ancient MS. of Proclus, *De Myst.* viii. 3 seems to be quoted by the latter as Iamblichus's. *Cf.* Meiners, "Judicium de Libro qui de Myst. Æg. inscribitur," in *Comment. Soc. Reg. Sci. Gott.*, vol. iv., 1781, p. 77.

second to Plato, and said that he would give all the gold of Lydia for one epistle of Iamblichus.

Theoretically, the philosophy of Plotinus was an attempt to harmonize the principles of the various Greek schools. At the head of his system he placed the transcendent incommunicable one (ἓν ἀμέθεκτον), whose first-begotten is intellect (νοῦς), from which proceeds soul (ψυχή), which in turn gives birth to φύσις, the realm of nature. Immediately after the absolute one, Iamblichus introduced a second superexistent unity to stand between it and the many as the producer of intellect, and made the three succeeding moments of the development (intellect, soul, and nature) undergo various modifications. He speaks of them as intellectual (θεοὶ νοεροί), supramundane (ὑπερκοσμίοι), and mundane gods (ἐγκοσμίοι). The first of these—which Plotinus represented under the three stages of (objective) being (ὄν), (subjective) life (ζωή), and (realized) intellect (νοῦς)—is distinguished by him into spheres of intelligible gods (θεοὶ νοητοί) and of intellectual gods (θεοὶ νοεροί), each subdivided into triads, the latter sphere being the place of ideas, the former of the archetypes of these ideas. Between these two worlds, at once separating and uniting them, some scholars think there was inserted by Iamblichus, as afterwards by Proclus, a third sphere partaking of the nature of both (θεοὶ νοητοὶ καὶ νοεροί). But this supposition depends on a merely conjectural emendation of the text. We read, however, that "in the intellectual hebdomad he assigned the third rank among the fathers to the Demiurge." The Demiurge, Zeus, or world-creating potency, is thus identified with the perfected νοῦς, the intellectual triad being increased to a hebdomad, probably (as Zeller supposes) through the subdivision of its first two members. As in Plotinus νοῦς produced nature by mediation of ψυχή, so here the intelligible gods are followed by a triad of psychic gods. The first of these is incommunicable and supramundane, while the other two seem to be mundane though rational. In the third class, or mundane gods (θεοὶ ἐγκοσμίοι), there is a still greater wealth of divinities, of various local position, function, and rank. We read of gods, angels, demons, and heroes, of twelve heavenly gods whose number is increased to thirty-six or three hundred and sixty, and of seventy-two other gods proceeding from them, of twenty-one chiefs (ἡγεμόνες) and forty-two nature-gods (θεοὶ γενεσιουργοί), besides guardian divinities, of particular individuals and nations. The world is thus peopled by a crowd of superhuman beings influencing natural events, possessing and communicating knowledge of the future, and not inaccessible to prayers and offerings.

The whole of this complex theory is ruled by a mathematical formulism of triad, hebdomad, &c., while the first principle is identified with the monad, νοῦς with the dyad, and ψυχή with the triad, symbolic meanings being also assigned to the other numbers. "The theorems of mathematics," he says, "apply absolutely to all things," from things divine to original matter (ὕλη). But though he thus subjects all things to number, he holds elsewhere that numbers are independent existences, and occupy a middle place between the limited and unlimited.

Another difficulty of the system is the account given of nature. It is said to be "bound by the indissoluble chains of necessity which men call fate," as distinguished from divine things which are not subject to fate. Yet, being itself the result of higher powers becoming corporeal, a continual stream of elevating influence flows from them to it, interfering with its necessary laws and turning to good ends the imperfect and evil. Of evil no satisfactory account is given: it is said to have been generated accidentally.

In his doctrine of man Iamblichus retains for the soul the middle place between intellect and nature it occupies in the universal order. He rejects the passionless and purely intellectual character ascribed to the human soul by Plotinus, distinguishing it sharply both from those above and those below it. He maintains that it moves between the higher and lower spheres, that it descends by a necessary law (not solely for trial or punishment) into the body, and, passing perhaps from one human body to another, returns again to the supersensible. This return is effected by the virtuous activities which the soul performs through its own power of free will, and by the assistance of the gods. These virtues were classified by Porphyry as political, purifying (καθαρτικαί), theoretical, and paradigmatic; and to these Iamblichus adds a fifth class of priestly virtues (ἱερατικαὶ ἀρεταί), in which the divinest part of the soul raises itself above intellect to absolute being.

Iamblichus does not seem ever to have attained to that ecstatic communion with and absorption in deity which was the aim of earlier Neo-Platonism, and which Plotinus enjoyed four times in his life, Porphyry once. Indeed his tendency was not so much to raise man to God as to bring the gods down to men—a tendency shown still more plainly in the "Answer of Abamon the master to Porphyry's letter to Anebo and solutions of the doubts therein expressed," afterwards entitled the *Liber de Mysteriis*, and ascribed to Iamblichus.

In answer to questions raised and doubts expressed by Porphyry, the writer of this treatise appeals to the innate idea all men have of the gods as testifying to the existence of divinities countless in number and various in rank (to the correct arrangement of which he, like Iamblichus, attaches the greatest importance). He holds with the latter that above all principles of being and intelligence stands the absolute one from whom the first god and king spontaneously proceeds; while after these follow the etherial, empyrean, and heavenly gods, and the various orders of archangels, angels, demons, and heroes distinguished in nature, power, and activity, and in greater profusion than even the imagination of Iamblichus had conceived. He says that all the gods are good (though he in another place admits the existence of evil demons who must be propitiated), and traces the source of evil to matter; rebuts the objection that their answering prayer implies passivity on the part of gods or demons; defends divination, soothsaying, and theurgic practices as manifestations of the divine activity; describes the appearances of the different sorts of divinities; discusses the various kinds of sacrifice, which he says must be suitable to the different natures of the gods, material and immaterial, and to the double condition of the sacrificer as bound to the body or free from it (differing thus in his psychology from Iamblichus); and, in conclusion, states that the only way to happiness is through knowledge of and union with the gods, and that theurgic practices alone prepare the mind for this union —again going beyond his master, who held assiduous contemplation of divine things to be sufficient. It is the passionless nature of the soul which permits it to be thus united to divine beings,—knowledge of this mystic union and of the worship associated with it having been derived from the Egyptian priests, who learnt it from Hermes.

On one point only does the author of the *De Mysteriis* seem not to go so far as Iamblichus in thus making philosophy subservient to priestcraft. He condemns as folly and impiety the worship of images of the gods, though his master held that these "simulacra" were filled with divine power, whether made by the hand of man or (as he believed) fallen from heaven. But images could easily be dispensed with from the point of view of the writer, who not only held that all things were full of gods (πάντα πλήρη θεῶν, as Thales said), but thought that each man had a special divinity of his own—an ἴδιος δαίμων—as his guard and companion.

Bibliography.—Of the five extant books of Iamblichus referred to above, (1) that *On the Pythagorean Life* (περὶ τοῦ Πυθαγορικοῦ βιοῦ) was first edited, in Greek and Latin, by Arcerius Theodoretus, 1598; again by Kuster, 1707; and by Kiessling, Leipsic, 1815-16; while a new edition is promised by E. Rhode, who discusses the sources, &c., of the work in the *Rhein. Museum*, vol. xxvi., 1871, pp. 554 *sq.*; *cf.* vol. xxxiv., 1879, pp. 260 *sq.* (2) The *Exhortation to Philosophy* (λόγοι προτρεπτικοὶ εἰς φιλοσοφίαν) was edited first along with the former in 1598, and again by Kiessling, Leipsic, 1813. (3) The treatise *On the General Science of Mathematics* (π. τῆς κοινῆς μαθηματικῆς) was edited by Villoison, *Anecd. Græca*, ii. 188-225, Venice, 1781; and a useful account of the same is given by J. G. Friis in his *Introductio in Librum Iamblichi Tertium*, 1790. (4) The book *On the Arithmetic of Nicomachus* (π. τῆς Νικομάχου ἀριθμητικῆς εἰσαγωγῆς), along with fragments on fate (π. εἱμαρμένης) and prayer (π. εὐχῆς), was edited in Greek and Latin by S. Tennulius, 1668; and (5) the *Theological Principles of Arithmetic* (θεολογούμενα τῆς ἀριθμητικῆς)—the seventh book of the series—by Ast, Leipsic, 1817. Two lost books, treating of the physical and ethical signification of numbers, stood fifth and sixth, while books on music, geometry, and astronomy followed.

The so-called *Liber de Mysteriis* was rendered into Latin by Marsilius Ficinus, Venice, 1497, fol.,—several times reprinted,—and again by N. Scutellius, Rome, 1556, 4to. The original Greek was edited, with Latin translation and notes, first by T. Gale, Oxford, 1678, fol., and more recently by G. Parthey, Berlin, 1857, 8vo.

There is a monograph on Iamblichus by Hebenstreit (*De Iamblichi, philosophi Syri, doctrina Christianæ religioni, quam imitari studet, noxia*, Leipsic, 1764), and one on the *De Myst.* by Harless (*Das Buch v. d. ägyp. Myst.*, Munich, 1858). The discussion by Meiners on the genuineness of the *De Myst.* has been already referred to, and seems to be conclusive against attributing it to Iamblichus. Thomas Taylor, the English Platonist, translated the *Life of Pythagoras* and the *Egyptian Mysteries* (London, 1818; Chiswick, 1821). The best accounts of Iamblichus are those of Zeller, *Phil. d. Griechen*, iii. 2, pp. 613 *sq.*, 2d ed., and Vacherot, *Hist. de l'École d'Alexandrie*, ii. 57 *sq.* (W. R. SO.)

IBADAN, a large and flourishing town of West Africa, in the Yoruba country, about 80 miles inland from Lagos, and about 50 miles to the north-east of Abeokuta. It occupies the slope of one of the hills of the Kong range, and stretches down into the valley through which the river Ona flows. The site is well drained by natural streams, but their waters are often polluted by the dead bodies flung out to the vultures. The mud walls by which the town is enclosed have a circuit of 18 miles, and it is encompassed by a circle of cultivated land about 5 or 6 miles in breadth. The houses are all low thatched structures, enclosing a square court, and the only break in the mud wall is the door; but the monotony of the streets is relieved by orishas or idol-houses, and open spaces shaded with trees. Most of the population are engaged in agriculture; but for a West-African town there is a great variety of handicrafts. The town is subject nominally to the king of Oya; but in reality it is not only an independent state but has a number of vassal towns. The government is in the hands of two chiefs, a civil and a military, the *bale* and the *balogun*; these together form the highest court of appeal. There is also an *iyaloda* or mother of the town, to whom are submitted all the disputes of the women. Any one causing a fire in the town, whether intentionally or by accident, is deprived of his possessions and put in prison. Ibadan has long had a feud with Abeokuta; and the two towns often engage in war with each other. In 1862 the people of Ibadan destroyed Ijaya, a neighbouring town of 60,000 inhabitants. Mr Hinderer, a missionary of the Church Society, established a station at Kudati on the outskirts of the town in 1853, and laboured there for seventeen years. The native church is still in a flourishing state. The population of Ibadan is not less than 100,000. The great bulk of the population consists of slaves. There are twenty-four mosques and several Mahometan schools in the town.

See *Seventeen Years in the Yoruba Country: Memorials of Anna Hinderer*, London, 1877, where a view of the town is given.

IBARRA, a city of Ecuador in South America, the capital of the province of Imbabura, is situated on a plain about 2000 feet lower than Quito, from which it is 30 miles distant. Before the earthquake of 1868 it was a place of considerable prosperity, with regular streets and well-built houses, and about 13,000 of a population, but in that terrible disaster it is estimated that no fewer than 10,000 of its inhabitants perished. Cotton and woollen stuffs, laces, hats, brandy, cordials, sugar, and salt were among its industrial products. Ibarra was founded in 1597 by Alvaro de Ibarra, the president of Quito. About a league distant was Carranqui, the birthplace of Atahuallpa, the last of the Incas.

IBERIANS (*Iberi*, Ἴβηρες). To the question, Who are the Iberians? it is impossible to give a satisfactory answer in the form of a concise definition. While our knowledge of their actual history is comparatively slight, the position which they have acquired in modern ethnographical theory is at once a prominent and a perplexing one. It is almost impossible to hazard any statement in regard to them which will not find an impugning voice from one quarter or other. Historical, numismatical, linguistic, and anthropological evidences have been brought to bear on the problem of their affinity, and the result is on the whole not so much light as darkness visible.

The name Iberians seems to have been applied by the earlier Greek navigators to the peoples who inhabited the eastern coast of Spain; and there is considerable probability in the suggestion that it originally meant the ripuarians of the Iberus or Ebro.[1] On the other hand, the term Iberia is said to have embraced in older Greek usage the country as far east as the Rhone (see Herodorus of Heraclea, *Fragmenta Historiarum Græcarum*, tom. ii. p. 34), and by the time of Strabo it was the common Greek name for the Spanish peninsula,—Iberians meaning sometimes the inhabitants of the peninsula in general, and sometimes, it would appear, the peoples of a definite race or γένος. Of the tribal distribution of this race, of its linguistic social and political characteristics, and of the history of its relation to the other peoples of Spain, we have only the most general, fragmentary, and in part self-contradictory accounts. On the whole our historical evidence authorizes the assertion that in Spain, when it first became known to the Romans and Greeks, there existed a large number of separate and variously civilized tribes connected with each other by at least apparent identity of race, and by similarity (but not identity) of language, their general characteristics sufficiently differencing them from Phœnicians, Romans, and Celts. The statement that the mingling of these Iberians with the immigrant Celts gave rise to the Celtiberians (Keltiberians) is in itself sufficiently probable, and has been impugned by nothing more precise than the general untrustworthiness of the author by whom it is made (Diodorus Siculus). Varro and Dionysius Afer went so far as to identify the Iberians of Spain with the Iberians of the Caucasus, the one regarding the eastern and the other the western settlements as of earlier date.

The only material relics which have come down to us with the imprint of the ancient Iberian or Celtiberian civilization are a variety of coins and a few inscriptions of dubious interpretation. So difficult has the reading of the legends of the coins been found that the Spanish numismatists have regularly catalogued them as the *desconocidas* or unknown; and the explanation of them has been sought now in Visigothic runes (Olaus Wormius and Olaus Rudbeck), now in Hebrew (L. J. Velasquez), now in Latin, and now in Celtic. By the general consensus of more modern investigators, however, their Iberian character is recognized, though the methods and results of

[1] A very different etymology is offered by Basque-Iberian theorists; M. Boudard, for example, derives the name from *ibay-erri*, the country of the river.

interpretation have been sufficiently various.[1] According to M. Heiss, the Celtiberian coins are found most frequently in the north-east and east of Spain, in smaller numbers in the centre, rarely in the south, and more rarely still in Portugal and Asturias. The legends, he maintains, belong to peoples who inhabited the country at the time when the Greeks were still coining pieces with the type of Apollo and the wheel,—that is, before the completion of the Roman

Fig. 1.—Coin of Illiberis or Granada.

conquest. Their monetary system seems to have been imitated from that of the Roman republic, having a division analogous to that of the denarii and quinarii. The principal type on the reverse is either a horseman galloping with lance in rest or bearing a palm-branch or laurel-branch, or a man leading two horses and brandishing a sword or a bow. The Latin coins of Bilbilis, Osca, Segobriga, &c., retain the type of the galloping horseman. Pieces with inscriptions in the same alphabet and similar images are found in the district of Narbonne.

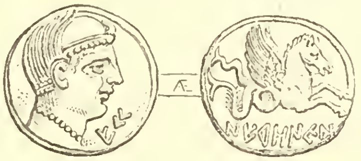

Fig. 2.—Coin of Narbonne.

The following is a list of M. Heiss's proposed identifications, and the accompanying alphabet is that which he has compiled from the coins:—

Ovriasav, Turiaso; klaqriqs, Kalaquri-qos, Calagurris; iak, Jaca; plplis, Pilpilis, Bilbilis; ilovre, Iluro; nerencon, Narbo; pavrp, Perpinianum; clse, Celsa; seqbrics, Segobrica; alaavn, Alavona; setiscon, Setisacon; oligem, Oligito; gli, Gili; aavsescon, Ausa, Ausenses; avsecrt, Osicerda; laavrh, Laurona; cse, Cose; qntrba, Contrebia; seqtzas, Segontia; ebiritz, Bebryces; hrnesqn, Huernes; hlscan, Hiosca, Osca; secisa, Segisa; tmaniav, Dumania; arciliqs, Arcocili, Ocili; oelieqs, Beliones; vrsones, Balsiones.

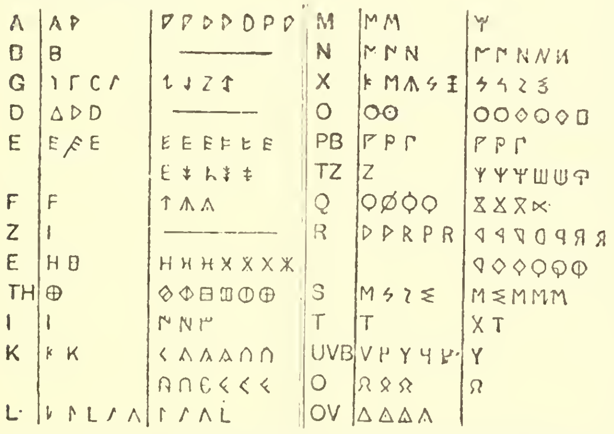

Fig. 3.—Table of alphabets. The first column contains the English characters; the second the archaic Greek; and the third the Celtiberian.

It was not till 1821 that the Iberian problem became an established *pièce de resistance* in the ethnographical programme. In that year Karl Wilhelm Humboldt published his *Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelst der Waskischen Sprache*, Berlin, 1821. As a matter of course this was a work of exuberant learning and bold hypothesis; and partly through its inherent attractiveness, partly through the prestige of its author, the theory which it expounded met with general acceptance. The main arguments were these:—that the Iberians were one great people, speaking a distinct language of their own; that they were to be found in Sicily, Sardinia, and Corsica, in southern France, and even in the British Isles; and that the Basques of the present day were the distinctly recognizable remnants of the race which had elsewhere been expelled or absorbed. This last was the central and seminal idea of the work, and it has been the point round which the battle of scholarship has mainly raged. The principal evidence which Humboldt adduced in its support was the possibility of explaining a vast number of the ancient topographical names of Spain, and of other asserted Iberian districts, by the forms and significations of Basque. The first serious attack on the theory was made by Graslin (*De l'Ibérie*, Paris, 1839), who maintained that the name Iberia was nothing but a Greek misnomer of Spain, and that there was no proof that the Basque people had ever occupied a wider area than at present; and M. Bladé has since, in his *Origine des Basques* (Paris 1869), taken up the same line of argument and brought to bear on the subject a vast amount of laborious and many-sided erudition. His criticism is almost purely negative. Of the whole structure of the Iberian theory he would not leave one stone upon another. He holds that Iberia is a purely geographical term, that there was no proper Iberian people or race, that the whole Basque-Iberian theory is a modern figment, that the Basques were always shut in by alien races, and that their affinity is still to seek. His main contention has met with some acceptance;[2] but the great current of ethnographical speculation still flows in the direction indicated by Humboldt, though it breaks up into a number of distinct channels. The anthropological researches of Broca, Thurnam and Davis, Huxley, Busk, Virchow, Tubino, and others have proved the existence in Europe of a Neolithic race, small of stature, with long or oval skulls, and accustomed to bury their dead in tombs. Their remains have been found in Belgium and France, in Britain, Germany, and Denmark, as well as in Spain; but they bear a closer resemblance to the Basques than to any other living people. This Neolithic race has consequently been identified with the Basques and the Iberians; and extreme exponents of the theory do not hesitate to speak of the Iberian ancestors of the people of England, recognizing the racial characteristics in the "small swarthy Welshman," the "small dark Highlander," and the "Black Celts to the west of the Shannon," as well as in the typical inhabitants of Aquitania and Brittany. (Compare the interesting *résumé* of the whole question in Boyd Dawkins's *Early Man in Britain*, London, 1880.[3]) Some investigators go even further. M. D'Arbois de Jubainville, for example (*Les premiers habitants de l'Europe*, Paris, 1877), regards the Iberians as the descendants of the Atlantes (*i.e.*, the hypothetical inhabitants of Plato's great western isle the Atlantis, see Atlantis), and maintains that in Europe they possessed Spain, Gaul, Italy, and the British Isles, penetrated into the Balkan peninsula, and occupied a part of northern Africa, Corsica, and Sardinia. And in reviewing M. Jubainville's work in *Revue d'Anthropologie* (1877), M. Hovelacque considers that it has been clearly made out that a race with distinctly marked characteristics was at one time in possession of the south of France (or at least of Aquitania), the whole of Spain from the Pyrenees to the straits, the Canary Islands (the Guanchos), a part of northern Africa, and Corsica. Tubino, in his *Los aborigenes ibericos* (Madrid, 1876), argues that the builders of the megalithic monuments of Spain and northern Africa, the ancient Iberians, and the modern Basques and Andalusian mountaineers, as well as the Berbers[4] in at least one of their main elements, are all of kindred blood; and in so doing he impugns the theory of Broca and his school.

Besides the works already mentioned, reference may be made to Hoffmann, *Die Iberer im Westen und Osten* (Leips. 1838), and to Phillips, *Ueber das iberische Alphabet* (Vienna, 1870), *Die Einwanderung der Iberer in die pyren. Halbinsel* (Vienna, 1870), and several other works by the same writer.

IBEX, the common name of several closely allied species of ruminant mammals, belonging to the genus *Capra* or goats, inhabiting the loftiest regions of Europe, Asia, and Africa. The European ibex or steinboc (*Capra ibex*) abounded during the Middle Ages among the higher

[1] The most important contributions to the subject are P. A. Boudard's *Études sur l'Alphabet ibérien*, Paris, 1852, and *Numismatique ibérienne*, Béziers, 1859; and Aloiss Heiss, *Notes sur les monnaies celtibériennes*, Paris, 1865, and *Description générale des monnaies antiques de l'Espagne*, Paris, 1870.

[2] W. van Eys, for example, "La langue Ibérienne et la langue Basque," in *Revue de linguistique*, goes against Humboldt; but Prince Napoleon and to a considerable extent A. Luchaire maintain the justice of his method and the value of many of his results. See Luchaire, *Les origines linguistiques de l'Aquitaine*, Paris, 1877.

[3] Mr Dawkins even accepts the very questionable identification of the Iberians of Spain with the Iberians of the Caucasus.

[4] The connexion of the Iberians with the Berbers was suggested by Bory de Saint Vincent in *Essai géologique sur le genre humain*.

mountain ranges of Germany, Switzerland, and the Ural, but has since disappeared from the greater part of this area, being now almost wholly confined to the Alps which separate Valais from Piedmont, and to the lofty peaks of Savoy, where its continued existence is mainly due to the action of protective game laws. The ibex is a handsome animal, measuring about $4\frac{1}{2}$ feet in length and $2\frac{1}{2}$ feet high; its skin is covered in summer with a short fur of an ashy grey colour, and in winter with much longer yellowish-brown hair concealing a dense fur beneath. A short beard is present in the male in winter, but, as it disappears altogether in spring, Darwin regards this appendage as rudimentary. The horns, especially in the male, form a striking feature: rising from the crest of the skull, they bend gradually backwards, attaining a length in old specimens of about 2 feet; they are thick and flat, and have the anterior face ridged with knotty transverse bands. In the female the horns never exceed half a foot in length, and are much less rugose than in the male. The front legs are somewhat shorter than those behind, which enables the

Ibex.

ibex to ascend the mountain slopes with more facility than it can descend, while its hoofs, according to Tschudi, are "as hard as steel, rough underneath, and when walking over a flat surface capable of being spread out." These, together with its powerful sinews, enable it to take prodigious leaps, to balance itself on the smallest foothold, and to scale almost perpendicular rocks. The ibex lives habitually at a greater height than the chamois or any other of the Alpine mammals, its vertical limit being the line of perpetual snow. There it rests in sunny nooks during the day, descending at night to the highest woods to graze, and retiring at sunrise to its snowy fastnesses. This return journey forms the ibex hunter's opportunity. To get within gunshot the huntsman has usually to approach from above; accordingly he ascends to the limit of perpetual snow, and there passes the night among the daily haunts of the ibex, lying in wait from early dawn for its return. The ibexes are gregarious, feeding in herds of ten to fifteen individuals; the old males, however, generally live apart from, and usually at greater elevations than, the females and young. They are said to give out a sharp whistling sound not unlike that of the chamois, but when greatly irritated or frightened they make a peculiar snorting noise. The period of gestation in the female is ninety days, after which she produces—usually at the end of June—a single young one, which is able at once to follow its mother. These when caught young and fed on goat's milk can, it is said, be readily tamed; and in the 16th century young tamed ibexes were, according to Tschudi, frequently driven to the mountains along with the goats, in whose company they would afterwards voluntarily return. Even wild specimens have thus been known to stray among the herds of goats, although, strange to say, they at all times shun the society of the chamois. The ibex was formerly hunted largely for its flesh and skin; but, although the latter, owing to its scarcity, now commands a high price, the difficulty arising from the operation of the game laws, and above all the difficulty and danger inseparable from the sport, have reduced the number of hunters to a few hardy mountaineers, who find in the pursuit of the ibex the keenest enjoyment of life. For weeks the sportsman will follow a track across fields of ice, along narrow ledges, over precipices, and across chasms, nearly frozen to death at night, and often with little more than a crust of bread for sustenance, yet considering himself more than repaid by the sight at last of his prey grazing within range of his rifle. Its flesh is said to resemble mutton, but has a flavour of game.

IBIS, one of the most sacred birds of the ancient Egyptians, which in modern times was identified by Bruce (*Travels*, v. p. 173, pl.) with the *Abou-Hannes* or "Father John" of the Abyssinians, and in 1790 received from Latham (*Index Ornithologicus*, p. 706) the name of *Tantalus æthiopicus*. This determination was placed beyond all question by Cuvier (*Ann. du Muséum*, iv. pp. 116–135) and Savigny (*Hist. Nat. et Mythol. de l'Ibis*) in 1805. They, however, shewed the removal of the bird from the Linnæan genus *Tantalus* to be necessary, and, Lacépède having some years before founded a genus *Ibis*, it was transferred thither, and is now generally known as *I. æthiopica*, though some speak of it as *I. religiosa*. No useful purpose would be served by dwelling on the vain attempts of older writers to discover what the much venerated bird was, or on the other synonyms applied to it by later ornithologists, some of whom (and among them the most recent) have shewn little acquaintance with the literature of the subject. Nor can the Ibis be here treated from a mythological or antiquarian point of view. Savigny's memoir above noticed contains a great deal of very interesting matter on the subject. Wilkinson (*Ancient Egyptians*, ser. 2, ii. pp. 217–224) has thereto added some of the results of modern research, and latest of all Mr Renouf in his *Hibbert Lectures* concisely explains the origin of the myth.

The Ibis is chiefly an inhabitant of the Nile basin in Nubia, from Dongola southward, as well as of Kordofan and Sennaar; whence (according to Savigny, whose opportunities for observation seem to have been greater than those enjoyed by any European since his time) about midsummer, as the river rises, it moves northwards to Egypt, and reaches the delta,[1] passing over the intermediate districts, in a way not unknown elsewhere among migratory birds. In Lower Egypt it bears the name of *Abou-mengel*, or "Father of the Sickle," from the form of its bill, but it does not stay long in that country, disappearing by all accounts when the inundation has subsided. Hence doubtless arises the fact that almost all European travellers have failed to meet with it there,[2] since their acquaintance with

[1] It has been said to occur occasionally in Europe (Greece and southern Russia), but further evidence is needed before the assertion can be taken as proved.

[2] Mr E. C. Taylor remarked some years ago (*Ibis*, 1859, p. 51), that the Buff-backed Heron, *Ardea bubulcus*, was made by the tourists' dragomans to do duty for the "Sacred Ibis," and this seems to be no novel practice, since by it, or something like it, Hasselqvist was misled, and through him Linnæus.

the birds of Egypt is mostly limited to those which frequent the country in winter, and consequently writers have not been wanting to deny to this species a place in its modern fauna (*cf.* Shelley, *Birds of Egypt*, p. 261); but, in December 1864, Von Heuglin (*Journ. für Ornithologie*, 1865, p. 100) saw a young bird which had been shot at Gata in the delta, and subsequently Mr E. C. Taylor (*Ibis*, 1878, p. 372) saw an adult which had been killed near Lake Menzaleh in November 1877. The old story told to Herodotus of its destroying snakes is, according to Savigny, devoid of truth,[1] and that naturalist found, from dissection of the examples he obtained, that its usual food was fresh-water univalve mollusks; but Cuvier asserts that he discovered partly digested remains of a snake in the stomach of a mummied Ibis which he examined, and there can be little doubt that insects and crustaceans, to say nothing of other living creatures, enter on occasion into the bird's diet.

The Ibis is somewhat larger than a Curlew, *Numenius arquata*, which bird it in appearance calls to mind, with a much stouter bill and stouter legs. The head and greater part of the neck are bare and black. The plumage is white, except the primaries which are black, and a black plume, formed by the secondaries, tertials, and lower scapulars, and richly glossed with bronze, blue, and green, which curves gracefully over the hind-quarters. The bill and feet are also black. The young lack the ornamental plume, and in them the head and neck are clothed with short black feathers, while the bill is yellow. The nest is placed in bushes or high trees, the bird generally building in companies, and in the middle of August Von Heuglin (*Orn. Nord Ost Afrika's*, p. 1138) found that it had from two to four young or much incubated eggs.[2] These are of a dingy white, splashed, spotted, and speckled with reddish-brown.

Congeneric with the typical Ibis are two or three other species, the *S. melanocephala* of India, the *S. molucca*, or *S. strictipennis*, of Australia, and the *S. bernieri* of Madagascar, all of which closely resemble *S. æthiopica*; while many other forms not very far removed from it, though placed by authors in distinct genera,[3] are also known. Among these are several beautiful species such as the Japanese *Geronticus nippon*, the *Lophotibis cristata* of Madagascar, and the Scarlet Ibis,[4] *Eudocimus ruber*, of America; but here there is only room to mention more particularly the Glossy Ibis, *Plegadis falcinellus*, a species of very wide distribution in both hemispheres, being found throughout the West Indies, Central and the south-eastern part of North America, as well as in many parts of Europe (whence it not unfrequently strays to the British islands), Africa, Asia, and Australia. This bird, which is no doubt the second kind of Ibis spoken of by Herodotus, is rather smaller than the Sacred Ibis, and mostly of a dark chestnut colour with brilliant green and purple reflexions on the upper parts, exhibiting, however, when young little of this glossiness. One of the most remarkable things about this species is that it lays eggs of a deep sea-green colour, having wholly the character of Heron's eggs, and it is to be noticed that it often breeds in company with Herons, while the eggs of all other Ibises whose eggs are known resemble those of the Sacred Ibis. Congeneric with the Glossy Ibis, some three or four other species, all from South America, have been described; but the propriety of deeming them distinct is questioned by some authorities.

Much as the Ibises resemble the Curlews externally, there is no real affinity between them. The *Ibididæ* are more nearly related to the Storks, *Ciconiidæ*, and still more to the Spoonbills, *Plataleidæ*, with which latter many systematists consider them to form one group, the *Hemiglottides* of Nitzsch. They belong to the *Pelargomorphæ* of Professor Huxley, one of the divisions of his *Desmognathæ*, while the Curlews are Schizognathous. The true Ibises above spoken of are also to be clearly separated from the Wood-Ibises, *Tantalidæ*, of which there are four or five species, by several not unimportant structural characters, which cannot here be particularized for want of space. Fossil remains of a true Ibis, *I. pagana*, have been found in considerable numbers in the middle Tertiary beds of France.[5] (A. N.)

IBN BATUTA (1304–78), whose proper name was Abu-Abdullah Mahommed, one of the most remarkable of travellers and autobiographers, was born at Tangier in 1304. He entered on his travels at the age of twenty-one (1325), and closed them in 1355. Their compass was so vast that we can but give the barest outline of them.

He began by traversing the whole African coast of the Mediterranean from Tangier to Alexandria, finding time to marry two wives on the road. After some stay at Cairo, then probably the greatest city in the world (excluding China), and an unsuccessful attempt to reach Mecca from Aidháb on the west coast of the Red Sea, he visited Palestine, Aleppo, and Damascus. He then made the pilgrimage to the holy cities of the Hedjaz, and visited the shrine of Ali at Meshed-Ali, travelling thence to Bussorah, and across the mountains of Khuzistan to Ispahan, thence to Shiraz, and back to Kufa and Baghdad. After an excursion to Mosul and Diarbekr, he made the *háj* a second time, staying at Mecca three years. He next sailed down the Red Sea to Aden (then a place of great trade), the singular position of which he describes, noticing its dependence for water-supply upon those great cisterns for preserving the scanty rainfall which have been cleaned out and restored in our own time. He continued his voyage down the African coast, visiting, among other places, Mombas, and Quiloa in 9° S. lat. Returning north he passed by the chief cities of Oman to New Hormuz, as he calls the city which had, not many years before, been transferred to the island where it became so famous. After visiting other parts of the gulf, he crossed the breadth of Arabia to Mecca, making the *háj* for the third time. Crossing the Red Sea he made a journey of great hardship to Syene, and thence along the Nile to Cairo. After this, travelling through Syria, he made an extensive circuit among the petty Turkish sultanates into which Asia Minor was divided after the fall of the kingdom of Rúm (or Iconium). He now crossed the Black Sea to Caffa, then mainly occupied by the Genoese, and apparently the first Christian city the Moor had seen, for he was much perturbed by the bell-ringing. He next travelled into Kipchak, or the country of the Mongol khans on the Volga, and joined the camp of the reigning khan Mahommed Uzbek, from whom the great and heterogeneous body that we know as *Uzbeks* is believed to have taken a name. Among other places in this empire he travelled to Bolgar (54° 54′ N. lat.) in order to witness the shortness of the summer night, and desired to continue his travels north into the "Land of Darkness," of which wonderful things were told, but was obliged to forego this. Rejoining the

[1] The suggestion that the "flying serpents" whose remains were seen by Herodotus were locusts is perhaps plausible, but there is considerable difficulty in accepting it.

[2] The Ibis has more than once nested in the gardens of the Zoological Society, and even reared its young there (*Ibis*, 1878, pp. 449–451, pl. xii.).

[3] For some account of these may be consulted Dr Reichenow's paper in *Journ. für Ornithologie*, 1877, pp. 143–156; Mr Elliot's in *Proc. Zool. Society*, 1877, pp. 477–510; and that of M. Oustalet in *Nouv. Arch. du Muséum*, ser. 2, i. pp. 167–184.

[4] It is a popular error—especially among painters—that this bird was the Sacred Ibis of the Egyptians. It was of course utterly unknown in the Old World until the discovery of the New.

[5] It will explain what to the uninitiated may be a puzzle to state that the name "*Ibis*" was selected as the title of an ornithological magazine, frequently referred to in this and other articles, which made its first appearance in 1859, and has since continued to be published.

sultan's camp, he was allowed to join the cortege of one of the Khátúns, who was a Greek princess by birth (probably an illegitimate one), and who was about to visit her own people. In her train he travelled to Constantinople, where he had an interview with the emperor Andronicus the Elder, whom he calls *Jirjis* (George). He tells us how, as he passed the city gates in the lady's train, he heard the guards muttering *Sarakinú! Sarakinú!* Returning to the court of Uzbek, at Sarai on the Volga, he took his way across the steppes to Khwarizm and Bokhara, and thence through Khorasan and Cabul. On this journey he crossed the HINDU KUSH (*q.v.*), to which he gives that name, its first occurrence. Travelling on, he reached the Indus,—according to his own statement, in September 1333. This closes the first part of his narrative.

From Sind, which he traversed to the sea and back again, he proceeded by Multan, and eventually, on the invitation of Mahommed Tughlak, the reigning sovereign, to Delhi. Mahommed was a singular character, full of pretence at least to many accomplishments and virtues, the founder of public charities, and a profuse patron of scholars, but a parricide, a fratricide, and as madly capricious, bloodthirsty, and unjust as Caligula. As Ibn Batuta pithily sums up the contradictions of his character, "there was no day that the gate of his palace failed to witness alike the elevation of some object to affluence and the torture and murder of some living soul." He appointed the traveller to be kází of Delhi, with a present of 12,000 silver dínárs (rupees) and an annual salary of the same amount, besides an assignment of village lands. In the sultan's service he remained eight years; but his good fortune only stimulated his natural extravagance, and at an early period his debts amounted to four or five times his salary. At last he fell into disfavour, and retired from the court, only to be summoned again on a congenial duty. The emperor of China, the last of the Mongol dynasty, had sent a mission to Delhi which was to be reciprocated, and the Moor was to go as one of the envoys. The account of the journey through Central India to Cambay is full of interest. Thence the party went by sea to Calicut, which is classed by the traveller with the neighbouring Kaulam (Quilon), Alexandria, Sudák in the Crimea, and Zayton (or CHINCHEW, *q.v.*) in China, as one of the greatest trading havens in the world,—an interesting enumeration from one who had seen them all. The mission party was to embark in Chinese junks (the word used) and smaller vessels, but that carrying the other envoys and the presents, which started before he was ready, was wrecked totally; the vessel that he had engaged went off with his property, and he was left on the beach of Calicut. Not daring to return to Delhi with such a tale, he remained about Honore and other cities of the western coast, taking part in various adventures, among others the capture of Sindábúr (or Goa), till he took it into his head to visit the Maldive Islands. There he was made welcome, was nominated kází, married four wives, and remained some months. But before long he was deep in quarrels and intrigues, and in August 1344 he left for Ceylon. In this island he made the pilgrimage to Adam's Peak ("The Footmark of our Father Adam," he calls it), of which he gives an interesting account. Thence he betook himself to Ma'abar (the Coromandel coast), where he joined a Musulman adventurer who had made himself master of much of that region, with his residence at Madura. After once more visiting Malabar, Canara, and the Maldives, he departed for Bengal, a voyage of forty-three days, landing at Sadkáwán (Chittagong). The chief circumstance of his sojourn in Bengal was a visit made to a Musulman saint of singular character and pretensions, Shaikh Jaláluddín, who dwelt in a hermitage among the Silhet hills, and where his shrine (at Silhet) is still maintained as a place of sanctity under the name of *Shah Jalál*. Returning to the delta, he took ship at Sunárgánw (near Dacca) on a junk bound for Java (*i.e.*, *Java Minor* of Marco Polo, or Sumatra). Touching on the coast of Arakan or Burmah, he reached Sumatra in forty days, and was hospitably received at the court of Malik al-Dháhir, a zealous disciple of Islám, which had then recently spread among the states on the northern coast of that island. The king provided him with a junk in which to prosecute his voyage to China. Some of the places which he describes on this line are hard to identify, but apparently one of them was the coast of Camboja. The port which received him in China was Zayton, famous in Marco Polo's book, and identified with the modern Chinchew. He also visited Sín-Kalán ("Great China" or Máchín), a name by which Canton was then known to the Arabs, and professes to have visited also Khansá (*Kinsay* of Marco Polo, *i.e.*, Hangchau), and Khánbálik (*Cambaluc* or Peking). The truth of his visit to these two cities, and especially to the last, is very questionable. The traveller's own history singularly illustrates the power of the freemasonry of Mahometanism in carrying him with a welcome over all the known world, and some anecdotes of his adventures in China illustrate this even more forcibly.

We cannot follow in detail his voyage back, or tell how he saw the great bird *Rukh* (evidently, from his description, an island lifted by refraction). Revisiting Sumatra, Malabar, Oman, Persia, Baghdad, he crossed the great desert to Tadmor and Damascus, where he got his first news of home, and heard of his father's death fifteen years before. Diverging to Hamath and Aleppo, on his return to Damascus he found the Black Death raging, so that two thousand four hundred died in one day. Revisiting Jerusalem and Cairo, he made the *háj* for a fourth time, and finally turned westward, reaching Fez, the capital of his native country, 8th November 1349, after an absence of twenty-four years. It was, he says, after all, the best of all countries. "The dirhems of the West are but little ones, 'tis true; but then you get more for them."

After going home to Tangier, he crossed into Spain and made the round of Andalusia, including Gibraltar, which had just then stood a siege from Alphonso XI. (whom the traveller calls "the Roman tyrant Adfunus"). In 1352 the restless man started for Central Africa, passing by the oases of the Sahara (where the houses were built of rock-salt, as Herodotus tells, and roofed with camel skins) to Timbuctoo and Gogo on the Niger, a river which he calls the Nile, believing it to flow down into Egypt, an opinion maintained by some up to the date of Landor's discovery. Being then recalled by his own king, he returned by Takadda, Hogar, and Tawat to Fez, which he reached in the beginning of 1354. This is the end of his recorded wanderings, which extended over a space of twenty-eight years, and in their main lines alone exceeded 75,000 miles.

By royal order his history was written down from his dictation by Mahommed Ibn Juzai, the king's secretary, a work concluded on the 13th December 1355. This editor ends the work with this appropriate colophon:—"Here ends what I have put into shape from the memoranda of the Shaikh Abu-Abdallah Mahommed Ibn Batúta, whom may God honour! No person of sense can fail to see that this Shaikh is the Traveller of Our Age; and he who should call him The Traveller of the whole Body of Islám would not exceed the truth!" The traveller died in 1377–78, aged seventy-three.

Ibn Batuta's travels have only been known in Europe during the present century, and were known then for many years only by Arabic abridgments existing in the Gotha and Cambridge libraries. Notices or extracts had been published by Seetzen (*c.* 1808), Kozegarten (1818), Apetz (1819), and Burckhardt (1819), when in 1829 Dr S. Lee published for the Oriental Translation Fund a version from the abridged MSS. at Cambridge, which attracted much interest. The French capture of Constantina at last afforded MSS. of the complete work, one of them the autograph of Ibn Juzai. And from these, after versions of fragments by various French scholars, was derived at last (1858–59) a careful edition and translation of the whole by M. Défrémery and Dr Sanguinetti, with a valuable index and other apparatus, in 4 vols. 8vo.[1]

Though there are some singular chronological difficulties in the narrative, and a good many cursory inaccuracies and exaggerations, there is no part of it except the voyage to China in which its substantial veracity is open to doubt. Nor can it be questioned, we think, that he really visited China, though it is probable that his visit was confined to the ports of the south. The whole of the second part of his story especially is full of vivacity and interest. His accounts, *e.g.*, of the Maldive Islands, and of the Negro countries on the Niger, are replete with interesting particulars, and appear to be accurate and unstrained. The former agrees surprisingly with that given by the only other foreign resident we know of, viz., Pyrard de la Val, two hundred and fifty years later. His full and curious statements and anecdotes regarding the showy virtues and very solid vices of Sultan Mahommed Tughlak are in entire agreement with Indian historians, and add many fresh details.

To do justice to the traveller's own character, as he has unconsciously drawn it, would require the hand of Chaucer and his freedom of speech. Not deficient either in acuteness or in humanity; full of vital energy and enjoyment; infinite in curiosity; daring, restless, impulsive, sensual, inconsiderate, extravagant; superstitious in his regard for the Moslem saints and quacks, and plying devout observances when in difficulties; an agreeable companion, for he is always welcomed at first, but clinging like a horseleech when he finds a full-blooded subject, and hence apt to disgust his patrons, and then to turn to intrigue against them,—such is the picture we form of this prince of Moslem travellers. (H. Y.)

IBN EZRA. See ABENEZRA.

IBN KHALDOUN (1332–1406), a celebrated Arabic historian, poet, and philosopher, was born at Tunis on the 1st Ramadhan 732 A.H. (February 8, 1332). His name was Abu Zeid Abdarrahmán, that of Ibn Khaldoun being a patronymic derived from an ancestor Khaldoun ibn Othmán, who came over with a band of Arab warriors and settled at Carmona in Spain. The family afterwards established itself in Seville, which it quitted for Tunis on the approach of Ferdinand III. Ibn Khaldoun at an early age applied himself to the study of the various branches of Arabic learning with very great success, and entered the employment of the sultan as private secretary at the age of twenty-one. Not believing, however, in the stability of his master's throne, he soon afterwards took refuge with and obtained employment under the Merinide sultan Abu Einán at Fez. In the beginning of the year 1356, his integrity having been suspected, he was thrown into prison until the death of Abu Einán in 1358, when the vizier El Hasan ibn Omar set him at liberty, and reinstated him in his rank and offices. He here continued to render great service to Abu Salem, Abu Einán's successor, but, having offended the prime minister, his position became less pleasant at court, and he sought and obtained permission to emigrate to Spain, where, at Granada, he was received with great cordiality by Ibn el Ahmer, who had been greatly indebted to his good offices when an exile at the court of Abu Salem. The favours and honours he received from the sovereign soon, however, excited the jealousy of the vizier, and he was driven back to Africa, where he was received with great cordiality by the sultan of Bujaiye, Abu Abdallah, who had been formerly his companion in prison. Jealousies and intrigues again drove him forth, this time to take refuge with the lord of Biskera, Ahmed ibn el Mozni. In answer to an appeal from the sultan of Tlemeen, Ibn Khaldoun raised a large force amongst the desert Arabs of the district, and passed over to the service of that prince. A few years later he was taken prisoner by Abd el Aziz, who had defeated the sultan of Tlemeen and seized upon the throne. He then entered a monastic establishment, and occupied himself with scholastic duties, until in the year 1370 he was sent for to Tlemeen by the new sultan, Abd el Aziz. After the death of Abd el Aziz he resided at Fez, enjoying the patronage and confidence of the regent. After some further vicissitudes he entered the service of the sultan of his native town of Tunis, where he devoted himself almost exclusively to his studies. Having received permission to make the pilgrimage to Mecca, he set out and reached Cairo, where his reputation had already preceded him, and was presented to the sultan, El Melek ed Dhaher Berkouk, who insisted on his remaining there, and in the year 1384 promoted him to the high rank of grand cadi of the Malekite rite for Cairo. This office he filled with great prudence and probity, and succeeded in removing a mass of abuses with which the administration of justice in Egypt was overgrown. A terrible misfortune now fell upon him; the ship in which his wife and family, with all his property, were coming to join him, was shipwrecked, and every one on board lost. He endeavoured to find consolation in fresh devotion to his studies, and to the completion of his great work the *History of the Arabs of Spain*, in which he had long been engaged. At the same time he was removed from his office of cadi, which gave him still more leisure for his work. Three years later he made the pilgrimage to Mecca, and on his return lived in strict retirement at the village of Faiyoum until 1399, when he was again called upon to resume his functions as cadi. He was removed and reinstated in the office no less than five times.

In the month of Rabia I. 803 A.H. (October to November 1400 A.D.), he was sent to Damascus, in connexion with the expedition intended to oppose the celebrated Timur or Tamerlane. When Timur had become master of the situation, Ibn Khaldoun let himself down from the walls of the city by a rope, and presented himself before the conqueror, who, charmed with his dignified appearance and his learned discourse, permitted him to return to Egypt. Ibn Khaldoun died on the 25th Ramadhan 808 A.H. (16th March 1406), at the age of sixty-four.

The great work by which he is known is a "Universal History," but it deals more particularly with the history of the Arabs of Spain and Africa. Its Arabic title is *Kitáb el 'Iber, wa diwán el Mubtadá wa 'l Khaber, fí aiyám el 'Arab wa 'l 'Ajam wa 'l Berber*; that is, "The Book of Examples and the Collection of Origins and Information respecting the History of the Arabs, Foreigners, and Berbers." It consists of three books, an introduction, and an autobiography. Book i. treats of the influence of civilization upon man; book ii. of the history of the Arabs and other peoples from the remotest antiquity until the author's own times; book iii. of the history of the Berber tribes and of the kingdoms founded by that race in North Africa. The introduction is an elaborate treatise on the science of history and the development of society, and the autobiography contains the history, not only of the author himself, but of his family and of the dynasties which ruled in Fez, Tunis, and Tlemeen during his lifetime. An admirable edition of the Arabic text has been printed at Boulak (Cairo), and a part of the work has been translated by the late Baron de Slane under the title of *Histoire des Berbères* (Algiers, 1852–56); it contains an admirable account of the author and analysis of his work. (E. H. P.)

IBN KHALLIKAN (1211–1282). Abu 'l Abbás Ahmed, better known as Ibn Khallikan,[2] author of the celebrated Arabic biographical dictionary, was born at Arbela on the 22d September 1211. Some of his biographers trace his descent to Jaafer the Barmecide, the well-known unfortunate friend and vizier of Haroun Alraschid. His life was that of a scholar and literary man, and he was promoted in his later years to the office of cadi of Damascus. He died in the Najibiyeh College of that city on the 29th October 1282. His great work is the *Kitáb Wafayát el 'Aiyán*, "The Obituaries of Eminent Men," and contains brief sketches of the lives of all the most important

[1] P. Jose de S. Antonio Moura previously published at Lisbon a Portuguese translation from a MS. obtained by him at Fez many years before.

[2] By some scholars this surname is written Ibn Khillikan; but his own autograph signature recently found upon a manuscript in the University Library, Cambridge, gives the usually accepted form.

personages of Muslim history and literature, with many appropriate anecdotes illustrative of their personal character, and extracts from the works of such of them as were authors or poets. It is the most complete and at the same time the most universal and comprehensive biographical dictionary in the Arabic language, and is the indispensable companion of the student of Mahometan literature. Ibn Khallikan has many imitators, the best-known work of the kind being the *Fuwát el' Wafayát*, "Omissions of the Wafayat," by Saláh ed dín Muhammed ibn Shákir, which has been published, as well as the work which it is intended to supplement, at the Boulak press.

Ibn Khallikan's work has been published in Arabic with an English translation by Baron MacGuckin de Slane for the Oriental Translation Fund of Great Britain and Ireland (Paris, 1842), and this edition, which is found in most public libraries, is the best and the most accessible one extant.

IBN SINA. See Avicenna.

IBO, Ibu, Igbo, or Eboe, a district of West Africa, situated in the delta of the Niger, and mainly on the left or eastern bank of the river. The chief town, which is frequently called by the same name, but is more correctly designated Abo or Áboh, lies on a creek which falls into the main stream about 150 miles from its mouth, and contains from 6000 to 8000 inhabitants. The Ibo are a strong well-built Negro race. Their women are distinguished by their embonpoint, which is considered by the people themselves as the perfection of beauty. The language of the Ibo is one of the most important in the Niger delta, and is gradually extending its area. The Rev. J. F. Schön began its reduction in 1841, and in 1861 he published a grammar of it (*Oku Ibo Grammatical Elements*, London, Church Miss. Soc.). Isoama is the dominant dialect, being spoken by the Aboh, Elugu, Aro, and Abadja tribes.

See Captain W. Allen's *Narrative*, London, 1848; M. Burdo, *Niger et Benué*, Paris, 1880 (English trans. by Mrs Strange, 1880).

IBRAHIM PASHA (1789-1848), viceroy of Egypt, a real or adopted son of Mehemet Ali, was born at Cavalla in Roumelia in 1789. Early associated with the Egyptian army, he won a name for himself by successful operations against the rebel tribes of Upper Egypt and the fugitive Mamelukes in Nubia, before he entered his twenty-fifth year. In an expedition which he led in 1816 against the Wahhábees of Arabia, the young general was seriously hampered by the want of organized discipline among his troops, and on his triumphant return to Cairo in 1819 he eagerly availed himself of the services of some French officers in his efforts to convert the Oriental turbulence of his forces into the disciplined steadiness of the West. Ibrahim's next campaign was in Greece, whither he was ordered in August 1824 to support the Turkish sultan's attempts to restrain the risings of Hellenic nationality. The defeat of the Turkish and Egyptian fleet at Navarino (October 20, 1827) by the united English, French, and Russian squadrons was the signal for Ibrahim's recall from the Morea, which had suffered keenly at the hands of the cruel Oriental. In Egypt he at once set himself afresh to the work of reorganization in army and navy, and in 1831, when Mehemet Ali ordered an almost unprovoked invasion of Syria, Ibrahim was again at the head of the Egyptian army. Unchecked by the loss of 5000 men from cholera before leaving Egypt, he appeared suddenly on the Syrian coast, took Gaza, Jaffa, and Kaiffa by surprise, and by the 29th of November had invested Acre. There he met with a stubborn resistance; twice in vain he attempted to carry the seaport by storm, and in the midst of the siege he was called away, to meet an army of relief, commanded by 'Osmán Pasha, governor of Aleppo. Near Tripoli he surprised 'Osmán, who decamped without fighting, and returning hastily to Acre, he threw his whole force on the place, carrying it (27th May 1832) with a loss of 1400 men. Without a pause he marched on Damascus, which offered no resistance. At Hims (July 28) he encountered and defeated a Turkish army of 30,000 men, with a force of 16,000, and passing swiftly through the defiles of Beylán, overtook and completely routed the retreating enemy at Adaneh. Another victory followed at Oulou-Kislák, and then, near Konieh, Ibrahim was met by the vizier Resheed Pasha at the head of 60,000 men. Favoured by a murky day—an advantage which helped to counterbalance the great disparity of his forces—he contrived to throw the Turkish army into confusion, and, by the capture of the vizier, converted an impending disaster into the most brilliant of his victories. Meantime his fleet, equally successful, had chased that of the sultan back to the Bosphorus, and the victor, without an army to oppose him, was within six marches of Constantinople. At the critical moment the order came from Mehemet Ali to await reinforcements. But before these arrived the golden opportunity was lost. The Russian army and fleet advanced to the protection of the Ottoman capital; the other Western powers combined in the effort to effect peace; and by treaty in February 1833 Syria and Adana were handed over to Mehemet on the condition of his paying tribute for them. As governor, Ibrahim reduced the new territory to order, and gave a strong impulse to industrial enterprise. But war again broke out in 1839, and at Nezeeb (24th June) Ibrahim dealt a second deadly blow to the Turkish power. Again the commands of Mehemet forbade him to follow up his success, and the campaign, cut short by the interference of the British, ended in the restoration of Syria to the Porte in 1841. After his retreat from Damascus, achieved with martial skill, although accompanied with serious losses, Ibrahim laid down his sword. Retiring to his estates in the plain of Heliopolis, he occupied himself in establishing cotton and olive plantations, till in 1844 he was called to succeed his father as viceroy. He died at Cairo, 9th November 1848, only a few months after the formal confirmation of his rank of viceroy. The finest qualities of a great commander were his, who out of semi-barbarous hordes fashioned a formidable army, and twice by his individual prowess threatened the overthrow of the Ottoman empire. His cruelty, the one blot on his valour, may be regarded as an accident of his life rather than as a fixed trait in his character. In times of peace, at least, he displayed the sagacity as well as the firmness of an enlightened administrator. See Egypt, vol. vii. p. 764.

IBRAILA, Braila, Brahilow, or Brailow, a town, formerly of Wallachia, now of Roumania, situated on the left bank of the Danube, about 9 miles south of Galatz and 102 miles from the Sulina mouth of the river. It has a railway station within a quarter of a mile to the north-west on the Bucharest and Galatz line—a branch line coming down to the harbour; and it is the seat of a chamber of commerce, a tribunal of commerce, and an agency of the Danube Navigation Company. Most of the town lies about 45 or 50 feet above the level of the sea, there being only a very narrow strip of low-lying ground (some 60 or 100 feet) between the edge of the river and the steep and lofty bank by which at this part its course is defined. Ibraila is one of the most regular places in Roumania, standing, indeed, in this respect, next after Bucharest itself. Few of the houses, however, are more than two stories high. Towards the land it has the shape of a crescent, the curve of the outer streets being controlled by the direction of the old fortifications, which were dismantled in 1828. A wide and tree-planted boulevard—the Strada Bulivardului—separates the town proper from the suburban portion. There is a public garden along the brow of the bank towards the river. Besides the cathedral of St

Michael, a large but ungainly building of grey sandstone, there are seven Greek churches, a Roman Catholic church, a Protestant church, a Jewish synagogue, and a church belonging to the strange Russian sect of the Lipovani or Skoptsi. Ibraila has long had a large share in the trade of the Danube. In 1836 it was visited by 382 ships. In 1870 there entered 4936 vessels and 6697 cleared, with a respective total burden of 867,189 tons and 821,274 tons. In 1877 the exports included 87,002 quarters of wheat, 87,314 of maize, 80,938 of barley, 11,964 of rye, besides a large quantity of grain which appears under the returns for Galatz. The railway between Ibraila and Galatz takes a wide circuit, instead of following the direct line of the river. The population, according to Henke (*Rumänien: Land und Volk*, Leipsic, 1877), is 42,000, of whom 53 per cent. are Roumanians, 20 per cent. Greeks, 15 per cent. Jews, and the remainder Germans, &c. According to the *Bulet. Soc. Geogr. Romine*, 1876, the total is 28,000.

In the latter part of the 18th century Ibraila was several times taken by the Russians, and on one occasion (1770) it was burned. By the peace of Bucharest (1812) the Turks retained the right of garrisoning the fortress. In 1828 it was gallantly defended by Soliman Pasha, who, after holding out from the middle of May till the end of June, was allowed to march out with the honours of war. At the peace of Adrianople the place was definitively assigned to Wallachia. It was the spot chosen by Gortschakoff for crossing the Danube with his division in 1854.

IBYCUS, a Greek lyric poet, who flourished about the 60th Olympiad—540 B.C.—was a native of Rhegium in Italy, but spent the greater part of his life at the court of Polycrates, tyrant of Samos. A curious story, not always accepted, is told in connexion with his death. While travelling in the neighbourhood of Corinth, the poet was waylaid and mortally wounded by robbers. As he lay dying on the ground, he saw a flock of cranes flying overhead, and called upon them to avenge his death. The murderers betook themselves to Corinth, and soon after, while sitting in the theatre, saw the cranes hovering above. One of them, either in alarm or jest, ejaculated, "Behold the avengers of Ibycus," and thus gave the clue to the detection of the crime. The phrase, "the cranes of Ibycus," passed into a proverb among the Greeks. Of the seven books of lyrics by Ibycus, which Suidas mentions, only a few fragments have come down to us, but these afford sufficient evidence to support Cicero's estimate of the author whom he pronounces (*Tusc.*, iv. 33) from his writings "maxime vero omnium flagrasse amore." Even from his mythical and heroic pieces, in which he was less successful, Ibycus did not exclude the erotic element. The dialect in which he wrote partook both of the Doric and of the Æolic peculiarities. The best edition of the fragments is *Ibyci Rhegini Carminum Reliquiæ*, edited by Schneidewin, and published at Göttingen in 1833.

ICA, YCA, or ECCA, an inland city of Peru, capital of a district in the department of Lima, situated 170 miles south-south-east of the city of Lima, and 48 miles south-south-west of Pisco on the Pacific Ocean, with which it is connected by a railway. Between Pisco and Ica the country is a desolate and barren desert, but Ica itself lies in a fruitful valley surrounded by corn-fields and vineyards. On account of the frequent earthquakes the town has a very ruinous appearance, but it enjoys considerable prosperity, and exports by way of Pisco large quantities of wheat, maize, cotton, cochineal, wine, and spirits. Originally the city, when founded in 1563, was built 4 miles south-east from where it now stands, the change of site taking place after a great earthquake in 1571. Another severe earthquake in 1664 led to a new town being built close to the old one. The population is about 7000.

ICE is the solid crystalline form which water assumes when exposed to a sufficiently low temperature. It is frequently precipitated from the air as hoarfrost, snow, or hail; and in the glaciers and snows of lofty mountain systems or of regions of high latitude it exists on a gigantic scale, being especially characteristic of the seas and lands around the poles, which consequently have hitherto been practically inaccessible to man. Also in various parts of the world, especially in France and Italy, great quantities of ice form in caves, which, in virtue of their depth below the earth's surface, their height above the sea-level, or their exposure to suitable winds, or to two or more of these conditions in combination, are unaffected by ordinary climatic changes, so that the mean annual temperature is sufficiently low to ensure the permanency of the ice. The great ice supply for the island of Teneriffe is obtained from such a cave, which is 100 feet long, 30 feet broad, and from 10 to 15 feet high, and which is situated on the Peak some 10,000 feet above the sea-level. According to the Rev. S. Browne (*Brit. Ass. Report*, 1864), such cave-ice is generally peculiar in its columnar appearance, and apparently less easy to melt than ordinary surface ice.

In the mutual transformations of water and ice, many remarkable physical phenomena occur. Thus, during the process of melting a block of ice or of freezing a quantity of water, no change of temperature can take place so long as there is a thorough mixture of water and ice. Consequently, the "freezing-point" or temperature at which water freezes is a temperature so readily determined that it is conveniently employed as one of the standard temperatures in the graduation of ordinary thermometer scales, such as the centigrade, the Fahrenheit, and the Réaumur. The centigrade scale, whose zero corresponds to this freezing-point of water, is the temperature scale that is employed throughout this article. In the act of freezing, water, though its temperature remains unchanged, undergoes a remarkable expansion or increase of bulk, so that ice at 0° C. is less dense than water—a fact demonstrated at once by its power of floating. "Ground-ice" or "anchor-ice," which forms in certain circumstances at the bottom of streams, is only an apparent exception to this relation between the densities of water in its solid and liquid states, being retained there by the cohesion between it and the stones or rocks which compose the river's bed. When forcibly released from this contact with the bottom, the ice at once ascends to the surface. Ground-ice may thus be the lowest stratum of the once completely frozen mass of water, adhering to the bottom during the thawing and melting of the ice at the surface; or it may even be formed under favourable conditions below briskly flowing water, probably by the action of eddies, which draw the surface water down through the warmer but denser liquid, and thus cool the stones and rocks at the bottom. As water then expands on freezing, so conversely ice contracts on melting; and the ice-cold water thus formed continues to contract when heated until it has reached its point of maximum density. Joule, from a series of careful experiments, determined the temperature at which water attains its maximum density to be 39°·1 Fahr., or very nearly 4° C. Hence water contracts as its temperature rises from 0° C. to 4° C.; but at higher temperatures it behaves like the great majority of other substances, expanding with rise of temperature. At no temperature, however, does water in the liquid state become less dense than ice, as the following table of relative densities shows:—

Density of ice	at 0° C.	=	·9175
,, water	at 0° C.	=	·99988
,, ,,	4° C.	=	1·00000
,, ,,	10° C.	=	·99976
,, ,,	100° C.	=	·95866

Under the influence of heat, ice itself behaves as most solids do, contracting when cooled, expanding when heated.

According to Plücker, the coefficient of cubical dilatation at moderately low temperatures is ·0001585. From a series of elaborate experiments, Person deduced ·505 as the specific heat of ice, or about half that of water; in other words, the heat required to raise 1 ℔ of water 1° C. will raise 2 ℔ of ice through the same range of temperature or 1 ℔ of ice through 2° C.

Though no rise of temperature accompanies the melting of ice, there is yet a definite quantity of heat absorbed, and a corresponding amount of work done—mainly in altering the physical condition of the substance. The heat which disappears is transformed into other and less evident forms of energy,—as, for example, the energy of translatory motion, which is the chief characteristic, according to the recognized molecular theory of matter, of the molecule in the liquid as compared with the molecule in the solid. The heat which is thus absorbed during the melting of unit mass of ice is called the latent heat of water, and its value in ordinary heat-units is 79·25, according to the determination of Person. Hence as much heat is required to transform 1 ℔ of ice at 0° C. into water at the same temperature as would raise in temperature 1 ℔ of water through a range of 79°·25 C., or 79·25 ℔ of water through a range of 1° C. The same amount of heat which is absorbed when ice becomes water is evolved when water becomes ice, so that the melting of ice is accompanied by the abstraction of heat from surrounding objects, that is, by a cooling effect; and the freezing of water by a heating effect. These thermal effects are generally masked by the processes whereby the change of state is effected; but the cooling which accompanies the melting of ice may be observed when pressure is used as the agent for accomplishing the change. That ice can be so melted by increase of pressure was first pointed out by Professor James Thomson (now of Glasgow) in a paper published in the *Transactions of the Royal Society of Edinburgh* for 1849; previous to that time the temperature of melting ice was believed to be absolutely constant under all conditions. Thomson showed that, since water expands on freezing, the laws of thermodynamics require that its freezing-point must be lowered by increase of pressure; and, by an application of Carnot's principle, he calculated that for every additional atmosphere of pressure the freezing-point of water was lowered by ·0075 of a degree centigrade. This remarkable result was soon after verified, even to its numerical details, by his brother, Sir William Thomson (*Proceedings of the Royal Society of Edinburgh*, 1850). The Thomsons and Helmholtz have since then successfully applied this behaviour of ice under pressure to the explanation of many curious properties of the substance. When two blocks of ice at 0° C. are pressed together or even simply laid in contact, they gradually unite along their touching surfaces till they form one block. This regelation, as it is called, is due to the increased pressure at the various points of contact causing the ice there to melt and cool. The water so formed tends to escape, thus relieving the pressure for an instant, refreezing, and returning to the original temperature. This succession of melting and freezing, with their accompanying thermal effects, goes on until the two blocks are cemented into one. Thus it is that a snowball is formed; and in virtue of the same succession of phenomena does the glacier mould itself to its rocky bed and flow down the valley, behaving in many respects like a viscous fluid.

Ice forms over fresh water if the temperature of the air has been for a sufficient time at or below the freezing-point; but not until the whole mass of water has been cooled down to its point of maximum density, so that the subsequent cooling of the surface can give rise to no convection currents, is the freezing possible. Sea-water, in the most favourable circumstances, does not freeze till its temperature is reduced to about – 2° C.; and the ice, when formed, is found to have rejected four-fifths of the salt which was originally present. In the upper provinces of India, water is made to freeze during cold clear nights by leaving it overnight in porous vessels, or in bottles which are enwrapped in moistened cloth. The water then freezes in virtue of the cold produced by its own evaporation or by the drying of the moistened wrapper. In Bengal the natives resort to a still more elaborate forcing of the conditions. Shallow pits are dug about 2 feet deep and filled three-quarters full with dry straw, on which are set flat porous pans containing the water to be frozen. Exposed overnight to a cool dry gentle wind from the north-west, the water evaporates at the expense of its own heat, and the consequent cooling takes place with sufficient rapidity to overbalance the slow influx of heat from above through the cooled dense air or from below through the badly conducting straw.

Ice ma

The growing demand for ice for domestic, medicinal, and other purposes has led, not only to the development of a regularly organized ice trade, but also to the invention of machines for the manufacture of ice in countries which do not possess a sufficient home supply. The various types of machines which have been or are in use call for a brief description. Freezing-mixtures, such as the familiar snow and salt or the mixture of sulphate or phosphate of sodium and dilute nitric acid, may be dismissed with a word, since they are restricted in use to the production of intense cold for a brief period of time, and are incapable of economic application to the formation of large quantities of ice.

All ice-machines which have proved of practical utility may be grouped under two great classes:—those which utilize the lowering of temperature that accompanies the rapid expansion of a compressed gas, and those which make use of the like thermal effect that results from the volatilization of some liquid. In machines of the first type, the gas usually employed is atmospheric air, which is first compressed to three or four atmospheres, and kept cool by circulating water or by other suitable means. It is then allowed to expand, and the heat necessarily absorbed during the expansion is drawn either from the water to be frozen or from a solution of brine which does not freeze at the ordinary freezing temperature, and thus becomes, so to speak, a vehicle for the cold. In 1849 Gorrie constructed such a machine, which, however, was unsatisfactory in its action, probably because the compressed air was not sufficiently cooled and dried. More efficient in their action were Kirk's machine (patented in 1863), and Windhausen's (1870), one of which at the Vienna exhibition produced 30 cwts. of ice per hour, at the cost of 1s. per cwt. The mode of action of Windhausen's is as follows. A piston works to and fro in a cylinder, compressing the air in the one end and allowing it to expand in the other. The compressed and therefore heated air forces its way through a valve to the cooling chambers, from which it is led towards the other end of the cylinder. Here the inlet valve is so arranged that it closes at a certain position of the receding piston, thus permitting what air has entered to expand and cool. At the return stroke this cooled air is forced out through easily opening valves,—part going to cool the chambers into which the heated compressed air enters from the cylinder, and part passing to the refrigerator, from which after serving its purpose it is pushed on by the fresh supply of cooled air to the compressing end of the piston chamber. Such machines, to work economically, require large cylinders, tight-fitting pistons working with little friction, and perfect regulation in the motions of the various parts—conditions so difficult to fulfil that refrigeration by means of compressed air may be regarded as a practical failure. The machines constructed by the Bell-Coleman Mechanical Refrigeration

Company (Glasgow) utilize as the cooling agent a mixture of certain hydrocarbon gases which are obtained from the distillation of carbonaceous shale. The gas is compressed to a pressure of about 8 atmospheres, and, after being cooled by expansion, is carried off and consumed as fuel. These machines are not specially intended for the production of ice; but, as refrigerators, they are successfully employed for preserving meat on board ship.

Among machines of the second group there is a great variety of construction, because of the great differences which exist in the properties of the liquids used. Thus water, sulphuric ether, bisulphide of carbon, ammonia, methylic ether, sulphurous acid, and other substances have been employed as refrigerating agents. In all cases, it is the so-called latent heat of vaporization that is utilized; and did the efficiency of the method depend only on this, water would undoubtedly be the best material on account of the great latent heat of its vapour. But as important from a practical point of view are the vapour pressures that come into play throughout the range of temperature employed. Thus at 10° C. the pressure of water vapour is so small, only ·012 of an atmosphere (and at lower temperatures of course it is still smaller), that, to make the evaporation of water an efficient means of refrigeration, the process must be conducted under a very much diminished pressure. As early as 1755, Dr Cullen managed to freeze water by its own evaporation in a vacuum; but this method, though greatly developed by Nairne, Leslie, and Vallance, can be applied to the production of ice in small quantities only.

The same objection applies, of course, to sulphuric ether, bisulphide of carbon, or any substance which boils under ordinary atmospheric pressure at a temperature above that of the air. Ether boils at 34°·8 C., and bisulphide of carbon at 46°·2 C.; and their vapour pressures at 10° C. are respectively ·377 and ·267 of an atmosphere. They thus volatilize much more readily than water, and require a comparatively slight vacuum to render their evaporation sufficiently rapid for refrigerating purposes. In the ether machine, which may be taken as a type, the ether, on being vaporized in the refrigerator under a partial vacuum, is drawn over and compressed to the liquid state in the condenser, which is kept cool by circulating water. From the condenser it is then led back to the refrigerator, to be re-evaporated. Perkins's machine (1834), Twining's patent of 1850, Harrison's machine (1857), Siebe's machine (1862), and Siddeley and Mackay's apparatus are ether-machines; and all except the first, which is hardly adapted for extensive freezing, surround the refrigerator with brine, which when cooled flows easily around and between the cases containing the water to be frozen. Van der Weyde (1869) substituted naphtha, gasolin, or chimogene for the ether; and in Johnston and Whitelaw's machine bisulphide of carbon is used somewhat similarly. The great difficulty in machines of the ether type is to prevent leakage, so as to keep the partial vacuum really efficient; and moreover ether, which is in most respects superior to all the other substances employed, has an awkward tendency, under the influence of frequent condensations and rarefactions, to transform itself into less volatile isomers.

The great characteristic of ice-machines which employ ammonia, methylic ether, or sulphurous acid, as compared with those of the ether type, is that they work at increased instead of diminished pressures, since these substances are gaseous at ordinary temperatures and pressures, and require for their liquefaction either the production of a low temperature or the application of a high pressure. For facility of reference the boiling points and vapour pressures at three different temperatures for these substances are given in the following table.

Name of Substane	Boiling Point.	Vapour-Pressures estimated in Atmospheres.		
		At 10°.	At 20°.	At 30°.
Ammonia	−38°·50 C.	6·1	8·5	11·6
Methylic ether	−23°·65	3·5	4·8	6·5
Sulphurous acid	−10°·08	2·3	3·2	4·5

The best known of the ammonia machines is Carré's (1859), the principle and construction of which are remarkably simple. Two strong metal vessels, the boiler and refrigerator, are connected above by a tube. In the boiler a saturated solution of ammonia is raised to 130°–150° C. The ammonia is driven over under high pressure into the refrigerator, round which cold water circulates, and in which the ammonia is condensed to a liquid. The boiler is then placed in cold water, and as its temperature falls the pressure in the apparatus is relieved and the liquid ammonia in the refrigerator vaporizes rapidly, thereby producing intense cold, and redissolves in the boiler. The temperature to which the boiler must be raised at first is determined by the condition that the pressure in the boiler must correspond to the pressure of the ammonia vapour at the temperature of the condenser. Now the pressure of ammonia vapour increases from $8\frac{1}{2}$ atmospheres at 20° C. to $11\frac{1}{2}$ at 30° C.; and this higher pressure is extremely difficult to keep up in such an apparatus as Carré's, because of inevitable leakage. In warm countries, accordingly, the ammonia-machine is practically useless because of the high pressures required; and in temperate climates, where natural ice can be stored throughout summer, an ice-machine is not in such great demand. One great drawback to the efficient working of Carré's machine is the difficulty of keeping the refrigerating liquid free of water—only 75 per cent. of it being ammonia. To remedy this defect Reece invented his machine (1869). The essential part of this ingenious apparatus is an upright cylinder in which a descending current of strong ammonia solution, drawn originally from the boiler, is met by an ascending current of steam. The ammonia is thus separated from the water, and is driven off into a rectifier, from which, after being freed from any small quantity of water it may have carried along with it, it passes into a condenser where it is kept liquid by its own pressure. It is then allowed to collect in the refrigerator, where at the required moment the pressure is relieved, permitting the ammonia to vaporize and escape to a separate chamber to be redissolved. Brine flowing through a coiled tube within the refrigerator is used as the vehicle for the cold produced; or even mere water may suffice if the object is simply to get a diminished temperature without freezing. Linde's ice-making machine, some twenty-two of which were in operation at the Düsseldorf Exhibition of 1880, is the latest form of ammonia machine; and its inventor claims for it superiority over all others as an economical refrigerator. The danger of explosion, one of the great disadvantages of ammonia, is obviated by carrying the liquefied gas through narrow iron tubes and by employing only a small quantity of the substance at one time. Blocks of ice are formed between the spokes of a revolving drum, which, cooled internally by the evaporating liquid, dips into a tank of water. Methylic ether is in some respects better than ammonia, having a higher boiling point, and requiring smaller pressures, without the necessity of heating. In Tellier's machine (described in the *Annales de Chimie et de Physique* for 1874), which is specially suitable for use on board ship, the methylic ether evaporates in a closed metallic vessel, the sides of which are in immediate contact with the water to be frozen or chilled.

Sulphurous acid, first successfully employed as a refrigerating agent by Pictet of Geneva (1876), and thereafter applied by Gamgee to the formation of his glaciarium or artificial skating rink, is in many respects far superior to any other known refrigerator. Thus it is more easily liquefied than ammonia and methylic ether, exerting a vapour pressure of only 4½ atmospheres at 30° C.; it has no chemical action upon metals or fats; it is incombustible; it is obtainable at small expense; and it has, besides, good lubricating properties;—in short, it seems to possess all the essentials of an efficient and economical refrigerator. In Pictet's machine, the liquid sulphurous acid passes under pressure from the condenser to the refrigerator, where on the pressure being relieved it vaporizes, cooling to −7° C. a current of brine which then flows round the tanks containing the water to be frozen. The sulphurous acid gas in the refrigerator is drawn over by an aspirating force-pump and recondensed in the condenser, which is kept cool by an ample supply of cold water. By a special modification of the sulphurous acid machine, Pictet obtained as low a temperature as −73° C.; under this low temperature he then compressed carbonic acid gas to a liquid, by the evaporation of which he produced such intense cold as to enable him to liquefy the so-called permanent gases under a pressure of several hundreds of atmospheres (*Bibliothèque Universelle*, 1878). Gamgee uses as his congealing liquid a solution of 4 parts of glycerin in 6 parts of water, which is conveyed in pipes beneath the water-surface to be frozen.

Machines which are capable of freezing water may in certain circumstances be much more efficiently employed to produce cooling without freezing. For instance, in curing-houses, breweries, sugar refineries, provision stores in hot climates, and in ships engaged in the transport of meat, where it is of importance to have the temperature moderately cool, it is usually by no means necessary to obtain ice. In many such cases, indeed, the production of ice would be a mere waste of labour. In tropical and subtropical climates refrigeration is of high importance from a sanitary point of view; and there seems little doubt that if a simple, economical, and thoroughly efficient means of cooling were discovered, houses would be cooled in warm weather with the same care and regularity with which they are when necessary heated. At present, however, the manufacture of ice and the artificial production of cold are arts still in their infancy, which have a powerful rival in the extensive and increasing ice-trade that has sprung up within the last half century.

Ice trade.

The idea of trading in ice first occurred to a Boston merchant, named Tudor, who in 1805 shipped ice to Martinique. In 1833 American ice began to be imported into Calcutta, where it was sold for 3d. per pound—exactly half the price of the Bengal manufactured ice. In America, which was for long the great ice-exporting country of the world, supplying especially the West Indies, India, and China, the cutting and storing of ice form an important industry during the winter months. When the ice is sufficiently thick, 9 to 12 inches for home consumption, 20 inches for exportation, the surface is scraped free of all porous ice, and is marked out into squares of 5 feet each way. Along these lines the ice is grooved to a depth of 3 inches by means of a plough. An instrument like a harrow is drawn over the grooves so as to deepen them; and, after the surface has been divided into smaller squares, the ice is cut up into blocks by means of handsaws. The blocks are then removed to large double-walled storehouses, many of which are capable of containing thousands of tons of ice. It is estimated that, in America, 2,000,000 tons of ice are cut and stored annually by companies supplying New York and the middle States. New York city alone consumes as much as 500,000 tons per annum. A considerable quantity of ice from Wenham Lake near Boston was at one time imported into Britain, but now the whole supply comes from Drobak near Christiania in Norway. The Norwegian ice is remarkably solid and pure, and is superior in its staying power to English ice or to manufactured ice. The total quantity imported into the United Kingdom may be estimated roughly at 150,000 tons per annum, of which the greater part is consumed in London, where it is retailed at from 2s. 6d. to 3s. 6d. per cwt. At present Norway is undoubtedly the great ice-store for the Old World; and quite recently (1880) Norwegian ice has been sold in the United States more cheaply than native ice. The transport on board ship offers practically no difficulty, since, as long as the hold is kept dry and cool, there is very little loss, and in the lading no special care need be taken. For the storing in houses, see ICE-HOUSE. (C. G. K.)

ICEBERG, a floating mass of ice, which has broken off from such ice-sheets as cover Greenland, Spitzbergen, and other polar lands, constituting vast glacier systems ever creeping out and down from the central heights to the shores. As the glacier is pushed out to sea, the lower margin is exposed to the destructive action of the waves, and breaks up into fragments of endless variety of form. These severed blocks, many of which are hundreds of millions of tons in mass, drift to lower latitudes under the influence of polar currents, and gradually melt away in the warmer water. Such is the natural history of icebergs, which, in their freshwater origin, are to be distinguished from the ice-fields, ice-floes, pack ice, and ice-hummocks, so familiar to the polar voyager. The iceberg, as it drifts along, melts most rapidly under water; and this unequal wasting must be accompanied by a change in the position of the centre of mass and a consequent shifting of the iceberg into its new position of equilibrium. Undermining and fracture also result; so that at length the mass of ice, however square-shaped or symmetrical it may have been originally, assumes a form irregular and fantastic in the extreme. The densities of ice and sea-water are nearly ·92 and 1·03 respectively, so that only $\frac{11}{103}$ or nearly $\frac{1}{9}$th of the iceberg is above water and visible. An iceberg observed by Sir John Ross and Lieutenant Parry was 2½ miles long, 2⅕ miles broad, and 153 feet high. Assuming the form to have been approximately a cone erected upon an elliptic base, the mass above water would be roughly 150 million tons—giving a total mass of nearly 15 hundred million tons. This iceberg, however, was by no means of extraordinary dimensions. In the southern seas, great fleets of icebergs have been observed as far north as the latitude of Cape Horn; and some of these ice masses have towered to a height of 700 or 800 feet. The limiting latitude to which icebergs drift is lower in the southern than in the northern hemisphere, probably because of the comparative scarcity of land in the south polar regions. Thus, icebergs have been observed off the Cape of Good Hope in 34° S. lat., while none has been noticed in the northern hemisphere lower than the 36th parallel. Generally speaking, the limiting latitudes may be fixed at 40° N. lat. and 35° S. lat. In the North Atlantic the distribution of icebergs is very remarkable, and indicates, in its peculiar way, the general set of ocean currents. Icebergs, of course, can only drift along with some polar current,—such, for example, as the Labrador current, which flows in a generally southerly direction round the coasts of Newfoundland and Nova Scotia. To the east of this track, in which icebergs abound during the early summer months, lies the region which is warmed by the waters of the Gulf Stream as it flows to the Scandinavian coast, and here floating ice is rarely seen. The same considerations regarding prevailing currents determine the distribution and limit of icebergs in the southern oceans, the great antarctic current that cools the coasts of Chili and Peru bearing upon its broad expanse the fragments of the shining ice-cliffs of South Victoria. The climatic effect of an iceberg is sometimes very marked; and not unfrequently the lowering of the temperature indicates to the mariner the presence of floating ice even before it is near enough to be visible. Geologically considered, icebergs, like glaciers, are great transporting agents, bearing away to the deep sea rocks, boulders, and stones, which are strewn along the ocean bed as the ice gradually melts. By this cause, rather than by the glacier in its integrity, some erratic blocks may doubtless have been transported at a time when the land was under water and exposed to ice-drift.

ICE-HOUSE. An ice-house, to supply ice for domestic use during the summer months, is one of the desirable adjuncts of a country residence. The old form of ice-house was a well several feet deep, dug out on sloping ground or against a bank. The bottom was made to slope towards a sunk drain, covered by an iron grating, to permit the water from the melted ice to pass away quickly; while a dip in the drain or a bend in the pipe prevented air from entering at the bottom of the well. The ice was filled in through an opening in the dome, which had to be carefully closed.

A good form of ice-house is that recommended many years ago by Mr Bailey, gardener at Nuneham Park, Oxford, and described in the *Gardener's Magazine of Botany* (i. 82). This house is shown in section and plan in fig. 1, where the dotted line indicates the ground level. The well or receptacle for the ice *a* is 10 feet 6 inches wide at the base, and 3 feet wider near the top; the walls are hollow, the outer portion being built of dry rough stone, and the inner wall and dome *f* of brick. The outer wall *e* might be replaced by a puddling of clay, carried up as the work proceeds. Over the top is a mound of clay and soil *g*, which is planted with shrubs to keep the surface cool in summer. The drain *i* carries off the water formed by the melted ice, and is provided with a trap *h* to prevent the ingress of air through the drain. There is a porch or lobby *b* provided with an outer and an inner door *c*, *c*; and there are apertures at *d*, *d*, to get rid of the condensed moisture, which, if not removed, would waste the ice. These ventilating doors should be opened every night, and closed again early in the morning. The most important conditions to be secured are dryness of the soil and of the enclosed atmosphere, compactness in the body of ice, which should be broken fine and closely rammed, and the exclusion as far as possible of air.

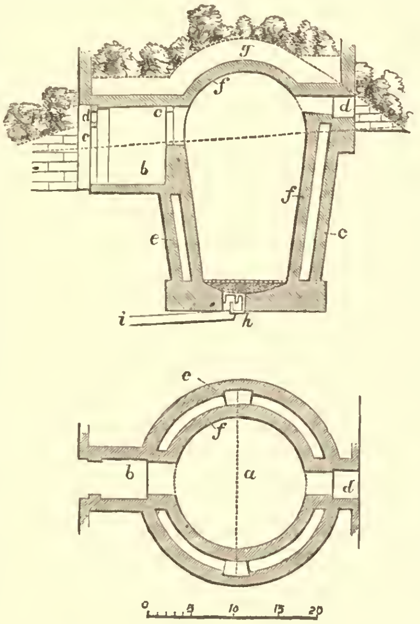

Fig. 1.

The Americans, who use large quantities of ice, always store it above ground. One of their ice-houses, of which the elevation is shown in fig. 2 and the plan in fig. 3, described in Allan's *Rural Architecture*, is both simple and ornamental in character. The house may be 12 feet square, or any larger size. A series of posts in pairs are set up $1\frac{1}{2}$ feet apart and 8 feet high, about 1 foot being inserted firmly in the ground; the distance between each pair is 3 feet. The tops being cut level all round, a plate 6 inches wide and 4 to 6 inches deep is spiked on to each line of posts, the two plates being strongly stayed by cross pieces so as to form a double frame. The inner face of each line of posts is now boarded up closely, leaving a space $6\frac{1}{2}$ feet by 3 feet at the sides, which are also boarded, to form a door-casing on each side. The spaces between the two lines of boards thus form a continuous box, which is to be completely filled up with moist tan, bark, or sawdust, well packed throughout. There must be a drain to carry off all water from the interior. Within the enclosed space some level joists are laid down, and on them loose planks to form a floor, which when covered 1 foot thick with straw is ready to receive the ice. The roof is formed of rafters, 4 inches by 3, long enough to project at least 4 feet outside the plates, to which they must be well secured by spikes. The rafters are to be boarded over and covered with shingle, and a small opening left at the top to admit a pipe 8 inches in diameter for a ventilator, over which a small ornamental cap, supported on four little posts, is to be placed. As a finish to the projecting roof, brackets of 3 by 4 inch scantling, if the joists are of sawed stuff, or of rough limbs of trees to match the posts, if these are rough, may be introduced. After the ice is stored, a close floor of boards should be laid on joists resting loosely on the wall plate (to admit of this upper floor being removed while the house is being filled), and they must be covered with 6 inches of tan or sawdust, or failing these with straw. A good layer of tan or sawdust should also be placed on the top of the ice when it is put in. There should be two doors, inside and outside the lining, both opening outwards. A shady place is desirable, but not essential.

Fig. 2.

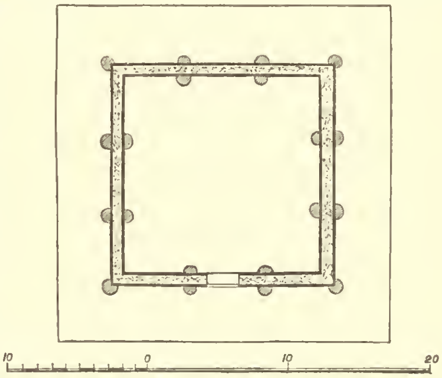

Fig. 3.

A still less expensive way of storing ice has been described by the late Mr Pearson of Kinlet in the *Gardener's Journal* (iii. 10). In this case the ice-stack was made on sloping ground close to the pond whence the ice was derived. The ice was beaten small, well rammed, and gradually worked up into a cone or mound 15 feet high, with a base of 27 feet, and protected by a compact covering of fern 3 feet thick. A dry situation with a sloping surface is necessary where this plan is adopted, and a small ditch should surround the heap, to drain away any water that may come from melted ice or from other sources.

ICELAND

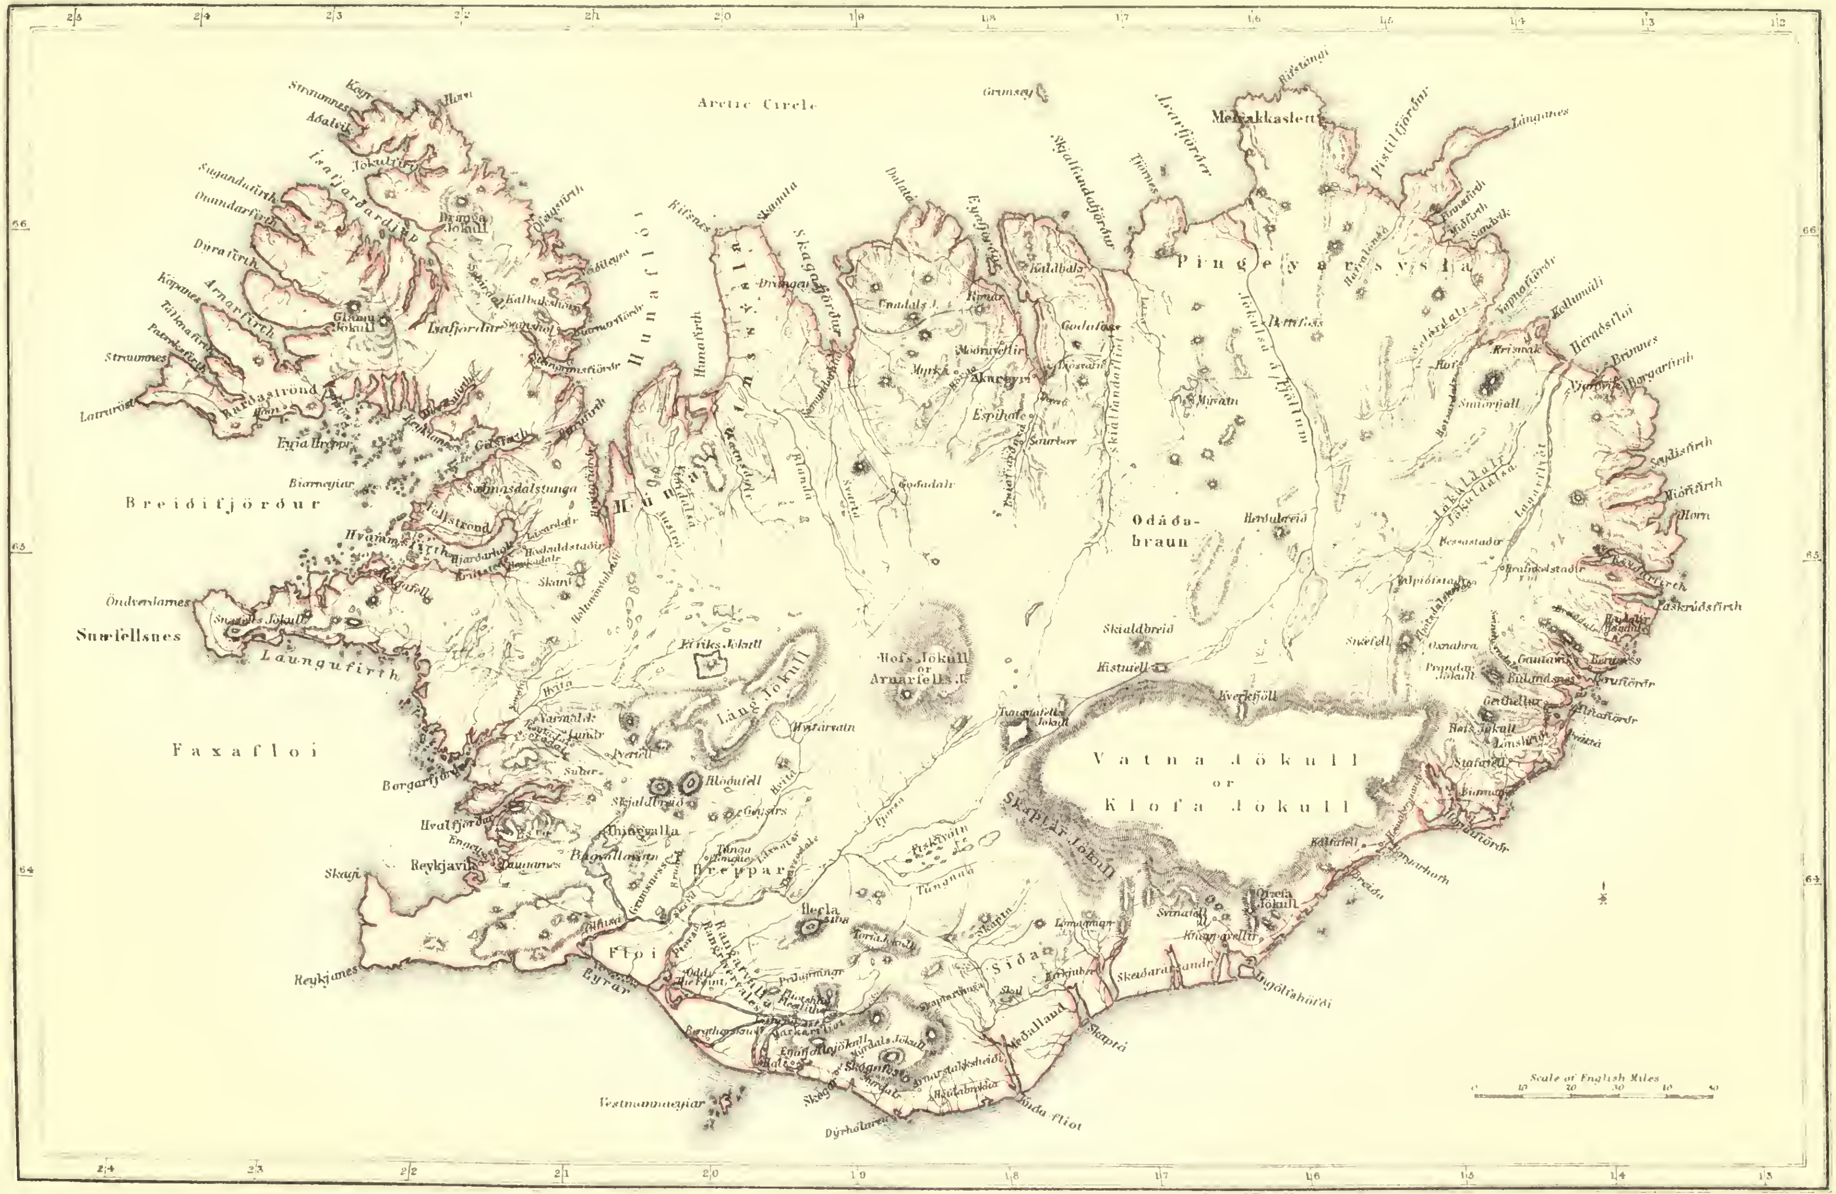
Plate IV. ICELAND (in Danish, *Island*) is an island in the North Atlantic Ocean, immediately to the south of the polar circle. It extends from 63° 23′ to 66° 33′ N. lat., and from 13° 22′ to 24° 35′ W. long. Its distance from the north of Scotland is 500 miles, from Norway 600 miles, and from Greenland 250 miles. The greatest length of the island is 300 miles, from east to west, and its greatest breadth 200 miles. The area is estimated at 39,200 square miles, 7000 more than that of Ireland.

The geological formation of the island is throughout volcanic. It rests on a foundation of palagonite, or palagonite tufa, called in Icelandic "móberg"; and on this foundation are raised plateaus of basalts, and mountains of trachyte and other volcanic ejections. The whole island seems to have been filled up by volcanic agency. In some of the mountains the lavas occur in tolerably regular parallel strata or terraces, separated here and there by layers containing lignite, as in the similar volcanic plateaus of Faroe and Greenland.

Coast. The whole of the south coast, from Hornafjörður in the south-east to Reykjanes in the south-west, is entirely unbroken by bays or firths. If such ever existed, they have been filled up by the glaciers and the sand and mud carried down from the volcanic ice-mountains situated close to the south coast. The coast-line is not, however, a straight line, but a broad arch, as the land swells out in the middle southwards to a considerable extent. On the north of Reykjanes a broad bay called Faxaflói (Faxi's Bay) cuts into the land; it is bounded on the north side by Snæfellsnes, and has an area of 54 miles by 30 On the north side of Snæfellsnes the long Breiðifjörður (Broadfirth) nearly cuts off the north-west peninsula from the rest of the island; it is 80 miles long and 40 broad. The Breiðifjörður is noted for its great number of small islands, most of them inhabited, and all of them affording breeding places for the eider duck. To the north of the Breiðifjörður, innumerable bays cut into the peninsula at every turn, giving it somewhat the look of the outstretched hand of a man; the longest of these is Ísafjarðardjúp (Icefirthdeep), 45 miles long. On the north side of the island, between Horn (Cape North) on the west and Melrakkaslétta (Fox Plain) on the east, there are several large firths. Furthest to the west is Húnaflói (Bearcubs' Bay), about 60 miles long, which nearly meets the Breiðifjörður running in from the west; the tongue of land which separates them and connects the north-west peninsula with the rest of the island is hardly 5 miles broad. The other firths on the north side are Skagafjörður, Eyafjörður (Firth of the Isles) 36 miles long, Skjálfandafjörður, and Axarfjörður (Axefirth). The Melrakkaslétta is separated from Langanes, the north-east point of Iceland, by the Þistilfjörður (Thistlefirth). The whole of the east coast of the island is indented by numerous narrow firths like those found in the north-west peninsula, but none of them are of any great length. Sailing round the island from point to point, the distance is 900 miles, but if we follow the coast-line it is not less than 2000 miles.

Interior. The centre of the island is a table-land, or rather a broad flattened ridge, sloping down to the north and the south, the average height of which above the level of the sea is about 2000 feet. It consists of arid sands and rugged tracts of lava, the most important of which bear the names of Ódáðahraun (the Lava of Evil Deeds), Sprengisandur (Bursting Sand), and Stórisandur (Big Sand). This wilderness is frequently broken by high and extensive ice-hills called jökull (plur. jöklar). The ice hills rise to the greatest height in the south-east, where the most extensive ice-field in the island, called Vatnajökull, covers about 4000 square miles. The outliers of this ice-field come close down to the water, hardly leaving room for passage between them and the sea; some of these are the loftiest summits in the island, as Öræfajökull, which is 6466 feet high. South of the west end of the Vatnajökull, called Skaptárjökull, stretches an inhabited slope, interrupted by several small hills, and intersected by considerable streams. The eastmost part is called Síða; then follow Landbrot, Meðalland, and Alptaver. West of this the land rises again in the Mýrdalsjökull and the Eyafjallajökull, the latter being 5593 feet high, and here again the mountains come close down to the sea. West of the Eyafjallajökull is the largest plain in the island, stretching westward to the mountain chain terminating in the low cape of Reykjanes, and backed on the north side by several isolated mountains, among which the far-famed Hecla is prominent; its height approaches 5000 feet. This plain consists of stretches of grass land and marshes, affording abundance of grass for pasture and haymaking.

The southern and part of the eastern coasts of Faxaflói, as far as Reykjavík, are very barren and desolate, being almost entirely rugged lava tracts; but the lower parts of the hills then begin to be clothed with grass, affording pasture for sheep, cattle, and horses. North of Reykjavík is a long and narrow firth called Hvalfjörður (Whalefirth), and further on a shorter one called Borgarfjörður (Burghfirth). Between the extremity of the latter and the central highlands there is a large and fertile district, consisting of grassy valleys, divided by low hills, and an extensive plain covered with marshy grasslands. This district is a fair specimen of many of the inhabited parts of Iceland. The level land, the valley bottoms along the river banks, and in many cases the slopes of the hills, are covered with grass, but the soil is too frequently boggy and marshy. The hills are partly covered with heather, and in a few places with stunted dwarf birch. Districts similar in character to Borgarfjörður are the Dalir (Dales) on the south side of Breiðifjörður, the Húnavatnssýsla on the south side of Húnaflói, the Skagafjörður, the Fljótsdalshérað on the east side of the island, and the western half of the plain lying between Eyafjallajökull and the Reykjanes range of mountains. The north-west peninsula consists, as already stated, of narrow firths divided by high and narrow mountain ridges, seldom lower than 2000 feet. In some places the top is a thin rocky edge; in others it consists of sharp-pointed peaks, denuded of all vegetation. Even at a considerable distance the different rocky strata may be distinguished. Sometimes these hills, or rather cliffs, rise perpendicularly out of the water to a height of a couple of thousand feet, affording breeding-places to an immense number of sea-fowl. More frequently the lower parts of these razor-backed hills slope towards the firths, the stony slopes being partly covered with grass or heather. The farms are therefore found along the shores and in short valleys cutting into the hills from the ends of the firths. The east coasts of Iceland present exactly the same character as that of the north-west peninsula. From the end of Eyafjörður a long and fertile valley, bounded on both sides by lofty mountains, runs due south into the country for about 25 miles. The north-east corner of the island, called Þingeyarsýsla, has good sheep pasturage, although its hills and slopes are covered with heather instead of grass to a greater extent than most other districts of the island. It will thus be seen that the inhabited parts run round the coasts, and from



This map with certain amendments belongs to the Story of Burnt Njal by Sir George W. Dasent who has kindly allowed its reproduction here

the end of the bays into the interior, the farms farthest inland being about 50 miles from the sea.

As the snow-line is at an altitude of from 2500 to 3000 feet, all the highest mountain-tops are cones covered with perpetual snow. Besides the ice-mountains already mentioned, there are several on the western part of the central highlands, such as Hofsjökull, Langjökull, Eiríksjökull, &c.; Snæfellsjökull, at the point of the peninsula separating the Faxaflói and Breiðifjörður, reaches the height of 4713 feet. All these mountains are snow-capped. Most parts of the island are studded with hills ranging in height from 2000 to 3000 feet. The tops are usually bare and rocky, but the slopes are to some extent covered with grass and heather.

Most of the mountains of Iceland have been volcanoes, and at least twenty-five of them have been active within the historical period of the island, that is, the last 1000 years. It was observed by Mackenzie that there are two volcanic formations in the island, one consisting of flat sheets of basalt, the other of more irregular hilly accumulations of trachyte, obsidian, ashes, and other volcanic masses. The former of these, there can be little doubt, is of Tertiary age—a part of the great Miocene volcanic plateaus, which on the one hand extend southwards through the Faroe Islands and the west of Scotland to the north of Ireland, and on the other stretch northwards and westwards far into Greenland. The other volcanic masses are of recent date. Iceland has thus been the theatre of volcanic activity at two widely separated periods, though we do not yet know whether during the interval the activity was wholly dormant. Of the existing volcanic mountains the best known is Hecla, from which eighteen eruptions have been recorded; the last took place in 1845–46. The intervals between the eruptions have varied greatly; sometimes it has remained quiet for six years only, at other times for seventy-two years. As with most other volcanoes, the height of this mountain varies with the eruptions. Thus before the eruption of 1845 its height was given on Gunlaugsson's map as 4951 feet, while Kjerulf measured the mountain in 1850, and found it to be only 4532 feet. The earliest historical eruption, that of 1104, is celebrated as the "sand-rain winter," the second, in 1158, as the "great darkness," from the quantity of ashes ejected. One feature of the Icelandic eruptions, not from Hecla only, but from other orifices in the island, has been the prodigious quantity of fine dust discharged and the great distance to which this material has been carried. Thus in the year 1766 a column of ashes rose out of the crater of Hecla to a height of 16,000 feet into the air. Volcanic dust from the Icelandic vents has frequently been borne by upper air currents so as to fall upon the Faroe Islands, and has even been carried in considerable quantities as far as Norway on the one side and the north of Scotland on the other. Next to Hecla, the Katla, or Kötlugjá, in Mýrdalsjökull may be mentioned; its last eruption (the thirteenth known) took place in 1860. The most tremendous volcanic outbreak in Iceland was that which took place in 1783 in or near the Skaptárjökull, on the north-west border of the Vatnajökull. Two principal lava streams flowed from it: one of them was 50 miles in length, from 12 to 15 miles in breadth, and 100 feet deep, and the other was 40 miles in length. It has been calculated that these two streams cover an area of 420 square miles. This eruption destroyed directly or indirectly one-sixth of the inhabitants of the whole island, or one-half of all the live stock. From nearly all the outliers of the Vatnajökull eruptions now and then take place. To the north of Vatnajökull a range of volcanic centres extends as far as Myvatn. The last outbreak here took place in 1875, when fine volcanic dust was discharged in great quantity, some of it being carried as far as Norway. The sea around the coasts of Iceland has been frequently disturbed by volcanic outbreaks, especially off Cape Reykjanes.

Hot springs. On account of the same volcanic activity, hot springs are frequently met with throughout the island. The common name for them in Icelandic is "hverr" (cauldron). The chief of these hot springs is Geysir (Gusher). See Geysers.

Minerals. The only mineral worked to any extent in Iceland is sulphur; the principal mines are those of Krísuvík and Mývatn. Of the Iceland spar used for polarizing optical instruments, only one mine has been worked, that of Helgustaðir in the east of the island. Limestone is found near Reykjavík, and has been worked a few years. Iron-ore is found in many parts of the island, but not in paying quantities, as suitable fuel is wanting. Aluminium occurs near Cape Reykjanes, but no attempt has been made to work the mine. Coal has also been found in one place, but has not been worked. There are considerable quantities of lignite, called in Icelandic surtarbrandur, in the north-west peninsula; some successful attempts have been made to use it as fuel, but it has not been worked to any extent. Peat is found, and is used as fuel, in most parts of the island.

Rivers. Iceland is rich in streams and rivers, some of them carrying a large volume of water; as, however, the fall is steep in every case, they are not navigable even by small boats. The longest are Þjórsá, running southwards from the central highlands, and Skjálfandafljót and Jökulsá á Fjöllum in the north-east, running northward. The last-named river is 113 miles in length, the other two 108 miles each. Of other rivers may be mentioned the Hvítá, part of which is called Ölfusá, running nearly parallel with Þjórsá, Hvítá in Borgarfjörður, Blanda running into Húnaflói, Héraðsvötn in Skagafjörður, and Lagarfljót in the east. There are several rivers named Hvítá (white river), so called from their milky waters, caused by the glacial mixtures carried down from the highlands. The principal waterfalls are—Skógafoss and Seljalandsfoss, south of Eyafjallajökull, Godafoss in Skjálfandafljót, and Dettifoss in Jökulsá á Fjöllum. Of the lakes Þingvallavatn, about 25 miles north-east of Reykjavík, and Mývatn in the north-east of Iceland are the largest. The former is 25 miles in circumference, and the latter 36 miles; its waters are studded with thirty-four small islands, affording breeding-places to a large number of water-fowl.

Climate. The climate of Iceland is not nearly so severe as might be supposed from the latitude. At Reykjavík the mean temperature of the year is 39° Fahr., of the summer 53° and of the winter 29° 18′. The temperature of Akureyri is 32° for the year, that of the summer 45° 5′ and the winter 20° 7′. There is therefore great difference between the north and the south of the island. Another difference may also be noticed; while the climate of the south is wet and variable, that of the north is dry and regular. The mean temperature of different years sometimes varies as much as 10°, and the mean temperature of the same month has been known to vary as much as 27°. One feature in the climate has been noticed by all travellers, that is, the clearness and purity of the atmosphere, rivalling that of Italy, mountains being seen distinctly at a distance of 100 miles. The rainfall is considerable in the south and the east of the island, and snow-storms and gales are frequent in winter. Thunderstorms occur mostly in winter.

Vegetation. No cereal is grown in Iceland, but in some places there is found a kind of wild oats (*Avena arenaria*), called in Icelandic "melur." Potatoes, carrots, turnips, and several kinds of cabbage have lately been cultivated with considerable success. The grasses, wild and cultivated, are of the greatest importance to the inhabitants. The only trees found are the dwarf birch, rarely higher than 12 feet, and some willow and juniper bushes. The wild flora of Iceland is small and delicate, with bright bloom, the heaths being especially admired. Wild crowberries and bilberries are the only kind of fruit found in the island.

Animals. The only wild animal in Iceland is the fox, of which both white and blue varieties occur; they are hunted for their skins, and also because they often attack the sheep. The domestic animals are the cow, the horse, the sheep, the dog, and the cat. The cows are of a small breed, resembling English shorthorns in general, and especially Alderneys. The horses are also of a small breed, the average height being twelve hands; they are hardy and enduring; many of them are never housed, and forage for themselves as best as they can throughout the winter. They are exported to Great Britain in considerable numbers, for use in the coal mines. The sheep generally are of nearly the same size as the Scotch blackfaced sheep; they are not unfrequently seen with three or four horns. The genuine Iceland dog, with his pointed snout, short ears, curled tail, and short legs, has some resemblance to the Esquimaux dog and the Scotch collie. Reindeer were imported in the last century, but they fled to the mountains and became wild; they are now nearly extinct. There are said to be ninety different species of birds, fifty-four of them being water-fowl. The most remarkable of the birds of prey are the Icelandic falcon (*Falco islandicus*) and the eagle. The only game bird is the ptarmigan, which is brown in summer and white in winter. Of the water-fowl the eider duck is of the greatest importance on account of its valuable down; the killing of it is therefore forbidden by law. Immense numbers of gulls, puffins, and guillemots are seen near their breeding places on the small islands and on the cliffs round the coasts. The hooper, or whistling swan, is found in large numbers in Iceland. The sea round the coast teems with cod, haddock, holibut, and the basking shark; the fin-backed-whale and seals of various kinds are also met with, but in smaller numbers. In the lakes and rivers salmon and trout are caught in considerable quantities.

Tillage. As no corn is grown, there is no agriculture to speak of, and only a little spade husbandry connected with the cultivation of kitchen gardens, where potatoes, turnips, and carrots are grown. The area thus under cultivation covers, according to the latest official returns, about 215 English acres throughout the island. The cultivation of the soil in Iceland can hardly indeed be said to have been attempted; such experiments, however, as have been made, have given good hope of success. Around every farmhouse is a field called "tún," which is but rarely enclosed or fenced. This is the only part of the land which is cultivated at all, and all that is done there is to spread dung on the top of the soil in autumn and scrape it off in spring. Even this most primitive cultivation makes the grass twenty-five to fifty per cent. better than elsewhere. The haymaking season extends from the middle of July to the 20th of September. The grass is cut with small scythes, first in the home field, and then on the uncultivated grass-lands belonging to the farms. Many of the fishermen hire themselves to the farmers during the haymaking season; and during the fishing season the farmers send their servants to the sea-coast to fish.

Live stock. According to the latest official returns the cattle in the island numbered 20,378, the horses (ponies) 31,312, and the sheep 415,339. It is obvious, however, from the quantities of wool exported that the number of sheep must be at least double that stated in the returns.

Manufactures. The manufactures are confined to spinning, weaving, and knitting the wool of the sheep. A sort of tweed, called in Icelandic "vaðmál," is the principal clothing of the inhabitants. The spinning of the yarn is done by the women in winter, and almost every farm has an old-fashioned loom. In the north considerable quantities of jackets and stockings are knitted and exported.

Trade. The trade with Iceland is entirely in the hands of Danish traders and a few Icelanders—who mostly reside in Copenhagen. It consists almost entirely in exchange, or barter. The principal exports of the Icelanders are cod fish, about 6,000,000 lb annually; train oil, 9500 barrels; wool, 1,500,000 lb; eider down, 7000 lb; and feathers, 20,000 lb. Ponies are now exported to Scotland,—about 2000 a year; and a few cargoes of live sheep have been sent over during the last two years. All bread stuffs have to be imported, as well as groceries, spirits, wines, and beer, tobacco, salt, building materials, and other items. Since 1854 the trade has been open to all nations; but any vessel trading with Iceland had to take out a sea pass at the cost of 2s. 3d. per ton down to 1879, when this duty was abolished. On the other hand, a trifling duty has been laid on spirits and tobacco.

Communication. There being no roads in the island, but merely tracks trodden down by the feet of the ponies, there are no carts nor carriages of any description. In the firths boats are chiefly used for conveying goods and passengers; but all inland communication and conveyance is by ponies. These hardy animals carry each a burden of about 200 lb weight, under which they walk about 25 miles a day. All travelling is also on ponies; two are considered necessary for every traveller, and on them he can make from 30 to 40 miles a day.

Divisions. Formerly Iceland was divided into four quarters, the east, the south, the west, and north. Now the north and the east are united under one governor, and the south and the west under another. The island is further divided into 18 sýslur (counties), and these again into 169 hreppur (rapes) or poor law districts. Ecclesiastically Iceland constitutes one bishopric, divided into 20 deaneries, and these again into 290 parishes.

Government. Iceland is subject to the king of Denmark. According to the constitution granted to Iceland in 1874, the king shares the legislative power with the Al-thing, an assembly of 36 members, 30 of whom are elected by household suffrage, and 6 nominated by the king. The Al-thing meets every second year, and sits in two divisions, the upper and the lower. The upper division consists of the 6 members nominated by the king and 6 elected by the representatives of the people out of their own body. The lower division consists of the remaining 24 representative members.

The secretary for Iceland, who resides in Copenhagen, is responsible to the king and the Al-thing for the maintenance of the constitution, and he submits to the king for confirmation the legislative measures proposed by the Al-thing. The king appoints a governor-general, who is resident in the island and carries on the government on the responsibility of the secretary in Copenhagen. Under the governor-general (landshöfðingi) are two under governors, one for the south and west, another for the north and east. Under these are the sheriffs (sýslumenn), who act as tax gatherers, notaries public, and judges of first instance; the sheriff has in every "hreppur" an assistant, called "hreppstjóri." In every hreppur there is also a representative committee, consisting of from three to five members, who administer the poor laws, and look after the general concerns of the hreppur. These committees are controlled by the committees of the sýslur (county boards), and these again are under the control of the amtsráð (quarter board), consisting of three members.

Justice. The administration of justice is carried out in the first instance by the sheriffs. From the sheriff courts appeals lie to the superior court at Reykjavík, consisting of three judges. Appeals may be taken in all criminal cases and most civil cases from this court to the supreme court at Copenhagen.

The state church of Iceland is the Lutheran; and all the Icelanders, without exception, belong to it. One bishop and 141 clergymen minister to the spiritual wants of the islanders. The bishop is appointed by the king. The parishes are 290, but the livings are only 141, from which it may be seen that many ministers have to serve two, and some even three parishes. The king appoints some of the ministers, and the governor-general others, with the advice of the bishop. The ministers are paid partly from the revenues of church property, and partly from tithes.

luca- on.

The Icelanders have long been famous for their education and learning, and it is no exaggeration to say that in no other country is such an amount of information found among the classes which occupy a similar position. A child of ten unable to read is not to be found from one end of the island to another. A peasant understanding several languages is no rarity, and the amount of general information which they possess might be envied by many who have had greater facilities for acquiring knowledge. Till within the last few years there were no elementary schools in the island; all children were taught by their parents or near neighbours. Now a few elementary schools have been started, but their number is still too small to make any general difference in the education. For classical and general education there is a college at Reykjavík, with seven professors and about one hundred students. There is also a college for ministers, with three professors. The general physician of the island, assisted by two medical men, gives lectures to medical students; but those who propose to enter the legal profession have to attend the university of Copenhagen.

tional arac- istics.

There is less difference in the material prosperity of the Icelanders than in that of the inhabitants of more advanced countries. One does not find the abject poverty so often seen in large towns and among the agricultural population of some of the most civilized countries of Europe. On the other hand, wealthy men, or owners of extensive properties, are unknown, the richest man in Iceland deriving only £300 a year from his property. Although no abject poverty is seen, there are more paupers comparatively than in more populous countries, and the poor-rates in many parishes exceed all the other taxes put together. The Icelanders are often too liberal in granting relief, which in many cases breeds idleness, carelessness, and want of forethought. It is also to be noticed that in few countries is it so easy to live with as little labour as in Iceland. On account of the climate, out-of-door work cannot be conducted for more than five months of the year at most, but even this time is not used with so much energy and skill as it might be. The haymaking, carried on for two months in the year, is the only work which is prosecuted with anything like energy. Fishing is prosecuted not continuously but periodically. The want of activity among the Icelanders is to be ascribed partly to their slow temperament, and partly to their utter want of training. They are very fond of gathering any amount of miscellaneous information, but their want of training prevents them from turning it to practical account. There is no doubt that they are endowed with intellectual faculties of a superior kind, and, with proper training, might make far more of their country than they do at present. It appears that the island could easily support eight times the number of the present population, if its resources were properly developed. Crime is rare; and the moral character of the Icelanders is about the same as that of the other countries of the north.

The census of 1870 returned the population of the island as 69,763. In 1801 the population was only 46,240: in 1880 it is estimated to have increased to 73,000. The birth-rate is about 33 per thousand, and the death-rate 24. Nearly the whole of the population live on isolated farms, the number of each family, including servants, being on an average seven. The chief town or village is Reykjavík, with about 2500 inhabitants. It is the seat of the governor-general, the bishop, the colleges, and the superior court. In the north-west is Ísafjörður, with about 400 inhabitants, and in the north Akureyri, with the same number. (J. A. H.)

Table of Icelandic Literature and History.

		I. *The Commonwealth.* 400 *years.*	
Heroic Age.	870–930	Poetry of Western Islands.	Settlement by colonists from Western Isles and Norway.
	930–980	Early Icelandic poets, chiefly abroad.	Constitution worked out—Events of earlier sagas take place.
	980–1030	Icelandic poets abroad.	Christianity comes in—Events of later sagas take place.
Saga Telling.	1030–1100	*First era of phonetic change.*	Peace—Ecclesiastical organization.
The Literary Age.	1100–1150	ARI and his school—THORODD—Vernacular writing begins.	
	1150–1220	SAGA-WRITERS—Second generation of historians.	First civil wars, 1208–22—Rise of Sturlungs.
	1220–1248	SNORRI and his school—Biographers.	Second civil wars, 1226–58—Fall of Great Houses.
	1248–1284	STURLA—*Second era of phonetic change.*	Change of law, 1271—Submission to Norwegian kings.
		II. *Mediævalism.* 250 *years.*	
Continental Influence, chiefly Norse.	1284–1320	Collecting and editing—Foreign romances.	Foreign influence through Norway.
	1320–1390	Annalists—Copyists—New Mediæval poetry begins.	Great eruptions, 1362 and 1389—Epidemics—Danish rule, 1380.
	1390–1413	Death of old traditions, &c.	Epidemics—Norse trade—Close of intercourse with Norway.
Dark Age.	1413–1530	Only Mediæval poetry flourishes.	Isolation from Continent—English trade.
		III. *Reformation—Absolute Rule—Decay.* 320 *years.*	
Reformation.	1530–1575	ODD—Printing—*Third era of phonetic change.*	Religious struggle—New organization—Hanse trade.
Renaissance.	1575–1610	First antiquarians.	Danish monopoly—Pirates' ravages.
	1610–1700	HALLGRIM—Paper copies taken.	
Gradual Decay.	1700–1730	JON WIDALIN—Arni Magnusson—MSS. taken abroad.	Increasing decay. Small-pox kills one-third population, 1707.
	1730–1768	Eggert Olafsson.	Great famine, 10,000 die, 1759—Sheep plague, 1762—Eruption, 1765.
	1768–1800	Finn Jonsson—Icelandic scholars abroad.	Great eruption, 1783.
	1800–1850	Rationalistic movement—European influences first felt.	Beginnings of recovery—Travellers make known island to Europe—Free constitution in Denmark, 1848
		IV. *Modern Iceland.*	
Recovery of Iceland.	1850–1874	Modern thought and learning—Icelandic scholars abroad.	Increasing wealth and population—Free trade, 1854—Jon Sigurdsson and home rule struggle—Emigration.
	1874		Home rule granted

HISTORY.

With its isolated situation, inclement climate, scant natural advantages, and sparse population, Iceland is yet of high interest to the historian, philologist, and *littérateur*. To the first the excellence and exactitude of its historical records, the curious phases of life to which they bear witness, and the singular circumstances which have determined the existence and life of the Teutonic community for a thousand years apart from the rest of the European family, are all attractive. By the philologist the island is reverenced as the home of a tongue which (though like our own it has suffered deep phonetic change) yet most nearly represents in a living form the tongue of our earliest Teutonic forefathers. And by many more than these students Iceland is fondly regarded as the land where, long before the "literary eras" of England or Germany, a brilliant period of intellectual life produced and elaborated in its own distinct form of expression a literature superior to any north of the Alps before the Renaissance since the downfall of Old Rome in power, purity, and life.

Settlement.

To begin with history, in which we are chiefly concerned with the first and fourth periods of the island's inhabited existence, and first the "settlement." Shortly after the discovery of Iceland by the Scandinavian, *c.* 850 (it had long been inhabited by a small colony of Irish Culdees), a stream of immigration set in towards it, which lasted for sixty years, and resulted in the establishment of some 4000 homesteads scattered round the habitable fringe about the great bays and firths.

In this immigration three distinct streams can be traced. (1) About 870–890 four great noblemen from Norway, Ingolf, Ketil Hæng, Skalla-Grim, and Thorolf, settled with their dependants in the south-west of the new found land. (2) In 890–900 there came from the Western Islands Queen Aud, widow of Olaf the White, king of Dublin, preceded and followed by a number of her kinsmen and relations (many like herself being Christians), Helgi Biolan, Biorn the Eastern, Helgi the Lean, Ketil the Foolish, &c., who settled the best land in the island (west, north-west, and north), and founded families who long swayed its destinies. Besides this most important immigration of all there came from the Western Islands a fellowship of vikings seeking a free home in the north. They had colonized the west in the viking times; they had "fought at Hafursfirth," helping their stay-at-home kinsmen against the centralization of the great head-king, who, when he had crushed opposition in Norway, sailed after these turbulent colonists across the North Sea, and followed up his victory by compelling them to bow to his rule or fly again to fresh haunts whence they could not so easily interfere with his projects. Such were Ingimund the Old, Geirmund Hellskin, Thord Beardie (who had wed St Edmund's grand-daughter), Audun Shackle, Bryniulf the Old, Uni, to whom Harold promised the earldom of the new land if he could make the settlers acknowledge him as king, a hopeless project, and others by whom the north-west, north, and east were almost completely "claimed." (3) In 900–930 a few more incomers direct from Norway completed the settlement of the south, north-east, and south-east. Among them were Earl Hrollaug (half brother of Hrolf Ganger and of the first earl of Orkney), Hialti, Hrafnkell Frey's priest, and the sons of Asbiorn. Fully three quarters of the land was settled from the west, and among these immigrants there was no small proportion of Irish blood. In 1100 there were 4500 franklins, *i.e.*, about 50,000 souls.

Organization.

The unit of Icelandic politics is the homestead with its franklin-owner (*buendi*), its primal organization the hundred-moot (*thing*), its tie the *gođorđ* or chieftainship. The chief who had led a band of kinsmen and dependants to the new land, taken a "claim" there, and parcelled it out freely among them, naturally became their leader, presiding as priest at the temple feasts and sacrifices of heathen times, acting as president and speaker of their moot, and as their responsible representative towards the neighbouring chiefs and their clients. He was not a feudal lord nor a local sheriff, for any franklin could change his gođorđ when he would, and the rights of "judgment by peers" were in full use; moreover, the office could be bequeathed, sold, divided, or pledged by the possessor; still the gođi had considerable power and influence as long as the commonwealth lasted.

At first there was no higher organization, but disputes between neighbouring chiefs and their clients, and uncertainty as to the law, brought about the *Constitution of Ulfliot*, *c.* 930, which appointed a central moot for the whole island, the Al-thing, and a speaker to speak a single "law" (principally that followed by the Gula-moot in Norway); the *Reforms of Thord Gellir*, 964, settling a fixed number of local moots and chieftaincies, dividing the island into four quarters (thus characterized by Ari:—north, thickest settled, most famous; east, first completely settled; south, best land and greatest chiefs; west, remarkable for noble families), to each of which a head-court, the "quarter-court," was assigned; and the *Innovations of Skapti* (ascribed in the saga to Nial) *the Law-Speaker* (d. 1030), who set up a "fifth court" as the ultimate tribunal in criminal matters, and strengthened the community against the chiefs. But here constitutional growth ceased: the law-making body made few and unimportant modifications of custom; the courts were still too weak for the chiefs who misused and defied them; the speaker's power was not sufficiently supported to enable him to be any more than a highly respected lord chief justice, whereas he ought to have become a *justiza* if anarchy was to be avoided; even the ecclesiastical innovations, while they secured peace for a time, provoked in the end the struggles which put an end to the commonwealth.

Christianity was introduced *c.* 1000. Tithes were established in 1096, and an ecclesiastical code made *c.* 1125.

The first disputes about the jurisdiction of the clergy were moved by Gudmund in the 13th century, bringing on a civil war, while the questions of patronage and rights over glebe and mortmainland occupied Bishop Arni and his adversaries fifty years afterwards, when the land was under Norwegian viceroys and Norwegian law. For the civil wars of the 13th century broke down and exterminated the great houses who had monopolized the chieftaincies and abused their power for their own ends; and after violent struggles (in which the Sturlungs of the first generation perished at Orlygstad, 1238, and Reykiaholt, 1241, while of the second generation Thord Kakali was called away by the king in 1250, and Thorgils Skardi slain in 1258) the submission of the island, quarter after quarter, took place in 1262–64, under Gizur's auspices, and the old Common Law was replaced by the New Norse Code "Ironside" in 1271.

The political life and law of the old days is abundantly illustrated in the sagas (especially Eyrbyggia, Hænsa-Thori, Reyk-dæla, Hrafnkell, and Niala), the two collections of law-scrolls (*Codex Regius*, *c.* 1235, and *Stadarhol's Book*, *c.* 1271), the Libellus, the Liber-fragments, and the Landnamabok of Ari, and the Diplomatarium. K. Maurer has made the subject his own in his *Beiträge*, *Island*, *Grágás*, &c.

The mediæval Icelandic church had two bishoprics, Skalholt (S., W., and E.) 1056, and Holar (N.) 1106, and about 175 parishes (two-thirds of which belonged to the southern bishopric). They belonged to the metropolitan see of Bremen, then to Lund, lastly to Nidaros, 1237. There were several religious foundations: Thingore (founded 1133), Thwera (1155), Hitardale (*c.* 1166), Kirkby Nunnery (1184), Stad Nunnery (1296), and Saurby (*c.* 1200) were Benedictine, while Ver (1168), Flatey after Holyfell (1172), Videy (1226), Madderfield Priory (1296), and Skrid Priory (14th century) were Augustinian. The bishops, elected by the people at the Al-thing till 1237, enjoyed considerable power and influence, and were most of them distinguished men; two, Thorlak of Skalholt and John of Holar, were publicly voted saints at the Al-thing after due examination of their claims to that distinction, and one, Gudmund, received the title of "Good" by decree of the bishop and chapter. Full details as to ecclesiastical history will be found in the *Bishops' Lives* (edited by Dr Vigfusson).

Mode of life.

Iceland was not agricultural but pastoral, depending upon flocks and herds for subsistence, for, though rye and other grain would grow in favoured localities, the hay, self-sown, was the only regular crop. In some districts the fisheries and fowling were of importance, but nine-tenths of the population lived by their sheep and cattle, which gave them food, clothing, and such products for export as enabled them to import wood for building, iron for tools, and a few luxuries, as honey, wine, grain for brewing, and foreign clothes, fur, &c. Life on each homestead was regularly portioned out:—out-door occupations—fishing, shepherding, fowling, and the important hay-making and fuel-gathering—occupying the summer; while in-door business—weaving, tool-making, &c., filled up the long winter. The year was broken by the spring feasts and moots, the great Al-thing meeting at midsummer, the marriage and arval gatherings after the summer, and the long yule feasts at midwinter. There were but two degrees of men, free and unfree, though only the franklins had any political power; and, from the very nature of the life, social intercourse was peculiarly unrestrained and unfettered; gođi and thrall lived the same lives, ate the same food, spoke the same tongue, and differed little in clothing or habits. The poorest franklin was the social equal of the proudest chief, and in a few generations the freed man or landless dependant might become their peer in public estimation, provided he got a homestead of his own. The thrall had a house of his own and was rather villein or serf than slave, having rights and a legal price by law. During the heathen days many of the great chiefs passed part of their lives in Norway at the king's court, but after the establishment of Christianity in Iceland they kept more at home, still visiting the Continent, however, for purposes of state, suits with clergy, &c. But the trade was from the first in foreign (Norse) hands almost entirely.

The introduction of a church system brought little change. The great families put their members into orders, and so continued to enjoy the profits of the land which they had given to the church; the priests married and otherwise behaved like the franklins around them in every-day matters, farming, trading, going to law like laymen; so that, in spite of the efforts of the more earnest church reformers, the church was powerless to promote centralization against the feuds and jealousies of the great houses.

Effects of the union and change of law.

The old life in the commonwealth was turbulent and anarchic, but free and varied; it produced men of mark, and fostered bravery, adventure, and progress. The great chiefs were indeed only greater franklins; but their wealth and comparative luxury gave them leisure and opportunities for culture which raised them as examples and leaders above their fellows; the pride of birth preserved a nobility of feeling and high standard of honour amid much of violence and chicane. But all this now ceased, and there was left but a low dead level of poor peasant proprietors without pride in the past, political interest in the present, or ambition of the future, careless of all save how to live by as little labour as possible, and pay as few taxes as they could to their foreign rulers. The island received a foreign governor (*Earl*, *Hirdstjori*, or *Stiptamtsmadr* as he has been successively called), and was parcelled out into local counties (*syslur*), administered by sheriffs (*syslumadr*) appointed by the king. A royal court took the place of the Al-thing courts;

the local business of the local things was carried out by the (*hreppstjori*) bailiff, a subordinate of the sheriff; and the goðorð, things, quarter-courts, trial by jury, &c., were all completely swept away by these innovations, which have continued with mere changes of detail till the present century. The power of the crown was increased by the confiscation of the great Sturlung estates, which were under-leased to farmers, while the early falling off of the Norse trade threatened to deprive the island of the means of existence; for the great epidemics and eruptions of the 14th century had gravely attacked its pastoral wealth and ruined much of its pasture and fishery, for the time at least. The union of the Three Crowns transferred the practical rule of Iceland to Denmark in 1280, and the old Treaty of Union, by which the island had reserved its essential rights, was disregarded by the absolute Danish monarchs; but, though new taxation was imposed, it was rather their careless neglect than their too active interference that damaged Iceland's interests. But for an English trade, which sprung up out of the half-smuggling, half-buccaneering enterprise of the Bristol merchants, the island would have fared badly indeed, for during the whole 15th century their trade with England, exporting sulphur, eider down (which the English taught them the value of), wool, and salt stock-fish, and importing as before wood, iron, honey, wine, grain, and flax goods, was their only link with the outer world. This period of Iceland's existence is torpid and eventless: she had got peace but with few of its blessings; all spirit seemed to have died with the commonwealth; even shepherding and such agriculture as there had been sank to a lower stage; waggons, ploughs, and carts went out of use and knowledge; architecture in timber became a lost art, and the fine carved and painted halls of the heathen days were replaced by turf-walled barns half sunk in the earth, and lasting at best a generation; the large decked luggers of the old days gave way to small undecked fishing-boats; it is needless to add that letters were neglected, and that all remembrance of the commonwealth perished utterly.

ıe Re- rma- on.

The Reformation here as elsewhere had a one-sided effect: it wakened men's minds, opening new vistas of hope and new fields of thought, but it left their bodies and circumstances little changed, or, if at all, for the worse. Its necessary complement, a social and political revolution, never came to Iceland. The Hanse trade replaced the English for the worse; and the wretched Danish monopoly which succeeded it when the Danish kings began to act again with vigour, under the stimulus of European changes, was still less profitable. The glebes and hospital lands were a fresh power in the hands of the crown, and the subservient Lutheran clergy became the most powerful class in the island, while the bad system of under-leasing at rackrent and short lease with unsecured tenant right extended in this way over a great part, at least a quarter, of the better land, stopping any possible progress. The details of the religious change are uninteresting: nearly all who took active part in it on either side were men of low type, moved by personal motives rather than religious zeal; and, though it should be noticed that the fires of martyrdom were never lighted in Iceland, the story of the easily accepted Reformation is not altogether a pleasant one. When it was once accomplished, the little knot of able men who came to the front for two or three generations, stirred by the new life that had been breathed into the age, did nobly in preserving the records of the past for a later time to value and appreciate, while Odd and Hallgrim exhibit the noblest impulses of their time.

ecad- ce.

A new plague, that of the English, Gascon, and Algerine pirates, marked the close of the 16th century and opening of the 17th, causing widespread panic and some devastation in 1579, 1613–16, and 1627. Nothing points more to the helplessness of the natives' condition than their powerlessness against these tiresome foes. But the 18th century is the most gloomy in Iceland's annals. Small-pox, famine, sheep disease, and the awful eruptions of 1765 and 1783 follow each other in terrible succession. Against such fearful visitations, which reduced the population by about a fourth, little could be done, and when the only man who might have roused the Icelanders from their misery, distress, and impoverishment, the noble and patriotic Eggert Olafsson, a hero of the old type, was drowned in full career in 1768, it is hardly to be wondered at that things grew from bad to worse, and that a listlessness and torpidity crept over the national character, the effects of which it is only beginning to shake off. The few literary men, whose work was done and whose books were published abroad, were only concerned with the past, and Jon Widalin is the one man of mark, beside Eggert Olafsson, who worked and wrote for his own generation.[1]

odern mes.

Gradually the ideas which were agitating Europe crept through Scandinavia into Iceland, and, now that scholars and travellers of mark and influence had drawn attention to the island, its claims were more respectfully listened to. The Continental system, which, by its leading to the blockade of Denmark, threatened to starve Iceland, was neutralized by special action of the British Government. Trade and fishery grew a little brisker, and at length the turn came.

The rationalistic movement, an unlovely attempt at reform, headed by Magnus Stephenson, a patriotic, narrow-minded lawyer, did little good as far as church reform went, but was accompanied by a more successful effort to educate the people by means of bringing within their reach the practical knowledge of the day. A Useful Knowledge Society, such as Brougham delighted in, was formed and did some honest work. Newspapers and periodicals were published, and the very stir which the ecclesiastical disputes encouraged did good. When free trade came, and when the free constitution of Denmark had produced its legitimate effects, the intelligent and able endeavours of a few patriots such as Jon Sigurdsson were able to push on the next generation a step further, in spite of such physical obstacles as the sheep disease. Questions of a modern political complexion arose; the cattle export controversy and the great home rule struggle began. The intelligence of a people whose love for knowledge and mental attainments have always been high seconded its leaders well, and after thirty years' agitation home rule was conceded in 1874. The absolute *syslumadr* and *hirdstjori* became popular officials assisted by elected boards. The *Al-thing*, a mere council of powerless delegates, was replaced by a representative assembly of two chambers (composed of thirty members chosen by a a popular and wide suffrage, and six crown nominees) with legislative powers, and other reforms were comprised in this grant. Further political changes, such as the introduction of a jury system to replace the Danish umpire-and-assessor procedure, are now being considered by the liberal party. There are many peculiar circumstances present in the condition of Iceland, the absence of towns, equality of society in a sense which exists in no other European community, difficulty of communication, and the intense conservatism and dislike of activity or change which must necessarily characterize a community so long isolated and "forced into lazy habits for lack of opportunity." But that emigration should have begun, and families left the old home for Canada and the United States to seek a better climate, a richer soil, and the hopes of progress which are so distant at home, is certainly remarkable; and, if the difficulties which must surround emigrants who have never seen a road, a tree, or a plough, on their first taking up an agricultural life, are overcome, the results may be very important to the mother country.

Literature.

Poetry

Poetry.—Iceland has always borne a high renown for song, but has never produced a poet of the highest order, a fact for which one can only account by noticing that the qualities which in other lands were most sought for and admired in poetry were in Iceland lavished on the saga, a prose epic, and that Icelandic poetry is to be rated very high for the one quality which its authors have ever aimed at—melody of sound. To these generalizations there are but few exceptions, albeit, in considering the history of this branch of Icelandic literature, we are at once met by an apparent contradiction to them, a group of poems which possess the very qualities of high imagination, deep pathos, fresh love of nature, passionate dramatic power, and noble simplicity of language which Icelandic poetry lacks. The solution is that these poems do not belong to Iceland at all. They are the poetry of the "Western Islands."

Poetry of the Westei Islands

It was among the Scandinavian colonists of the British coasts that in the first generations after the colonization of Iceland therefrom a magnificent school of poetry arose, to which we owe works that for power and beauty can be paralleled in no Teutonic language till centuries after their date. To this school, which is totally distinct from the Icelandic, ran its own course apart, and perished before the 13th century, the following works belong (of their authors we have scarcely a name or two; their dates can be rarely exactly fixed; but they lie between the beginning of the 9th and the end of the 10th centuries), classified into groups:—

a. The *Helgi* trilogy (last third lost save a few verses, but preserved in prose in *Hromund Gripsson's Saga*), the *Raising of Anganty* and *Death of Hialmar* (in *Hervarar Saga*), the fragments of a *Wolsung Lay* (part interpolated in earlier poems, part underlying the prose in *Volsunga Saga*), all by one poet, to whom Dr Vigfusson would also ascribe *Völuspá*, *Vegtamskriða*, *Thrymskviða*, *Grötta Song*, and *Volundar-kriða*.

b. The Dramatic Poems:—*Flyting of Loki*, the *Lay of Skirni*, the *Lay of Harbard*, and several fragments, all one man's work, to whose school belong, probably, the *Lay* underlying the story of Ivar's death in *Skioldunga Saga*.

c. The Didactic Poetry:—*Grimnismal*, *Vafthrudnismal*, *Alvismal*, &c.

d. The Genealogical and Mythological Poems:—*Hyndla-Lioð*, written for one of the Haurda-Kari family, so famous in the Orkneys; *Ynglinga-tal* and *Haust-löng*, by Thiodulf of Hvin; *Rig's Thul*, &c.

e. The Dirges and Battle Songs,—such as that on *Hafur-firth Battle*, by Thiodulf of Hvin or Hornklofi, shortly after 870; *Eirik's Dirge*, between 950 and 969; the *Dart-Lay on Clontarf Battle*, 1014; *Biarka-mal* (fragments of which we have, and paraphrase of more is found in *Hrolf Kraki's Saga* and in Saxo).

There are also fragments of poems in *Half's Saga*, *Asmund Kappa-Bana's Saga*, in the Latin verses of Saxo, and the *Shield Lays* by

[1] For the periods succeeding the union, Danish state papers and the *History* of Finn Jonsson are the best authority.

Bragi, &c., of this school, which closes with the *Sun-Song*, a powerful Christian Dantesque poem, recalling some of the early compositions of the Irish Church, and with the 12th century *Lay of Ragnar*, *Lay of Starkad*, *The Proverb Song* (*Havamal*), and *Krakumal*, to which we may add those singular Gloss-poems, the *Thulur*, which also belong to the Western Isles.

Poetry of Greenland.

To Greenland, Iceland's farthest colony, founded in the 10th century, we owe the two *Lays of Atli*, and probably *Hymiskriða*, which, though, as was to be expected, of a weirder harsher cast, yet belong to the Western Isles school and not to Iceland. In form all these poems belong to two or three classes:—*kriða*, an epic "cantilena"; *tal*, a genealogical poem; *drapa*, songs of praise, &c., written in modifications of the old Teutonic metre which we know in Beowulf; *galdr* and *lokkr*, spell and charm songs in a more lyric measure; and *mal*, a dialogue poem, and *liod*, a lay, in elegiac measure suited to the subject.

The characteristics of this Western school are no doubt the result of the contact of Scandinavian colonists of the viking-tide, living lives of the wildest adventure, tossed by war and storm, with an imaginative and civilized race, that exercised upon them a very strong and lasting influence (the effects of which were also felt in Iceland, but in a different way). The frequent intermarriages which mingled the best families of either race are sufficient proof of the close communion of Northmen and Celts in the 9th and 10th centuries, while there are in the poems themselves traces of Celtic mythology, language, and manners.[1]

Poetry of the commonwealth.

When one turns to the early poetry of the Scandinavian continent, preserved in the rune-staves on the memorial stones of Sweden, Norway, and Denmark, in the didactic *Havamal*, the *Great Wolsung Lay* (*i.e.*, Sigurd II., Fafnis's Lay, Sigrdrifa's Lay), and *Hamdismal*, all continental, and all entirely consonant to the remains of our own Old English poetry in metre, feeling, and treatment, one can see that it is with this school that the Icelandic "makers" are in sympathy, and that from it their verse naturally descends. The only difference between them is that, while the fundamental characteristics of shrewdness, plain straightforwardness, and a certain stern way of looking at life are common to both, the Icelandic school adds a complexity of structure and ornament, an elaborate mythological and enigmatical phraseology, and a regularity of rhyme, assonance, luxuriance, quantity, and syllabification, which it caught up from the Latin and Celtic poets, and adapted with exquisite ingenuity to its own main object, that of securing the greatest possible beauty of sound.

The first generations of Icelandic poets were very remarkable men, and resemble in many ways the later troubadours; the books of the kings and the sagas are full of their strange lives. Men of good birth (nearly always, too, of Celtic blood on one side at least), they leave Iceland young and attach themselves to the kings and earls of the north, living in their courts as their henchmen, sharing their adventures in weal and woe, praising their victories, and hymning their deaths if they did not fall by their sides—men of quick passion, unhappy in their loves, jealous of rival poets and of their own fame, ever ready to answer criticism with a satire or with a sword-thrust, but clinging through all to their art, in which they attained most marvellous skill.

Such men were Egill, the foe of Eirik Bloodaxe and the friend of Æthelstan; Kormak, the hot-headed champion; Eyvind, King Hakon's poet, called Skaldspoiler, because he copied in his dirge over that king the older and finer *Eiriks-mal*; Gunnlaug, who sang at Æthelred's court, and fell at the hands of a brother bard Hrafn; Hallfred, Olaf Tryggvason's poet, who lies in Iona by the side of Macbeth; Sighvat, Saint Olaf's henchman, most prolific of all his comrades; Thormod, Coalbrow's poet, who died singing after Sticklestad battle; Ref, Ottar the Black, Arnor the earls' poet, and, of those whose poetry was almost confined to Iceland, Gretti, Biorn the Hitdale champion, and the two model Icelandic masters, Einar Skulason and Markus the Lawman, both of the 12th century.

It is impossible to do more here than mention the names of the most famous of the long roll of poets which are noted in the works of Snorri and in the two *Skalda-tal*. It is evident that they must differ greatly in style and tone, as they range from the rough and noble pathos of Egill, the mystic obscurity of Kormak, the pride and grief of Hallfred, and the marvellous fluency of Sighvat, to the florid intricacy of Einar and Markus.

The art of poetry, which stood to the Icelanders in lieu of music, was, and is still, much cultivated in the island; scarcely any prominent man but knew how to turn a mocking or laudatory stanza, and down to the fall of the commonwealth the accomplishment was in high request. In the literary age the chief poets belong to the great Sturlung family, Snorri and his two nephews, Sturla and Olaf, the White Poet, being the most famous "makers" of their day. Indeed, it is in Snorri's *Edda*, a poetic grammar of a very perfect kind, that the best examples of the whole of northern poetry are to be found. The last part, *Hattatal*, a treatise on metre, was written for Earl Skuli about 1222, in imitation of Earl Rognvald and Hall's *Hattalykill* (*Clavis metrica*), of 1150. The second part, *Skaldskapar-mal*, a gradus of synonyms and epithets, which contains over 240 quotations from 65 poets, and 10 anonymous lays,—a treasury of verse—was composed *c.* 1230. The first part, an exquisite sketch of northern mythology, *Gylfa-ginning*, was probably prefixed to the whole later.[2] There is some of Sturla's poetry in his *Islendinga Saga*, and verses of Snorri occur in the *Grammatical Treatise* on figures of speech, &c., of Olaf, which contains about one hundred and forty quotations from various authors, and was written about 1250.

Besides those sources, the *Kings' Lives* of Snorri and later authors contain a great deal of verse by Icelandic poets. King Harold Sigurdsson, who fell at Stamford Bridge 1066, was both a good critic and composed himself. Many tales are told of him and his poet visitors and henchmen. The Icelandic sagas also comprise much verse which is partly genuine, partly the work of the 12th and 13th century editors. Thus there are genuine pieces in *Nial's Saga* (chaps. 34, 78, 103, 126, 146), in *Eyrbyggia*, *Laxdæla*, *Egil's Saga* (part only), *Grettla* (two and a half stanzas, *cf. Landnamabok*), *Biorn's Saga*, *Gunnlaug's Saga*, *Havard's Saga*, *Kormak's Saga*, *Viga-Glum's Saga*, *Erik the Red's Saga*, and *Fostbrædra Saga*. In *Nial's*, *Gisli's*, and *Droplaug's Sons' Sagas* there is good verse of a later poet, and in many sagas worthless rubbish foisted in as ornamental wherever there was a chance of doing so.

To these may be added two or three works of a semi-literary kind, composed by learned men, not by heroes and warriors. Such are *Konunga-tal*, *Hugsvinnsmal* (a paraphrase of Cato's Distichs), *Merlin's Prophecy* (paraphrased from Geoffrey of Monmouth by Gunnlaug the monk), *Jomsviking -drapa* (by Bishop Ketil), and the *Islendinga-drapa*, which has preserved brief notices of several lost sagas concerning Icelandic worthies, with which *Gudmundar-drapa*, though of the 14th century, may be also placed.

Mediæval poetry.

Just as the change of law gave the death-blow to an already perishing commonwealth, so the rush of mediæval influence, which followed the union with Norway, merely completed a process which had been in force since the end of the 11th century, when it overthrew the old Icelandic poetry in favour of the Rimur.

The introduction of the *Danz*, ballads (or *fornkvædi*, as they are now called) for singing, with a burden, usually relating to a love-tale, which were immensely popular with the people and performed by whole companies at weddings, yule feasts, and the like, had relegated the regular Icelandic poetry to more serious events or to the more cultivated of the chiefs. But these "jigs," as the Elizabethans would have called them, dissatisfied the popular ear in one way: they were, like our own old ballads, which they closely resembled, in rhyme, but void of alliteration, and accordingly they were modified and replaced by the "Rimur," the staple literary product of the 15th century. These were rhymed but also alliterative, in regular form, with prologue or *mansong* (often the prettiest part of the whole), main portion telling the tale (mostly derived in early days from the French romances of the Carlovingian, Arthurian, or Alexandrian cycles, or from the mythic or skrök-sögur), and epilogue. Their chief value to us lies in their having preserved versions of several French poems now lost, and in their evidence as to the feelings and bent of Icelanders in the "Dark Age" of the island's history. The ring and melody which they all possess is their chief beauty.

Of the earliest, *Olafsrima*, by Einar Gilsson (*c.* 1350), and the best, the Aristophanic *Skida-rima* (*c.* 1430), by Einar Fostri, the names may be given. Rimur on sacred subjects was called "Diktur"; of these, on the legends of the saints' lives, many remain. The most notable of its class is the *Lilia* of Eystein Asgrimsson, a monk of Holyfell (*c.* 1350), a most "sweet sounding song." Later the poems of the famous John Arason, last Catholic bishop of Holar (*c.* 1530), *Liomr* ("Gleam") and *Píslargrátr* ("Passion-tears"), deserve mention.

Taste has sunk since the old days; but still this Rimur poetry is popular and genuine, and in such hard and evil days as came upon Iceland after the fall of the old houses had destroyed such traditional history and civilization as had fostered the saga, it is perhaps rather a wonder that the torch was still alight than that its glimmer was feeble and smoky. Moreover, the very prosaic and artificial verse of Sturla and the last of the old school certainly deserved the oblivion which came over them, as a casual perusal of the stanzas scattered through *Islendinga* will surely prove. It is interesting to notice that a certain number of *kenningar* (poetical paraphrases) have survived from the old school even to the present day, though the mass of them have happily perished. The change in the *phonesis*

[1] Many of these poems were Englished in prose by the translator of Mallet, by B. Thorpe in his *Sæmund's Edda*, and two or three by Messrs Morris and Magnussen, as appendices to their translation of *Volsunga Saga*. Earlier translations in verse are those in Dryden's *Miscellany* (vol. vi.), A. Cottle's *Edda*, Mathias's *Translations*, and W. Herbert's *Old Icelandic Poetry*. Gray's versions of *Darradar-liod* and *Vegtamskrida* are well known.

[2] This prose *Edda* (from which the *Eddic Lays* got their name) has been partly turned into English by Sir G. W. Dasent, by the translator of Mallet, and by Mr Anderson, and will be found treated of more at length under EDDA. Mallet's *Northern Mythology*, a book which first drew Englishmen's attention to the religious ideas of their forefathers, is not to be depended on in any way, belonging, as it does, to the pre-scientific age. Bunsen's speculations at a later date are entirely fanciful and visionary.

of the language is well illustrated by the new metres as compared with the old Icelandic *Drott-kvædi* in its varied forms. Most of the older Rimur and Diktur are as yet unprinted. Many of the *fornkvædi* are printed in a volume of the old *Nordiske Literatur-Samfund*.

for- tion riod.

The effects of the Reformation was deeply felt in Icelandic literature, both prose and verse. The name of Hallgrim Petersen, whose *Passion-hymns*, "the flower of all Icelandic poetry," have been the most popular composition in the language, is foremost of all writers since the Second Change of Faith. The gentle sweetness of thought, and the exquisite harmony of wording in his poems, more than justify the popular verdict. His *Hymns* were finished in 1660, and published in 1666, two great Protestant poets thus being contemporaries. A collection of Reformation hymns, adapted, many of them, from the German, the *Holar-book*, had preceded them in 1619. There was a good deal of verse-writing of a secular kind, far inferior in every way, during this period. In spite of the many physical distresses that weighed upon the island, ballads (*fornkvædi*) were still written, ceasing about 1750, Rimur composed, and more elaborate compositions published.

The most notable names are those of the improvisatore Stephen the Blind; Thorlak Gudbrandsson, author of *Ulfar-Rimur*, d. 1707; John Magnusson, who wrote *Hristafla*, a didactic poem; Stefan Olafsson, composer of Psalms, Rimur, &c., d. 1688; Gunnar Pálsson, the author of *Gunnarslag*, often printed with the Eddic poems, *c.* 1791; and the famous Eggert Olafsson, traveller, naturalist, and patriot, whose untimely death in 1768 was a great loss to his country, which his energy and talents might have roused from its torpor. His *Bunadar-balkr*, a Georgic written, like Tusser's *Points*, with a practical view of raising the state of agriculture, has always been much prized. Paul Widalin's ditties are very naive and clever.

dern etry.

The Reformation had produced a real poet, but the material rise of Iceland has not yet done so. Many have written, but few have shown any great talent; perhaps the best has been Sigurd of Broadfirth, many of whose prettiest poems were composed in Greenland, like those of Jon Biarnisson before him, *c.* 1750; John Thorlaksson's translation of Milton's great epic into Eddic verse is praiseworthy in intention, but, as may be imagined, falls far short of its aim. He also turned Pope's *Essay on Man* and Klopstock's *Messiah* into Icelandic. Benedikt Gröndal tried the same experiment with Homer in his *Ilion's Kvædi*, *c.* 1825. There is a fine prose translation of the *Odyssey* by Sweinbiorn Egillson, the lexicographer, both faithful and poetic in high degree. Many poems of varying but little merit will be found in the periodicals of this and last century, the serious verse being pseudo-classic for the most part and falsetto in tone. The satiric verse, such as John Thorlaksson's on Magnus Stephenson's projects and "reforms," and the ditties on all kinds of *sujets d'occasion*, are better, but much of their meaning is lost to a stranger. With the latest school of poets who have begun to imitate foreign metres (unalliterative) and to translate foreign poets, it is hardly worth while to linger. A translation of Shakespeare and of several of Byron's poems may be noticed as curiosities. Of minor poetry there is still an abundant crop; even in Gimli, the far-off Canadian colony, "In Memoriam" verses and wedding-hymns of irreproachable form, but wooden thought, are printed and admired. That Iceland, most idyllic of modern lands, is capable of supplying subject and material for something higher than all this there is no doubt; but, before anything of real worth can be written, the old stock-in-trade of worn-out mythology and pseudo-patriotism must be thrown aside for ever.

e saga.

History and Biography.—The real strength of Icelandic literature is shown in its most indigenous growth, the "Saga." This is, in its purest form, the life of a hero, composed in regular form, governed by fixed rules, and intended for oral recitation. It bears the strongest likeness to the epic in all save its unversified form; in both are found, as fixed essentials, simplicity of plot, chronological order of events, set phrases used even in describing the restless play of emotion or the changeful fortunes of a fight or a storm, while in both the absence of digression, comment, or intrusion of the narrator's person is invariably maintained. The saga grew up in the quieter days which followed the Change of Faith (1002), when the deeds of the great families' heroes were still cherished by their descendants, and the exploits of the great kings of Norway and Denmark handed down with reverence from the mouths of those that had fought and sung by their side. Telling of stories was a recognized form of entertainment at all feasts and gatherings, and it was the necessity of the reciter which gradually worked them into a regular form, by which the memory was relieved and the artistic features of the story allowed to be more carefully elaborated. That this form was so perfect must be attributed to Irish influence, without which indeed there would have been a saga, but not the same saga. It is to the west that the best sagas belong; it is to the west that nearly every classic writer whose name we know belongs; and it is precisely in the west that the admixture of Irish blood is greatest. In comparing the Irish tales with the saga, there will be felt deep divergencies in matter, style, and taste, the richness of one contrasting with the chastened simplicity of the other; the one's half-comic half-earnest bombast is wholly unlike the other's grim humour; the marvellous, so unearthly in the one, is almost credible in the other; but in both are the keen grasp of character, the biting phrase, the love of action, and the delight in blood which almost assumes the garb of a religious passion.

When the saga had been fixed by a generation or two of oral reciters, it was written down; and this stereotyped the form, so that afterwards when literary works were composed by learned men (such as Abbot Karl's *Swerri's Saga* and Sturla's *Islendinga*) the same style was adopted.

Icelandic sagas.

Taking first the sagas relating to Icelanders, of which some thirty-five or forty remain out of thrice that number, we find that they were first written down between 1140 and 1220, in the generation which succeeded Ari and felt the impulse his books had given to writing, on separate scrolls, no doubt mainly for the reciter's convenience; that they then went through all the different phases which such popular compositions have to pass in all lands,—editing and compounding (1220–1260), padding and amplifying (1260–1300), and finally collection in large MSS. (14th century). Sagas exist showing all these phases, some primitive and rough, some refined and beautified, some again diluted and weakened, according as their copyists have been faithful, artistic, or foolish; for the first generation of MSS. have all perished. We have also complex sagas put together in the 13th century out of the scrolls relating to a given locality, such a group as still exists untouched in *Vapnfirdinga* being fused into such a saga as *Niala* or *Laxdæla*. Of the authors nothing is known; we can only guess that some belong to the Sturlung school. According to subject they fall into two classes, those relating to the older generation before Christianity and those telling of St Olaf's contemporaries; only two fall into a third generation.

Of the west.

Beginning with the sagas of the west, most perfect in style and form, the earliest in subject is that of *Gold-Thori* (*c.* 930), whose adventurous career it relates; *Hen-Thori's Saga* tells of the burning of Blund-Ketil, a noble chief, an event which led to Thord Gelli's reforms next year (*c.* 964); *Gisli's Saga* (960–80) tells of the career and death of that ill-fated outlaw; it is beautifully written, and the verses by the editor (13th century) are good and appropriate; it has been Englished by Sir G. Dasent; *Hord's Saga* (980) is the life of a band of outlaws on Whalesfirth, and especially of their leader Hord. Of later subject are the sagas of *Havard* and his revenge for his son, murdered by a neighbouring chief (997–1002); of the *Heath Slaughter* (990–1014), a typical tale of a great blood feud, written in the most primitive prose; of *Gunnlaug and Hrafn* (980–1008), the rival poets and their ill-starred love. The verse in this saga is important and interesting. It has been Englished by Messrs Morris and Magnusson. To the west also belong the three great complex sagas *Egla*, *Eyrbyggia*, and *Laxdæla*. The first (870–980), after noticing the migration of the father and grandfather of the hero poet Egill, and the origin of the feud between them and the kings of Norway, treats fully of Egill's career, his enmity with Eirik Bloodaxe, his service with Æthelstan, and finally, after many adventures abroad, of his latter days in Iceland at Borg, illustrating very clearly what manner of men those great settlers and their descendants were, and the feelings of pride and freedom which led them to Iceland. The style is that of Snorri, who had himself dwelt at Borg, and Dr Vigfusson is inclined to refer it to him. *Eyrbyggia* (890–1031) is the saga of Politics, the most loosely woven of all the compound stories. It includes a mass of information on the law, religion, traditions, &c., of the heathen days in Iceland, and the lives of Eirik, the real discoverer of Greenland, Biorn of Broadwick, a famous chief, and Snorri, the greatest statesman of his day. Dr Vigfusson would ascribe its editing and completion to Sturla the Lawman, *c.* 1250. It is known to many Englishmen from Sir Walter Scott's paraphrase. *Laxdæla* (910–1026) is the saga of Romance. Its heroine Gudrun is the most famous of all Icelandic ladies. Her love for Kiartan the poet, and his career abroad, his betrayal by his friend Bolli, the sad death of Kiartan at his hands, the revenge taken for him on Bolli, whose slayers are themselves afterwards put to death, and the end of Gudrun, who becomes an anchorite after her stormy life, make up the pith of the story. The contrast of the characters, the rich style and fine dialogue which are so remarkable in this saga, have much in common with the best works of the Sturlung school. Mr Morris's *Lovers of Gudrun* is founded upon it.

Of the north.

Of the north there are the sagas of *Kormak* (930–60), most primitive of all, a tale of a wild poet's love and feuds, containing many notices of the heathen times; of *Waterdale* (890–980), relating to the settlement and the chief family in Waterdale; of *Hallfred* the Poet (996–1014), narrating his fortune at King Olaf's court, his love affairs in Iceland, and finally his death and burial at Iona; of *Reek-dale* (990), which preserves the lives of Askell and his son Viga-Skuti; of *Swarf-dale* (980–90), a cruel coarse story of the old days, with some good scenes in it, unfortunately imperfect, chapters 1–10 being forged; of *Viga-Glum* (970–90), a fine story of a heathen hero, brave, crafty, and cruel; it has been Englished by Sir Edmund Head. To the north also belong the sagas of *Gretti* the Strong (1010–31), the life and death of the most famous of Icelandic outlaws, the real story of whose career is mixed up with the mythical adventures of Beowulf, here put down to Gretti, and with late romantic episodes and fabulous folk-tales (Dr Vigfusson would ascribe the best parts of this saga to Sturla; its last editor, whose additions would be better away, must have touched it up about 1300; Messrs Morris and Magnusson have Englished it), and the stories of the *Lightwater Men* and *Liot O' Vall* (1009-60). Gudmund the Mighty and his family and neighbours are the heroes of these tales, which form a little cycle. The *Banda-manna Saga* (1050-60), the only comedy among the sagas, is also a northern tale; it relates the struggles of a plebeian who gets a chieftaincy against the old families of the neighbourhood, whom he successfully outwits; *Öl-kofra Thattr* is a later imitation of it in the same humorous strain. The sagas of the north are rougher and coarser than those of the west, but have a good deal of individual character.

Of the east.

Of tales relating to the east there survive the Weapon-firth cycle,—the tales of *Thorstein the White* (c. 900), of *Thorstein the Staffsmitten* (c. 985), Englished by Mr Morris, of *Gunnar Thidrand's Bane* (1000–1008), and of the *Weapon-firth Men* (975–990), all relating to the family of Hof and their friends and kin for several generations,—and the story of *Hrafnkell Frey's Priest* (c. 960), the most idyllic of sagas and best of the eastern tales. Of later times there are *Droplaug's Sons' Saga* (997-1007), written probably about 1110, and preserved in the uncouth broken style of the original (a brother's revenge for his brother's death is the substance of it; *Brand-krossa Thattr* is an appendix to it), and the tales of *Thorstein Hall of Side's Son* (c. 1014), and his brother *Thidrandi* (c. 996), which belong to the cycle of *Hall o' Side's Saga*, unhappily lost; they are weird tales of bloodshed and magic, with idyllic and pathetic episodes.

Of the south.

The sagas of the south are either lost or absorbed in that of *Nial* (970-1014), a long and complex story into which are woven the tales of *Gunnar, Nial*, and parts of others, as *Brian Boroimhe, Hall o' Side*, &c. It is, whether we look at style, contents, or legal and historical weight, the foremost of all sagas. It deals especially with law, the sole bond of a rough heathen community, and contains in itself, as it were, at once the pith and the moral of all early Icelandic history. Its hero Nial, type of the good lawyer, is contrasted with its villain Mord, the ensample of cunning, chicane, and legal wrong-doing; and a great part of the saga is taken up with the three cases and suits of the divorce, the death of Hoskuld, and the burning of Nial, which are given with great minuteness and care. The number and variety of its dramatis personæ give it the liveliest interest throughout. The women Hallgerda, Bergthora, and Ragnhild are as sharply contrasted as the men Gunnar, Skarphedin, Flosi, and Kari. The pathos of such tragedies as the death of Gunnar and Hoskuld and the burning is interrupted by the humour of the Al-thing scenes and the intellectual interest of the legal proceedings. The plot dealing first with the life and death of Gunnar, type of the chivalry of his day, then with the burning of Nial by Flosi, and how it came about, and lastly with Kari's revenge on the burners, is the ideal saga-plot, and affords ample room for the finest treatment of incident. The author must have been of the east, a good lawyer and genealogist, and have composed it about 1250, to judge from various internal evidence. It has been overworked by a later editor, c. 1300, who inserted many spurious verses. It has been translated by Sir G. Dasent.

Of Greenland and North America.

Relating partly to Iceland, but mostly to Greenland and Wineland (N. America), are the sagas of the *Floe-Men* (985-90), a good story of the adventures of Thorgils and of the struggles of shipwrecked colonists in Greenland, a graphic and terrible picture; and of *Eirik the Red* (990-1000), two versions, one northern (Flatey-book), one western, the better (in *Hawk's Book*, and AM. 557, translated by the Rev. J. Sephton), the story of the discovery of Greenland and Wineland (America) by the Icelanders at the end of the 9th century. Later are the story of *Thormod and Thorgeir, the Foster Brethren* (1015-30), a very interesting story, told in a quaint romantic style, of Thorgeir, the reckless henchman of King Olaf, and how his death was revenged in Greenland by his sworn brother the true-hearted Thormod Coalbrow's poet, who afterwards dies at Sticklestad. The tale of *Einar Sookisson* (c. 1125) may also be noticed. The lost saga of *Poet Helgi*, of which only fragments remain, was also laid in Greenland.

Besides complete sagas, such as have been noticed, there are embedded in the *Kings' Lives* numerous small *thættir* or episodes, small tales of Icelanders' adventures, often relating to poets and their lives at the kings' courts; one or two of these seem to be fragments of sagas now lost. Among the more notable are those of *Orm Storolfsson, Ogmund Dijtt. Halldor Snorrason, Thorstein Oxfoot, Hromund Halt, Thorwald Tasaldi, Svadi* and *Arnor Herlingar-nef, Audunn of Westfirth, Sneglu-Halli, Hrafn of Hrutfiord, Hreidar Heimski, Gisli Illugison, Ivar* the poet, *Gull-Æsu Thord, Einar Skulason* the poet, *Mani* the poet, &c.

The forged Icelandic sagas appear as early as the 13th century. They are very poor, and either worked up on hints given in genuine stories, or altogether apocryphal. Some of them have been composed within the present century.

Histo[ry]

About the year of the battle of Hastings was born one of the blood of Queen Aud, who founded the famous historical school of Iceland, and himself produced its greatest monument in a work which can only be compared for value with the English Domesday Book. Nearly all that we know of the heathen commonwealth may be traced to the collections of Ari. It was he too that fixed the style in which history should be composed in Iceland. It was he that secured and put into order the vast mass of fragmentary tradition that was already dying out in his day. And perhaps it is the highest praise of all to him that he wrote in his own "Danish tongue," and so ensured the use of that tongue by the learned and cultured of after generations, when, had he chosen to imitate the learned of other lands, not only would the freshness and life of the northern history as we have it have been crushed out, but the vernacular literature (heightened and purified by his influence as it has now been) would have sunk and disappeared. Ari's great works are *Konungabók*, or *The Book of Kings*, relating the history of the kings of Norway from the rise of the Yngling dynasty down to the death of Harald Sigurdsson in the year of his own birth. This book he composed from the dictation of old men such as Odd Kolsson, who had preserved traditions in their family and got information from contemporaries, from the genealogical poems, and from the various dirges, battle-songs, and eulogia of the poets. It is most probable that he also compiled shorter *Kings' Books* relating to Denmark and perhaps to England. The *Konungabók* is preserved under the *Kings' Lives* of Snorri, parts of it almost as they came from Ari's hands, for example, *Ynglinga* and *Harold Fairhair's Saga*, and the prefaces stating the plan and critical foundations of the work, parts of it only used as a framework for the magnificent superstructure of the lives of the two Olafs, and of Harald Hardrada and his nephew Magnus the Good. The best text of Ari's *Konungabók* (*Ynglinga*, and the sagas down to but not including Olaf Tryggvason's) is that of Frisbók.

Ari.

The *Book of Settlements* (*Landnamabók*) is a most wonderful performance, both in its scheme and carrying out. It is divided into five parts, the first of which contains a brief account of the discovery of the island; the other four, one by one taking a quarter of the land, describe the name, pedigree, and history of each settler in geographical order, notice the most important facts in the history of his descendants, the names of their homesteads, their courts and temples, thus including mention of 4000 persons, one-third of whom are women, and 2000 places. The mass of information contained in so small a space, the clearness and accuracy of the details, the immense amount of life which is somehow breathed into the whole, can hardly fail to astonish the reader, when he reflects that this colossal task was sketched out and accomplished by one man, for his collaborateur Kolskegg merely filled up his plan with regard to part of the east coast, a district with which Ari in his western home at Stad was little familiar. *Landnamabók* has reached us in two complete editions, one edited by Sturla, who brought down the genealogies to his own grandfather and grandmother, Sturla and Gudny, and one by Hawk, who traces the pedigrees still later to himself.

Ari also wrote a *Book of Icelanders* (*Islendingabók*, c. 1127), which has perished as a whole, but fragments of it are embedded in many sagas and *Kings' Lives*; it seems to have been a complete epitome of his earlier works, together with an account of the constitutional history, ecclesiastical and civil, of Iceland. An abridgment of the latter part of it, the little *Libellus Islandorum* (to which the title of the bigger *Liber—Islendingabók—*is often given), made by the historian for his friends Bishops Ketil and Thorlak, for whom he wrote the *Liber* (c. 1137). This charming little book is, with the much later collections of laws, our sole authority for the Icelandic constitution of the commonwealth, but, "much as it tells, the lost *Liber* would have been of still greater importance." *Kristni-Saga*, the story of the christening of Iceland, is also a work of Ari's, "overlaid" by a later editor no doubt, but often preserving Ari's very words. This saga, together with several scattered tales of early Christians in Iceland before the Change of Faith (1002), may have made up a section of the lost *Liber*. Of the author of these works little personal is known. He lived in quiet days a quiet life; but he shows himself in his works, as Snorri describes him, "a man wise, of good memory, and a speaker of the truth." Surely, if Thucydides is justly accounted the first political historian, Ari may be fitly styled the first of scientific historians.

Sæ[mund]

A famous contemporary and friend of Ari is Sæmund (1056–1133), a great scholar and churchman, whose learning so impressed his age that he got the reputation of a magician. He was the friend of Bishop John, the founder of the great Odd-Verjar family, and the author of a *Book of Kings* from Harald Fairhair to Magnus the Good, in which he seems to have fixed the exact chronology of each reign. It is most probable that he wrote in Latin. The idea that he had anything to do with the poetic *Edda* in general, or the *Sun's Song* in particular, is of course unfounded and modern.

The flame which Ari had kindled was fed by his successors in the 12th century. Eirik Oddsson (c. 1150) wrote the lives of Sigurd

Evil-deacon and the sons of Harold Gille, in his *Hryggiar-Stykki* (Sheldrake), of which parts remain in the MSS. collections of *Kings' Lives, Morkin-skinna*, &c. Karl Jonsson, abbot of Thingore the Benedictine minister, wrote (*c.* 1184) a *Life of Swerri* from the lips of that great king, a fine racy biography, with a style and spirit of its own. *Böglunga-Sögur* tell the story of the civil wars which followed Swerri's death. They are probably by a contemporary.

The Latin *Lives of St Olaf*, Odd's in Latin (*c.* 1175), compiled from original authorities, and the *Legendary Life*, by another monk whose name is lost, are of the mediæval Latin school of Sæmund to which Gunnlaug belonged.

Snorri was known to his contemporaries as a statesman and poet; to us he is above all an historian. His position as a poet and his authorship of the prose *Edda* have been noticed above. Snorri was born in 1178, being on his mother's side sprung from the Myra family of Borg; he was brought up in fosterage with Sæmund's great grandson Jon Loptsson, a great chief. His career begins with his marriage, 1199, which made him a wealthy man. In 1205 he moved from Borg to Reekholt. He was twice lawman, and twice visited Norway, where he gained great influence with the king; but when the civil war broke out he sided with Duke Skuli and disobeyed the king's orders, whereupon letters were sent out to his enemies to slay him (Skuli his patron having fallen), which command was carried out on the night of 22d Sept. 1241, his own friends and kinsmen being his murderers. Snorri wrote the *Lives of the Kings*, from Olaf Tryggvason to Sigurd the Crusader inclusive; and we have them substantially as they came from his hand in the *Great King Olaf's Saga*, which has been interpolated with thættir and bits of other sagas in such a way as that they can be easily omitted; *St Olaf's Saga*, as in *Heimskringla* and the Stockholm MS.; and the succeeding *Kings' Lives*, as in Hulda and Hrokkinskinna, in which, however, a few episodes have been inserted.

These works were no doubt indebted for their facts to Ari's labours, and to sagas written since Ari's death; but the style and treatment of them are Snorri's own. The fine Thucydidean speeches, the dramatic power of grasping character, and the pathos and poetry that run through the stories, along with a humour such as is shown in the *Edda*, and a varied grace of style that never flags or palls, make Snorri one of the greatest of historians.

Here it should be noticed that *Heimskringla* and its class of MSS. (*Eirspennit, Jofraskinna, Gullinskinna, Fris-bok*, and *Kringla*) do not give the full text of Snorri's works. They are abridgments made in Norway by Icelanders for their Norwegian patrons, the *Life of St Olaf* alone being preserved intact, for the great interest of the Norwegians lay in him, but all the other *Kings' Lives* being more or less cut down and mutilated, so that they cannot be trusted for historic purposes; nor do they give a fair idea of Snorri's style. As Englishmen's knowledge of these works is often derived from Mr Laing's translation of a Danish version of *Heimskringla* ("Sea-Kings of Norway"), this caution is needed.

Agrip is a 12th century compendium of the *Kings' Lives* from Harold Fairhair to Swerri, by a scholastic writer of the school of Sæmund. As the only Icelandic abridgment of Norwegian history taken not from Snorri but sources now lost, it is of worth. Its real title is *Konunga-tal*.

Noregs Konunga-tal, now called *Fagrskinna*, is a Norse compendium of the *Kings' Lives* from Halfdan the Black to Swerri's accession, probably written for King Hakon, to whom it was read on his death-bed. It is an original work, and contains much not found elsewhere. As non-Icelandic it is only noticed here for completeness.

Styrmi Karason, a contemporary of Snorri's, dying in 1245, was a distinguished churchman (lawman twice) and scholar. He wrote a *Life of St Olaf*, now lost; his authority is cited. He also copied out *Landnamabok* and *Swerri's Life*, from his MSS. of which our surviving copies were taken.

Sturla, Snorri's nephew, of whom more must be said below, wrote the *Lives of Kings Hakon and Magnus* at the request of the latter, finishing the first *c.* 1265, the latter *c.* 1280. *King Hakon's Life* is preserved in full; of the other only fragments remain. These are the last of the long and valuable series of historic works which Ari's labours began, from which the history of Norway for 500 years must be gathered.

A few books relating the history of other Scandinavian realms will complete this survey. In *Skioldunga-bok* was told the history of the early kings of Denmark, perhaps derived from Ari's collections, and running parallel to *Ynglinga*. The earlier part of it has perished save a fragment *Sogu-brot*, and citations and paraphrases in Saxo, and the mythical *Ragnar Lodbrok's* and *Gongu-Hrolf's Sagas*; the latter part, *Lives of Harold Blue-tooth and the Kings down to Sweyn II.*, is still in existence and known as *Skioldunga*.

The *Lives of St Knut and his Brethren* are of later origin and separate authorships, parallel to Snorri's *Lives of the great Norwegian Kings*, but earlier in date. The *Lives of King Waldimar and his Son*, written *c.* 1185, by a contemporary of Abbot Karl's, are the last of this series. The whole were edited and compiled into one book, often quoted as *Skioldunga*, by a 13th century editor, possibly Olaf, the White Poet, Sturla's brother, guest and friend of King Waldimar II., as Dr Vigfusson has guessed. *Jomsvikinga Saga*, the history of the pirates of Jom, down to Knut the Great's days, also relate to Danish history. Several versions of it exist.

The complex work now known as *Orkneyinga* is made up of the *Earls' Saga*, lives of the first great earls, Turf-Einar, Thorfinn, &c.; the *Life of St Magnus*, founded partly on Abbot Robert's Latin life of him, *c.* 1150, an Orkney work, partly on Norse or Icelandic biographies; a *Miracle-book* of the same saint; the *Lives of Earl Rognwald and Sweyn* the last of the vikings, and a few episodes such as the *Burning of Bishop Adam*. A scholastic sketch of the rise of the Scandinavian empire, the *Foundation of Norway*, dating *c.* 1120, is prefixed to the whole. The Flatey-book text of this work has been translated by Mr Hjaltalin in Mr Anderson's *Orkneyinga Saga*.

Færeyinga tells the tale of the conversion of the Færeys or Faroes, and the lives of its chiefs Sigmund and Leif, composed in the 13th century from their separate sagas by an Icelander of the Sturlung school.

Biographies.

The saga has already been shown in two forms, its original epic shape and its later development applied to the lives of Norwegian and Danish kings and earls, as heroic but deeper and broader subjects than before. In the 13th century it is put to a third use, to tell the plain story of men's lives for their contemporaries, after satisfying which demand it dies away for ever.

Lives of chiefs.

These biographies are more literary and mediæval and less poetic than the Icelandic sagas and king's lives; their simplicity, truth, realism, and purity of style are the same. They run in two parallel streams, some being concerned with chiefs and champions, some with bishops. The former, as more important, will be taken first. They are mostly found embedded in the complex mass of stories known as *Sturlunga*, from which Dr Vigfusson has extricated them, and for the first time set them in order. Among them are the sagas of *Thorgils and Haflidi* (1118–21), the feud and peacemaking of two great chiefs contemporaries of Ari; of *Sturla* (1150–83), the founder of the great Sturlung family, down to the settlement of his great lawsuit by Jon Loptsson, who thereupon took his son Snorri the historian to fosterage,—a humorous story but with traces of the decadence about it, and glimpses of the evil days that were to come; of the *Burning of Onund* (1185–1200), a tale of feud and fire-raising in the north of the island, the hero of which, Gudmund Dyri, goes at last into a cloister; of *Hrafn Sweinbiornsson* (1190–1213), the noblest Icelander of his day, warrior, leech, seaman, craftsman, poet, and chief, whose life at home, travels and pilgrimages abroad (Hrafn was one of the first to visit Becket's shrine), and death at the hands of a foe whom he had twice spared, are recounted by a loving friend in pious memory of his virtues, *c.* 1220; of *Aaron Hiorleifsson* (1200–55), a man whose strength, courage, and adventures befit rather a henchman of Olaf Tryggvason than one of King Hakon's thanes (the beginning of the feuds that rise round Bishop Gudmund are told here), of the *Swinefell-men* (1248–52), a pitiful story of a family feud in the far east of Iceland.

Sturla and his brother Thord.

But the most important works of this class are the *Islendinga Saga* and *Thorgils Saga* of Lawman Sturla. Sturla and his brother Olaf were the sons of Thord Sturlason and his mistress Thora. He was born and brought up in prosperous times, when all was fair for the Sturlungs, but his manhood was passed in the midst of strife and war, in which his family fell one by one, and he himself, though a peaceful man who cared little for politics, was more than once forced to fly for his life. While in refuge with King Magnus, in Norway, he wrote his two sagas of that king and his father. After his first stay in Norway he came back in 1271, with the new Norse law-book, and served a second time as lawman. The *Islendinga* must have been the work of his later years, composed at Fairey in Broadfirth, where he died, 30th July 1284, aged about seventy years. The saga of *Thorgils Skardi* (1252–61) seems to have been the first of his works on Icelandic contemporary history; it deals with the life of his own nephew, especially his career in Iceland from 1252 to 1258. The second part of *Islendinga* (1242–1262), which relates to the second part of the civil war, telling of the careers of Thord Kakali, Kolbein the Young, Earl Gizur, and Hrafn Oddsson. The end is imperfect, there being a blank of some years before the fragmentary ending to which an editor has affixed a notice of the author's death. The first part of *Islendinga* (1202–42) tells of the beginning and first part of the civil wars, the lives of Snorri and Sighvat, Sturla's uncles, of his cousin and namesake Sturla Sighvatsson, of Bishop Gudmund, and Thorwald Gizursson,—the fall of the Sturlungs, and with them the last hopes of the great houses to maintain the commonwealth, being the climax of the story.

Sturla's power lies in his faithfulness to nature, minute observance of detail, and purity of style. The great extent of his subject, and the difficulty of dealing with it in the saga form, are most skilfully overcome; nor does he allow prejudice or favour to stand in the way of the truth, a thing hard to avoid for one writing of contemporary events in which his own kinsmen have been concerned. He ranks below Ari in value and below Snorri in power; but no one else can dispute his place in the first rank of Icelandic writers.

Of the ecclesiastical biographers, an anonymous Skalholt clerk is

Bishops' lives. the best. He wrote *Hunger-waker*, lives of the first five bishops of Skalholt, and biographies of his patron *Bishop Paul*, and also of *St Thorlak*. They are full of interesting notices of social and church life. Thorlak was a learned man, and had studied at Paris and Lincoln, which he left in 1161. These lives cover the years 1056–1193. The *Life of St John*, a great reformer, a contemporary of Thorodd, whom he employed to build a church for him, is by another author (1052–1121). The *Life of Gudmund*, as priest, recounts the early life of this Icelandic Becket till his election as bishop (1160–1202); his after career must be sought out in *Islendinga*. It is written by a friend and contemporary. A later life by Arngrim, abbot of Thingore, written *c*. 1350, as evidence of his subject's sanctity, tells a good deal about Icelandic life, &c. The *Lives of Bishops Arni and Lawrence* bring down our knowledge of Icelandic history into the 14th century. The former work is unhappily imperfect; it is the record of the struggles of church and state over patronage rights and glebes, written *c*. 1315; it now covers only the years 1269–91; a great many documents are given in it, after the modern fashion. The latter, *Lawrence's Life*, by his disciple, priest Einar Haflidason, is a charming biography of a good and pious man, whose chequered career in Norway and Iceland is picturesquely told (1324–31). It is the last of the sagas. *Bishop Jon's Table-Talk* (1325–39) is also worth noticing; it contains many popular stories which the good bishop, who had studied at Bologna and Paris, was wont to tell to his friends.

Annals. The *Annals* are now almost the sole material for Icelandic history; they had begun earlier, but after 1331 they got fuller and richer, till they end in 1430. The best are *Annales Regii*, ending 1306, *Einar Haflidason's Annals*, known as "Lawman's Annals," reaching to 1392, and preserved with others in *Flatey-book*, and the *New Annals*, last of all. The *Icelandic Diplomatarium*, edited by Jon Sigurdsson, contains what remains of deeds, inventories, letters, &c., from the old days, completing our scanty material for this dark period of the island's history.

Literature of foreign origin. After the union and change of law genuine tradition died out with the great houses, and the kings' lives and biographies ceased to please. The ordinary mediæval literature reached Iceland through Norway, and every one began to take delight in it and put it into a vernacular dress, so neglecting their own classics that but for a few collectors like Lawman Hawk they would have perished entirely.

Romantic sagas. The Norwegian kings, Hakon Hakonson, *c*. 1225, and Hakon V., *c*. 1305, employed Icelanders at their courts in translating the French romances of the Alexander, Arthur, and Charlemagne cycles. Some forty or fifty of these *Riddara-Sögur* (Romances of Chivalry) still remain. They reached Iceland and were eagerly read, many Rimur being founded on them. Norse versions of *Mary of Brittany's Lays*, the stories of *Brutus* and of *Troy*, and part of the *Pharsalia* translated are also found. The *Speculum Regale*, with its interesting geographical and social information, is also Norse, written *c*. 1240, by a Halogalander.

Scientific works. The computistic and arithmetical treatises of Stiorn-Odd, Biarni the Number-skilled, d. 1173, and Hawk the Lawman, d. 1334, and the geography of Ivar Bardsson, a Norwegian, *c*. 1340, are of course of foreign origin. A few tracts on geography, &c., in Hawk's book, and a *Guide to the Holy Land*, by Nicholas, abbot of Thwera, d. 1158, complete the list of scientific works.

Mythical sagas. The stories which contain the last lees of the old mythology and pre-history seem to be also non-Icelandic, but stuffed out and amplified by Icelandic editors, who probably got the plots from the Western Islands. *Wolsunga Saga* and *Hervarar Saga* contain quotations and paraphrases of lays by the Helgi poet, and *Half's*, *Ragnar's*, and *Asmund Kappabana's Sagas* all have bits of Western poetry in them. *Hrolf Kraki's Saga* paraphrases part of *Biarkamal; Hromund Gripsson's* gives the story of Helgi and Kara (the lost third of the Helgi trilogy); *Gautrek's*, *Arrow-Odd's*, *Frithiof's Sagas*, &c., contain shreds of true tradition amidst a mass of later fictitious matter of no worth. With the *Riddara-Sögur* they enjoyed great popularity in the 15th century, and gave matter for many Rimur. *Thidrek's Saga*, a late version of the Wolsung story, is of Norse composition, *c*. 1230, from North German sources.

Religious works. The mediæval religious literature of Western Europe also reached and influenced Iceland, and the *Homilies* (like the *Laws*) were, according to Thorodd, the earliest books written in the vernacular, antedating even Ari's histories. The lives of the *Virgin*, the *Apostles*, and the *Saints* fill many MSS. (edited in four large volumes by Professor Unger), and are the works of many authors, chiefly of the 13th and 14th centuries (of course they were known in Latin long before); amongst them are the lives of *SS. Edward the Confessor*, *Oswald of Northumbria*, *Dunstan*, and *Thomas of Canterbury*. Of the authors we know Priest Berg Gunsteinsson, d. 1211; Kygri-Biorn, bishop-elect, d. 1237; Bishop Brand, d. 1264; Abbot Runolf, d. 1307; Bishop Lawrence's son Arni, *c*. 1330; Abbot Berg, *c*. 1340, &c. A paraphrase of the historical books of the Bible was made by Bishop Brand, d. 1264, called *Gydinga Sögur*. About 1310 King Hakon V. ordered a commentary on the Bible to be made, which was completed down to Exodus xix. To this Brand's work was afterwards affixed, and the whole is known as *Stiorn*. The Norse version of the famous *Barlaam and Josaphat*, made for Prince Hakon, *c*. 1240, must not be forgotten.

Post-clas[sical] liter[a]ture. Re[ligious] wor[ks]. The post-classical literature falls chiefly under three heads,—religious, literary, and scientific. Under the first comes foremost the noble translation of the New Testament by Odd Gottskalksson, son of the bishop of Holar. Brought up in Norway, he travelled in Denmark and Germany, and took upon him the new faith before he returned to Iceland, where he became secretary to Bishop Ogmund of Skalholt. Here he began by translating the Gospel of Matthew into his mother-tongue in secret. Having finished the remainder of the New Testament at his own house at Olves, he took it to Denmark, where it was printed at Roskild in 1540. Odd afterwards translated the Psalms, and several devotional works of the day, Corvinus's *Epistles*, &c. He was made lawman of the north and west, and died from a fall in the Laxa in Kios, June 1556. Three years after his death the first press was set up in Iceland by John Matthewson, at Breidabolstad, in Hunafloe, and a *Gospel and Epistle Book*, according to Odd's version, issued from it in 1562. In 1584 Bishop Gudbrand, who had brought over a splendid fount of type from Denmark in 1575 (which he completed with his own hands), printed a translation of the whole Bible at Holar, incorporating Odd's versions and some books (Proverbs and the Son of Sirach, 1580) translated by Bishop Gizar, but supplying most of the Old Testament himself. This fine volume has been the basis of every Bible issued for Iceland till 1826, when it was replaced by a bad modern version. For beauty of language and faithful simplicity of style the finer parts of this version, especially the New Testament, have never been surpassed in any tongue; they stand worthily beside the work of Tyndale, Luther, and Ulfila, foremost monuments of the Teutonic tongues.

The most notable theological work Iceland ever produced is the *Postill-Book* of Bishop John Widalin (1666–1720), whose bold homely style and stirring eloquence made "John's Book," as it is lovingly called, a favourite in every household, till in the present century it has been replaced for the worse by the more sentimental and polished Danish tracts and sermons. Theological literature is very popular, and many works on this subject, chiefly translations, will be found in the lists of Icelandic bibliographers.

Lite[rary] wor[ks]. The Renaissance of Iceland dates from the beginning of the 17th century, when a school of antiquarians arose and betook themselves to the task of reconstructing their country's history from the remains their pious care gathered and preserved. Arngrim Jonsson's *Brevis Commentarius*, 1593, and *Crymogæa*, 1609, were the first-fruits of this movement, of which Bishops Odd, Thorlak, and Bryniulf (worthy parallels to Parker and Laud) were the wise and earnest supporters. The first (d. 1630) collected much material for church history. The second (d. 1656) saved *Sturlunga* and the *Bishops' Lives*, encouraged John Egilsson to write his *New Hunger-waker*, lives of the bishops of the Dark Ages and Reformation, and helped Biorn of Skardsa (d. 1655), a bold and patriotic antiquary (whose *Annals* continue Einar's), in his researches. The last (d. 1675) collected a fine library of MSS., and employed the famous copyist John Erlendsson, to whom and the bishop's brother, John Gizurarsson (d. 1648), we are much beholden for transcripts of many lost MSS.

Torfæus (1636–1719) and Bartholin, a Dane (d. 1690), roused the taste for northern literature in Europe, a taste which has never since flagged; and soon after them Arni Magnusson transferred all that remained of vellum and good paper MSS. in Iceland to Denmark, and laid the foundations of the famous library and bequest, for which all Icelandic students are so much beholden. For over forty years Arni stuck to his task, rescuing every scrap he could lay hands on from the risks of the Icelandic climate and carelessness, and when he died in 1730, aged fifty-seven, only one good MSS. remained in the island. Besides his magnificent collection, there are a few MSS. of great value at Upsala, at Stockholm, and in the old royal collection at Copenhagen. Those in the university library in the latter city perished in the fire of 1728. Sagas were printed at Upsala and Copenhagen in the 17th century, and the Arna-Magnæan fund has been working since 1772. In that year appeared also the first volume of Bishop Finn Johnsson's *Historia Ecclesiastica Islandiæ*, a work of high value and much erudition, containing not only ecclesiastical but civil and literary history, illustrated by a well-chosen mass of documents, 870–1740. It has been continued by Bishop P. Peterson to modern times, 1740–1840. The results, however, of modern observers and scholars must be sought for in the periodicals, *Safn*, *Felagsrit*, *Ny Felagsrit*, and others. John Espolin's *Arbækr* is very good up to its date, 1821.

By far the best history of Icelandic classic literature is the brilliant sketch by Dr Vigfusson, Prolegomena to *Sturlunga Saga*, Oxford, 1879, to which we must here acknowledge our obligations. It replaces much earlier work, especially the *Sciagraphia* of Halfdan Einarson, 1777, and the *Saga-Bibliotek* of Müller. The numerous editions of the classics by the Icelandic societies, the Danish Société des Antiquités, Nordiske Literatur Samfund, and the new Gammel Nordisk Literatur Samfund, the splendid Norwegian editions of Unger, the labours of the Icelanders Sigurdsson and

Gislason, and of those foreign scholars in Scandinavia and Germany who have thrown themselves so heartily into the work of illustrating, publishing, and editing the sagas and poems (men like Munch, Bugge, Bergmann, Möbius, and Maurer, to name only a few), can only be referred to here.

The first modern scientific work is the *Iter per patriam* of Eggert Olafsson and Biarni Paulsson, which gives a careful and correct account of the physical peculiarities—fauna, flora, &c.—of the island as far as could be done at the date of its appearance, 1772. The island was first made known to "the world" by this book and by the sketch of Unno von Troil, a Swede, who accompanied Sir Joseph Banks to Iceland in 1772, and afterwards wrote a series of "letters" on the land and its literature, &c. This tour was the forerunner of an endless series of "travels," of which those of Hooker (1809), Mackenzie (1810), Henderson (1818), Gaimard (1838-43), Paijkull (1867), and, lastly, that of Captain Burton, an excellent account of the land and people, crammed with information of every kind (1875), are the best.

The maps by Olson and his colleagues, by Gunnlaugson, and by the French Admiralty are good. Kalund's work on the historical geography of the island is valuable and interesting. *Safn* and other periodicals above mentioned contain many able papers on scientific and sociological matters. Iceland is an interesting field for the pathologist and physician, and numerous medical treatises, Icelandic and foreign, have attacked it. Dr Hjaltalin, the present medical director, is perhaps the best modern authority.

The cathedral high school merged into a college in 1801, which was fixed at Bessastad during its palmiest days (1805-46), and is now at Reykjavik. Among its lists of masters several distinguished names figure, for example, Sweinbiorn Egilsson, whose Homeric translations were issued as college "programs." A law school has been recently formed at Reykjavik and a technical school at Mödruvellir. The museum and library, both at Reykjavik, still in the rudimentary state, are to be newly housed and extended.

Iceland is emphatically a land of proverbs, which occur on almost every page of the dictionary, while of folk-tales, those other keys to the people's heart, there is plentiful store. Early work in this direction was done by Jon Gudmundsson, Olaf the Old, and John Olafsson in the 17th century, who all put traditions on paper, and their labours have been completed by the magnificent collection of Jon Arnason (1862-64), who, inspired by the example of the Grimms, spent great toil on his self-imposed task. Many tales are but weak echoes of the sagas; many were family legends, many the old fairy tales we all know so well, dressed in a fresh garb suited to their new northern home; but, besides all these, there are a number of traditions and superstitions not found elsewhere, the mass of which is of indigenous growth and origin. Some of Arnason's collections have been put into English by Messrs J. G. G. Powell and E. Magnusson, and Sir G. Dasent.

A few translations of popular and famous books, such as the *Arabian Nights*, one or two classics, and a tale, *Piltr og Stulka* ("Lad and Lass"), 1850, complete the notabilities of Icelandic bibliography. Mr Lidderdale has prepared a list of Icelandic-printed books, which it is hoped may be published; the excellent *Catalogus* of Möbius is of use for dates, &c., of editions.

Unlike England and France, Iceland has had but one golden age of literature upon which all her fame must rest. Of its creations it has been truly said that they fill a place none others could take in the high ranks of Aryan classics. The noblest of them are distinguished by pure and strict form, noble heroic subject, and simple truthful self-control of style and treatment, free alike from overwrought sentiment or extravagant passion, and raised equally above euphemism and commonplace, but ever inspired by a weird Æschylean power, grim and tender, and splendid as that which breathes through those historical books of the Old Testament, to which alone should the masterpieces of Iceland's greatest writers be compared.

Language.

The relations of Icelandic to the other Teutonic tongues may be best shown by a chronological treatment. It presents the following anomalies:—on the one hand, it has a highly inflexional grammar, a pure vocabulary, and a simple syntax, points which would place it side by side with Gothic; but, on the other hand, it shows such strong marks of contraction and such deep phonetic changes, especially in the vowels, as can only be paralleled in the modern English. It is further noteworthy for its unity or lack of dialectic variation, and possesses exceptional advantages for the philologist in the complete series of documents dating from the 11th century downwards in which its history may be most accurately and minutely studied.

There is little doubt but that the Teutonic tribes of the 4th century all spoke one language, that, in fact, of which the remains of Ulfila (which may be supplemented by a few inscriptions, such as those of the Golden Horn and the earliest Danish rune-stones, and a few stray words preserved in classic authors) afford us such a noble specimen. The first differentiation occurred when the English colony separated in the 5th century from the parent stock, and, following its own course of development, already by the time of Bede presented many new and peculiar characteristics in form and vocabulary. With the changes which produced the High German dialects it does not behove us to deal here, so we may pass on to the Viking Tide (775-925), the results of which were felt over a wide area, and are evidenced by the changes which gave to the tongue of those tribes that took part in it a distinctly Scandinavian character.

Just as the earlier movement left its mark in Old English, so this one is clearly seen in the speech of the Scandinavian colonies of the West, especially in Icelandic, but it is still well marked in the Eastern Scandinavian dialects—Swedish, Danish, &c., as the following points common to all east and west, and marking them off clearly from all other Teutonic tongues, will show:—strong stem-contraction reducing all words as far as possible to a trochaic form; *i-umlaut* carried out very fully and consistently; the suffixing of the article; and a peculiar vocabulary which has chosen out of the common Teutonic stock certain words for daily use, rejecting others which are common to all the other sister tongues—*e.g.*, *eld* for *fire*, *ekkia* for *widow*, *gamol* for *old*, *eigi* for *not*, *ok* for *and*, *göra* for *do*, *taka* for *niman*, &c. The later Danish rune-stones and those of Sweden, published by Wimmer, Säve, Dybeck, &c., will be the best documents for this stage of the Scandinavian tongue.

We may now leave the Eastern Scandinavian dialects to follow their own course, which has led them through a path not entirely dissimilar to that which English has taken, and confine ourselves to the Western Colonial dialects. Those in their earliest monuments, the rune-stones of Man, the coins of the "Danish" kings and earls in Ireland and England, the lays of the Western poets in the *Edda* collection, and the earliest poetry of such Icelandic bards as Egill and Kormak, exhibit certain idiosyncrasies which show them to have already started on their own career. Such are the *u-umlaut*, the loss of *w* before *r* and *l*, the simplification of the vowel system (all aggravations, as it were, of the Scandinavian peculiarities noticed above, while their vocabulary is, as one would expect, affected by the introduction of many English, Gaelic, and Latin words, especially those relating to ideas unknown in earlier heathen days, ecclesiastical terms, &c.). Of these western colonies we are only concerned with the most important, Iceland; the Orkneys and Hebrides have no linguistic monuments later than the Edda lays of the 10th and 11th, and epigonic poetry and rhymed gradus-jingles of the 12th century; the influence of the Danes on our dialects and book-English must be left to English philologists; while in Ireland only a few personal and local names now betray to the ear the former presence of the Ostman.

The fact that one of the first Icelandic writers, *c.* 1120, Ari's contemporary, Thorodd, is a grammarian, and one of no mean power, is our greatest help towards ascertaining the phonesis of the tongue during the heroic age; and his evidence is supplemented by the Icelandic poets, whose strict adherence to metres, which depend for their effect on a delicate harmony of sound and a rigid observance of quantity, is absolutely to be trusted. Thorodd's scheme for the proper phonetic representation of Icelandic (which the English student may contrast with that of Orm, our first spelling reformer) is briefly as follows. The letters *b,c,d,f,g,l,m,n,p,r,s,t*, are used in their ordinary classic values (*c* always hard), the capitals B,K,D,F, G,L,M,N,P,R,S,T, being employed for the doubled letters *bb*, &c. (each consonant of these doubles was of course separately and distinctly pronounced as in Italian now, and, as Mr A. J. Ellis has proved, in Latin formerly); þ is used as in Old English for *th*; *h* for the aspirate pure or combined *hl, hn*, &c.; both these are of unvarying form; *x* for *cs, gs*, and ŋ for *ng* can only be found in medial and final positions. Thus we get twenty-eight consonants. The vowels, *a,e,i,o,u,y,æ,œ* long and short, have their ordinary values [pal. a,e,i,o,u,I,E,əi and aa, ee, &c.], and to them Thorodd has added *ao* [æ] long and short. All these vowels may also be nasalized, *ã,ẽ*, &c., making twenty-seven in all; *i* and *u*, whether consonantal or vocal, do not vary in form. The following points characterize the tongue at this period:—adherence to *o* in the terminations, right employment of the subjunctive, which has since gone completely out of use, retention of *s* in inflexion and the substantive verb. Quantity was strictly observed in speaking, and also accent, and no doubt people, as in Old England, spoke much more clearly, slowly, and energetically than they do now. The introduction of quantitative metres measured by syllables is no doubt to be ascribed to Celtic influence, as are the line-rhymes and assonances and rhyme-endings, which, as any reader of Snorri's *Hatta-tal* or Earl Rognwald's *Hatta-lykill* will see at the first glance, completely separated Icelandic poetry from the original Teutonic metric of the Continental rune-stones, of Beowulf, and of Havamal.

Thorodd's scheme was unfortunately never used in its strict completeness, but it is partly employed in the following MSS., which are of the highest authority for this era of the Icelandic:—*Elucidarius*, *c.* 1130, ed. *facsimile*; *Libellus*, *c.* 1150, ed. Möbius; the *Law Scroll-fragments* affixed by W. Finsen to the end of his ed. of *Cod. Regius Grágás*; the *Stockholm Homilies*, *c.* 1145, ed. Wisen; *Physiologus*, AM. 673, ed. *facsimile*; *Agrip*, *c.* 1185, ed.

Dahlerup. For others see Table II. Prolegomena to *Sturlunga Saga*, Oxford, 1879.

13th century changes.

The first era of change, ascribed by Dr Vigfusson to about the lifetime of Snorri, is the mark left by the civil wars and the connexion with Norway (our 14th century Wars of the Roses transition is in many respects its parallel). It is seen in the normal spelling of the editions of the sagas, &c., and is best exemplified by the famous AM. 132, *c.* 1300, and the *Annales Regii*, 1290–1306 (accurately printed in pp. 348-91, vol. ii., *Sturlunga Saga*, Oxford, 1879),—the loss of the *s* replaced by *r*, the vanishing of the *u-umlauted á*, the confusion of *œ* and *æ*, *æ* and *e*, *ao* and *eo* (the latter of each couple prevailing), the hardening of the dental finals and the blurring of *st*, *sk*, &c. into *z*. This stage of spelling and pronunciation is that which should be adhered to in all works which must be printed in an uniform way, dictionaries, grammars, classic editions, &c. The student may be cautioned not to take the vagaries of Norse scribes, or Noricized Icelanders (such as Hawk) for important phonetic variations.

16th century changes.

The second era of change is that which accompanied the Reformation, and witnesses to the mental and physical stir produced by that movement. It is only heard in the spoken tongue (for all books, save a few printed during the last few years, follow the normal type of the 14th and 15th century MSS. with few variations), but it is none the less deep and important. Its leading features are the loss of quantity and intonation, the confusion of the vowels *y* and *u*, *æ* and *ai*, *ey* and *au*, *au* and *á*, *ei i í* and *ey y ý* (the latter taking the sound of the former in each case), the diphthongization of the long vowels *ī*, *ē*, *ō*, *ū*,—all changes which from their symmetry must have taken place at one date,—the differentiation of doubled and touching consonants, *ll*, *nn*, *gn*, &c., and of final *r*. The vocabulary, which during the connexion with Norway and England through the "Dark Age" had been enriched with many French and English words, now received an important augmentation in a new religious terminology from Germany, while the intercourse with Denmark began to leave its mark in loan-words and Danicisms, the stock of which tended greatly to increase, till a reaction arose in the present century, which, though excusable, has been carried to laughable lengths. The metre of Icelandic poetry had begun to show signs of mediæval influence (of French origin) even before the death of Snorri, as a ditty in *Sturlunga* shows. During the Dark Age the Rimur metric system, depending largely on time-ending and burden for new effects though still retaining line rhyme and alliteration (the latter being absolutely essential), revolutionized poetry, and later the hymns of the Reformation, shaking themselves free from the somewhat monotonous beat of the Rimur, contain examples of many new and ingenious metres.

Absence of dialects.

The absence of dialects in Iceland results from the essential unity of life in that island, and the lack of any of the conditions which during the Middle Ages produced dialects in England, Germany, and France, such as town-life with its guilds and varied interests, the great corporations, ecclesiastical, legal, and medical, which by their necessary use of Latin cut off the most highly educated classes from exercising any influence on the vernacular, and the caste influences of chivalry, &c., which sometimes, as in England, allowed the upper classes to use a separate foreign language. In early times before the Danish conquest there were no dialects, because, life being single, king and serf, soldier and peasant, merchant and priest must live and speak alike. So we see in our own days the newspaper, the state school, the railway, the conscription, and the theatre, all tending to bring about in each great European state a sameness of life, thought, and speech through every nook and corner of its area.

The general characteristics of the Icelandic tongue are those of a spoken speech, *par excellence*,—a pure and correct vocabulary well suited to the every-day needs of a pastoral life, a pithy and homely vigour of idiom (this shows especially in the saws and proverbs which often recall those of Spain), a delicacy and regularity of syntax, which can express much with few and simple means, and an accuracy of terminology well becoming a legal-minded people. All these salient characters strike every observer, but the full beauty and power of the tongue as a vehicle of the highest expression can only be tested by a careful study of the masterpieces written in it. No one that has not read the finest chapters of *Niala* or *Olaf Tryggvasson's Life*, the *Tales* of Snorri, or a *Gospel* in Odd's translation, not to speak of other works almost equally worthy of mention, can judge fairly of the capacity, force, and sweetness of this most classic language.

Phil logic worl

A few words are due to those whose labours have rendered the task of mastering it easy and pleasant. The oldest philologist, Thorodd, has been noticed; an anonymous grammarian of the next generation, *c.* 1175, attempted a classification of letters and sounds; Sturla's brother Olaf, the White Poet, applied the figures, &c., of Donatus and Priscian to Icelandic, in which task he was followed by a continuator. All these treatises were published along with the *Thulur*, rhymed glossaries (compiled in the Western Islands, probably in the Orkneys), in vol. ii. of the AM. edition of the *Edda*, to a MS. of which they are found affixed, Copenhagen, 1832.

Of modern works, those of Rask, the founder of modern Icelandic philology, Egillson, the learned author of the *Poetic Lexicon*, otherwise well known by his translation of Homer, and Fritzner, the first real Icelandic lexicographer, deserve reverent mention. But for all practical purposes their labours have been superseded and their designs fulfilled by Dr Gudbrand Vigfusson, whose *Icelandic-English Dictionary*, Oxford, 1869–75, must, whether one looks to its scientific philology, completeness, accuracy, or arrangement, be pronounced the best existing dictionary of any Teutonic tongue. It comprises a grammar and phonology, &c. The university of Oxford has recently published, under the editorship of Messrs Vigfusson and Powell, a very complete *Icelandic Prose Reader*. In the scattered opuscula of Dr Bugge, as well as in his notes to the poetic *Edda*, are to be found many interesting "equations" and observations on the language and comparative mythology of Scandinavia.

To English philologists the study of Icelandic is of high importance, as bearing upon the grammar and vocabulary of our most important dialect, the Northumbrian, to a scientific knowledge of which it is absolutely necessary. A list of words occurring in every-day English which we owe to the Scandinavian settlers of the Danelaw will be found in the Oxford *Icelandic Reader*. To Irish scholars the old northern tongue is also of interest, as not only did those who spoke it borrow much from their Celtic friends and foes, but there was also a certain amount of reflex action which it would be desirable to fully trace out. As the most regular and pure of the Teutonic dialects, its value to the comparative philologist is sufficiently obvious. (F. Y. P.)

ICELAND MOSS, a lichen, *Cetraria islandica* (Achar.), whose erect or ascending foliaceous habit gives it something of the appearance of a moss, whence probably the name. The thallus has a pale chestnut colour, and grows to a height of from 3 to 4 inches, the branches being channelled or rolled into tubes, which terminate in flattened lobes with fringed edges. It grows abundantly in the mountainous regions of northern countries, and specially it is characteristic of the lava slopes and plains of the west and north of Iceland. As met with in commerce it is a light-grey harsh cartilaginous body, almost destitute of odour, and having a slightly bitter taste. It contains about 70 per cent. of lichenin or lichen-starch, a body isomeric with common starch, but wanting any appearance of structure. It also yields a peculiar modification of chlorophyll, called thallochlor, fumaric acid, licheno-stearic acid, and cetraric acid, to which last it owes its bitter taste. In medicine it is used as a mild tonic, and at the same time it forms a nutritious and easily digested amylaceous food, being used in place of starch in some preparations of cocoa. It is not, however, in great request, and even in Iceland it is only habitually resorted to in seasons of scarcity.

I-CHANG, or Y-CHANG, also called Y-LIN in some maps, a town of China, in the province of Hoo-pih, one of the four new ports opened to foreign trade by treaty in 1877. It is situated in 30° 42′ N. lat. and (approximately) 111° 20′ E. long,—363 geographical miles up the Yang-tze-Keang from Hankow. Built on the left bank of the river just where it escapes from the ravines and gorges which for 350 miles have imprisoned its channel, I-chang is exposed to considerable risk of floods; in 1870 the waters rose as much as 20 feet in one day, and the town had many of its houses and about half of its wall swept away. The first English vessels to make the ascent of the river as far as I-chang were those of Admiral Sir James Hope's expedition in 1861. In 1878 the port was visited by 16 Chinese steamers with a burden of 5440 tons, and the net value of the trade was 71,014 Hk. taels (of about 6s.); in the following year the net value had increased to 612,508 Hk. taels. Trepang was one of the principal articles. The

Chinese population is estimated at 33,560 (*Deutsches Handels Archiv*, 1880); and in 1878 there were fifteen foreign residents.

See *Journ. of R. Geogr. Soc.*, 1862; and Blakiston, *Five Months on the Yang-tze-Keang*, 1862.

ICHNEUMON (*Herpestes*), a genus of small carnivorous mammals belonging to the family *Viverridæ*, and resembling the true civets in the elongated weasel-like form of the body and in the shortness of the limbs. There are, according to Gray (*British Museum Catalogue*, 1869), 22 species of ichneumons, the great majority of which are confined to the African continent, the remainder occurring in Persia, India, and the Malay archipelago, and one, the Andalusian ichneumon (*H. Widdringtonii*, Gray), in the Sierra Morena of Spain, the last probably an African straggler. The Egyptian and Indian ichneumons are the forms best known. The former (*Herpestes ichneumon*, L.) is an inhabitant of Egypt and the north of Africa, where it is known to foreign residents as "Pharaoh's rat." When full grown it is about the size of the domestic cat. It is covered with a fur of long harsh hairs of a tawny grey colour, darker on the head and along the middle of the back, its legs reddish and its feet and tail black. It feeds on rats and mice, birds and reptiles, and for this reason is occasionally domesticated. Its fondness for eggs leads it to search for those of the crocodile, buried as these usually are beneath a thin covering of sand on the river banks; and its services in thus checking the multiplication of those reptiles were so appreciated by the ancient Egyptians that they regarded the ichneumon as a sacred animal, and when it died buried it, says Herodotus, "in holy repositories." It is, however, equally fond of poultry and their eggs, and its depredations among fowls considerably detract from its undoubted merits as a vermin-killer. During the inundations of the Nile it is said to approach the habitations of man, but at other seasons it keeps to the fields and to the banks of the crocodile-frequented river. The Indian ichneumon or mungoos (*Herpestes griseus*, Desm.) is considerably smaller than the Egyptian form; its fur is of a pale grey colour, the hairs being largely white-ringed, while the cheeks and throat are more or less reddish. Like the preceding species, it is frequently domesticated, and is then put to a similar use. It is especially serviceable in India as a serpent killer, destroying not only the eggs and young of these creatures, but attacking without hesitation and killing the most venomous adult snakes. The fact that it invariably survives those encounters has led to the belief that it either enjoys immunity from the effects of snake poison, or that after being bitten it has recourse, as the Hindoos have always maintained, to the root of a plant as an antidote. Neither of these suppositions has stood the test of scientific examination, for it has been found that when actually bitten it falls a victim to the poison as rapidly as other mammals, while there is no trustworthy evidence of its seeking a vegetable antidote. The truth seems to be that the mungoos by its exceeding agility and quickness of eye avoids the fangs of the snake while fixing its own teeth in the back of the reptile's neck. The whole Thanatophidia of India stand in awe of this tiny but tenacious mammal, and seek to escape from its presence. The mungoos, on the other hand, never hesitates to attack; the moment he sees his enemy, "his whole nature," says a recent spectator of one of those fights, "appears to be changed. His fur stands on end, and he presents the incarnation of intense rage. The snake invariably attempts to escape, but, finding it impossible to evade the rapid onslaught of the mungoos, he raises his crest and lashes out fiercely at his little persecutor, who seems to delight in dodging out of the way just in time. This goes on until the mungoos sees his opportunity, when like lightning he rushes in and seizes the snake with his teeth by the back of the neck close to the head, shaking him as a terrier does a rat. These tactics are repeated until the snake is killed." The mungoos is equally dexterous in killing rats and other four-footed vermin.

Egyptian Ichneumon.

ICHNEUMON-FLY is a general name applied to parasitic insects of the section *Pupivora* (or *Entomophaga*), order *Hymenoptera*, from the typical genus *Ichneumon*, belonging to the chief family of that section,—itself fancifully so called after the Egyptian mammal (*Herpestes*), notorious for its habit of destroying the eggs of reptiles. The species of the families *Ichneumonidæ*, *Braconidæ*, *Evaniidæ*, *Proctotrypidæ*, and *Chalcididæ* are often indiscriminately called "Ichneumons," but the term is perhaps properly applicable only to the first and second of these, which are respectively equivalent to the *Ichneumones genuini* and *I. adsciti* of older naturalists, chiefly differing in the former having two recurrent nerves to the anterior wing, whilst the latter has only one such nerve. The *Ichneumonidæ* proper are one of the most extensive groups of insects, and have been much studied by entomologists since the time of Linnæus and Gravenhorst. Their sexual differences of colour, &c., are, however, often so great that fresh discoveries are constantly being made with regard to their true specific relations, as well as new species detected by biological observers. Gravenhorst described some 1650 European species, to which considerable subsequent additions have been made; and at the latest computation of the English *Ichneumonidæ* (in 1872, by the Rev. T. A. Marshall), 1186 species, contained in 136 genera, were recognized,—439 *Braconidæ* being also enumerated. There are 6 subfamilies of the *Ichneumonidæ*, viz., the *Ichneumonides*, *Cryptides*, *Agriotypides*, *Ophionides*, *Tryphonides*, and *Pimplides*, differing considerably in size and facies, but united in the common attribute of being in their earlier stage parasitic upon other insects. They have all long narrow bodies; a small free head with long filiform or setaceous antennæ, which are never elbowed, and have always more than sixteen joints; the abdomen attached to the thorax at its hinder extremity between the base of the posterior coxæ, and provided in the female with a straight ovipositor often exserted and very long; and the wings veined, with perfect cells on the disk of the front pair.

The parasitic habits above alluded to render these flies of very great importance in the economy of nature, as they effectually serve to check any inordinate increase in the numbers of injurious insects. Without their aid, indeed, it would in many cases be impossible for the agriculturist to hold his own against the ravages of his minute hexapod foes, whose habits are not sufficiently known to render artificial checks or destroying agents available. The females of all the species are constantly on the alert to discover the proper living food for their own larvæ, which are hatched from the eggs they deposit in or on the eggs, larvæ, or pupæ of other insects of all orders, chiefly *Lepidoptera*, the caterpillars of butterflies and moths being specially attacked (as also are spiders). Any one who has watched insect life, even in a suburban garden, during summer, can hardly have failed to notice the busy way in which the parent ichneumon, a small four-winged fly, with constantly vibrating antennæ, searches for her prey; and the clusters of minute cocoons round the remains of some unfortunate cabbage-butterfly caterpillar, which has had just enough vitality left in it to crawl instinctively to a proper place for undergoing that change to pupa which it will never make, must also have been observed by many. This is the work of *Apanteles* (or *Microgaster*) *glomeratus*, one of the *Braconidæ*, which in days past was a source of disquietude to naturalists, who believed that the life of the one defunct larva had *transmigrated* into the numerous smaller flies reared from it. Ichneumon-flies which attack external feeders have a short ovipositor; but those attached to wood-feeding insects have that organ of great length, for the purpose of reaching their concealed prey. Thus a species from Japan (*Bracon penetrator*) has its ovipositor nine times the length of the body; and the large species of *Rhyssa* and *Ephialtes*, parasitic on *Sirex* and large wood-boring beetles in temperate Europe, have very long instruments (with which when handled they will endeavour to sting, sometimes penetrating the skin), in order to get at their secreted victims. This length of ovipositor is, in the female of a species of *Pelecinus*, common in the boreal parts of North America in pine forests, replaced by an excessively attenuated development of abdomen, causing the insect to resemble a small dragon-fly, and fulfilling the same mechanical purpose. A common reddish-coloured species of *Ophion* (*O. obscurum*), with a sabre-shaped abdomen, is noteworthy from the fact of its eggs being attached by stalks outside the body of the caterpillar of the puss-moth (*Diranura vinula*). Lepidopterists wishing to breed the latter cut off the eggs of the parasite with scissors.

The larvæ of the ichneumon-flies are white fleshy cylindrical footless grubs; the majority of them spin silk cocoons before pupating, often in a mass (sometimes almost geometrically), and sometimes in layers of different colours and texture.

The reader desirous of investigating more fully the structure and habits of this interesting family will, in addition to the older works of Gravenhorst, Esenbeck, Wesmael, and Haliday, find much matter in the recent writings of Brischke, Cresson, Provancher, Holmgren, Woldstedt, Tischbein, Vollenhoven, Förster, Kriechbaumer, Taschenberg, F. Smith, C. G. Thomson, and Rondani. The last-mentioned author has published (in the Bulletin of the Italian Entomological Society, 1871–78) a valuable list of parasitic insects and the species to which they are attached. (E. C. R.)

ICHTHYOLOGY

ICHTHYOLOGY[1] is that branch of zoology which treats of the internal and external structure of fishes, their mode of life, and their distribution in space and time. According to the views generally adopted at present, all those Vertebrate animals are referred to the class of Fishes which combine the following characteristics:—they live in water, and by means of gills or branchiæ breathe air dissolved in water; the heart consists of a single ventricle and single atrium; the limbs, if present, are modified into fins, supplemented by unpaired median fins; and the skin is either naked, or covered with scales or with osseous plates or bucklers. With few exceptions fishes are oviparous. There are, however, as we shall see hereafter, not a few members of this class which show a modification of one or more of these characteristics, and which, nevertheless, cannot be separated from it. The distinction between the class of Fishes and that of Batrachians is very slight indeed.

History and Literature.

The commencement of the history of ichthyology coincides with that of zoology generally. Aristotle. Aristotle (384–322 B.C.) had a perfect knowledge of the general structure of fishes, which he clearly discriminates both from the aquatic animals with lungs and mammæ, *i.e.*, Cetaceans, and from the various groups of aquatic invertebrates. According to him, "the special characteristics of the true fishes consist in the branchiæ and fins, the majority having four fins, but those of an elongate form, as the eels, having two only. Some, as the *Muræna*, lack the fins altogether. The rays swim with their whole body, which is spread out. The branchiæ are sometimes furnished with an operculum, sometimes they are without one, as in the cartilaginous fishes. . . . No fish has hairs or feathers; most are covered with scales, but some have only a rough or a smooth skin. The tongue is hard, often toothed, and sometimes so much adherent that it seems to be wanting. The eyes have no lids, nor are any ears or nostrils visible, for what takes the place of nostrils is a blind cavity; nevertheless they have the senses of tasting, smelling, and hearing. All have blood. All scaly fishes are oviparous, but the cartilaginous fishes (with the exception of the sea-devil, which Aristotle places along with them) are viviparous. All have a heart, liver, and gall-bladder; but kidneys and urinary bladder are absent. They vary much in the structure of their intestines: for, whilst the mullet has a fleshy stomach like a bird, others have no stomachic dilatation. Pyloric cæca are close to the stomach, and vary in number; there are even some, like the majority of the cartilaginous fishes, which have none whatever. Two bodies are situated along the spine, which have the function of testicles; they open towards the vent, and are much enlarged in the spawning season. The scales become harder with age. Not being provided with lungs, fishes have no voice, but several can emit grunting sounds. They sleep like other animals. In most cases the females exceed the males in size; and in the rays and sharks the male is distinguished by an appendage on each side of the vent."

Aristotle's information on the habits of fishes, their migrations, mode and time of propagation, and economic uses, is, so far as it has been tested, surprisingly correct. Unfortunately, we too often lack the means of recognizing the species of which he gives a description. His ideas of specific distinction were as vague as those of the fishermen whose nomenclature he adopted; it never occurred to him that vernacular names are subject to change, or may be entirely lost in course of time, and the difficulty of identifying his species is further increased by the circumstance that sometimes several popular names are applied by him to the same fish, or different stages of growth are designated by distinct names. The number of fishes known to Aristotle seems to have been about one hundred and fifteen, all of which are inhabitants of the Ægean Sea.

That one man should have discovered so many truths, and laid so sure a basis for future progress in zoology, is less surprising than the fact that for about eighteen centuries a science which seemed to offer particular attractions to men gifted with power of observation was no farther advanced. Yet such is the case. Aristotle's disciples, as well as his successors, remained satisfied to be his copiers or commentators, and to collect fabulous stories or vague notions. With very few exceptions (such as Ausonius, who wrote a small poem, in which he describes from his own observations the fishes of the Moselle) authors entirely abstained from original research; and it was not until about the middle of the 16th century that ichthyology made a new step in advance by the appearance of Belon, Rondelet, and Salviani, who almost simultaneously published their great works, by which the idea of species was established definitely and for all time.

[1] From ἰχθύς, fish, and λόγος, doctrine or treatise.

B n. P. Belon travelled in the countries bordering on the eastern part of the Mediterranean, in the years 1547–50; he collected rich stores of positive knowledge, which he embodied in several works. The one most important for the progress of ichthyology is that entitled *De aquatilibus libri duo*, Paris, 1553. Belon knows about one hundred and ten fishes, of which he gives rude but generally recognizable figures. In his descriptions he pays regard to the classical as well as to the vernacular nomenclature, and states the outward characteristics, sometimes even to the number of fin rays; frequently also he gives the most conspicuous anatomical peculiarities. Although Belon but rarely gives definitions of the terms used by him, it is not generally very difficult to ascertain the limits which he intended to assign to each division of aquatic animals. He very properly divides them into such as are provided with blood and those without it,—two divisions corresponding in modern language to vertebrate and invertebrate aquatic animals. The former are classified by him according to size, the further subdivisions being based on the structure of the skeleton, mode of propagation, number of limbs, form of the body, and physical character of the habitat.

iani. The work of the Roman ichthyologist, H. Salviani (1514–72), bears evidence of the high social position which the author held as physician to three popes. Its title is *Aquatilium animalium historia*, Rome, 1554–57, fol. It treats exclusively of the fishes of Italy. Ninety-two species are figured on seventy-six plates, which, as regards artistic execution, are masterpieces of that period, although those specific characteristics which nowadays constitute the value of a zoological drawing were entirely overlooked by the author or artist. No attempt is made at a natural classification, but the allied forms are generally placed in close proximity. The descriptions are quite equal to those given by Belon, entering much into the details of the economy and uses of the several species, and were evidently composed with the view of collecting in a readable form all that might prove of interest to the class of society in which the author moved. Salviani's work is of a high order, very remarkable considering the age in which he lived. It could not fail to convey valuable instruction, and to render ichthyology popular in the country to the fauna of which it was devoted, but it was not fitted to advance ichthyology as a science generally; in this respect Salviani is not to be compared with Rondelet or Belon.

leiet. G. Rondelet (1507–57) had the great advantage over Belon of having received a medical education at Paris, and especially of having gone through a complete course of instruction in anatomy as a pupil of Guentherus of Andernach. This is conspicuous throughout his works—*Libri de piscibus marinis*, Lyons, 1554; and *Universæ aquatilium historiæ pars altera*, Lyons, 1555. Nevertheless they cannot be regarded as more than considerably enlarged editions of Belon's work. For, although he worked independently of the latter, and differs from him in numerous details, of which he had a much more extensive knowledge, the system adopted by him is characterized by the same absence of the true principles of classification. His work is almost entirely limited to European and chiefly to Mediterranean forms, and comprises no less than one hundred and ninety-seven marine and forty-seven freshwater fishes. His descriptions are more complete and his figures much more accurate than those of Belon; and the specific account is preceded by introductory chapters, in which he treats in a general manner of the distinctions, the external and internal parts, and the economy of fishes. Like Belon, he had no conception of the various categories of classification—confounding, for instance, throughout his work the terms "genus" and "species"; but he had an intuitive notion of what his successors called a "species," and his principal object was to collect and give as much information as possible regarding such species.

For nearly a century the works of Belon and Rondelet continued to be the standard works on ichthyology; but the science did not remain stationary during that period. The attention of naturalists was now directed to the fauna of foreign countries, especially of the Spanish and Dutch possessions in the New World; and in Europe the establishment of anatomical schools and academies led to careful investigation of the internal anatomy of the most remarkable European forms. Limited as these efforts were as to their scope, being restricted either to the fauna of some particular district or to the dissection of a single species, they were sufficiently numerous to enlarge the views of naturalists, and to destroy that fatal dependence on preceding authorities which had continued to keep in bonds the minds of such men even as Rondelet and Belon. The most noteworthy of those engaged in these inquiries in tropical countries were W. Piso and G. Margrav, who accompanied as physicians the Dutch governor, Prince Maurice of Nassau, to Brazil (1637–44).

Of the men who left records of their anatomical researches, we may mention Borelli (1608–79), who wrote a work *De motu animalium*, Rome, 1680, 4to, in which he explained the mechanism of swimming and the function of the air-bladder; M. Malpighi (1628–94), who examined the optic nerve of the sword-fish; the celebrated J. Swammerdam (1637–80), who described the intestines of numerous fishes; and J. Duverney (1648–1730), who investigated in detail the organs of respiration.

A new era in the history of ichthyology commences with Ray, Willughby, and Artedi, who were the first to recognize the true principles by which the natural affinities of animals should be determined. Their labours stand in so intimate a connexion with each other that they represent but one great step in the progress of this science.

J. Ray (1628–1705) was the friend and guide of F. Willughby (1635–72). They found that a thorough reform in the method of treating the vegetable and animal kingdoms had become necessary; that the only way of bringing order into the existing chaos was by arranging the various forms according to their structure; that they must cease to be burdened with inapplicable passages and quotations from ancient writers, and to perpetuate the vague and erroneous notions of their predecessors. They therefore substituted facts for speculation, and one of the first results of this change, perhaps the most important, was that, having recognized "species" as such, they defined the term, and fixed it as the starting point of all sound zoological knowledge. Ray and Willughby.

Although they had divided their work so that Ray attended to the plants principally, and Willughby to the animals, the *Historia piscium*, Oxf., 1686, which bears Willughby's name on the title page, and was edited by Ray, is clearly their joint production. A great part of the observations contained in it were collected during the journeys they made together in Great Britain and in the various countries of Europe; and it is no exaggeration to say that at that time these two Englishmen knew the fishes of the Continent, and especially those of Germany, better than any native zoologist.

By the definition of fishes as animals with blood, breathing by gills, provided with a single ventricle of the heart, and either covered with scales or naked, the Cetaceans are excluded. The fishes proper are arranged primarily according to the cartilaginous or the osseous nature of the skeleton, and then subdivided according to the general form of the body, the presence or the absence of ventral fins, the soft or the spinous structure of the dorsal rays, the number of dorsal fins, &c. No fewer than four hundred and twenty species are thus arranged and described, of which about one hundred and eighty were known to the authors from personal examination,—a comparatively small proportion, but descriptions and figures still formed in great measure the substitute for our modern collections and museums. With the increasing accumulation of forms, the want of a fixed nomenclature had become more and more felt.

Artedi. Peter Artedi would have been a great ichthyologist if Ray or Willughby had not preceded him. But he was fully conscious of the fact that both had prepared the way for him, and therefore he did not fail to reap every possible advantage from their labours. Born in 1705 in Sweden, he studied with Linnæus at Upsala; from an early period he devoted himself entirely to the study of fishes, and was engaged in the arrangement and description of the collection of Seba, a wealthy Dutchman who had formed what was perhaps the richest museum at that time, when he was accidentally drowned in one of the canals of Amsterdam in the year 1734, at the age of twenty-nine. His manuscripts were fortunately secured by an Englishman, Count Clifford, and edited by his early friend Linnæus. The work is divided into the following parts:—

(1) In the *Bibliotheca Ichthyologica* Artedi gives a very complete list of all preceding authors who had written on fishes, with a critical analysis of their works. (2) The *Philosophia Ichthyologica* is devoted to a description of the external and internal parts of fishes; Artedi fixes a precise terminology for all the various modifications of the organs, distinguishing between those characters which determine a genus and such as indicate a species or merely a variety; in fact he establishes the method and principles which subsequently have guided every systematic ichthyologist. (3) The *Genera Piscium* contains well-defined diagnoses of forty-five genera, for which he has fixed an unchangeable nomenclature. (4) In the *Species Piscium* descriptions of seventy-two species, examined by himself, are given,—descriptions which even now are models of exactitude and method. (5) Finally, in the *Synonymia Piscium* references to all previous authors are arranged for every species, very much in the manner which is adopted in the systematic works of the present day.

Artedi has been justly called the Father of Ichthyology. So admirable was his treatment of the subject, that even Linnæus. Linnæus could only modify and add to it. Indeed, so far as ichthyology is concerned, Linnæus has scarcely done anything beyond applying binominal terms to the species properly described and classified by Artedi. His classification of the genera appears in the 12th edition of the *Systema* thus:—

A. *Amphibia Nantes.*—*Spiraculis compositis.*—Petromyzon, Raia, Squalus, Chimæra. *Spiraculis solitariis.*—Lophius, Acipenser, Cyclopterus, Balistes, Ostracion, Tetrodon, Diodon, Centriscus, Syngnathus, Pegasus.

B. *Pisces Apodes.*—Muræna, Gymnotus, Trichiurus, Anarrhichas, Ammodytes, Ophidium, Stromateus, Xiphias.

C. *Pisces Jugulares.*—Callionymus, Uranoscopus, Trachinus, Gadus, Blennius.

D. *Pisces Thoracici.*—Cepola, Echeneis, Coryphæna, Gobius, Cottus, Scorpæna, Zeus, Pleuronectes, Chætodon, Sparus, Labrus, Sciæna, Perca, Gasterosteus, Scomber, Mullus, Trigla.

E. *Pisces Abdominales.*—Cobitis, Amia, Silurus, Teuthis, Loricaria, Salmo, Fistularia, Esox, Elops, Argentina, Atherina, Mugil, Mormyrus, Exocœtus, Polynemus, Clupea, Cyprinus.

Two contemporaries of Linnæus, L. T. Gronow and J. T. Klein, attempted a systematic arrangement of fishes; both had considerable advantages for the study, especially in possessing extensive collections; but neither exercised any influence on the progress of ichthyology.

The works of Artedi and Linnæus led to an activity of research, especially in Scandinavia, Holland, Germany, and England, such as has never been equalled in the history of biological science. Whilst some of the pupils and followers of Linnæus devoted themselves to the examination and study of the fauna of their native countries, others proceeded on voyages of discovery to foreign and distant lands. Of these latter the following may be especially mentioned:—O. Fabricius worked out the fauna of Greenland; Kalm collected in North America, Hasselquist in Egypt and Palestine, Brünnich in the Mediterranean, Osbeck in Java and China, Thunberg in Japan; Forskål examined and described the fishes of the Red Sea; Steller, Pallas, S. T. Gmelin, and Güldenstedt traversed nearly the whole of the Russian empire in Europe and Asia. Others attached themselves as naturalists to the celebrated circumnavigators of the last century, such as the two Forsters (father and son) and Solander, who accompanied Cook; Commerson, who travelled with Bougainville; and Sonnerat. Numbers of new and remarkable forms were discovered by those men, and the foundation was laid for a knowledge of the geographical distribution of animals.

Of those who studied the fishes of their native countries, the most celebrated were Pennant (Great Britain), O. F. Müller (Denmark), Duhamel (France), Meidinger (Austria), Cornide (Spain), and Parra (Cuba).

The mass of materials brought together by those and other zoologists was so great that, not long after the death of Linnæus, the necessity made itself felt for collecting them in a compendious form. Several compilers undertook this task; they embodied the recent discoveries in new editions of the classical works of Artedi and Linnæus, but, not possessing either a knowledge of the subject or any critical discernment, they only succeeded in burying those noble monuments under a chaotic mass of rubbish. For ichthyology it was fortunate that two men at least, Bloch and Lacépède, made it a subject of prolonged original research.

Mark Eliezer Bloch (1723–1799), a physician of Berlin, Bloch had reached the age of fifty-six when he commenced to write on ichthyological subjects. To begin at his time of life a work in which he intended not only to give full descriptions of the species known to him from specimens or drawings, but also to illustrate each species in a style truly magnificent for his time, was an undertaking the execution of which most men would have despaired of. Yet he accomplished not only this task, but even more than he at first contemplated.

His work consists of two divisions:—(1) *Oeconomische Naturgeschichte der Fische Deutschlands*, Berl., 1782–84; (2) *Naturgeschichte der ausländischen Fische*, Berl., 1785–95. The first division, which is devoted to a description of the fishes of Germany, is entirely original, and based upon the author's own observations. His descriptions as well as figures were made from nature, and are, with but few exceptions, still serviceable; indeed many continue to be the best existing in literature. Bloch was less fortunate, and is much less reliable, in his natural history of foreign fishes. For many of the species he had to trust to more or less incorrect drawings and descriptions by travellers; frequently, also, he was deceived as to the origin of specimens which he acquired by purchase. Hence his accounts contain numerous confusing errors, which it would have been difficult to correct had not nearly the whole of the materials on which his work is based been preserved in the collections at Berlin.

After the completion of his great work Bloch occupied himself with systematizing. He prepared a general system of fishes, in which he arranged not only those described in his great work, but also those with which he had afterwards become acquainted from the descriptions of others. The work was ably edited and published after Bloch's death by a philologist, J. G. Schneider, under the title *M. E. Blochii Systema ichthyologiæ iconibus CX. illustratum*, Berl., 1801. The number of species enumerated in it amounts to 1519. The system is based upon the number of the fins, the various orders being termed *Hende-*

capterygii, *Decapterygii*, &c. We need not add that an artificial method like this led to the most unnatural combinations and distinctions.

Bloch's *Naturgeschichte* remained for many years the standard work, and, with its great number of excellent illustrations, proved a most useful guide to the student. But as regards originality of thought Bloch was far surpassed by his contemporary, B. G. E. de Lacépède, born at Agen, in France, in 1756, a man of great and general erudition, who became professor at the museum of natural history in Paris, where he died in 1826.

Lacépède.

Lacépède had to contend with great difficulties in the preparation of his *Histoire des Poissons*, Paris, 1798–1803, 5 vols., which was written during the most disturbed period of the French Revolution. A great part of it was composed whilst the author was separated from collections and books, and had to rely on his notes and manuscripts only. Even the works of Bloch and other contemporaneous authors remained unknown, or at least inaccessible, to him for a long time. We need not therefore be surprised that his work abounds in the kind of errors into which a compiler is liable to fall. Not only does the same species appear under two or more distinct specific names, but it sometimes happens that the author so little understands the source from which he derives his information that the description is referred to one genus and the accompanying figure to another. The names of genera are unduly multiplied; and the figures with which the work is illustrated are far inferior to those of Bloch. Thus the influence of Lacépède on the progress of ichthyology was vastly less than that of his fellow-labourer; and the labour laid on his successors in correcting the numerous errors into which he had fallen probably outweighed the assistance which they derived from his work.

The work of the principal cultivators of ichthyology in the period between Ray and Lacépède was chiefly systematizing and describing; but the internal organization of fishes also received attention from more than one great anatomist. Haller, Camper, and Hunter examined the nervous system and the organs of sense; and above all Alexander Monro, *secundus*, published a classical work, *The Structure and Physiology of Fishes explained and compared with those of Man and other Animals*, Edin., 1785. The electric organs of fishes (*Torpedo* and *Gymnotus*) were examined by Réaumur, Allamand, Bancroft, Walsh, and still more exactly by J. Hunter. The mystery of the propagation of the eel called forth a large number of essays, and even the artificial propagation of *Salmonidæ* was known and practised by Gleditsch (1764).

Bloch and Lacépède's works were almost immediately succeeded by the labours of Cuvier, but his early publications were of necessity tentative, preliminary, and fragmentary, so that some little time elapsed before the spirit infused into ichthyology by this great anatomist could exercise its influence on all the workers in this field. Several of such ante-Cuvierian works must be mentioned on account of their importance to our knowledge of certain faunas. The *Descriptions and Figures of Two Hundred Fishes collected at Vizagapatam on the Coast of Coromandel*, Lond., 1803, 2 vols., by Patrick Russel, and *An Account of the Fishes found in the River Ganges and its Branches*, Edin., 1822, 2 vols., by F. Hamilton (formerly Buchanan), were works distinguished by greater accuracy of the drawings (especially the latter) than was ever attained before. A *Natural History of British Fishes* was published by E. Donovan, Lond., 1802–8; and the Mediterranean fauna formed the study of the lifetime of A. Risso (*Ichthyologie de Nice*, Paris, 1810; and *Histoire naturelle de l'Europe Méridionale*, Paris, 1827). A slight beginning in the description of the fishes of the United States was made by S. L. Mitchell, who published, besides various papers, a *Memoir on the Ichthyology of New York*, in 1815.

Cuvier.

G. Cuvier (1769–1832) did not occupy himself with the study of fishes merely because the class formed part of the *Règne Animal*, but devoted himself to it with particular predilection. The investigation of their anatomy, and especially of their skeleton, was taken up by him at an early period, and continued until he had succeeded in completing so perfect a framework of the system of the whole class that his immediate successors required only to fill up those details for which their master had had no leisure. Indefatigable in examining all the external and internal characters of the fishes in a rich collection, he ascertained the natural affinities of the infinite variety of forms, and accurately defined the divisions, orders, families, and genera of the class, as they appear in the various editions of the *Règne Animal*. His industry equalled his genius: he formed connexions with almost every accessible part of the globe; not only French travellers and naturalists, but also Germans, Englishmen, Americans, rivalled one another in assisting him with collections; and for many years the museum of the Jardin des Plantes was the centre where all ichthyological treasures were deposited. Thus Cuvier brought together a collection the like of which had never been seen before, and which, as it contains all the materials on which his labours were based, must still be considered as the most important. Soon after the year 1820, Cuvier, assisted by one of his pupils, A. Valenciennes, commenced his great work on fishes, *Histoire naturelle des Poissons*, of which the first volume appeared in 1828. The earlier volumes, in which Cuvier himself took his share, bear evidence of the enthusiasm with which both authors devoted themselves to their task. After Cuvier's death in 1832, the work was left entirely in the hands of Valenciennes, whose energy and interest gradually slackened, rising to their former pitch in some parts only, as, for instance, in the treatise on the herring. He left the work unfinished with the twenty-second volume (1848), which treats of the Salmonoids. Yet, incomplete as it is, it is indispensable to the student.

Valenciennes.

The system finally adopted by Cuvier is the following:—

A. POISSONS OSSEUX.

I. A Branchies en Peignes ou en Lames.

1. *A Mâchoire Supérieure Libre.*

a. *Acanthoptérygiens.*

Percoïdes.	Sparoïdes.	Branchies labyrinthiques.
Polynèmes.	Chétodonoïdes.	Lophioïdes.
Mulles.	Scomberoïdes.	Gobioïdes.
Joues cuirassées.	Muges.	Labroïdes.
Scienoïdes.		

b. *Malacoptérygiens.*

Abdominaux.	*Subbrachiens.*	*Apodes.*
Cyprinoïdes.	Gadoïdes.	Murenoïdes.
Siluroïdes.	Pleuronectes.	
Salmonoïdes.	Discoboles.	
Clupeoïdes.		
Lucioïdes.		

2. *A Mâchoire Supérieure Fixée.*

Sclérodermes. Gymnodontes.

II. A Branchies en Forme de Houppes.

Lophobranches.

B. CARTILAGINEUX OU CHONDROPTÉRYGIENS.

Sturioniens. Plagiostomes. Cyclostomes.

We have only to compare this system with that of Linnæus if we wish to measure the gigantic stride made by ichthyology during the intervening period of seventy years. The various characters employed for classification have been examined throughout the whole class, and their relative importance has been duly weighed and understood. Though Linnæus had formed a category of "Amphibia Nantes" for fishes with a cartilaginous skeleton, which should coincide with Cuvier's "Poissons Cartilagineux," he had failed to understand the very nature of cartilage, apparently comprising under this term any skeletal framework of less firmness than ordinary bone. Hence he considered *Lophius*, *Cyclopterus*, *Syngnathus* to be cartilaginous fishes. Adopting the position and development of the ventral fins as a highly important character, he had been obliged to associate fishes having rudimentary and inconspicuous ventral fins, like *Trichiurus*, *Xiphias*, &c., with the true eels. The important category of "family" appears now in Cuvier's system fully established as intermediate between genus and order. Important changes in Cuvier's system have been made and proposed by his successors, but in the main it is still that of the present day.

Cuvier had extended his researches beyond the living forms, into the field of palæontology; he was the first to observe the close resemblance of the scales of the fossil *Palæoniscus* to those of the living *Polypterus* and *Lepidosteus*, the prolongation and identity of structure of the upper caudal lobe in *Palæoniscus* and the sturgeons, the presence of peculiar "fulcra" on the anterior margin of the dorsal fin in *Palæoniscus* and *Lepidosteus*, and inferred from these facts that the fossil genus was allied either to the sturgeons or to *Lepidosteus*. But it did not occur to him that there was a close relationship between those recent fishes. *Lepidosteus* and, with it, the fossil genus remained in his system a member of the order of *Malacopterygii abdominales*.

Agassiz. It was left to L. Agassiz (1807–73) to point out the importance of the structure of the scales as a characteristic, and to open a path towards the knowledge of a whole new subclass of fishes, the *Ganoidei*.

Impressed with the fact that the peculiar scales of *Polypterus* and *Lepidosteus* are common to all fossil osseous fishes down to the Chalk, he takes the structure of the scales generally as the base for an ichthyological system, and distinguishes four orders:—

1. *Placoids.*—Without scales proper, but with scales of enamel, sometimes large, sometimes small, and reduced to mere points (Rays, Sharks, and Cyclostomi, with the fossil Hybodontes). 2. *Ganoids.*—With angular bony scales, covered with a thick stratum of enamel: to this order belong the fossil Lepidoides, Sauroides, Pycnodontes, and Cœlacanthi; the recent Polypterus, Lepidosteus, Sclerodermi, Gymnodontes, Lophobranches, and Siluroides; also the Sturgeons. 3. *Ctenoids.*—With rough scales, which have their free margins denticulated: Chætodontidæ, Pleuronectidæ, Percidæ, Polyacanthi, Sciænidæ, Sparidæ, Scorpænidæ, Aulostomi. 4. *Cycloids.*—With smooth scales, the hind margin of which lacks denticulation: Labridæ, Mugilidæ, Scombridæ, Gadoidei, Gobiidæ, Murænidæ, Lucioidei, Salmonidæ, Clupeidæ, Cyprinidæ.

We have no hesitation in affirming that if Agassiz had had an opportunity of acquiring a more extensive and intimate knowledge of existing fishes before his energies were absorbed in the study of fossil remains, he would himself have recognized the artificial character of his classification. The distinctions between cycloid and ctenoid scales, between placoid and ganoid fishes, are vague, and can hardly be maintained. So far as the living and post-Cretacean forms are concerned, he abandoned the vantage-ground gained by Cuvier; and therefore his system could never supersede that of his predecessor, and finally shared the fate of every classification based on the modifications of one organ only. But Agassiz has the merit of having opened an immense new field of research by his study of the infinite variety of fossil forms. In his principal work, *Recherches sur les Poissons fossiles*, Neuchatel, 1833–43, 4to, atlas in fol., he placed them before the world arranged in a methodical manner, with excellent descriptions and illustrations. His power of discernment and penetration in determining even the most fragmentary remains is truly astonishing; and, if his order of Ganoids is an assemblage of forms very different from what is now understood by that term, he was at any rate the first who recognized that such an order of fishes exists.

J. Mü The discoverer of the *Ganoidei* was succeeded by their explorer, Johannes Müller (1801–58). In his classical memoir *Ueber den Bau und die Grenzen der Ganoiden*, Berl., 1846, he showed that the Ganoids differ from all the other osseous fishes, and agree with the Plagiostomes, in the structure of the heart. By this primary character, all heterogeneous elements as Siluroids, *Osteoglossidæ*, &c., were eliminated from the order as understood by Agassiz. On the other hand, he did not recognize the affinity of *Lepidosiren* to the Ganoids, but established for it a distinct subclass, *Dipnoi*, which he placed at the opposite end of the system. By his researches into the anatomy of the lampreys and *Amphioxus*, their typical distinctness from other cartilaginous fishes was proved; they became the types of two other subclasses, *Cyclostomi* and *Leptocardii*.

Müller proposed several other not unimportant modifications of the Cuvierian system; and, although all cannot be maintained as the most natural arrangements, yet his researches have given us a much more complete knowledge of the organization of the Teleosteous fishes, and later inquiries have shown that, on the whole, the combinations proposed by him require only some further modification and another definition to render them perfectly natural.

The discovery (in the year 1871) of a living representative of a genus hitherto believed to be long extinct, *Ceratodus*, threw a new light on the affinities of fishes. The writer of the present article, who had the good fortune to examine this fish, was enabled to show that, on the one hand, it was a form most closely allied to *Lepidosiren*, and, on the other, that it could not be separated from the Ganoid fishes, and therefore that *Lepidosiren* also was a Ganoid,—a relation already indicated by Huxley in a previous paper on "Devonian Fishes." This discovery led to further consideration[1] of the relative characters of Müller's subclasses, and to the system which is followed in the present article.

Having followed the development of the ichthyological system down to the most recent date, we have to retrace our steps to enumerate the most important contributions to ichthyology which appeared contemporaneously with or subsequently to the publication of the great work of Cuvier and Valenciennes. As in other branches of zoology, almost every year was marked by increased activity. For the sake of convenience we may arrange these works under three heads.

I. VOYAGES, CONTAINING GENERAL ACCOUNTS OF ZOOLOGICAL COLLECTIONS. Bibliography

A. *French.*—1. *Voyage autour du monde sur les Corvettes de S. M. l'Uranie et la Physicienne, sous le commandement de M. Freycinet*, "Zoologie—Poissons," par Quoy et Gaimard, Paris, 1824. 2. *Voyage de la Coquille*, "Zoologie," par Lesson, Paris, 1826–30. 3. *Voyage de l'Astrolabe, sous le commandement de M. J. Dumont d'Urville*, "Poissons," par Quoy et Gaimard, Paris, 1834. 4. *Voyage au Pôle Sud par M. J. Dumont d'Urville*, "Poissons," par Hombron et Jacquinot, Paris, 1853–4.

B. *English.*—1. *Voyage of H.M.S. Sulphur*, "Fishes," by J. Richardson, Lond., 1844–45. 2. *Voyage of H.M.SS. Erebus and Terror*, "Fishes," by J. Richardson, Lond., 1846. 3. *Voyage of H.M.S. Beagle*, "Fishes," by L. Jenyns, Lond., 1842. 4. *Voyage of H.M.S. Challenger*, "Fishes," by A. Günther.

C. *German.*—1. *Reise der österreichischen Fregatte Novara*, "Fische," von R. Kner, Vienna, 1865.

II. FAUNÆ.

A. *Great Britain.*—1. R. Parnell, *The Natural History of the Fishes of the Firth of Forth*, Edin., 1838. 2. W. Yarrell, *A History of British Fishes*, 3d edit., Lond., 1859. 3. J. Couch, *History of the Fishes of the British Islands*, Lond., 1862-65.

B. *Denmark and Scandinavia.*—1. H. Kröyer, *Danmark's Fiske*, Copenhagen, 1838–53. 2. S. Nilsson, *Skandinavisk Fauna*, vol. iv. "Fiskarna," Lund, 1855. 3. Fries och Ekström, *Skandinaviens Fiskar*, Stockh., 1836.

C. *Russia.*—1. Nordmann, "Ichthyologie Pontique," in Demidoff's *Voyage dans la Russie méridionale*, tom. iii., Paris, 1840.

D. *Germany.*—1. Heckel und Kner, *Die Süsswasser-fische der*

[1] "Description of Ceratodus," *Phil. Trans.*, 1871, ii.

österreichischen Monarchie, Leips., 1858. 2. C. T. E. Siebold, *Die Süsswasser-fische von Mitteleuropa*, Leips., 1863.

E. *Italy and Mediterranean.*—1. Bonaparte, *Iconografia della Fauna Italica*, tom. iii., "Pesci," Rome, 1832-41. 2. Costa, *Fauna del Regno di Napoli*, "Pesci," Naples, about 1850.

F. *France.*—1. E. Blanchard, *Les Poissons des eaux douces de la France*, Paris, 1866.

G. *Spanish Peninsula.*—The freshwater fish fauna of Spain and Portugal was almost unknown, until F. Steindachner paid some visits to those countries for the purpose of exploring the principal rivers. His discoveries are described in several papers in the *Sitzungsberichte der Akademie zu Wien*. B. du Bocage and F. Capello made contributions to our knowledge of the marine fishes on the coast of Portugal (*Jorn. Scienc. Acad. Lisb.*).

H. *North America.*—1. J. Richardson, *Fauna Boreali-Americana*, part iii., "Fishes," Lond., 1836. The species described in this work are nearly all from the British possessions in the north. 2. Dekay, *Zoology of New York*, part iv., "Fishes," New York, 1842. 3. *Reports of the United States Commission of Fish and Fisheries*, 5 vols., Washington, 1873-79, contain much valuable information. Besides these works, numerous descriptions of North American freshwater fishes have been published in the reports of the various U. S. Government expeditions, and in North American scientific journals, by Storer, Baird, Girard, W. O. Ayres, Cope, Jordan, Brown Goode, &c., but a good general, and especially critical, account of the fishes of the United States is still a desideratum.

I. *Japan.*—1. *Fauna Japonica*, "Poissons," par H. Schlegel, Leyden, 1850.

J. *East Indies*; *Tropical parts of the Indian and Pacific Oceans.*—1. E. Rüppell, *Atlas zu der Reise im Nördlichen Afrika*, Frankf., 1828. 2. E. Rüppell, *Neue Wirbelthiere*, "Fische," Frankf., 1837. 3. R. L. Playfair and A. Günther, *The Fishes of Zanzibar*, Lond., 1876. 4. C. B. Klunzinger, *Synopsis der Fische des Rothen Meers*, Vienna, 1870-71. 5. F. Day, *The Fishes of India*, Lond., 1865, 4to, contains an account of the freshwater and marine species. 6. A. Günther, *Die Fische der Südsee*, Hamburg, 4to, from 1873 (in progress). 7. Unsurpassed in activity, as regards the exploration of the fish fauna of the East Indian archipelago, is P. Bleeker (1819-78), a surgeon in the service of the Dutch East Indian Government, who, from the year 1840, for nearly thirty years, amassed immense collections of the fishes of the various islands, and described them in extremely numerous papers, published chiefly in the journals of the Batavian Society. Soon after his return to Europe (1860) Bleeker commenced to collect the final results of his labours in a grand work, illustrated by coloured plates, *Atlas Ichthyologique des Indes Orientales Néerlandaises*, Amsterd., fol., 1862; the publication of which was interrupted by the author's death in 1878.

K. *Africa.*—1. A. Günther, "The Fishes of the Nile," in Petherick's *Travels in Central Africa*, Lond., 1869. 2. W. Peters, *Naturwissenschaftliche Reise nach Mossambique*, iv., "Flussfische," Berl., 1868, 4to.

L. *West Indies and South America.*—1. L. Agassiz, *Selecta genera et species Piscium, quæ in itinere per Brasiliam collegit J. B. de Spix*, Munich, 1829, fol. 2. F. de Castelnau, *Animaux nouveaux ou rares, recueillis pendant l'expédition dans les parties centrales de l'Amérique du Sud*, "Poissons," Paris, 1855. 3. L. Vaillant and F. Bocourt, *Mission scientifique au Mexique et dans l'Amérique centrale*, "Poissons," Paris, 1874. 4. F. Poey, the celebrated naturalist of Havana, devoted many years of study to the fishes of Cuba. His papers and memoirs are published partly in two periodicals, issued by himself, under the title of *Memorias sobre la Historia natural de la Isla de Cuba* (from 1851), and *Repertorio Fisico-natural de la Isla de Cuba* (from 1865), partly in North American scientific journals. And, finally, F. Steindachner and A. Günther have published many contributions, accompanied by excellent figures, to our knowledge of the fishes of Central and South America.

M. *New Zealand.*—1. F. W. Hutton and J. Hector, *Fishes of New Zealand*, Wellington, 1872.

N. *Arctic Regions.*—1. C. Lütken, "A Revised Catalogue of the Fishes of Greenland," in *Manual of the Natural History, Geology, and Physics of Greenland*, Lond., 1875, 8vo. 2. The fishes of Spitzbergen were examined by A. J. Malmgren (1865).

III. Anatomical Works.

The number of authors who have investigated the anatomy of fishes is almost as great as that of faunists; and we should go beyond the limits of the present article if we mentioned more than the most prominent and successful. M. H. Rathke, J. Müller, J. Hyrtl, and H. Stannius left scarcely any organ unexamined, and their researches had a direct bearing either on the relation of the class of fishes to the other vertebrates, or on the systematic arrangement of the fishes themselves. E. E. von Baer, F. de Filippi, C. Vogt, W. His, W. K. Parker, and F. M. Balfour investigated their embryology; A. Kölliker and G. Pouchet their histology. The osteology was specially treated by G. Bakker, F. C. Rosenthal, L. Agassiz, and C. Gegenbaur; the nervous system by Gottsche, Philipeaux, Stannius, L. de Sanctis, L. Stieda, Baudelot, and Miclucho-Maclay; the organ of hearing by E. H. Weber, C. Hasse, and G. Retzius. The electric fishes were examined by E. Geoffroy, C Matteuci, P. Pacini, T. Bilharz, and Max Schultze. The development and metamorphosis of the lamperns was made the subject of research by H. Müller, M. Schultze, and P. Owsjannikow; Müller's examination of *Branchiostoma* was continued by J. Marcusen, A. Kovalevsky, L. Stieda, W. Müller, C, Hasse, T. H. Huxley, and F. M. Balfour. The most comprehensive accounts of the anatomy of fishes are contained in the subjoined works, which have been chiefly followed in the following anatomical description:—

1. H. Stannius, *Zootomie der Fische*, 2d edit., Berl., 1854. 2. R. Owen, *Anatomy of Vertebrates*, vol. i., Lond., 1866. 3. R. Owen, *Lectures on the Comparative Anatomy and Physiology of the Vertebrate Animals*, part i., "Fishes," Lond., 1846. 4. T. H. Huxley, *Manual of the Anatomy of Vertebrated Animals*, Lond., 1871.

It has been mentioned above that the great work of Cuvier and Valenciennes had been left incomplete. Several authors, therefore, have supplied detailed accounts of the orders omitted in that work. Müller and Henle published an account of the Plagiostomes, and Kaup of the *Murænidæ* and *Lophobranchii*; while A. Duméril commenced an *Histoire naturelle des Poissons ou Ichthyologie générale*, of which, however, only two volumes appeared, containing a complete account of the Plagiostomes (Paris, 1865) and of the Ganoids and Lophobranchs (Paris, 1870).

The activity which had prevailed in ichthyology since the publication of the *Histoire naturelle* by Cuvier and Valenciennes had been so great, and the results of the numerous investigations were scattered over such a multitude of publications, that it ultimately became imperative to collect all these materials in one comprehensive work. This was done in the *Catalogue of Fishes*, published by the trustees of the British Museum, in eight volumes (Lond., 1859-70). Besides the species previously described, many new forms were added, the total number of species referred to in those volumes amounting to 8525. As regards the systematic arrangement, Müller's system was adopted in the main, but the definition of the families was much modified. This, however, need not be further entered on now, as it will become sufficiently apparent in the systematic portion of this article.

For fuller details than can be given here regarding the structure, classification, and life-history of fishes, the reader is referred to the *Introduction to the Study of Fishes*, by A. Günther, Edin., 1880.

External Parts.

In the body of a fish four parts are distinguished,—the head, trunk, tail, and fins; the boundary between the first and second is generally indicated by the gill-opening, and that between the second and third by the vent. The form of the body and the relative proportions of these principal parts are subject to greater variation than is to be found in any other class of vertebrates. In fishes which are endowed with the power of steady and more or less rapid locomotion, a deviation from that form of body which we observe in a perch, carp, or mackerel is never excessive. The body is a simple, equally-formed wedge, compressed or slightly rounded, well fitted for cleaving the water. In fishes which are in the habit of moving on the bottom, the whole body, or at least the head, is vertically depressed and flattened; and the latter may be so enormously enlarged that the trunk and tail appear merely as an appendage. In one family of fishes, the *Pleuronectidæ* or flat-fishes, the body is compressed into a thin disk; they swim and move on one side only, which remains constantly directed towards the bottom, a peculiarity by which the symmetry of all parts of the body has been affected. In fishes moving comparatively slowly through the water, and able to remain (as it were) suspended in it, a lateral compression of the body, in conjunction with a lengthening of the vertical and a shortening of the longitudinal axis, is found. This deviation from the typical form may proceed so far that the vertical axis greatly exceeds the longitudinal in length; generally all the parts of the body participate in this form, but in one kind of fish (the *Orthagoriscus* or sun-fish) it is chiefly the tail that has been shortened, that being reduced so much as to present the appearance of being cut off. An excessive lengthening of the longitudinal axis, with a shortening of the vertical, occurs in eels and eel-like fishes, and in the so-called band-fishes. They are bottom-fish, capable of insinuating themselves into narrow crevices and holes. The form of the body in these long fishes is either cylindrical (snake-like), as in the eels and many codfishes, or strongly compressed, as in the band-fishes (*Trichiurus, Regalecus,* &c.). It is chiefly the tail that is lengthened, but frequently the head and trunk participate more or less in this form. Every possible variation occurs between these and other principal types of form. The old ichthyologists, even down to Linnæus, depended in great measure on them for classification; but, although the same form of body often obtains in the same groups of fishes, similarity of form by no means indicates natural affinity; it only indicates similarity of habits and mode of life.

Head. *The External Parts of the Head.*—The eye divides the head into the ante-orbital and post-orbital portions. In most fishes, especially in those with a compressed head, it is situated on the side and in the anterior half of the length of the head; in many others, chiefly those with a depressed head, it is directed upwards, and sometimes situated quite at the upper side; in a very few, the eyes look obliquely downwards. In the flat-fishes both eyes are on the same side of the head, either the right or the left, always on that which is directed towards the light, and coloured.

Fishes in general, as compared with other Vertebrata, have large eyes. Sometimes these organs are enormously enlarged, indicating either that the fish is nocturnal in its habits, or lives at a depth to which only a part of the sun's rays penetrate. On the other hand, small eyes occur in fishes inhabiting muddy places, or great depths, to which scarcely any light descends, or in fishes in which the want of an organ of sight is compensated by the development of other organs of sense. In a few fishes, more particularly those inhabiting caves or the greatest depths of the ocean, the eyes have become quite rudimentary and hidden under the skin.

In the ante-orbital portion of the head, or the snout, are situated the mouth and nostrils.

Mouth. The mouth is formed by the intermaxillary and maxillary bones or the intermaxillary only in the upper jaw, and by the mandibular bone in the lower. These bones are either bare or covered by integument, to which frequently labial folds or lips are added. As regards form, the mouth offers as many variations as the body itself, according to the nature of the food, and the mode of feeding. It may be narrow, or extremely wide and cleft nearly to the hind margin of the head; it may be semi-elliptical, semicircular, or straight in a transverse line; it may be quite in front of the snout (anterior), on its upper surface (superior), on its lower (inferior), or extending along each side (lateral); sometimes it is subcircular, organized for sucking. The jaws of some fishes are modified into a special weapon of attack (sword-fish, saw-fish); in fact, throughout the whole class of fishes the jaws are the only organ ever specialized for this purpose, weapons on other parts of the body being purely defensive.

Both jaws may be provided with skinny appendages, barbels, which, if developed and movable, are sensitive organs of touch.

Nostrils. In the majority of fishes the nostrils exhibit a double opening on each side of the upper surface of the snout, the openings of each side being more or less close together. They lead into a shallow groove, and only in one family (the Myxinoids) perforate the palate. In this family, as well as in the lampreys, the nasal aperture is single. In

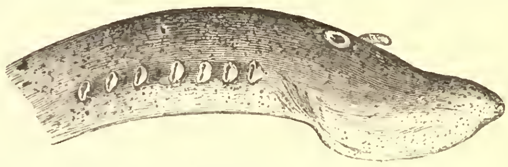


FIG. 1.—Head of *Mordacia mordax*, showing the single nostril and seven branchial openings.

many eels the openings are lateral, the lower perforating the upper lip. In the sharks and rays (figs. 2, 3, 4) they are at the lower surface of the snout, and more or less confluent. And, finally, in the Dipnoi (fig. 35) and other Ganoids, one at least is within the labial boundary of the mouth.

FIG. 2.—Confluent nasal and buccal cavities of *Chiloscyllium trispeculare*; tooth of the natural size.

The space across the forehead, between the orbits, is called the interorbital space; that below the orbits, the infraorbital or suborbital region.

In the postorbital part of the head there are distinguished, at least in most Teleosteous fishes and many Ganoids, the præoperculum, a sub-semicircular bone, generally with a free and often serrated or variously-armed margin; the operculum, forming the posterior margin of the gill-opening; and the suboperculum and interoperculum along its inferior margin. All these bones, collectively called opercula, form the gill-cover, a thin bony lamella covering the cavity containing the gills.

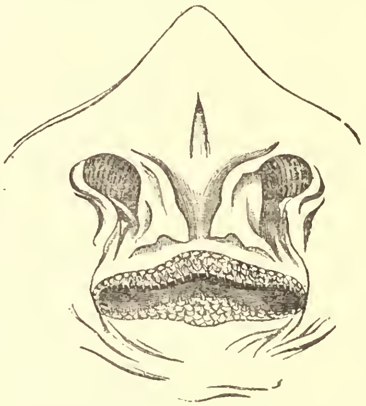

FIG. 3.—Nostrils of *Raia lemprieri*, with nasal flaps reverted.

Gills. The gill-opening is a foramen, or slit, behind or below the head, by which the water that has been taken up through the mouth for the purpose of breathing is again expelled. This slit may extend from the upper end of the operculum all round the side of the head to the symphysis of the lower jaw; or it may be shortened and finally reduced to a small opening on any part of the margin of the gill-cover. Sometimes (*Symbranchus*) the two openings, thus reduced, coalesce, and form what externally appears as a single opening only. The margin of the gill-cover is provided with a cutaneous fringe, in order more effectually to close the gill-opening; and this fringe is supported by one or several or many bony rays, the branchiostegals. The space on the chest between the two rami of the lower jaw and between the gill-openings is called the isthmus.

The sharks and rays differ from the Teleosteous and Ganoid fishes in having five branchial slits (six or seven in *Hexanchus* and *Heptanchus*), which are lateral in the sharks, and at the lower surface of the head in the rays (fig. 4). In *Myxine* only the gill-opening is at a great distance from the head; in that family (*Cyclostomi*) it is either single or there are six or more on each side (fig. 1), as in the lampreys.

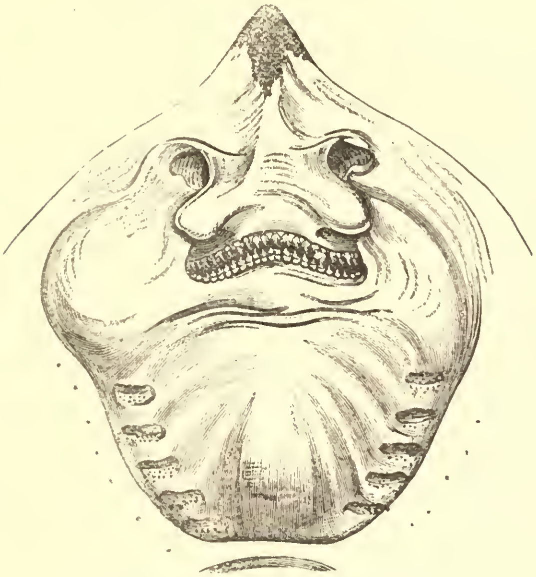

FIG. 4.—Lower aspect of head of *Raia lemprieri*.

The Trunk and Tail.—In the trunk are distinguished the back, sides, and abdomen. It gradually passes in all fishes into the tail, the termination of the abdominal cavity and the commencement of the tail being generally indicated by the position of the vent. The exceptions are numerous: not only may certain abdominal organs, such as the sexual, extend to between the muscles of the tail, but the intestinal tract itself may pass far backwards, or it may even be reflected forwards, so that the position of the vent may be either close to the extremity of the tail or to the foremost part of the trunk.

In many fishes the greater part of the tail is surrounded by fins, leaving finless only a small portion between the dorsal, caudal, and anal fins; this finless part is called the free portion or the peduncle of the tail.

The Fins.—The fins are divided into vertical or unpaired, and horizontal or paired fins. Any of them may be present or absent; and their position, number, and form are most important guides in determining the affinities of fishes.

The vertical fins are situated in the median dorsal line, from the head to the extremity of the tail, and in the ventral line of the tail. In fishes in which they are least developed or most embryonic, the vertical fin appears as a simple fold of the skin surrounding the extremity of the tail. In its further progress of development in the series of fishes, it gradually extends further forwards, and it may reach even the head and the vent. In this embryonic condition the fin is generally supported by fine rays, which are the continuations of, or articulated to, other stronger rays supported by the processes or apophyses of the vertebral column. This form of the vertical fin is very common,—for instance in the eels, and many Gadoid, Blennioid, and Ganoid fishes, in which the rays have ceased, besides, to be simple rods, showing more or less numerous joints (simple articulated rays, fig. 5). Branched rays are dichotomously split, the joints increasing in number towards the extremity.

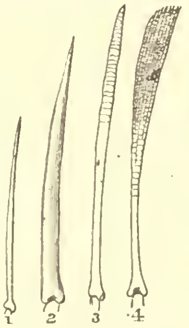

FIG. 5.—1, Simple ray, 2, spine; 3, simple articulated ray (soft); 4, branched ray (soft).

The continuity of the vertical fin, however, is interrupted in the majority of fishes, and three fins are then distinguished: one in the dorsal line—the dorsal fin; one in the ventral line behind the anus—the anal fin; and one confined to the extremity of the tail—the caudal fin.

The caudal fin is rarely symmetrical so that the upper half is equal to the lower; the greatest degree of asymmetry obtains in fishes with a heterocercal termination of the vertebral column. In fishes in which it is nearly symmetrical it is frequently prolonged into an upper and lower

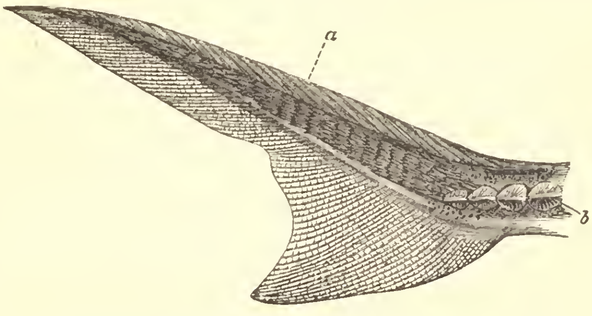

FIG. 6.—Heterocercal tail of *Acipenser*. *a*, fulcra: *b*, osseous bucklers.

lobe, its hind margin being concave or more or less deeply excised; in others the hind margin is rounded, and, when the middle rays greatly exceed in length the outer ones, the fin assumes a pointed form.

Many and systematically important differences are observed in the dorsal fin, which is either spiny-rayed (spinous) (*Acanthopterygian*), or soft-rayed (*Malacopterygian*). In the former, a smaller or greater number of the rays are simple and without transverse joints; they may be flexible, or so much osseous matter is deposited in them that they appear hard and truly spinous (fig. 7); these

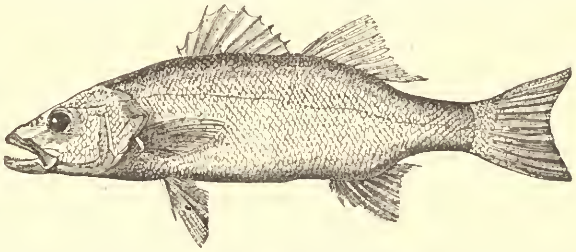

FIG 7.—*Labrax lupus* (Bass), an Acanthopterygian with anterior spinous and posterior soft dorsal fin.

spines form always the anterior portion of the fin, which is either detached from or continuous with the remaining jointed rays. The spines can be erected or depressed at the will of the fish; if in the depressed position the spines cover one another completely, their points lying in the same line, the fish is called homacanth; but if the spines are asymmetrical, alternately broader on one side than on

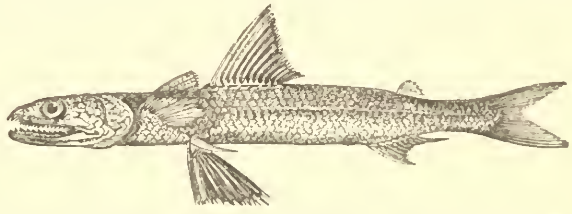

FIG. 8.—*Saurus undosquamis*, a Malacopterygian with anterior soft dorsal and additional adipose fin.

the other, the fish is called heteracanth. The spinous division, as well as the one consisting of jointed rays, may again be subdivided. In the Malacopterygian type all the rays remain jointed; indeed, sometimes the foremost ray, with its preceding short supports, is likewise ossified, and is a hard spine, but the articulations can nearly always be distinctly traced. Sometimes the dorsal fin of Malacopterygian fishes is very long, extending from the head to the end of the tail; sometimes it is reduced to a few rays only; and in a few cases it is entirely absent. In addition to the rayed dorsal fin, many Malacopterygian fishes (as the Salmonoids, many Siluroids, Scopeloids, &c.) have another of greater or lesser extent, without any rays; and as fat is always deposited within this fold, it is called a fatty fin (*pinna adiposa*) (figs. 8 and 9).

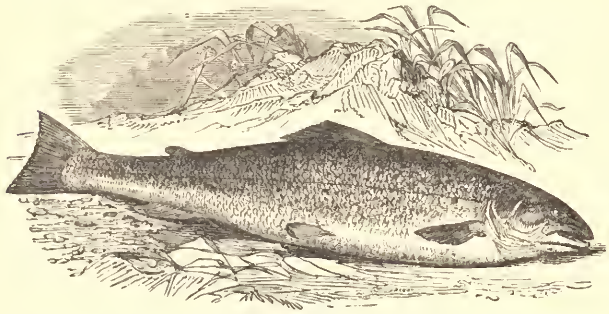

Fig. 9.—*Salmo salar* (Salmon), with abdominal ventral fins.

The anal fin is built on the same plan as the dorsal; it may be single, or there may be more than one; it may also be long or short, or entirely absent; in Acanthopterygians its foremost rays are frequently simple and spinous.

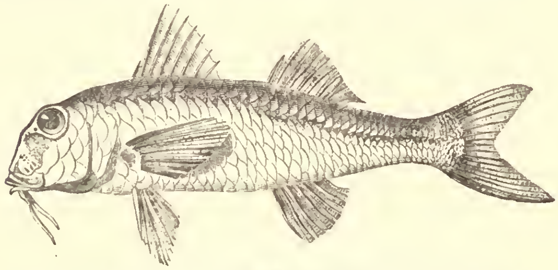

Fig. 10.—*Mullus barbatus* (Red Mullet), with thoracic ventral fins.

The horizontal or paired fins consist of two pairs, the pectorals and ventrals.

The pectoral fins (with their osseous supports) are the homologues of the anterior limbs of the higher Vertebrata. They are always inserted immediately behind the gill opening,—either symmetrical, with a rounded posterior

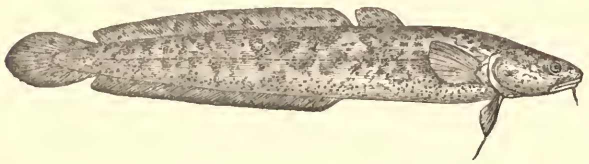

Fig. 11.—Burbot (*Lota vulgaris*), with jugular ventral fins.

margin, or asymmetrical, with the upper rays longest and strongest; in Malacopterygians with a dorsal spine the upper pectoral ray is frequently developed into a similar defensive weapon.

The ventral fins are the homologues of the hind-limbs, and are inserted on the abdominal surface, either behind the pectorals (*Pisces* or *Pinnæ abdominales*) (fig. 9), or below them (*Pisces* or *Pinnæ thoracicæ*) (fig. 10), or in advance of them (*Pisces* or *Pinnæ jugulares*) (fig. 11). They are generally narrow, and composed of a small number of rays, the outer of which is frequently osseous.

For the definition of the smaller systematic groups, and the determination of species, the numbers of the spines and rays are generally of the greatest importance. This holds good especially for the ventral rays, by the number of which the Acanthopterygian affinities of a fish can nearly always be determined. The numbers of the dorsal and anal rays generally correspond to the number of vertebræ in a certain portion of the spinous column, and are therefore constant specific, generic, or even family characters; but when their number is very great, a proportionally wide margin must be allowed for variation, and the taxonomic value of this character becomes uncertain. The numbers of the pectoral and caudal rays are rarely of any account.

The fins are organs of motion, but it is chiefly the tail and the caudal fin by which the fish impels itself forward. To execute energetic locomotion, the tail and caudal fin are strongly bent with rapidity, alternately towards the right and left; whilst a gentle motion forwards is effected by a simple undulating action of the caudal fin, the lobes of which act like the blades of a screw. Retrograde motions can be made by fishes in an imperfect manner only, by forward strokes of the pectoral fins. When the fish wants to turn towards the left, he gives a stroke of the tail towards the right, the right pectoral acting simultaneously, whilst the left remains pressed close to the body. Thus the pectoral fins assist in the progressive motions of the fish, but rather by directing its course than by acting as powerful propellers. The chief function of the paired fins is to maintain the balance of the fish in the water, which is always most unsteady where there is no weight to sink it: when the pectoral of one side, or the pectoral and ventral of the same side, are removed, the fish loses its balance and falls on the side opposite; when both pectorals are removed, the fish's head sinks; on removal of the dorsal and anal fins the motion of the fish assumes a zigzag course; deprived of all fins, it floats like a dead fish, with the belly upwards, the back being the heavier part of the body.

In numerous groups of fishes which live in mud, or are able to pass a longer or shorter time in soil periodically dried and hardened during the hot season, forms occur entirely devoid of, or with only rudimentary, ventral fins (*Cyprinodon*, *Ophiocephalidæ*, *Galaxiidæ*, *Siluridæ*). The chief function of these fins being to balance the body of the fish whilst swimming, it is evident that in fishes moving during a great part of their life over swampy ground, or through more or less consistent mud, this function of the ventral fins ceases, and nature can readily dispense with these organs altogether.

In certain fishes the shape and function of the fins are considerably modified: thus, in the rays, locomotion is almost entirely effected and regulated by the broad and expanded pectoral fins acting with an undulatory motion of their margins, similar to the undulations of the long vertical fins of the flat-fishes; in many blennies the ventral fins are adapted for walking on the sea-bottom; in some Gobioids (*Periophthalmus*), Trigloids, Scorpænioids, and *Pediculati* the pectoral fins are perfect organs of walking; in the gobies, *Cyclopteri*, and *Discoboli* the ventral fins are transformed into an adhesive disk (see fig. 13); and finally in the flying-fish the pectorals act as a parachute. In the eels and other snake-like fishes, the swimming as well as the gliding motions are effected by several curvatures of the body alternately to-

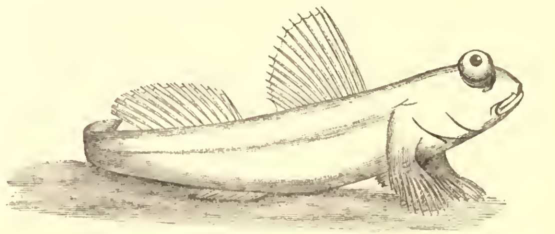

Fig. 12.—*Periophthalmus koelreuteri*.

wards the right and left, resembling the locomotion of snakes. In the *Syngnathi* (pipe-fishes) and *Hippocampi* (sea-horses), whose body admits of but a slight degree of lateral curvature, and whose caudal fin is generally small if present at all, locomotion is very limited, and almost wholly dependent on the action of the dorsal fin, which consists of a rapid undulating movement.

Fig. 13.—Ventrals of *Gobius*.

The Skin and Scales.—The skin of fishes is either covered with scales, or naked, or provided with more or less numerous scutes of various forms and sizes. Some parts, like the head and fins, are more frequently naked than scaly. All fishes provided with electric organs, the majority of eels, and the lampreys are naked. Scales of fishes are very different from those of reptiles,—the latter being merely folds of the cutis, whilst the former are distinct horny elements, developed in grooves or pockets of the skin, like hairs, nails, or feathers.

Very small or rudimentary scales are extremely thin, homogeneous in structure, and more or less imbedded in the skin, and do not cover each other. When more developed, they are imbricated (arranged in the manner of tiles), with the posterior part extruded and free, the surface of the anterior portion being usually covered by the skin to a greater or less extent. On their surface (fig. 14) may be observed a very fine striation concentric with and parallel to the margin, and coarser striæ radiating from a central point towards the hind margin.

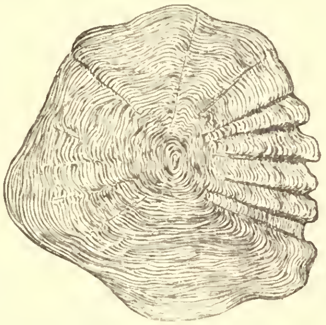

Fig. 14.—Cycloid scale of *Scopelus resplendens* (magn.).

Scales without a covering of enamel, with an entire (not denticulated) posterior margin, and with a concentric striation, are called cycloid scales. Ctenoid scales (figs. 15, 16)

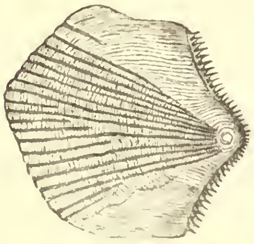

Fig. 15.—Ctenoid scale of *Gobius ommaturus* (magn.).

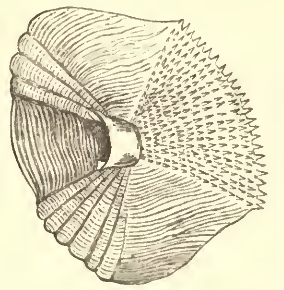

Fig. 16.—Ctenoid scale of *Lethrinus* (magn.).

are generally thicker, and provided with spinous teeth on the posterior edges of the layers of which the scale consists. In some species, only the layer nearest to the margin is provided with denticulations (fig. 15). Scales the free surface of which is spiny, and which have no denticulation on the margin, have been termed sparoid scales; but their distinction from ctenoid scales is by no means sharp, and there are even intermediate forms between the cycloid and ctenoid types. Both kinds of scales may occur, not only in species of the same genus of fishes, but in the same fish.

Ganoid scales are hard and bony, covered with a layer of enamel; they are generally rhombic or quadrangular, rarely rounded and imbricate, and are arranged in oblique rows, those of one row being linked together by an articulary process. This type of scales, common in fossil Ganoid fishes, occurs among recent fishes in *Lepidosteus* and *Polypterus* only.

Finally, in sharks, the *Balistidæ*, and others, true scales are absent, and are replaced by the ossified papillæ of the cutis (fig. 18), which give the surface the appearance of fine-

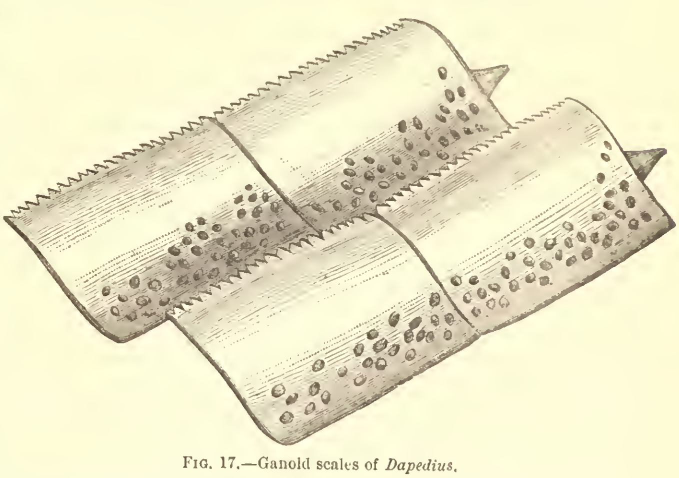

Fig. 17.—Ganoid scales of *Dapedius*.

grained shagreen. These generally small bodies, as well as the large osseous scutes (figs. 6 and 20) of the rays, stur-

Fig. 18.—Dermal papillæ of *Monacanthus trossulus*.

geons, &c., have been comprised under the common name placoid scales, a term which is being deservedly abandoned.

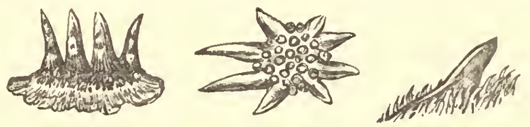

Fig. 19.—Dermal papillæ of *Monacanthus hippocrepis* (magn.).

Along the side of the body of osseous fishes runs a series of perforated scales, which is called the lateral line (fig. 23). The perforating duct is simple at its base, and may be simple also at its outer opening (fig. 21), or (a frequent case) the portion on the free surface of the scale is ramified (fig. 22). The lateral line runs from the head to the tail, sometimes reaching the caudal fin, sometimes stopping short of it, sometimes advancing over its rays. Some species have several lateral lines, an upper one following the dorsal, a lower the abdominal outline, while a third runs along the middle as usual. The scales of the lateral line are sometimes larger than the others, sometimes smaller; sometimes they are modified into scutes; sometimes there are no other scales besides these, the rest of the body being naked. The foramina of the lateral line are the outlets of a muciferous duct which is continued on to the head, running along the infraorbital bones, and sending off a branch into the præopercular margin and mandible. The muciferous system is abundantly provided with nerves, and has therefore been considered to be the seat of a sense peculiar to fishes,

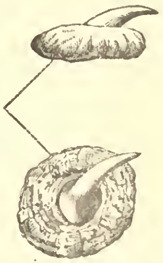

Fig. 20.—Dermal spines of a male Thornback, *Raia clavata*.

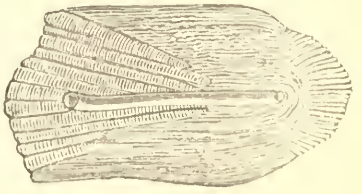

Fig. 21.—Cycloid scale from the lateral line of *Odax lineatus* (magn.).

but there cannot be any doubt that its function is the excretion of mucus, although probably mucus is excreted also from the entire surface of the fish.

The scales, their structure, number, and arrangement, constitute an important character for the determination of

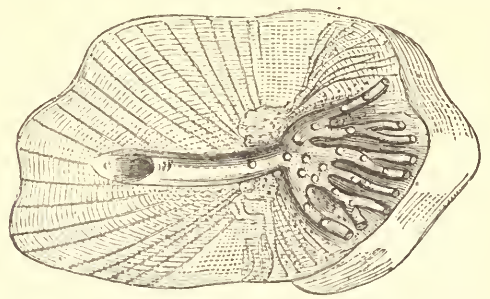

FIG. 22.—Cycloid scale from the lateral line of *Labrichthys laticlavius* (magn.).

fishes. In most scaly fishes they are arranged in oblique transverse series; and, as the number of scales in the lateral line generally corresponds to the number of transverse series, it is usual to count the scales in that line. To ascertain the number of longitudinal series of scales, the

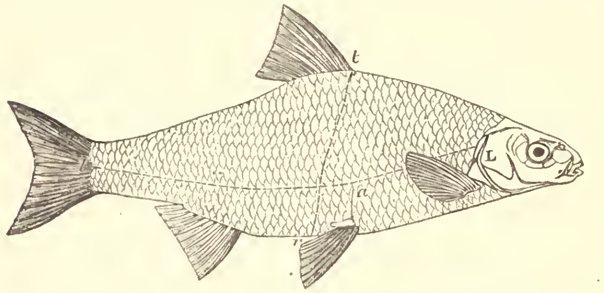

FIG. 23.—Arrangement of scales in the Roach (*Leuciscus rutilus*). *Ll*=Lateral line; *t r* = transverse line; *a*, tranverse line from lateral line to ventral fin.

scales are counted in one of the transverse series, generally in that running from the commencement of the dorsal fin, or the middle of the back, to the lateral line, and from the lateral line down to the vent or ventral fin, or the middle of the abdomen.

Osteology.

In order readily to comprehend the following account of the modifications of the skeleton in the various sub-classes and groups of fishes, the student should acquaint himself with the terms used for the numerous bones of the fish skeleton, as well as with their relative position. For this purpose we commence this section with an account of the skeleton of the *Teleostei*, which is composed of the greatest number of specialized bones, and is most readily accessible. The skeleton of any of the more common kinds of osseous fish may serve for this purpose; that of the perch was chosen by Cuvier, and is employed here (fig. 24), as it was in the last edition of the present work.

In the Teleosteous fishes the spinous column consists of Vert.
completely ossified amphicœlous vertebræ; its termination is homocercal—that is, the caudal fin appears to be more or less symmetrical, the last vertebra occupying a central position in the base of the fin, and being united to a flat fan-like bone, the hypural (70 in fig. 24), on the hind margin of which the fin-rays are fixed. The hypural is but a union of modified hæmapophyses which are directed backwards, and the actual termination of the notochord is bent upwards, and lies along the upper edge of the hypural, hidden below the last rudimentary neural elements. In some Teleosteans, as the *Salmonidæ*, the last vertebræ are conspicuously bent upwards: in fact, strictly speaking, this homocercal condition is but one of the various degrees of heterocercy, different from that of many Ganoids in this respect only, that the caudal fin itself has assumed a higher degree of symmetry.

The neural and hæmal arches generally coalesce with the centrum, but there are many exceptions, inasmuch as some portion of the arches of a species, or all of them, may show the original division.

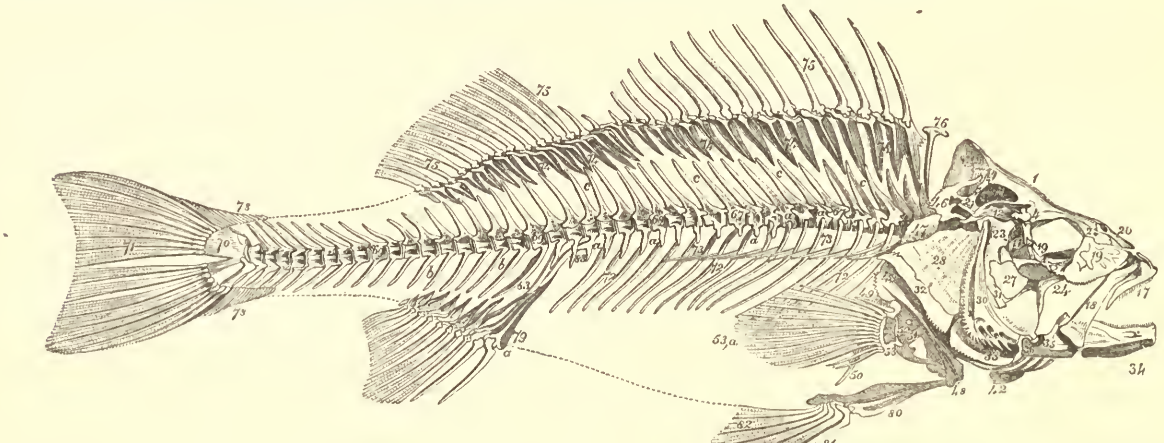

FIG. 24.—Skeleton of the Perch.

The vertebræ are generally united with one another by zygapophyses, and frequently similar additional articulations exist at the lower parts of the centra. Parapophyses and ribs are very general, but the latter are inserted on the centra and the base of the processes, and never on their extremities.

The spinal column consists of abdominal and caudal vertebræ, the coalescence of the parapophyses into a complete hæmal ring and the suspension of the anal fin generally forming a sufficiently well-marked boundary between the abdominal and caudal regions (fig. 24). In the perch there are twenty-one abdominal and as many caudal vertebræ. The centrum of the first vertebra or atlas is very short, with the apophyses scarcely indicated; neither the first nor the second vertebra has ribs. All the other abdominal vertebræ, with the exception of the last or the two last, are provided with ribs, many of which are bifid (72). A series of flat spines (74), called interneurals, to which the spines and rays of the dorsal fins are articulated, are supported by the neural spines, the strength of the neurals and interneurals corresponding to that of the dermal spines (75). The caudal vertebræ differ from the abdominal in having the hæmapophyseal elements converted into spines similar to the neurals, the anterior being likewise destined to support a series of interhæmals (79), to which the anal rays are articulated.

There is a great amount of variation as regards the degree in which the primordial cartilaginous cranium persists; it is always more or less replaced by bone; frequently it disappears entirely, but in some fishes like the *Salmonidæ* or *Esocidæ,* the cartilage persists to the same or even to a greater extent than we shall find in the *Ganoidei holostei.* Besides the bones preformed in cartilage there are a great number of membrane-bones, that is, bones originating in membranous or tegumentary tissue. The different kinds of these membrane-bones occur with greater or less constancy throughout the subclass *Teleostei*; they often coalesce with and are no longer separable from the neighbouring or underlying cartilage-bones.

1. *Cartilage-Bones of the Primordial Skull.*—The basioccipital (5 in figs. 25–27) has retained the form of a vertebral centrum; it is generally concave behind, the

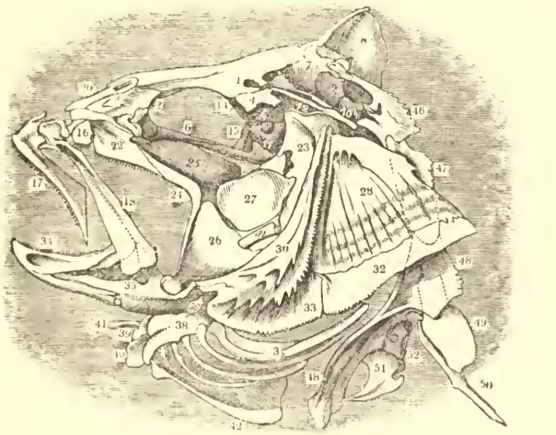

FIG. 25.—Skeleton of Perch's Skull.

concavity containing remains of the notochord. The exoccipitals (10) are situated on the side of the basioccipital, and contribute the greater portion of the periphery of the foramen magnum. The supraoccipital (8) is intercalated between the exoccipitals, and forms a most prominent part by its median crest, which sometimes extends far forward on the upper side of the skull, and offers attachment to the dorsal portion of the large lateral muscle of the trunk. A transverse supraoccipital ridge, coming from each side of the base of this crest, runs outward to the external angles of the bone. When the interior portion of this bone remains cartilaginous, some part of the semicircular canals may be lodged in it.

The region of the skull which succeeds these bones encloses at least the greater portion of the labyrinth, and its component parts have been named with reference to it by some anatomists.[1] The alisphenoids (11) (*prooticum*) form sutures posteriorly with the basi- and ex-occipitals, and meet each other in the median line at the bottom of the cerebral cavity; they contribute to the formation of a hollow in which the hypophysis cerebri and the saccus vasculosus are received; in conjunction with the exoccipital they form another hollow for the reception of the vestibulum; generally they are perforated by the trigeminal and facial nerves. The paroccipitals (9) (*epioticum*) lodge a portion of the posterior vertical semicircular canal, and form a projection of the skull on each side of the occipital crest, to which a terminal branch of the scapular arch is attached. The mastoid (12 + 13) (*opisthoticum*) occupies the postero-external projection of the head; it encloses a part of the external semicircular canal, is generally united to a membrane-bone, the superficial squamosal, which emits a process for the suspension of the scapular arch, and is frequently, as in the perch, divided into two separate bones.

The anterior portion of the skull varies greatly as regards form, which is chiefly dependent on the extent of the cere-

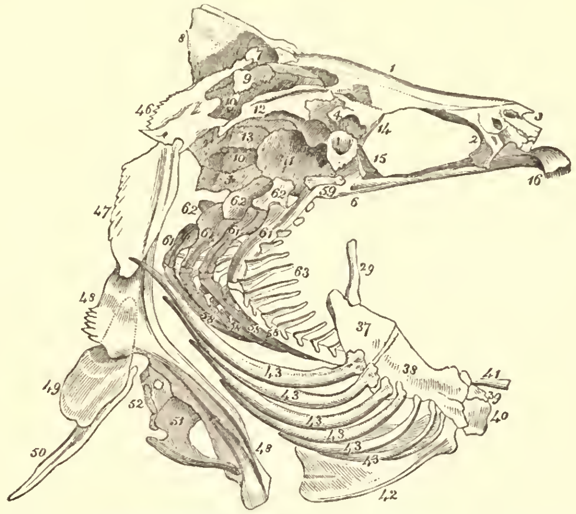

FIG. 26.—Hyoid arch, branchial apparatus, and scapulary arch of the Perch.

bral cavity; if the latter is advanced far forwards, the lateral walls of the primordial cranium are protected by more developed ossifications than is the case if the cerebral cavity is shortened by the presence of a wide and deep orbit. In the latter case parts which normally form the side of the skull are situated in front of the brain-case, between it and the orbit, and, being generally reduced in extent, are often replaced by membranes; the interorbital septum especially may thus be reduced to a membrane. The most constant ossifications of this part of the skull are the orbitosphenoids (14), which join the upper anterior margin of the alisphenoids; superiorly the olfactory and inferiorly the optic nerves pass between them out of the cranium. They vary much with regard to their development: they are small in Gadoids; larger in the perch, pike, Salmonoids, *Macrodon,* and the Clupeoids; and very large in Cyprinoids and Siluroids, in which they contribute to the formation of the side of the brain-case. The single Y-shaped *sphenoideum anterius* (15) (ethmoid of Owen and basisphenoid of Huxley) is as frequently absent as present; each lateral branch is connected with an orbitosphenoid, whilst the lower branch rests upon the long basal bone; it forms the anterior margin of the fossa for the hypophysis. Finally, to this group of cartilage-bones belongs also the postfrontal (4), a small bone from which the infraorbital ring is suspended.

The centre of the foremost part of the skull is occupied by the ethmoid (3), which shows great variations as regards its extent and the degree of ossification; it may extend backwards into the interorbital septum, and reach the orbitosphenoids, or it may be confined to the extremity of the skull; it may remain entirely cartilaginous, or it may ossify into a lamina which separates the two orbits and encloses an anterior prolongation of the brain-case, along which the olfactory nerves pass,—modifications occurring again in higher vertebrates. A paired ossification attached to the forepart of the ethmoid is the prefrontals (2), which form the base of the nasal fossa.

2. *Membrane-Bones attached to the Primordial Skull.*—To this group belong the parietals (7) and frontals (1). The latter form the upper margin of the orbits, and extend from the nasal cavities to the occipital. They are enlarged at the expense of the parietals, which are of much smaller extent

[1] As first proposed by Huxley.

than in higher vertebrates, and are separated from each other by the anterior prolongation of the supraoccipital. The squamosal (12) has been mentioned above in connexion with the mastoid. The prefrontal (2) and supraorbital are always small, and the latter is frequently absent. The lower surface of the skull is protected by the basisphenoid (parasphenoid) (6), a very long and narrow bone extending from the basioccipital beyond the brain-capsule to between the orbits, where it forms the support of the interorbital septum. Anteriorly it is connate with another long hammer-shaped bone (16), the vomer. Both these bones, especially the latter, may be armed with teeth.

3. *Cartilage-Bones of the Alimentary Portion of the Visceral Skeleton of the Skull.*—The suspensorium consists of three cartilage-bones, and affords a base for the opercular apparatus as well as a point of attachment to the hyoid, whilst in front it is connected with the pterygo-palatine arch (fig. 27). These are the hyomandibular (23), sym-

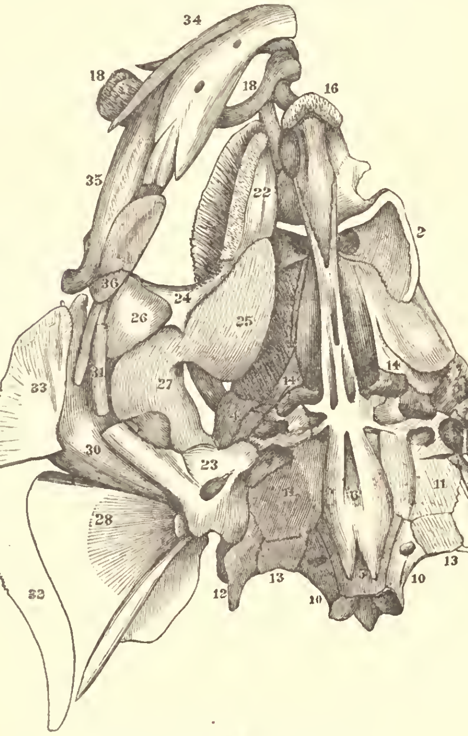

FIG. 27.—Lower view of Skull of Perch.

plectic (31), and quadrate (26); they are connected by means of the metapterygoid (27) with the pterygoid (24) and entopterygoid (25), the foremost bone of the arch being the palatine (22). Of these bones the uppermost, the epitympanic or hyomandibular (23), is articulated by a double articulary head with the mastoid and posterior frontal. Another articulary head is destined for the opercular joint. The mesotympanic or symplectic (31) appears as a styliform prolongation of the lower part of the hyomandibular; it is cartilaginous in the young, but almost completely ossified in the adult. The position of this bone is noteworthy, because, directly inwards from its cartilaginous junction with the hyomandibular, there is situated the uppermost piece of the hyoid arch, the stylohyal. The next bone of the series is the pretympanic or metapterygoid (27), a flat bone forming a bridge towards the pterygoid, and not rarely absent in the subclass. Finally, the large triangular hypotympanic or quadrate (26) has a large condyle for the mandibular joint. The palatine arch proper is formed by three bones: the entopterygoid (25) is an oblong and thin bone attached to the inner border of the palatine and pterygoid, and increasing the surface of the bony roof of the mouth towards the median line; it constitutes also the floor of the orbit; the pterygoid (or *os transversum*) (24) starts from the quadrate, and is joined by suture to the palatine, which is toothed in the perch and many other fishes, and reaches to the vomer and anterior frontal. The piece of the mandible which articulates with the quadrate is the articulary bone (35), distinctly part of Meckel's cartilage; it sends upwards a coronoid process to which the masticatory muscles, as well as a ligament from the maxillary, are attached; it also sends forwards a long-pointed process to be sheathed in a deep notch of the dentary piece. Frequently another portion of cartilage below the articulary remains persistent, or is replaced by a separate membrane-bone, the angular.

4. *Membrane-Bones of the Alimentary Portion of the Visceral Skeleton of the Skull.*—The suspensorium has one tegumentary bone attached to it, viz., the præoperculum (30); it is but rarely absent, as for instance in *Murænophis*; as it is quite a superficial bone, and frequently armed with spines (as in the perch), its form and configuration constitute an important item in the description of many fishes. The premaxillary (17) and maxillary (18) of the *Teleostei* appear to be also membrane-bones, although they are clearly analogous to the upper labial cartilages of the sharks. The premaxillaries sometimes coalesce into a single piece (as in *Diodon*, *Mormyrus*), or they are firmly united with the maxillaries (as in all Gymnodonts, *Serrasalmo*, &c.). The relative position and connexion of these two bones differ much, and form a valuable character in the discrimination of the various families. In some, the front margin of the jaw is formed by the premaxillary only, the two bones having a parallel position, as in the perch, in which case the maxillary is constantly toothless; in others, the premaxillary is shortened, allowing the maxillary to enter, and to complete, the margin of the upper jaw; and finally, in many, no part of the maxillary is situated behind the premaxillary, but the entire bone is attached to the end of the premaxillary, forming its continuation. In the last case the maxillary may be quite abortive. The mobility of the upper jaw is greatest in those fishes in which the premaxillary alone forms its margin. The form of the premaxillary is subject to great variation: the beak of *Belone* and *Xiphias* is formed by the prolonged and coalesced premaxillaries. The maxillary consists sometimes of one piece, sometimes of two or three. The principal membrane-bone of the mandible is the dentary (34), to which is added the angular (36) and rarely a smaller one, the splenial or *os operculare*, which is situated at the inner side of the articulary.

5. *Cartilage-Bones of the Respiratory Portion of the Visceral Skeleton of the Skull.*—With few exceptions all the ossifications of the hyoid and branchial arches belong to this group.

The hyoid arch is suspended by a slender styliform bone, the stylohyal (29), from the hyomandibulars; it consists of three segments, the epihyal (37), the ceratohyal (38), which is the longest and strongest piece, and the basihyal, which is formed by two juxtaposed pieces (39, 40). Between the latter there is a median styliform ossicle (41), extending forwards into the substance of the tongue, called the glossohyal or *os linguale*.

The branchial arches (figs. 26 and 28) are enclosed within the hyoid arch, with which they are closely connected at the base. In the perch and in the majority of Teleosteans they are five in number, of which four bear gills, whilst the fifth (56) remains dwarfed, and is beset with teeth; it is called the lower pharyngeal bone. The arches adhere by their lower extremities to a chain of ossicles (53, 54, 55), the basibranchials, and, curving as they ascend, nearly meet at the base of the cranium, to which they are attached by a layer of ligamentous and cellular tissue. Each of the first three branchial arches consists of four pieces movably connected with one another. The lowest is the hypobranchial (57), the next, a much longer one, the

Fig. 28.—Hyoid bone of the Perch.

ceratobranchial (58), and, above this, a slender and short irregularly-shaped epibranchial. In the fourth arch the hypobranchial is absent. The uppermost of these segments, especially of the fourth arch, are dilated, and more or less confluent; they are beset with fine teeth, and generally distinguished as the upper pharyngeal bones. Only the ceratobranchial is represented in the fifth arch or lower pharyngeal. On their outer convex side the branchial segments are grooved for the reception of large blood-vessels and nerves; on the inner side they support horny processes, called the gill-rakers, which do not form part of the skeleton.

6. *Membrane-Bones of the Respiratory Portion of the Visceral Skeleton of the Skull.*—These include the opercular pieces, viz., the operculum (28), suboperculum (32), and interoperculum (33). The last of these is the least constant; it may be entirely absent, and represented by a ligament extending from the mandible to the hyoid. The operculum is the principal piece, situated behind, and movably united with, the vertical limb of the præoperculum. There is an articulary cavity at its upper anterior angle for its junction with the hyomandibular. The interoperculum is connected by ligament with the angular piece of the mandible, and is also attached to the outer face of the hyoid, so that the gill-covers cannot open or shut without the hyoid apparatus executing a corresponding movement. The remaining membrane-bones are the urohyal (42), a single bone, which is connected by ligament with the anterior extremity of the humeral arch, and separates the musculi sternohyoidei, serving as an increased surface for their insertion; and, finally, the branchiostegals (43), which vary greatly in number, but are always fixed to the ceratohyals and epihyals by ligaments; the branchiostegal membrane is extended between them.

7. *Dermal Bones of the Skull.*—To this category are referred some bones which are ossifications of, and belong to, the cutis. They are the turbinals (20), the suborbitals (19), and the supratemporals. They vary much with regard to the degree in which they are developed, and are seldom entirely absent. Nearly always they are wholly or partly transformed into tubes or hollows, in which the muciferous canals with their numerous nerves are lodged. Those in the temporal and scapulary regions are not always developed; on the other hand, the series of those ossicles may be continued on to the trunk, accompanying the lateral line. The foremost suborbital is termed the præorbital.

The pectoral arch or shoulder-girdle of the Teleosteous fishes exhibits but a remnant of a primordial cartilage, which is replaced by two ossifications,[1] the caracoid (51) and scapula (52); posteriorly they offer attachment to two series of short rods (53), of which the proximal are nearly always ossified, whilst the distal frequently remain small cartilaginous nodules hidden in the base of the pectoral rays; they have been termed carpals and metacarpals. The bones by which this portion is connected with the skull are membrane-bones, viz., the clavicle (48), with the postclavicle (49 + 50), the supraclavicle (47), and the post-temporal (46). By this last bone the shoulder-girdle is suspended from the skull; it is attached, in the perch, by a triple prong to the occipital and mastoid bones. The clavicle completes the arch below by the symphysis or natural connexion of the bones of each side. Many Teleosteous fishes lack pectoral fins, and in them the pectoral arch is frequently more or less reduced or rudimentary, as in many species of *Murænidæ*. In others the membrane-bones are exceedingly strong, contributing to the outer protective armour of the fish, and then the clavicles are generally suturally connected in the median line. The postclavicula and the supraclavicula may be absent. It is only exceptionally that the shoulder-girdle is not suspended from the skull, but from the anterior portion of the spinous column (*Symbranchidæ*, *Murænidæ*, *Notacanthidæ*). The number of elements in each of the two series of basalia never exceeds five, but may be smaller; and the distal series is absent in Siluroids.

Pectoral arch.

The pubic bones (80) of the Teleosteous fishes undergo many modifications of form in the various families, but they are essentially of the same simple type as in the perch, viz., a pair of flat or styliform simple bones, to which the ventral fins are articulated.

Pubic bones.

The bones of the skull of the fish have received so many different interpretations that no two accounts agree in their nomenclature, so that their study is a matter of considerable difficulty. The table of synonyms given on p. 644 will tend to overcome difficulties arising from this cause; it contains the terms used for the different bones of the skeleton by Cuvier, those introduced by Owen, and finally the nomenclature of Stannius, Huxley, and Parker. Those adopted here are printed in italics. The numbers in the table are those used in the preceding pages and in figs. 24–28.

Modifications of the Skeleton.

We now proceed to pass briefly in review the modifications of the skeleton in the principal types of fishes, commencing at the lowest, and pointing out its gradual development in the other three subclasses.

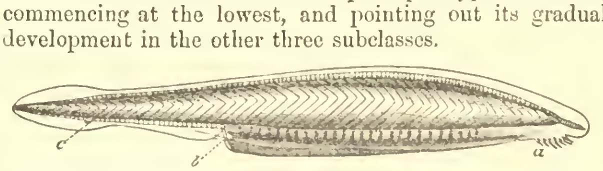

Fig. 29.—*Branchiostoma lanceolatum.* *a*, mouth; *c*, vent; *b*, abdominal porus.

The lowermost subclass of fishes, which comprises one form only, the Lancelet (*Branchiostoma* [s. *Amphioxus*] *lanceolatum*), possesses the skeleton of the most primitive

[1] Parker's nomenclature is adopted here.

TABLE *of Nomenclature used by Cuvier, Owen, Stannius, Huxley, &c., to indicate the Bones in the Skeleton of a Fish.*

CUVIER.	OWEN.	STANNIUS.	HUXLEY, PARKER, &C.
1. Frontal principal	*Frontal*	Os frontale	
2. Frontal antérieur	*Prefrontal*	Os frontale anterius	Lateral ethmoid (Parker)
3. *Ethmoid*	Nasal	Os ethmoideum	
4. Frontal postérieur	*Postfrontal*	Os frontale posterius	Sphenotic (Parker
5. Basilaire	*Basioccipital*	Os basilare	
6. Sphénoide	*Basisphenoid*	Os sphenoideum basilare	Sometimes referred to as "*Basal*"
7. Pariétal	*Parietal*	Os parietale

[1] Pterotic of Parker.

type. The vertebral column is represented by a simple chorda dorsalis or notochord only, which extends from one extremity of the fish to the other, and, so far from being expanded into a cranial cavity, is pointed at its anterior end as well as at its posterior. It is enveloped in a simple membrane like the spinal cord and the abdominal organs,

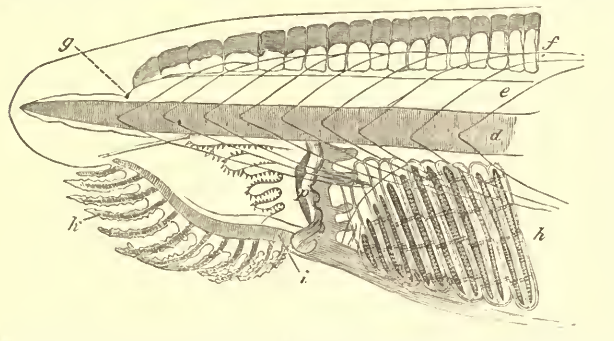

FIG. 30.—Anterior end of body of *Branchiostoma* (magn.). *d*, chorda dorsalis; *e*, spinal cord; *f*, cartilaginous rods; *g*, eye; *h*, branchial rods; *i*, labial cartilage; *k*, oral cirrhi.

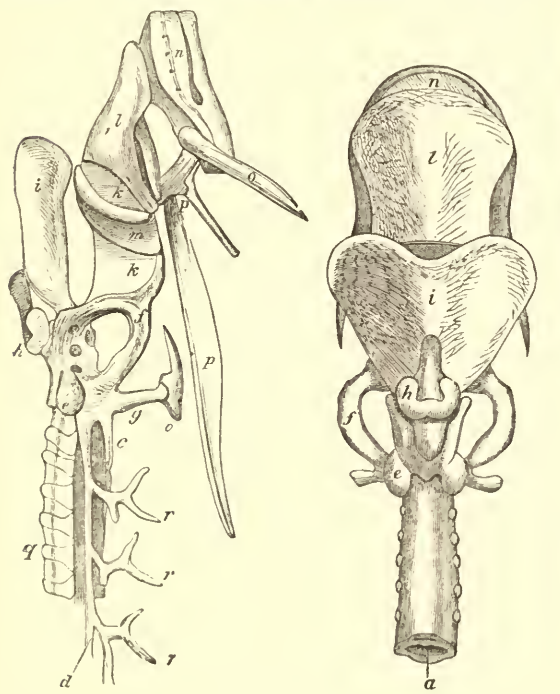
and there is no trace of vertebral segments or ribs; a series of short cartilaginous rods, however, above the spine evidently represent apophyses. A maxillary or hyoid apparatus, or elements representing limbs, are entirely absent.

The skeleton of the *Cyclostomata* (or *Marsipobranchii*) (lampreys and sea-hags) shows a considerable advance of development. It consists of a notochord, the anterior pointed end of which is wedged into the base of a cranial capsule, partly membranous, partly cartilaginous. This skull, therefore, is not movable upon the spinal column. No vertebral segmentation can be



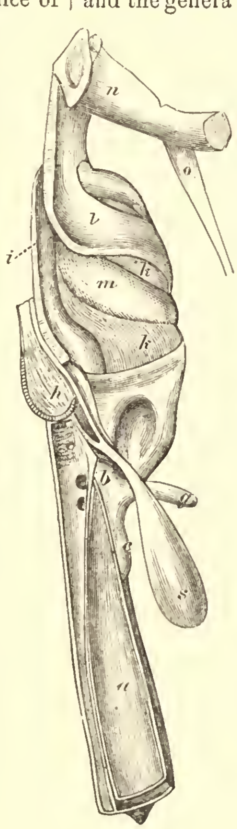


FIG. 31.—Upper (*A*) and side (*B*) views, and vertical section (*C*), of the skull of *Petromyzon marinus*. *a*, notochord; *b*, basis cranii; *c*, inferior, and *d*, lateral process of basis; *e*, auditory capsule; *f*, subocular arch; *g*, stylohyal process; *h*, olfactory capsule; *i*, ethmo-vomerine plate; *k*, palato-pterygoid portion of subocular arch; *l*, *m*, *n*, accessory labial or rostral cartilages, with *o*, appendage; *p*, lingual cartilage; *q*, neural arches; *r*, branchial skeleton; *s*, blind termination of the nasal duct between the notochord and œsophagus.

observed in the notochord, but neural arches are represented by a series of cartilages on each side of the spinal chord. In *Petromyzon* (fig. 31) the basis cranii emits two prolongations on each side, an inferior, extending for some distance along the lower side of the spinal column, and a lateral, which is ramified into a skeleton supporting the branchial apparatus. A stylohyal process and a subocular arch with a palato-pterygoid portion may be distinguished. The roof of the cranial capsule is membranous in *Myxine* and in the larvæ of *Petromyzon*, but more or less cartilaginous in the adult *Petromyzon* and in *Bdellostoma*. A cartilaginous capsule on each side of the hinder part of the skull contains the auditory organ, whilst the olfactory capsule occupies the anterior upper part of the roof. A broad cartilaginous lamina, starting from the cranium and overlying part of the snout, has been determined as representing the ethmo-vomerine elements, whilst the oral organs are supported by large, very peculiar cartilages (labials), greatly differing in general configuration and arrangement in the various Cyclostomes. There are three in the sea-lamprey, of which the middle one is joined to the palate by an intermediate smaller one; the foremost is ring-like, tooth-bearing, emitting on each side a styliform process. The lingual cartilage is large in all Cyclostomes. There is no trace of ribs or limbs.

The Chondropterygians exhibit a most extraordinary diversity in the development of their vertebral column; almost every degree of ossification, from a notochord without a trace of annular structure to a series of completely ossified vertebræ, being found in this order. The sharks in which the notochord is persistent are the *Holocephali* (if they be reckoned as belonging to this order) and the genera *Notidanus* and *Echinorhinus*. In the other sharks the segmentation is complete, each vertebra having a deep conical excavation in front and behind, with a central canal through which the notochord is continued; but the degree in which the primitive cartilage is replaced by concentric or radiating lamellæ of bone varies greatly in the various genera, and according to the age of the individuals. In the rays all the vertebræ are completely ossified, and the anterior ones confluent into one continuous mass. In the majority of Chondropterygians the extremity of the vertebral column shows a decidedly heterocercal condition, and only a few, like *Squatina* and some rays, possess a diphycercal tail.

The advance in the development of the skeleton in Chondropterygians beyond the primitive condition of the previous subclasses manifests itself further by the presence of neural and hæmal elements, extending to the foremost part of the axial column; but of these the hæmal form a closed arch in the caudal region only, whilst on the trunk they appear simply as a lateral longitudinal ridge. The neural and hæmal apophyses are either merely attached to the axis, as in Chondropterygians with persistent notochord (the rays and some sharks); or their basal portions penetrate like wedges into the substance of the centrum, so that, in a transverse section, in consequence of the difference in their texture, they appear in the form of an X (figs. 32–34). The interspaces between the neurapophyses of the vertebræ are not filled by fibrous membrane, as in other fishes, but by separate cartilages (laminæ or cartilagines intercrurales), to which frequently a series of terminal pieces is superadded, which must be regarded as the first appearance of the interneural spines of the *Teleostei* and many Ganoids. Similar terminal pieces are sometimes observed on the hæmal arches. Ribs are either absent or but imperfectly represented (*Carcharias*).

The substance of the skull of the Chondropterygians is cartilage, interrupted especially on its upper surface by more or less extensive fibro-membranous fontanelles. Superficially it is covered by a more or less thick shagreen-

like osseous deposit. The articulation with the vertebral column is effected by a pair of lateral condyles. In the sharks, besides, a central conical excavation corresponds to that of the centrum of the foremost vertebral segment, whilst in the rays this central excavation of the skull receives a condyle of the axis of the spinous column. The cranium itself is a continuous undivided cartilage, in which the limits of the orbit are well marked by an anterior and posterior protuberance. The ethmoidal region sends horizontal plates over the nasal sacs, the apertures of which retain their embryonic situation upon the under surface of the skull. In the majority of Chondropterygians these plates are produced conically, forming the base of the soft projecting snout; and in some forms, especially in the long-snouted rays and the saw-fishes (*Pristis*), this prolongation appears in the form of three or more tubiform rods. As separate cartilages there are appended to the skull a suspensorium, a palatine, a mandible, a hyoid, and rudimentary maxillary elements. The suspensorium is movably attached to the side of the skull. It generally consists of one piece only, but in some rays of two. In the rays it is articulated to the mandible only, their hyoid possessing a distinct point of attachment to the skull. In the sharks the hyoid is suspended from the lower end of the suspensorium together with the mandible. What is generally called the upper jaw of a shark is, as Cuvier has already stated, not the maxillary, but the palatine. It consists of two simple lateral halves, each of which articulates with the corresponding half of the lower jaw, which is formed by the simple representative of Meckel's cartilage. Some cartilages of various sizes are generally developed on each side of the palatine, and one on each side of the mandible. They are called labial cartilages, and seem to represent maxillary elements. The hyoid consists generally of a pair of long and strong lateral pieces, and a single mesial piece. From the former, cartilaginous filaments (representing branchiostegals) pass directly outwards. Branchial arches, varying in number, and similar to the hyoid, succeed it. They are suspended from the side of the foremost part of the spinous column, and, like the hyoid, bear a number of filaments.

The vertical fins are supported by interneural and interhæmal cartilages, each of which consists of two or more pieces; to these fins the fin-rays are attached without articulation. The scapular arch of the sharks is formed by a single coracoid cartilage bent from the dorsal region downwards and forwards. In some genera (*Scyllium*, *Squatina*) a small separate scapular cartilage is attached to the dorsal extremities of the coracoid; but in none of the Elasmobranchs is the scapular arch suspended from the skull or vertebral column; it is merely sunk and fixed in the substance of the muscles. Behind, at the point of its greatest curvature, three carpal cartilages are joined to the coracoid, which Gegenbaur has distinguished as propterygium, mesopterygium, and metapterygium, the first occupying the front, the last the hind margin of the fin. Several more or less regular transverse series of styliform cartilages follow. They represent the phalanges, to which the horny filaments which are imbedded in the skin of the fin are attached. In the rays, with the exception of torpedo, the scapular arch is intimately connected with the confluent anterior portion of the vertebral column. The anterior and posterior carpal cartilages are followed by a series of similar pieces, which extend like an arch forwards to the rostral portion of the skull, and backwards to the pubic region. Extremely numerous phalangeal elements, longest in the middle, are supported by the carpals, and form the skeleton of the lateral expansion of the so-called disk of the ray's body, which thus, in fact, is nothing but the enormously enlarged pectoral fin.

The pubic is represented by a single median transverse cartilage, with which a tarsal cartilage articulates. The latter supports the fin-rays. To the end of this cartilage is also attached, in the male Chondropterygians, a peculiar accessory generative organ or clasper.

The *Holocephali* differ from the other Chondropterygians in several important points of the structure of their skeleton, and unmistakably approach certain Ganoids. That their spinal column is persistently notochordal has been mentioned already. Their palatal apparatus, with the suspensorium, coalesces with the skull, the mandible articulating with a short apophysis of the cranial cartilage (autostylic skull). The mandible is simple, without anterior symphysis. The spine with which the dorsal fin is armed articulates with a neural apophysis, and is not immovably attached to it, as in the sharks. The pubic consists of two lateral halves, with a short, rounded tarsal cartilage.

The skeleton of the Ganoid fishes presents extreme variations with regard to the degree in which ossifications replace the primordial cartilage. Whilst some exhibit scarcely any advance beyond the Plagiostomes with persistent cartilage, others, as regards the development and specialization of the several parts of their osseous framework, approach the Teleosteans so closely that their Ganoid nature can be demonstrated by, or inferred from, other considerations only. All Ganoids possess a separate gill-cover.

The diversity in the development of the Ganoid skeleton is well exemplified by the few representatives of the order in the existing fish fauna. Lowest in the scale in this respect are those with a persistent notochord, and an autostylic skull, that is, a skull without separate suspensorium—the fishes constituting the suborder *Dipnoi*, of which the existing representatives are *Lepidosiren*, *Protopterus*, and *Ceratodus*, and the extinct (so far as demonstrated at present) *Dipterus*, *Chirodus* (and *Phaneropleuron*?). In these fishes the notochord is persistent, passing uninterruptedly into the cartilaginous base of the skull. Some *Dipnoi* are diphy-, others hetero-cercal. Neural and hæmal elements and ribs are well developed.

The primordial cranium of the *Dipnoi* is cartilaginous, but with more or less extensive ossifications in its occipital, basal, or lateral portions, and with large tegumentary bones, which, from this suborder upwards in the series, will be found to exist throughout the remaining forms of fishes. A strong process descends from the cranial cartilage, and offers by means of a double condyle (fig. 35, *s*) attachment to corresponding articulary surfaces of the lower jaw. Maxillary and intermaxillary elements are not developed, but are perhaps represented in *Ceratodus* by some inconstant rudimentary labial cartilages situated behind the posterior nasal opening. Facial cartilages and an infraorbital ring are developed, at least in *Ceratodus*. The presence of a pair of small teeth in front indicates the vomerine portion (*v*) which remains cartilage, whilst the posterior pair of teeth are implanted in a pterygo-palatine ossification (*l*), which sometimes is paired, sometimes continuous. The base of the skull is constantly covered by a large basal ossification (*o*). The hyoid is well developed, sometimes reduced to a pair of ceratohyals, sometimes with a basihyal and glossohyal. The skeleton of the branchial apparatus approaches the Teleosteous type, less so in *Lepidosiren* than in *Ceratodus*, in which five branchial arches are developed, but with the lateral and mesial pieces reduced in number. A large operculum, and a smaller sub- or inter-operculum are present.

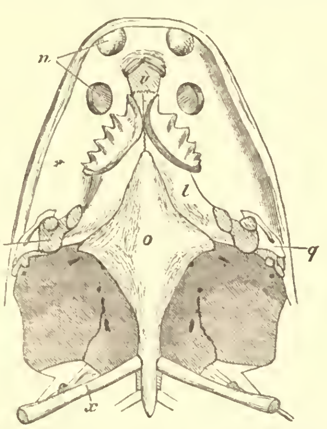

Fig. 35.—Palatal view of skull of *Ceratodus*.

The scapular arch consists of a single median transverse cartilage, and a pair of lateral cartilages which bear the articular condyle for the pectoral limb. The latter cartilages form the base of a large membrane-bone, and the whole arch is suspended from the skull by means of an osseous supraclavicle. The fore-limb of the *Dipnoi* (fig. 36) greatly differs externally from the pectoral fin of other Ganoid fishes. It is covered with small scales along the middle, from the root to its extremity, and surrounded by a rayed fringe similar to the vertical fin (crossopterygian type of fin). A muscle split into numerous fascicles extends all the length of the fin, which is flexible in every part and in every direction. The cartilaginous framework supporting it is joined to the scapular arch by an oblong cartilage, followed by a broad basal cartilage (*a*), generally single, but sometimes showing traces of a triple division. Along the middle of the fin runs a jointed axis (*b*), the joints gradually becoming smaller and thinner towards the extremity; each joint bears on each side a three-, two-, or one-jointed branch (*c*, *d*). This axial arrangement of the pectoral skeleton, which evidently represents one of its first and lowest conditions, has been termed the *archipterygium* by Gegenbaur. It is found in *Ceratodus* and other genera, but in *Lepidosiren* the jointed axis only has been preserved, while rudimentary rays are added in *Protopterus*.

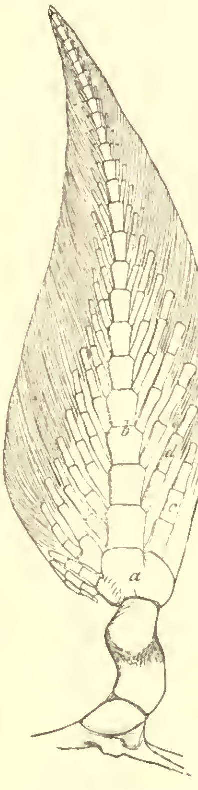

Fig. 36.—Fore-limb of *Ceratodus*.

The pubic consists of a single flattened subquadrangular cartilage, produced into a long single anterior process. Posteriorly it terminates on each side in a condyle, to which the basal cartilage of the ventral paddle is joined. The endoskeleton of the paddle is almost identical with that of the pectoral.

The Ganoid fishes with persistent notochord, but with a hyostylic skull (that is, a skull with a separate suspensorium), consist of the suborder *Chondrostei*, of which the existing representatives are the sturgeons (*Acipenser*, *Scaphirhynchus*, *Polyodon*), and the extinct the *Chondrosteidæ*, *Palæoniscidæ*, and (according to Traquair) *Platysomidæ*.

Their spinal column does not differ essentially from that of the *Dipnoi*. Segmentation is represented only so far as the neural and hæmal elements are concerned. All are eminently heterocercal. Ribs are present in most, but are replaced by ligaments in *Polyodon*.

The primordial cranium of the sturgeons consists of persistent cartilage without ossifications in its substance, but superficial bones are still more developed and specialized than in the *Dipnoi*; so it is, at least, in the true sturgeons, but less so in *Polyodon* (fig. 37). The upper and lateral parts of the skull are covered by well-developed membrane-bones. The lower surface of the skull is covered by an extremely large basal bone, which extends from the vomerine region on to the anterior part of the spinal column. The nasal excavation in the skull is rather lateral than inferior. The ethmoidal region is generally much produced, forming the base of the long projecting snout. The suspensorium is movably attached to the side of the skull, and consists of two pieces, a hyomandibular and a symplectic, which now appears for the first time as a separate piece, and to which the hyoid is attached. The palato maxillary apparatus is more complex than in the sharks and *Dipnoi*; a palato-pterygoid consists of two mesially-connected rami in *Polyodon*, and of a complex cartilaginous disk in *Acipenser*, being articulated in both to the Meckelian cartilage. In addition, the sturgeons possess one or two pairs of osseous rods, which, in *Polyodon* at least, represent the maxillary, and therefore must be the representatives of the labial cartilages of the sharks. The Meckelian cartilage is more or less covered by tegumentary bones. In the gill-cover, besides the operculum, a sub- and inter-operculum may be distinguished in *Acipenser*. The hyoid consists of three pieces, of which the posterior bears a broad branchiostegal in *Polyodon*.

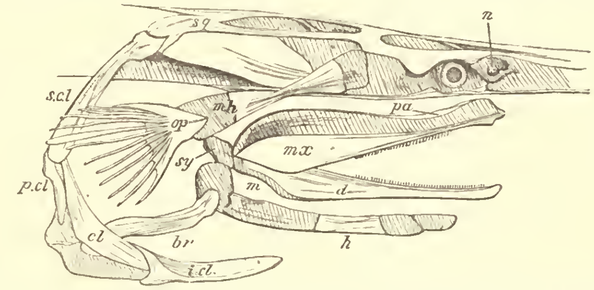

Fig. 37.—Skull of *Polyodon*. (After Traquair.) *n*, nasal cavity; *sq*, squamosal; *mh*, hyomandibular; *sy*, symplectic; *pa*, palato-pterygoid; *m*, Meckelian cartilage; *mx*, maxillary; *d*, dentary; *h*, hyoid; *op*, operculum; *br*, branchiostegal; *s.cl*, supraclavicular; *p.cl*, postclavicular; *cl*, clavicle; *i.cl*, infraclavicular.

In the scapulary arch the primordial cartilaginous elements scarcely differ from those of the *Dipnoi*. The membrane-bones are much expanded, and show a continuous series suspended from the skull. Their division in the median ventral line is complete. The pectoral is supported by a cartilaginous framework (fig. 38) similar to that of *Ceratodus*, but much more shortened and reduced in its periphery, the branches being absent altogether on one side of the axis. This modification of the fin is analogous to the heterocercal condition of the end of the spinous column. To the inner corner of a basal cartilage (*a*) a short axis (*b*) is joined, which on its outer side bears a few branches (*d*) only, the remaining branches (*c*) being fixed to the basal cartilage. The dermal fin-rays are opposed to the extremities of the branches, as in the *Dipnoi.*

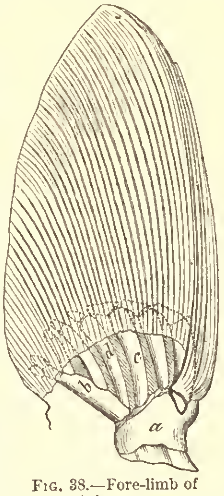

Fig. 38.—Fore-limb of *Acipenser.*

The pubic consists of a paired cartilage, to which tarsal pieces supporting the fin-rays are attached.

The other existing Ganoid fishes have the spinous column entirely or almost entirely ossified; these have been comprised under the common name *Holostei.* They form, however, three very distinct types; several attempts have been made to co-ordinate with them the fossil forms, but this task is beset with extreme difficulties, of which no satisfactory solution has as yet been advanced.

The *Polypteroidei* have their spinous column formed by distinct osseous amphicœlous vertebræ, that is, vertebræ with concave anterior and posterior surfaces. It is nearly diphycercal. The neural arches, though ossified, do not coalesce with the

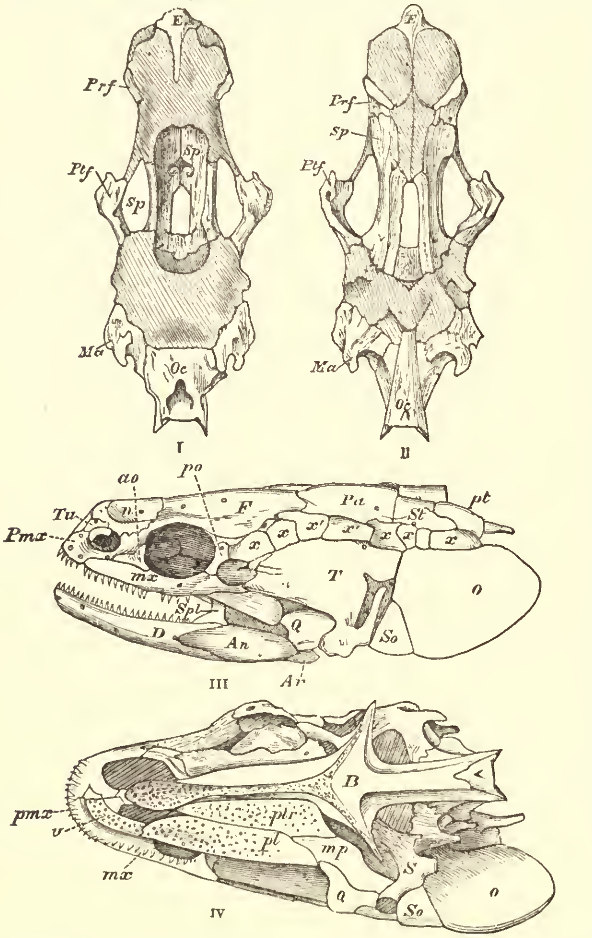

Fig. 39.—Skull of *Polypterus.* (After Traquair.) I. Upper aspect of the primordial cranium, with the membrane-bones removed. II. Lower aspect of the same. III. Side view, with the membrane-bones. IV. Lower aspect of the skull, part of the bones being removed on one side. The parts shaded with oblique lines are cartilage of the primordial skull. *An*, angular; *ao*, anteorbital; *Ar*, articulary; *B*, basal; *D*, dentary; *E*, ethmoid; *F*, frontal; *Ma*, mastoid; *Mp*, metapterygoid; *Mx*, maxillary; *N*, nasal; *O*, operculum; *Oc*, occipital; *Pa*, parietal; *Pl*, palatine; *Pmx*, præmaxillary; *po*, postorbital; *Prf*, prefrontal; *Pt*, post-temporals; *Ptf*, postfrontal; *Ptr*. pterygoid; *Q*, quadrate; *S*, suspensorium; *So*, suboperculum; *Sp*, sphenoid; *Spl*, splenial; *St*, supratemporals; *T*, tympanic lamina; *Tu*, turbinal; *v*, vomer; *x x*, small ossicles; *x′ x′*, spiraculars.

centrum, and form one canal only for the myelon. There are no intermediate elements between the neural spines. Interneurals are developed, but are simple, articulating with the dermoneurals. The abdominal vertebræ have parapophyses developed with epipleural spines. Only the caudal vertebræ have hæmal spines, which, like the interhæmals, agree in every essential respect with the opposite neurals. Ribs are inserted, not on the parapophyses, but on the centra, immediately below the parapophyses.

The skull of *Polypterus* (fig. 39) shows a great advance towards the Teleosteous type, the number of separable bones being greatly increased. They are arranged much in the same fashion as in *Teleostei*, but a great portion of the primordial cranium remains cartilaginous. The membrane-bones which cover the upper and lower surfaces of the brain-case are so much developed as to cause the underlying cartilage to disappear, so that a large vacuity or fontanelle exists in the substance of the upper as well as of the lower cartilaginous wall. Of ossifications belonging to the primordial skull must be noticed the single occipital with a mastoid on each side. They are separated by persistent cartilage from the sphenoids and postfrontals; the former, which are the largest ossification of the primordial cranium, enclose the anterior half of the brain cavity. Finally, the nasal portion contains a median ethmoid and a pair of præfrontal bones. Only a very small portion of the bones described are visible externally, nearly the whole of the primordial cranium being covered by the membrane-bones. Of these are seen on the upper surface a pair of parietals, frontals, "nasals," and turbinals; on the lower surface a large cross-shaped basal, anteriorly bordered on each side by a pterygoid, parallel to a palatine which forms a suture with the double vomer. The suspensorium has in front a metapterygoid and quadrate bone, and an operculum and suboperculum are attached to it behind. Præmaxillaries and maxillaries are now fully developed, but immovably attached to the skull. The lower jaw is ossified, and consists of an articulary, angular, dentary, and splenial. Of labial cartilages a rudiment at the angle of the mouth has remained persistent. The side of the skull, in front of the operculum, is covered by a large irregularly-shaped bone (*T*) (corresponding to the "tympanic lamina" of *Ceratodus*, fig. 35, *q*), held by some to be the præoperculum; along its upper circumference lies a series of small ossicles, of which two may be distinguished as spiraculars, as they form a valve for the protection of the spiracular orifice of these fishes. An infraorbital ring is represented by a præorbital and postorbital only.

Each hyoid consists of three pieces, none of which bear branchiostegals, the single median piece being osseous in front and cartilaginous behind. Four branchial arches are developed, the foremost consisting of three, the second and third of two, and the last of a single piece. There is no lower pharyngeal. Between the rami of the lower jaw the throat is protected by a pair of large osseous laminæ (gular plates), which have been considered to represent the urohyal of osseous fishes. The scapulary arch is almost entirely formed by the well-developed membrane-bones, which in the ventral line are suturally united. The pectoral fin is supported by three bones, pro-, meso-, and meta-pterygium, of which the dilated middle one alone bears rays, and is excluded from the articulation with the shoulder-girdle.

The pubic consists of a paired bone, to which tarsal bones supporting the fin-rays are attached.

In the *Lepidosteoidei* the vertebræ are completely ossified and opisthocœlous, having a convexity in front and a concavity behind, as in some amphibians. Though the end of the body externally appears nearly diphycercal, the termination of the vertebral column is, in fact, distinctly heterocercal. The caudal fin is suspended from hæmapophyses only, and does not extend to the neural side of the vertebral column. The neural arches coalesce with the centrum; the interneurals are simple. The abdominal vertebræ have parapophyses, to which the ribs are attached. Only the caudal vertebræ have hæmal spines.

In the skull of *Lepidosteus* the cartilage of the endocranium is still more replaced by ossifications than in *Polypterus*, those ossifications, moreover, being represented by a greater number of discrete bones. The membrane-bones in particular are greatly multiplied: the occipital, for instance, consists of three pieces; the vomer is double, as in *Polypterus*; the maxillary consists of a series of pieces firmly united by suture. The symplectic reaches the lower jaw, so that the articulary is provided with a double joint, viz., for the symplectic and quadrate; the component parts of the lower jaw are as numerous as in reptiles, a dentary, splenial, articulary, angular, supra-angular, and coronary being distinct. The sides of the head are covered with numerous bones, and a præoperculum is developed in front of the gill-cover, which, again, consists of an operculum and suboperculum.

Each hyoid consists of three pieces, of which the middle is the longest, the upper bearing the largest of the three branchiostegals which *Lepidosteus* possesses; a long and large glossohyal is intercalated between the lower ends of the hyoids. There are five branchial arches, the hindmost of which is modified into a lower pharyngeal; upper pharyngeals are likewise present as in the majority of Teleosteous fishes, but there is no gular plate.

Of the scapulary arch the two halves are separated by a suture in the median line; the membrane-bones are well developed, only a remnant of the primordial cartilage remaining; the supraclavicle is very similar to that of Teleosteous fishes, and in a less degree the post-temporal. The base to which the limb is attached is a single osseous plate, supporting on its posterior margin semi-ossified rods in small number, which bear the pectoral rays. The pubic consists of a paired bone. The elements representing a tarsus are quite rudimentary, and reduced in number (two or three).

The vertebral column of the *Amioidei* shows unmistakable characters of the Palæichthyic type. The arrangement of its component parts is extremely simple. The centra of the amphicœlous vertebræ are well ossified, but the neural and hæmal arches do not coalesce with the centra, from which they are separated by a thin layer of cartilage. All the vertebræ do not possess apophyses: in the caudal portion of *Amia* only every alternate vertebra is provided with them. The heterocercal condition of the spinous column is well marked; as in the other *Holostei*, the hindmost vertebræ are turned upwards, become gradually smaller in size, and lose their neural arches, the hæmals remaining developed to the end. Finally, the column terminates in a thin cartilaginous band, which is received between the lateral halves of the fifth or sixth upper caudal ray. The interneurals and interhæmals are simple. Only the abdominal vertebræ have parapophyses, with which the ribs are articulated.

The configuration of the skull, and the development and arrangement of its component parts, approach so much the Teleostean type, that perhaps there are greater differences in skulls of truly Teleostean fishes than between the skulls of *Amia* and of many *Physostomi*. Externally the cranium is entirely ossified; the remains of the cartilaginous primordial cranium can only be seen in a section, and are of much less extent than in many Physostomous fishes. The immovable intermaxillary, the double vomer, the double articulary cavity of the mandible for junction with the quadrate and symplectic bones, remind us still of similar conditions in the skull of *Lepidosteus*; but the mobility and formation of the maxillary, the arrangement of the gill-covers, the development of a præoperculum, the suspensorium, the palate, the insertion of a number of branchiostegals on the long middle hyoid piece, the composition of the branchial framework (with upper and lower pharyngeals), are as in the Teleosteous type. A gular plate replaces the urohyal.

The scapular arch is composed entirely of the membrane-bones found in the *Teleostei*, and the two sides are loosely united by ligament. The base to which the limb is attached is cartilaginous; short semi-ossified rods are arranged along its hinder margin, and bear the pectoral rays.

Myology.

In the lowest vertebrate, *Branchiostoma*, the whole of the muscular mass is arranged in a longitudinal band running along each side of the body; it is vertically divided into a number of flakes or segments (myocommas) by aponeurotic septa, which serve as the surfaces of insertion to the muscular fibres. But this muscular band has no connexion with the notochord except in its foremost portion, where some relation has been formed to the visceral skeleton. A very thin muscular layer covers the abdomen. In the Cyclostomes also the greater portion of the muscular system is without direct relation to the skeleton, and, again, it is only on the skull and visceral skeleton that distinct muscles have been differentiated for special functions.

To the development of the skeleton in the more highly organized fishes corresponds a similar development of the muscles: the maxillary and branchial apparatus, the pectoral and ventral fins, the vertical fins and especially the caudal, possess a separate system of muscles. But the most noteworthy is the muscle covering the sides of the trunk and tail (already noticed in *Branchiostoma*), which Cuvier described as the "great lateral muscle," and which, in the higher fishes, is a compound of many smaller segments (myocommas), corresponding in number with the vertebræ. Each lateral muscle is divided by a median longitudinal groove into a dorsal and ventral half; the depression in its middle is filled by an embryonal muscular substance which contains a large quantity of fat and numerous blood-vessels, and therefore differs from ordinary muscle by its softer consistency, and by its colour, which is reddish or greyish. Superficially the lateral muscle appears crossed by a number of white parallel tendinous zigzag stripes, forming generally three angles, of which the upper and lower point backwards, the middle one forwards. These are the outer edges of the aponeurotic septa between the myocommas. Each septum is attached to the middle and to the apophyses of a vertebra, and, in the abdominal region, to its rib; frequently the septa receive additional support by the existence of epipleural spines.

In connexion with the muscles reference has to be made to the electric organs with which certain fishes are provided. That these have been developed out of muscular substance is more than probable, not only from the examination of peculiar muscular organs (the function of which is still conjectural) occurring in the rays, and in *Mormyrus* and *Gymnarchus*, but especially from the researches into the development of the electric organ of *Torpedo*. The fishes possessing fully developed electric organs, with the power of accumulating electric force and communicating it in the form of shocks to other animals, are the electric rays (*Torpedinidæ*), the electric sheath-fish of tropical Africa (*Malapterurus*), and the electric eel of tropical America (*Gymnotus*). The structure and arrangement of the electric organ are very different in these fishes.

In *Torpedo* the electric organs are large, flat, uniform bodies, lying one on each side of the head, bounded behind by the scapular arch, and laterally by the anterior crescent-shaped tips of the pectoral fins. They consist of an assemblage of vertical hexagonal prisms, whose ends are in contact with the integuments above and below; and each prism is subdivided by delicate transverse septa, forming cells filled with a clear, trembling, jelly-like fluid, and lined within by an epithelium of nucleated corpuscles. Between this epithelium and the transverse septa and walls of the prism there is a layer of tissue on which the terminations of the nerves and vessels ramify. Hunter counted four hundred and seventy prisms in each battery of *Torpedo marmorata*, and demonstrated the enormous supply of nervous matter which they receive. Each organ receives one branch of the trigeminal nerve and four branches of the vagus, the former, and the three anterior branches of the latter, being each as thick as the spinal chord (electric lobes).

In *Malapterurus* the electric organ extends over the whole body, but is thickest on the abdomen; it lies between two aponeurotic membranes below the skin, and consists of rhomboidal cells which contain a rather firm gelatinous substance. The electric nerve takes its origin from the spinal chord, does not enter into connexion with ganglia, and consists of a single enormously-strong primitive fibre, which distributes its branches in the electric organ.

The electric eel is the most powerful of electric fishes. Its electric organ consists of two pairs of longitudinal bodies, situated immediately below the skin, above the muscles,—one pair on the back of the tail, and the other pair along the anal fin. Each fasciculus is composed of flat partitions or septa, with transverse divisions between them. The outer edges of the septa appear in nearly parallel lines in the direction of the longitudinal axis of the body, and consist of thin membranes, which are easily torn; they serve the same purpose as the columns in the analogous organ of the torpedo, making the walls or abutments for the perpendicular and transverse dissepiments, which are exceedingly numerous, and so closely aggregated as to seem almost in contact. The minute prismatic cells, intercepted between these two sorts of plates, contain a gelatinous matter; the septa are about $\frac{1}{30}$th of an inch from each other, and a length of one inch contains a series of two hundred and forty cells, giving an enormous surface to the electric organs. The whole apparatus is supplied with more than two hundred nerves, which are the continuations of the rami anteriores of the spinal nerves. In their course they give out branches to the muscles of the back, and to the skin of the animal. In the Gymnotes, as in the torpedo, the nerves supplying the electric organs are much larger than those bestowed on any part for the purposes of sensation or movement.

The phenomena attending the exercise of this extraordinary faculty closely resemble muscular action. The time and strength of the discharge are entirely under the control of the fish. The power is exhausted after some time, and needs repose and nourishment to restore it. If the electric nerves are cut and divided from the brain, the cerebral action is interrupted, and no irritant to the body has any effect in exciting electric discharge; but if their ends be irritated the discharge takes place, just as a muscle is excited to contraction under similar circumstances. Singularly enough, also, the application of strychnine causes simultaneously a tetanic state of the muscles and a rapid succession of involuntary electric discharges. The strength of the discharges depends entirely on the size, health, and energy of the fish, an observation completely agreeing with that made on the efficacy of snake-poison. Like this latter, the property of the electric force serves two ends in the economy of the animals which are endowed with it: it is necessary to them for overpowering, stunning, or killing the creatures on which they feed, whilst incidentally they use it as the means of defending themselves from their enemies.

Neurology.

The most simple condition of the nervous central organ known in vertebrates is found in *Branchiostoma*. In this fish the spinal cord tapers at both ends, no anterior cerebral swelling, or anything approaching a brain, being present. It is band-like along its middle third, and groups of darker cells mark the origins of the fifty or sixty pairs of nerves which accompany the intermuscular septa, and divide into a dorsal and a ventral branch, as in other fishes. The two anterior pairs pass to the membranous parts above the mouth, and supply with nerve filaments a ciliated depression near the extremity of the fish, which is considered to be an olfactory organ, and two pigment spots, the rudiments of eyes. An auditory organ is absent. The spinal cord of the Cyclostomes is flattened in its whole extent, band-like, and elastic; also in *Chimæra* it is elastic, but flattened in its posterior portion only. In all other fishes it is cylindrical, non-ductile, and generally extending along the whole length of the spinal canal. The Plectognaths offer a singular exception in this respect, that the spinal cord is much shortened, the posterior portion of the canal being occupied by a long cauda equina; this shortening of the spinal cord has become extreme in the sun-fish (*Orthagoriscus*), in which it has shrunk into a short and conical appendage of the brain. In the devil-fish (*Lophius*) also a long cauda equina partly conceals the cord which terminates on the level of about the twelfth vertebra.

The brain of fishes is relatively small; in the burbot (*Lota*) it has been estimated to be the $\frac{1}{720}$th part of the weight of the entire fish, in the pike the $\frac{1}{1305}$th part, and in the large sharks it is relatively still smaller.

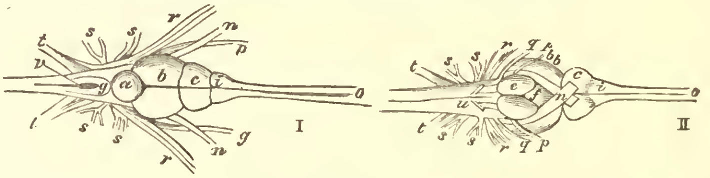

Fig. 40.—Brain of Perch. I. Upper aspect. II. Lower aspect. *a*, cerebellum; *b*, optic lobes; *c*, hemispheres; *e*, lobi inferiores; *f*, hypophysis; *g*, lobi posteriores; *i*, olfactory lobes; *n*, nervus opticus; *o*, nervus olfactorius; *p*, nervus oculo-motorius; *q*, nervus trochlearis; *r*, nervus trigeminus; *s*, nervus acousticus; *t*, nervus vagus; *u*, nervus abducens; *v*, fourth ventricle.

The brain of osseous fishes (fig. 40) viewed from above shows three protuberances, respectively termed the prosencephalon, mesencephalon, and metencephalon, the two anterior of which are paired, the hindmost being single. The foremost pair are the hemispheres, which are solid in their interior, and provided with two swellings in front, the olfactory lobes. The second pair are the optic lobes, which generally are larger than the hemispheres, and succeeded by the third single portion, the cerebellum. The optic lobes possess a cavity (ventriculus lobi optici), at the bottom of which some protuberances of variable development represent the corpora quadrigemina of higher animals. On the lower surface of the base of the optic lobes, behind the crura cerebri, two swellings are observed, the lobi inferiores, which slightly diverge in front for the passage of the infundibulum, from which a generally large hypophysis or pituitary gland is suspended. The relative size of the cerebellum varies greatly in the different osseous fishes: in the tunny and silurus it is so large as nearly to cover the optic lobes; sometimes distinct transverse grooves and a median longitudinal groove are visible. The cerebellum possesses in its interior a cavity which communicates with the anterior part of the fourth ventricle. The medulla oblongata is broader than the spinal cord, and contains the fourth ventricle. In most fishes a perfect roof is formed over the fourth ventricle by two longitudinal pads, which meet each other in the median line (lobi posteriores).

The brain of Ganoid fishes shows great similarity to that of the *Teleostei*; there is, however, considerable diversity in the arrangement of its various portions in the different types. In the sturgeons and *Polypterus* (fig. 41) the hemispheres are more or less remote from the mesencephalon, so that in an upper view the crura cerebri, with the intermediate entrance into the third ventricle (fissura cerebri magna), may be seen. A vascular membranous sac, epiphysis, containing lymphatic fluid, takes its origin from the third ventricle, its base being expanded over the anterior interspace of the optic lobes, and the apex being

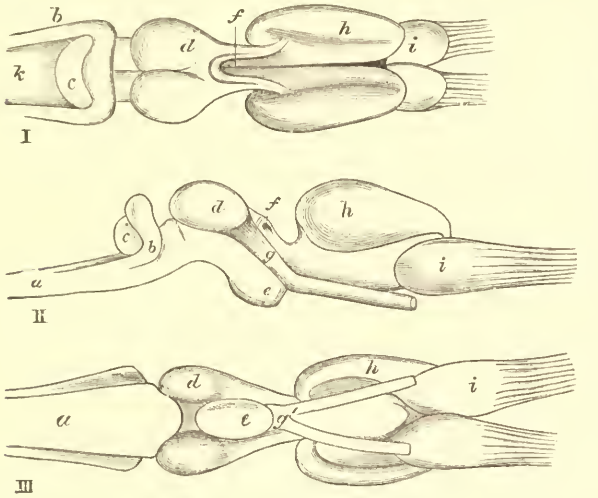

Fig. 41.—Brain of *Polypterus*. (After Müller.) I. Upper, II., Lateral, III. Lower aspect. *a*, medulla; *b*, corpora restiformia; *c*, cerebellum; *d*, lobi optici; *e*, hypophysis; *f*, fissura cerebri magna; *g*, nervus opticus; *g'*, chiasma; *h*, hemispheres; *i*, lobus olfactorius; *k*, sinus rhomboidalis (fourth ventricle).

fixed to the cartilaginous roof of the cranium. This structure is not peculiar to the Ganoids, but is found in various stages of development in Teleosteans, marking, when present, the boundary between the prosencephalon and mesencephalon. The lobi optici are essentially as in Teleosteans. The cerebellum penetrates into the ventriculus lobi optici, and extends thence into the open sinus rhomboidalis. At its upper surface it is crossed by a commissure formed by the corpora restiformia of the medulla.

As regards external configuration, the brain of *Lepidosteus* and *Amia* approach still more the Teleosteous type. The prosencephalon, mesencephalon, and metencephalon are contiguous, and the cerebellum lacks the prominent transverse commissure at its upper surface. The sinus rhomboidalis is open.

The brain of Chondropterygians (fig. 42) is more developed than that of other fishes, and is distinguished by well-marked characters. These are—first, the prolongation of the olfactory lobes into pedicles of greater or less length, which dilate into great ganglionic masses, where they come into contact with the olfactory sacs; secondly, the space which generally intervenes between the prosencephalon and mesencephalon, as in some Ganoids; thirdly, the large development of the metencephalon.

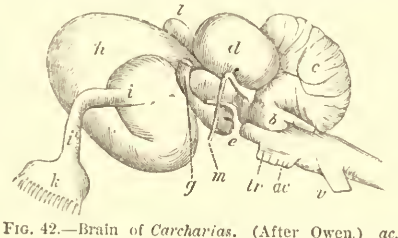

Fig. 42.—Brain of *Carcharias*. (After Owen.) *ac*, nervus acousticus; *b*, corpus restiforme; *c*, cerebellum; *d*, lobus opticus; *e*, hypophysis; *g*, nervus opticus; *h*, hemisphere; *i*, lobus olfactorius; *i'*, olfactory pedicle; *k*, nervus olfactorius; *l*, epiphysis; *m*, nervus oculo-motorius; *tr*, nervus trigeminus; *v*, nervus vagus.

The cerebellum is very large, overlying a portion of the optic lobes and of the sinus rhomboidalis, and is often transversely grooved. The side-walls of the fourth ventricle, which are formed by the corpora restiformia, are singularly folded, and appear as two pads, one on each side of the cerebellum (lobi posteriores or lobi nervi trigemini).

The brain of the Cyclostomes represents a type different from that of other fishes, showing at its upper surface three pairs of protuberances in front of the cerebellum; they are all solid. The foremost pair are the large olfactory tubercles, which are extremely large in *Petromyzon*. They are followed by the hemispheres, with a single body wedged in between their posterior half; in *Petromyzon*, at least, the vascular tissue leading to an epiphysis seems to be connected with this body. Then follows the lobus ventriculi tertii, distinctly paired in Myxinoids, but less distinctly in *Petromyzon*. The last pair are the corpora quadrigemina. According to this interpretation, the cerebellum would be absent in Myxinoids, and represented in *Petromyzon* by a narrow commissure only, stretching over the foremost part of the sinus rhomboidalis. In the Myxinoids the medulla oblongata ends in two divergent swellings, free and obtuse at their extremity, from which most of the cerebral nerves take their origin.[1]

Two very important conditions require mention. The first relates to the optic nerves, viz., to their mutual relation immediately after their origin, which is very characteristic of the subclasses of fishes. In the Cyclostomes they have no further connexion with each other, each going to the eye of its own side. In the *Teleostei* (fig. 40, *n*) they simply cross each other (decussate), so that the one starting from the right half of the brain goes to the left eye and *vice versa*. Finally, in the *Palæichthyes* (fig. 41, *g'*) the two nerves are fused together, immediately after their origin, into a chiasma.

The second noteworthy peculiarity occurs in the distribution of the nervus vagus; it emits a strong branch, called nervus lateralis, which accompanies the lateral mucous system of the trunk and tail. This is either a single longitudinal stem, gradually becoming thinner behind, and running superficially below the skin (*Salmonidæ*, *Cyclopterus*) or deeply between the muscles (sharks, *Chimæra*), or is divided into two parallel branches (most *Teleostei*); thus in the perch there are two branches on each side, the superficial one supplying the lateral line, whilst the deep-seated branch communicates with the spinal nerves and supplies the septa between the myocommas and the skin. In fishes which lack the lateral muciferous system and possess hard integuments, as the Ostracions, the lateral nerve is more or less rudimentary. It is entirely absent in Myxinoids, but the gastric branches of the vagus are continued, united as a single nerve, along the intestine to the anus.

Fishes possess all the spino-cerebral nerves of the higher Vertebrata, with the exception of the nervus accessorius. A separate nervus hypoglossus is also absent, but elements from the first spinal nerve are distributed over the area normally supplied by this nerve in higher vertebrates. The number of spinal nerves corresponds to that of the vertebræ, through or between which they pass out.

A sympathic nervous system appears to be absent in *Branchiostoma*, and has not yet been clearly made out in the Cyclostomes. It is well developed in the *Palæichthyes*, but without the cephalic portion. This latter is present in all osseous fishes, in which the communication of sympathy has been found to exist between all the cerebral nerves, except the olfactory, optic, and acoustic. The sympathic trunks run along each side of the aorta and the back of the abdomen into the hæmal canal, communicate in their course with the ventral branches of each of the spinal nerves, and, finally, often blend together into a common trunk beneath the tail. At the points of communication with the cerebral and spinal nerves ganglia are frequently developed, from which nerves emerge which are distributed to the various viscera.

[1] For a more detailed account of the spino-cerebral nerves, see *Introduction to the Study of Fishes*, by A. Günther.

ORGANS OF SENSE.

Organ of Smell.—It is characteristic of the organ of smell in fishes that it has no relation whatever to the respiratory function, with the exception of the *Dipnoi*, in which possibly part of the water received for respiration passes through the nasal sac.

The olfactory organ is single in *Branchiostoma* and the Cyclostomes. In the former a small depression on the front end of the body, clothed with a ciliated epithelium, is regarded as a rudimentary organ of smell. In the adult *Petromyzon* a membranous tube leads from the single opening on the top of the head into the cartilaginous olfactory capsule, the inside of which is clothed by membranes prolonged into a posterior blind tube (fig. 31, *s*), which penetrates the cartilaginous roof of the palate, but not the mucous membrane of the buccal cavity. In the Myxinoids the outer tube is strengthened by cartilaginous rings like a trachea; the capsule is lined by a longitudinally folded pituitary membrane, and the posterior tube opens backwards on the roof of the mouth, the opening being provided with a valve. In all other fishes the organ of smell is double, there being one on each side; it consists of a sac lined with a pituitary membrane, and may be provided with one or with two openings, or may have none. The position of these openings is very different in the various orders and suborders of fishes.

It is certain that fishes possess the faculty of perceiving odours, and that various scents attract or repel them. A mangled carcase or fresh blood attracts sharks, as well as the voracious Serrasalmonoids of the South American rivers. There is no reason to doubt that the seat of that perception is in the olfactory sac; and it may be reasonably conjectured that its strength depends mainly on the degree of development indicated by the number and extent of the interior folds of the pituitary membrane.

Organ of Sight.—The position, direction, and dimensions of the eyes of fishes vary greatly. In some they have an upward aspect, and are often very close together; in others they are lateral, and in a few they are even directed downwards. In a very few this organ appears to be entirely absent. In some Gobioids and Trachinoids (*Periophthalmus, Boleophthalmus, Uranoscopus*, &c.) the eyes, which are on the upper side of the head, can be elevated and depressed at the will of the fish. In the range of their vision and in their acuteness of sight, fishes are very inferior to the higher classes of vertebrates, yet at the same time it is evident that they perceive their prey, or approaching danger, from a considerable distance; and it would appear that the visual powers of a *Periophthalmus* (fig. 12), when hunting insects on the mud-flats of the tropical coasts, are quite equal to those of a frog.

The eye of *Branchiostoma* (fig. 30, *g*) is of the most rudimentary kind. It is simply a minute speck coated with a dark pigment, and receiving the end of a short nerve. In Myxinoids the minute rudiment of the eye is covered by skin and muscles. This is also the case in many of the blind Teleosteous fishes; whilst in the former fishes, however, the organ of sight has not attained to any degree of development, the rudimentary eye of blind *Teleostei* is a retrogressive formation, in which a lens and other portions of the eye can often be recognized. In fishes with a well-developed eye it is imbedded in a layer of gelatinous and adipose substance, which covers the cavity of the orbit. A lachrymal gland is absent. In the Chondropterygians the eyeball is supported by and moves on a cartilaginous peduncle of the orbital wall. In the majority of Teleosteans, and in *Acipenser*, a fibrous ligament attaches the sclerotic to the wall of the orbit. The proper muscles of the eyeball are always present. In all fishes the general integument of the head passes over the eye, and becomes transparent where it enters the orbit; sometimes it simply passes over the orbit, sometimes it forms a circular fold. The anterior and posterior portions may be specially broad, becoming the seat of an adipose deposit (adipose eyelids), as in *Scomber, Caranx, Mugil*, &c. In many of these fishes the extent of the eyelids varies with the seasons; during the spawning season they are so much loaded with fat as nearly to hide the whole eye. Many sharks possess a nictitating membrane, developed from the lower part of the palpebral fold, and moved by a proper set of muscles.

The form of the bulbus (fig. 43) is subhemispherical, the cornea (*co*) being flat. If it were convex, as in higher vertebrates, it would be more liable to injury; but, as it is level with the side of the head, the chances of injury by friction are diminished. The sclerotica (*sc*) is cartilaginous in Chondropterygians and Acipensers, fibrous and of varying thickness in Teleosteans, in the majority of which it is supported by a pair of cartilaginous or ossified hemispheroid cups (*c*). In a few fishes, as in *Ceratodus, Xiphias*, the cups are confluent into one cup, which possesses a foramen behind to allow the passage of the optic nerve (*o*).

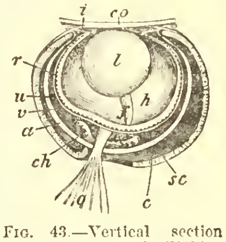

FIG. 43.—Vertical section through eye of *Xiphias*. (After Owen.) *co*, cornea; *sc*, sclerotica; *o*, nervus opticus; *c*, sclerotic capsule; *a*, membrana argentea; *v*, membrana vasculosa; *u*, membrana uvea; *ch*, choroid gland; *r*, retina; *f*, processus falciformis; *h*, humor vitreus; *l*, lens; *i*, iris.

The membranes situated between the sclerotica and retina are collectively called choroidea, and are three in number. The one in immediate contact with the sclerotic, and continued upon the iris, is by no means constantly present; it is the membrana argentea (*a*), and is composed of microscopical crystals reflecting a silvery or sometimes golden lustre. The middle layer is the membrana vasculosa or Halleri (*v*), the chief seat of the ramifications of the choroid vessels; the innermost layer is the membrana Ruyscheana or uvea (*u*), which is composed of hexagonal pigment-cells, usually of a deep-brown or black colour.

In many *Teleostei* a rete mirabile surrounds the entry of the optic nerve; it is situated between the membrana argentea and vasculosa, and called the choroid gland (*ch*). It receives its arterial blood from the artery issuing from the pseudobranchia, the presence of a choroid gland being always combined with that of a pseudobranchia. Teleosteans without pseudobranchia have no choroid gland. In the *Palæichthyes*, on the other hand, the pseudobranchia is present and a choroid gland absent.

The iris (*i*) is merely the continuation of the choroid membrane; its capability of contracting and expanding is much more limited than in higher vertebrates. The pupil is generally round, sometimes horizontally or vertically elliptical, sometimes fringed. In the rays and *Pleuronectidæ* a lobe descends from the upper margin of the pupil, and the outer integument overlying this lobe is coloured and non-transparent,—a structure evidently preventing light from entering the eye from above.

In most *Teleostei* a fold of the choroidea, called the processus falciformis (*f*), extends from the vicinity of the entrance of the optic nerve to the lens. It seems to be constantly absent in Ganoids.

The vitreous humour (*h*), which fills the posterior cavity of the eye-ball, is of a firmer consistency than in the higher vertebrates. The lens is spherical, or nearly so, firm, denser towards the centre, and lies in a hollow of the vitreous humour. When a falciform process is present, it has one end attached to the lens, which is thus steadied in its position. It is composed of concentric layers consisting of fibres, which in the nucleus of the body have marginal teeth, by which they are interlocked together. In *Petromyzon* this serrature is absent, or but faintly indicated.

The anterior cavity of the eye is very small in fishes, in consequence of the small degree of convexity in the cornea; the quantity of the aqueous humour, therefore, is very small, just sufficient to float the free border of the iris; and the lessened refractive power of the aqueous humour is compensated by the greater convexity of the lens.

Organ of Hearing.—No trace of an organ of hearing has been found in *Branchiostoma*. In the Cyclostomes the labyrinth is enclosed in externally visible cartilaginous capsules laterally attached to the skull; it consists of a single semicircular canal in the Myxinoids, whilst the *Petromyzontes* possess two semicircular canals with a vestibulum.

In all other fishes the labyrinth consists of a vestibule and three semicircular canals, the vestibule dilating into one or more sacs, which contain the otoliths. A tympanum, tympanic cavity, and external parts are entirely absent in the class of fishes.

In the Chondropterygians and *Dipnoi*, the labyrinth is enclosed in the cartilaginous substance of the skull. In the former the excavation in the cartilage is larger than the membranous labyrinth, but nearly corresponds to it in form; the part which receives the membranous vestibulum is called vestibulum cartilagineum, from which a canal issues and penetrates to the surface of the skull, where it is closed by the skin in sharks, but opens by a minute foramen in rays. The otolithic contents are soft and chalklike.

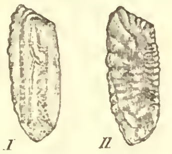

Fig. 44.—Otolith of Haddock (*Gadus æglefinus*). I. Outer, II. Inner aspect.

In the Teleosteans the sac which contains the otoliths lies on each side of the base of the cranial cavity, and is often divided by a septum into two compartments of unequal size, each containing a firm and solid otolith (fig. 44); these bodies possess indented margins, frequently other impressions and grooves, in which nerves from the N. acousticus are lodged; they vary much in size and form, but in both respects show a remarkable constancy in the same kind of fishes. Outwards the vestibule is in contact with the osseous side wall of the skull, inwards with the metencephalon and medulla oblongata; it contains another firm concretion, and opens by five foramina into the three semicircular canals. The terminations of the acoustic nerve are distributed over the vestibular concretion and the ampulliform ends (fig. 45) of the semicircular canals, without being continued into the latter, which are filled with fluid. The semicircular canals (fig. 45) are sometimes lodged in the cranial bones, sometimes partly free in the cranial cavity. Many *Teleostei* have fontanelles in the roof of the skull, closed only by skin or very thin bone at the place where the auditory organ approaches the surface, by which means sonorous undulations must be conducted with greater ease to the ear.

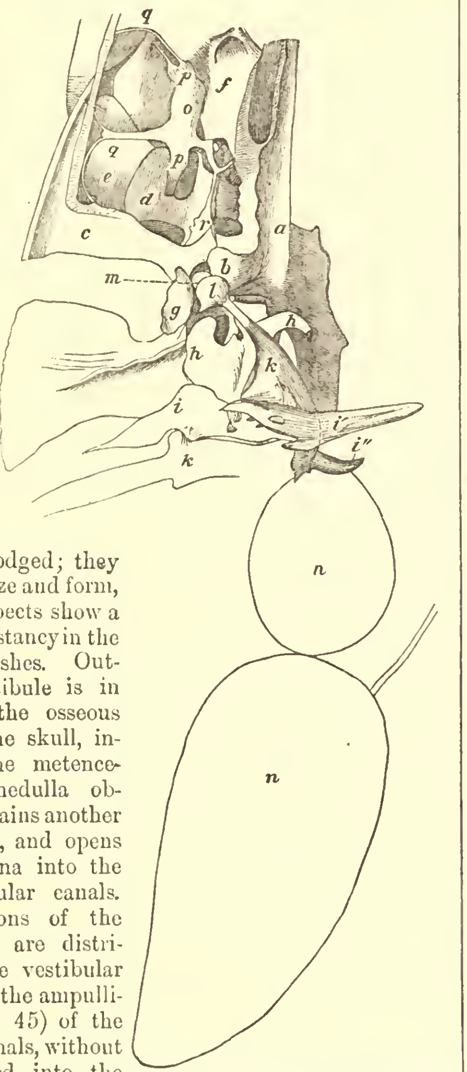

Fig. 45.—Communication between auditory organ and air-bladder in the Carp. (After E. H. Weber.) *a*, basisphenoid; *b*, occipital; *c*, supraoccipital; *d*, exoccipital; *e*, paroccipital; *f*, alisphenoid; *g*, neural arch of first vertebra; *h*, *i*, *k*, second, third, and fourth vertebræ; *h′*, *i′*, parapophyses of second and third vertebræ; *i″*, process of the third vertebra for the attachment of the air-bladder; *k*, *l*, *m*, chain of ossicles; *n*, air-bladder; *o*, vestibulum; *p*, *p*, ampullæ; *q*, *q*, canales semicirculares; *r*, sinus impar.

In many *Teleostei* a most remarkable relation obtains between the organ of hearing and the air-bladder. In the most simple form this connexion is established in Percoids and the allied families, in which the two anterior horns of the air-bladder are attached to fontanelles of the occipital region of the skull, the vestibulum occupying the opposite side of the membrane by which the fontanelle is closed. The condition is similar, but more complicated, in many Clupeoids. The anterior narrow end of the air-bladder is produced into a canal at the base of the skull, and divided into two very narrow branches, which again bifurcate and terminate in a globular swelling. An appendage of the vestibulum meets the anterior of these swellings, and comes into close contact with it. In addition, the two vestibules communicate with each other by a transverse canal, crossing the cranial cavity below the brain.

The connexion is effected by means of a chain of ossicles in *Siluridæ*, *Characinidæ*, *Cyprinidæ*, and *Gymnotidæ*. A canal issues from the communication between the vestibule and its sac, and meeting that from the other side forms with it a common sinus impar (fig. 45, *r*), lodged in the substance of the basioccipital; this communicates on each side by a small orifice with two subspherical atria, on the body of the atlas, close to the foramen magnum. Each atrium is supported externally by a small bone (*m*); a a third and larger bone (*k*) completes the communication with the anterior part of the air-bladder. From the sinus impar a bifid canal penetrates into the alisphenoids, in which it terminates. In *Cobitis* and several loach-like Siluroids the small air-bladder consists of two globular portions placed side by side, and wholly included within two bullæ formed by the modified parapophyses of the second and third vertebræ. The three ossicles on each side are present, but concealed by the fore part of the osseous bulla.

Organ of Taste.—Some fishes, especially vegetable feeders, or those provided with broad molar-like teeth, masticate their food; and it may be observed in carps and other Cyprinoid fish that this process of mastication frequently takes some time. But the majority of fishes swallow their food rapidly, and without mastication, and therefore we may conclude that the sense of taste cannot be keen. The tongue is often entirely absent, and, even when it exists in its most distinct state, it consists merely of ligamentous or cellular substance, and is never furnished with muscles capable of producing the movements of extension or retraction as in most of the higher vertebrates. A peculiar organ on the roof of the palate of Cyprinoids is perhaps adapted for the perception of this sense; in these fishes the palate between and below the upper pharyngeal bones is cushioned with a thick, soft, contractile substance, richly supplied with nerves from the nervus vagus and nervus glosso-pharyngeus.

Organs of Touch.—The faculty of touch is more developed than that of taste, and there are numerous fishes which possess special organs of touch. Most fishes are very sensitive to external touch, although their body may be protected by hard horny scales. They perceive impressions even on those parts which are covered by osseous scutes, in the same manner as a tortoise perceives the slightest touch of its carapace. The seat of the greatest sensitiveness however, appears to be the snout and the labial folds surrounding the mouth. Many species possess soft and delicate appendages, called barbels, which are almost constantly in action, and clearly used as organs of touch. Among the *Triglidæ* and allied families, there are many species which have one or more rays of the pectoral fin detached from the membrane, and supplied with strong nerves. Such detached rays (also found in the *Polynemidæ* and in *Bathypterois*) are used partly for locomotion, partly for exploring the ground over which the fish moves.

Some fishes appear to be much less sensitive than others, or at least lose their sensitiveness under peculiar circumstances. It is well known that a pike whose mouth has been lacerated and torn by the hook continues to yield to the temptation of a bait immediately afterwards. The Greenland shark, when feeding on the carcase of a whale, allows itself to be repeatedly stabbed in the head without abandoning its prey. A pair of congers are so dead to external impression at the time of copulation, and, as it were, so automatically engaged, that they have been taken by the hand together out of the water.

Organs of Nutrition and Digestion.

Fishes are for the most part either exclusively carnivorous or herbivorous, but not a few feed on vegetable as well as animal substances, or on mud containing alimentary matter in a living or decomposing state. Generally they are very voracious, especially the carnivorous kinds, and the rule of "eat or be eaten" applies to them with unusual force. They are almost constantly engaged in the pursuit and capture of their prey, the degree of their power in these respects depending on the dimensions of the mouth and gullet and the strength of the teeth and jaws. If the teeth are sharp and hooked, they are capable of securing the most slender and agile animals; if with teeth of this kind are combined a wide gullet and distensible stomach, the fish is able to overpower and swallow others larger than itself; if the teeth are broad, strong molars, they are able to crush the hardest alimentary substances; if they are feeble, they are only serviceable in procuring some small or inert and unresisting prey. Teeth may be wanting altogether. Whatever the prey, in the majority of cases it is swallowed whole; but some of the most voracious fishes, like some sharks and *Characinidæ*, are provided with cutting teeth, which enable them to tear their prey to pieces if too large to be swallowed whole. Auxiliary organs, similar to the claws of some carnivorous mammals and birds, for the purpose of seizing and overpowering their prey before it is torn by the teeth, are not found in this class; but in a few fishes the jaws themselves are modified for that purpose. In the sword-fishes the bones of the upper jaw form a long dagger-shaped weapon, with which they not only attack large animals, but also frequently kill fishes on which they feed. The saw-fishes are armed with a similar but still more complex weapon, the saw, which is armed on each side with large teeth implanted in deep sockets, specially adapted for killing and tearing the prey before it is seized and masticated by the small teeth within the mouth. Fishes show but little choice in the selection of their food, and some devour their own offspring indiscriminately with other fishes. Their digestive powers are strong and rapid, but are affected in some degree by the temperature, which, when it sinks below a certain point, lowers the vital powers of these cold-blooded animals. On the whole, marine fishes are more voracious than those inhabiting fresh waters; and, whilst the latter may survive total abstinence from food for weeks or months, the marine species succumb to hunger within a few days.

The organs of nutrition, manducation, and deglutition are lodged in two large cavities—an anterior (the mouth or buccal cavity), and a posterior (the abdominal cavity). In the former the alimentary organs are associated with those fulfilling the respiratory functions, the transmission of food to the stomach and of water to the gills being performed by similar acts of deglutition. The abdominal cavity commences immediately behind the head, so, however, that an extremely short thoracic cavity for the heart is partitioned off in front. Besides the alimentary organs it contains also those of the urogenital system and the air-bladder. The abdominal cavity is generally situated in the trunk only, but in numerous fishes it extends into the tail, being continued for some distance along each side of the hæmal apophyses. In numerous fishes the abdominal cavity opens outwards by one or two openings. A single porus abdominalis in front of the vent is found in *Lepidosiren* and some sturgeons; a paired one, opening on each side of the vent, in *Ceratodus*, some species of sturgeon, *Lepidosteus*, *Polypterus*, *Amia*, and all Chondropterygians. As in these fishes semen and ova are discharged by their proper ducts, the abdominal openings may serve for the expulsion of semen, and of those ova only which, having lost their way to the abdominal aperture of the oviduct, would be retained in the abdominal cavity. In those Teleosteans which lack an oviduct a single porus genitalis opens behind the vent.

Mouth.—The mouth of fishes shows extreme variation with regard to form, size, and position. Generally opening in front, it may be turned upwards, or it may lie at the lower side of the snout, as in most Chondropterygians, sturgeons, and some Teleosteans. In most fishes the jaws are covered by the skin, which, before passing over the jaws, is often folded, forming more or less fleshy lips. In the sharks the skin retains its external character even within the teeth, but in other fishes it changes into a mucous membrane. A tongue may exist as a more or less free and short projection, formed by the glossohyal and a soft covering, or may be entirely absent. Salivary glands and a velum palati are absent in fishes.

Teeth.—With regard to the dentition, the class of fishes offers an amount of variation such as is not found in any of the other classes of vertebrates. As the teeth form one of the most important elements in the classification of fishes, their special arrangement and form will be referred to in the account of the various families and genera. Whilst not a few fishes are entirely edentulous, in others most of the bones of the buccal cavity, or some of them, may be toothed, as the bones of the jaws, the palatines, pterygoids, vomers, basi-sphenoid, glossohyal, branchial arches, upper and lower pharyngeals. In others teeth may be found fixed in some portion of the buccal membrane without being supported by underlying bone or cartilage; or the teeth have been developed in membrane overlying one of the dentigerous bones mentioned, without having become anchylosed to the bone. When the tooth is fixed to the bone the attachment has generally been effected by the ossification of the bone of the tooth, but in some fishes a process of the bone projects into the cavity of the tooth; in others the teeth are implanted in alveoli. In these, again, frequently a process of bone rises from the bottom, on which the tooth rests.

Many of the class, especially predatory fishes, with long, lancet-shaped teeth, have all or some of these capable of being bent towards the interior of the mouth. Such "hinged" teeth resume at once the upright position when pressure is removed from them. They are, however, depressible in one direction only, thus offering no obstacle to the ingress, while they oppose the egress of prey. Mr C. S. Tomes has shown that the means by which this mechanism is worked are different in different fishes; for, whilst in the *Pediculati* and Gadoids (hake) the elasticity resides solely in the tissue of the hinge (the tooth being as resilient as ever after everything else is severed), in the pike the hinge is not in the least endowed with elasticity, but the bundles of fibres proceeding from the interior of the dentine cap are exceedingly elastic.

The teeth may be, and generally are, very different as regards size or form in the different parts of the mouth; they may be also different according to the age or sex of the fish (*Raia*). The teeth may be few in number and isolated, or placed in a single, double, or triple series, distant from one another or closely set; they may form narrow or broad bands, or patches of various forms. As regards form, they may be cylindrical or conical, pointed, straight, or curved, with or without an angular bend near their base; some are compressed laterally or from the front backwards (the latter may be triangular in shape, or truncated at the top like the incisors of mammals); they may have one apex (cusp) only, or be bi- or tri-lobate (bi- or tri-cuspid), or may have the margins denticulated or serrated. Compressed teeth may be confluent, and form a cutting edge in both jaws, which assume the shape of a parrot's beak. In some the apex is hooked or provided with barbs. Again, some teeth are broad, with flat or convex surface, like molar teeth. With regard to size, the finest teeth are like fine flexible bristles, ciliiform or setiform; or, if very short and anchylosed to the bone, they appear only as inconspicuous asperities of the bone. Very fine conical teeth arranged in a band are termed villiform teeth; when they are coarser, or mixed with coarser teeth, they are cardlike (dents en râpe or en cardes); molar-like teeth of very small size are termed granular.

In all fishes the teeth are shed and renewed during the whole course of their life. In fishes which have compound teeth, as the *Dipnoi*, Chimæroids, *Scari*, Gymnodonts, as well as in those which have apparently permanent teeth, as in the saw of *Pristis*, the detrition of the surface is made up by a constant growth of the tooth from its base. When the teeth are implanted in alveoli, they are generally succeeded by others in the vertical direction; but in other forms they succeed one another side by side. In the majority of fishes the new tooth is not developed (as in reptiles and mammals) in a diverticulum of the sac of its predecessor, but, like it, from the free surface of the buccal membrane. Generally there are more than one tooth growing which are in various stages of development, destined each to replace the others in function. This is very conspicuous in sharks, in which the whole phalanx of their numerous teeth is ever marching slowly forwards (or in some backwards), in rotatory progress, over the alveolar border of the jaw, the teeth being successively cast off after having reached the outer margin and fulfilled for a longer or shorter period their special function.[1]

Intestines.—The intestinal tract is divided into four portions,—the œsophagus, the stomach, the small and the large intestine; two or more of these divisions may coalesce in fishes and become indistinguishable. But it is characteristic of the class that the urinary apertures are constantly situated behind the termination of the intestinal tract.

In *Branchiostoma* the whole intestinal tract is straight, and coated with a ciliated mucous membrane. The liver is represented by a green-coloured cœcal diverticulum of the stomachic dilatation. In the *Cyclostomi* the intestinal tract is likewise straight, and without clearly defined divisions.

The *Palæichthyes* show differences in the structure of their intestinal tract as considerable as are found among the *Teleostei*, but they have this in common that the absorbent surface of their intestine is enlarged by the development of a spiral valve, evidence of the presence of which in extinct *Palæichthyes* is still preserved in the fossilized fæces or coprolites, so abundant in some of the older strata.

In Chondropterygians (fig. 46) the stomach is divided into a cardiac and a pyloric portion, the former frequently terminating in a blind sac, and the latter varying in length. The pyloric portion is bent both at its origin and its end, and is separated from the short duodenum (called *Bursa entiana* in these fishes) by a valve; the ductus hepaticus and ductus pancreaticus enter the duodenum. This is succeeded by the straight intestine, provided with the spiral valve, the coils of which may either be longitudinal and wound vertically about the axis of the intestine, as in *Carcharias*, *Galeocerdo*, *Thalassorhinus*, and *Zygæna*, or they may be transverse to that axis, as in the other genera. The number of gyrations in the latter case varies; there may be as many as forty. The short rectum passes into a cloaca, which contains also the orifices of the urogenital ducts. Only the beginning and end of the intestinal tract are fixed by mesenterial folds.

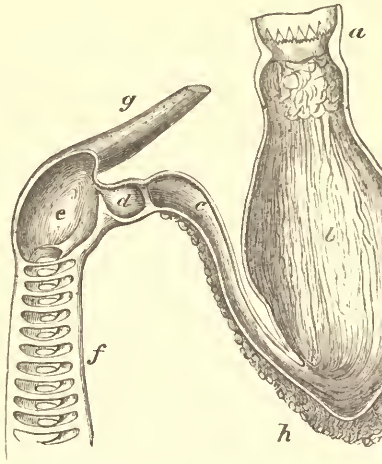

Fig. 46.—Siphonal stomach and spiral valve of Basking-Shark (*Selache*). (After Home and Owen.) *a*, œsophagus; *b*, cardiac portion of stomach; *c*, pyloric portion; *d*, pouch intermediate between stomach and duodenum, with circular valves at both ends; *e*, duodenum; *f*, valve of intestine; *g*, ductus hepaticus; *h*, spleen.

The structure of the intestinal tract of Teleosteous fishes is subject to so numerous modifications that we should go beyond the limits of the present article were we to attempt to enter into details. Great differences in this respect may be found even in groups of the same natural families. Frequently the intestinal tract remains of nearly the same width throughout its course, and only the entrance of the various ducts serves as a guide for the distinction of its divisions. An intestine of such uniform width may be straight and short, as in *Scombresocidæ*, *Symbranchidæ*, or it may be more or less convoluted and long, as in many *Cyprinidæ*, *Doradina*, &c. On the whole, carnivorous fishes have a much shorter and simpler intestinal tract than the herbivorous.

In the majority of Teleosteans, however, the œsophagus, stomach, duodenum, small intestine, and rectum can be more or less clearly distinguished, even externally.

There are two predominant forms of the stomach, intermediate forms, however, being numerous. In the first, the siphonal, it presents the form of a bent tube or canal, one-half of the horse-shoe being the cardiac, the other the pyloric portion. In the second, the cæcal, the cardiac division is prolonged into a long descending blind sac, the cardiac and pyloric openings of the stomach lying close together (*Clupea*, *Scomber*, *Thynnus*, &c.).

The duodenum always receives the hepatic and pancreatic secretions, and also those of the appendices pyloricæ, which, in varying numbers (from 1 to 200), are of very common occurrence in Teleosteans. They vary also in length and width, and whilst the narrowest serve only as secretory organs, the widest are frequently found filled with the same contents as the intestine.

Glands.—The liver of fishes is distinguished by the great quantity of fluid fat (oil) which it contains. The gall-bladder is but rarely absent; it is attached to the right lobe, or towards the centre; in some fishes, however, it is detached from the liver and connected with it by the cystic duct only. The bile may be conveyed by one or more hepatic ducts into a common duct which is continued towards the gall-bladder as ductus cysticus, and towards the duodenum as ductus choledochus; or some of the hepatic ducts enter the gall-bladder directly, or the duodenum directly, without communicating with the common duct. Individual variations in this respect are of common occurrence.

[1] The richest materials for our knowledge of the teeth of fishes are contained in Owen's *Odontography*, Lond., 1840, 8vo.

A pancreas has been found hitherto in all Chondropterygians, in *Acipenser*, and in many Teleosteans.

The spleen, which is substantially a lymphatic gland, may be mentioned here, as it is constantly situated in the immediate vicinity of the stomach, generally near its cardiac portion. With the exception of *Branchiostoma*, it is found in all fishes, and appears as a rounded or oblong organ of dark red colour.

Organs of Respiration.

Fishes breathe the air dissolved in water by means of gills or branchiæ. The oxygen consumed by them is not that which forms the chemical constituent of the water, but that contained in the air which is dissolved in the water. Hence fishes transferred to water from which the air has been driven out by a high temperature, or in which the air absorbed by them is not replaced, are speedily suffocated. The absorption of oxygen by fishes is comparatively small; it has been calculated that a man consumes fifty thousand times more than is required by a tench. Some fishes, however, evidently require a much larger supply of oxygen than others: eels and carps, and other fishes of similar low vitality, can survive removal from their element for days, the small quantity of moisture retained in their gill-cavity being sufficient to sustain life, whilst other fishes, especially such as have very wide gill-openings, are immediately suffocated after being taken out of the water. In some fishes noted for their muscular activity, like the *Scombridæ*, the respiratory process is so energetic as to raise the temperature of their blood far beyond that of the medium in which they live. A few fishes, especially such as are periodically compelled to live in water thickened into mud by desiccation and vitiated by decomposing substances, breathe atmospheric air, and generally have special contrivances for this purpose. These are so much habituated to breathing air that many of them, even when brought into pure water of normal condition, are obliged to rise to the surface at frequent intervals to take in a quantity of air, and, if they are kept beneath the surface by means of a gauze net, they perish from suffocation. The special contrivances consist of additional respiratory organs, lodged in cavities either adjoining the gill-cavity or communicating with the ventral side of the œsophagus, or of the air-bladder which enters upon respiratory functions (*Dipnoi*, *Lepidosteus*, *Amia*).

The water used by fishes for respiration is received by the mouth, driven to the gills by an action similar to that of swallowing, and expelled by the gill-openings, of which there may be one or several on each side behind the head, or rarely one only in the median line of the ventral surface.

The gills or branchiæ consist essentially of folds of the mucous membrane of the gill-cavity (laminæ branchiales), in which the capillary vessels are distributed. In all fishes the gills are lodged in a cavity, but during the embryonic stage the Chondropterygians have the gill-laminæ extended into long filaments projecting beyond the gill-cavity, and in a few young Ganoids external gills are superadded to the internal.

In *Branchiostoma* the dilated pharynx is perforated by numerous clefts, supported by cartilaginous rods (fig. 30, *h*). The water passes between these clefts into the peritoneal cavity, and makes its exit by the porus abdominalis, situated considerably in advance of the vent. The water is propelled by cilia.

In the Cyclostomes the gills of each side are lodged in a series of six or more antero-posteriorly compressed sacs, separated from each other by intervening septa. Each sac communicates by an inner duct with the œsophagus, the water being expelled by an outer duct. In *Bdellostoma* each outer duct has a separate opening, but in *Myxine* all the outer ducts pass outwards by one common gill-opening on each side. In the lampreys the ducts are short, the outer ones having separate openings (fig. 1). The inner ducts lead into a single diverticulum or bronchus, situated below the œsophagus, blind behind, and communicating in front with the pharynx, where it is provided with two valves by which the regurgitation of the water into the buccal cavity is prevented.

The same type of branchial organs persists in Chondropterygians, which possess five, rarely six or seven, flattened pouches with transversely plaited walls. The septa between them are supported by cartilaginous filaments rising from the hyoidean and branchial arches. Each pouch opens by a cleft outwards, and by an aperture into the pharynx, without intervening ducts. The anterior wall of the first pouch is supported by the hyoidean arch. Between the posterior wall of the first and the anterior of the second sac, and between the adjacent walls of the succeeding, a branchial arch with its two series of radiating cartilaginous filaments is interposed. Consequently the first and last pouches have one set of gill-laminæ only, viz., the first on its posterior and the last on its anterior wall. The so-called spiracles on the upper surface of the head of Chondropterygians must be referred to in connexion with the respiratory organs. They are the external openings of a canal leading on each side into the pharynx, and situated generally close to and behind the orbit. They frequently possess valves or an irregularly indented margin, and are found in all species during the embryonic stage, but it is only in some that they remain persistent. The spiracles are the remains of the first visceral cleft of the embryo, and in the fœtal state long branchial filaments have been observed to protrude as from the other branchial clefts.

The *Holocephali* and *Ganoidei* show numerous deviations from the Chondropterygian type, all leading towards the Teleosteans. As a whole they take an intermediate position between the preceding types and the Teleosteans, but they show a great variation among themselves, and have in common only the imperfect separation of the branchial sacs and the presence of a single outer branchial aperture.

In the *Teleostei* the gills with their supporting branchial arches lie in one undivided cavity; more or less wide clefts between the arches lead from the pharynx to the gills, and a more or less wide opening gives exit to the water after it has washed the gills. The interbranchial clefts have sometimes nearly the same extent as the branchial arches; sometimes they are reduced to small openings, the integuments stretching from one arch to the other. Sometimes there is no cleft behind the fourth arch, in which case this arch has only a uniserial gill developed. The gill-opening likewise varies much in its extent, and when reduced to a foramen may be situated at any part of the posterior boundary of the head. In the *Symbranchidæ* the gill-openings coalesce into a single narrow slit in the median line of the isthmus. In the majority of Teleosteans the integument of the concave side of the branchial arches develops a series of horny protuberances of various form, the so-called gill-rakers. These serve to catch any solid corpuscles or substances which would be carried into the gill-cavity with the water. In some fishes they are setiform, and make a complete sieve, whilst in others they are merely rough tubercles, the action of which must be very incomplete if they have any function at all.

The majority of Teleosteans possess four complete gills.

The gills of the Teleosteans, as well as of the Ganoids, are supported by a series of solid cartilaginous or horny pointed rods, arranged along the convex edges of the branchial arches. Arches bearing a complete gill have two series of those rods, one along each edge; those with uniserial gills bear one row of rods only. The rods are not part of the arch, but fixed in its integument, the several rods of the one row corresponding to those of the other, forming pairs (feuillet, Cuvier) (fig. 47). Each rod is covered by a loose mucous membrane passing from one rod to its fellow opposite, which again is finely plaited transversely, the extent of surface being greatly increased by these plaits. In most *Teleostei* the branchial lamellæ are compressed, and taper towards their free end, but in the Lophobranchs their base is attenuated and the end enlarged. The mucous membrane contains the finest terminations of the vessels, which, being very superficial, impart a blood-red colour to living gills. The arteria branchialis, the course of which lies in the open canal in the convexity of the branchial arch, emits a branch (*a*) for every pair of lamellæ, which ascends (*b*) along the inner edge of the lamella, and supplies every one of the transverse plaits with a branchlet. The latter break up into a fine network of capillaries, from which the oxygenized blood is collected into venous branchlets, returning by the venous branch (*d*), which occupies the outer edge of the lamella.

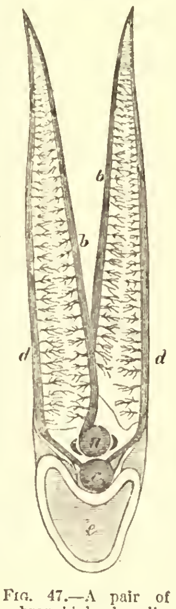

Fig. 47.—A pair of branchial lamellæ (magnified) of the Perch. *a*, branch of arteria branchialis; *b*, ascending branch of the same; *c*, branch of vena branchialis; *d*, descending branch of the same; *e*, transverse section through the branchial arch.

The so-called pseudobranchiæ (fig. 48) are the remains of an anterior gill which had respiratory functions during the embryonic life of the individuals. By a change in the circulatory system these organs have lost those functions, and appear in the adult fish as retia mirabilia, as they receive oxygenized blood, which, after having passed through their capillary system, is carried to other parts of the head. In *Palæichthyes* the pseudobranchia is a rete mirabile caroticum for the brain and eye; in Teleosteans a rete mirabile ophthalmicum only. Pseudobranchiæ are as frequently absent as present in Chondropterygians as well as Teleosteans. Among the Ganoids, the organs occur in *Ceratodus*, *Acipenser*, *Polyodon*, and *Lepidosteus*, and are absent in *Lepidosiren*, *Protopterus*, *Scaphirhynchus*, *Polypterus*, and *Amia*.

In Chondropterygians and sturgeons the pseudobranchiæ are situated within the spiracles; in those in which spiracles have become obliterated, the pseudobranchiæ lie on the suspensorium, hidden below cellular tissue; but pseudobranchiæ are not necessarily coexistent with spiracles. In the other Ganoids and Teleosteans the pseudobranchiæ (fig. 48, *h*) are within the gill-cavity, near the base of the gill-cover; in *Ceratodus* even rudiments of the gill-rakers (*x'*, *x''*) belonging to this embryonic gill are preserved, part of them (*x''*) being attached to the hyoid arch. Pseudobranchiæ are frequently hidden below the integuments of the gill-cavity, and have the appearance of a glandular body rather than of a gill.

Fig. 48.—Gills of *Ceratodus*. *x*, arcus aortæ; *gl*, glossohyal; *ch*, ceratohyal; *u*, attachment of the first gill to the walls of the gill-cavity; *h*, pseudobranchia; *x'*, *x''*, two series of gill-rakers belonging to the pseudobranchia

Accessory respiratory organs for retaining water or breathing air are found in the *Labyrinthici*, *Ophiocephalidæ*, certain *Siluridæ*, and *Lutodira*.

Air-bladder.—The air-bladder, one of the most characteristic organs of fishes, is a hollow sac, formed of several tunics, containing gas, situated in the abdominal cavity, but outside the peritoneal sac, entirely closed or communicating by a duct with the intestinal tract. Being compressible, its special functions consist in altering the specific gravity of the fish or in changing the centre of gravity. In a few fishes it assumes the function of the organ of higher vertebrates of which it is the homologue—viz., of a lung. The gas contained in the air-bladder is secreted from its inner surface. In most freshwater fishes it consists of nitrogen, with a very small quantity of oxygen and a trace of carbonic acid; in sea-fishes, especially those living at some depth, oxygen predominates, as much as 87 per cent. having been found. Davy found in the air-bladder of a fresh-run salmon a trace of carbonic acid and 10 per cent. of oxygen, the remainder of the gas being nitrogen.

An air-bladder is absent in *Leptocardii*, *Cyclostomi*, *Chondropterygii*, and *Holocephali*, but occurs in all Ganoids, in which, besides, its respiratory functions more or less clearly manifest themselves. Its occurrence in Teleosteans is very irregular, closely allied species sometimes differing from each other in this respect; it shows in this subclass the most extraordinary modifications, but has no respiratory function whatever.

Constantly situated within the abdominal cavity, below the vertebral column, but outside the sac of the peritoneum which covers only its ventral portion, the air-bladder is frequently prolonged into the tail, the prolongation being either single and lodged between the non-united parapophyses, or double and penetrating between the muscles and hæmapophyses of each side. In the opposite direction processes of the air-bladder may penetrate into the skull, as has been mentioned above (p. 653). In some fishes the air-bladder is almost loose in the abdominal cavity, whilst in others it adheres most intimately by firm and short tissue to the vertebral column, the walls of the abdomen, and the intestines. In the *Cobitina* and many Siluroids it is more or less completely enclosed in osseous capsules formed by the vertebræ.

There are two tunics in the greater number of air-bladders,—an extremely thin internal one, frequently shining with a silvery lustre, containing crystalline corpuscles, sometimes covered with a pavement-epithelium, and a thicker outer one of a fibrous texture, which sometimes attains to considerable thickness and yields isinglass. The outer wall is strengthened in many fishes by muscular layers for the compression of the whole organ or of some portion of it.

A distinction has been made between air-bladders which communicate by a duct with the intestinal tract and those which are entirely closed. It is to be remembered, however, that at an early stage of development all air-bladders are provided with such a duct, which in some fishes is more or less completely obliterated, being then represented by a fine ligament only. Air-bladders without duct are found in Acanthopterygians, Pharyngognaths, Anacanths, and Lophobranchs. They may consist of a single cavity, or may be divided by constrictions into two or three chambers situated behind one another; they may consist of two lateral divisions, assuming a horseshoe-like form, or of a single sac with a pair of simple or bifid processes in front or behind. The families of *Sciænidæ* and *Polynemidæ* possess air-bladders with a most extraordinary development of appendages rising from each side. Air-bladders with a pneumatic duct are found in Ganoids and Physostomes, the duct entering the dorsal side of the intestinal tract, with the exception of *Polypterus* and the *Dipnoi*, in which it enters on the ventral side of the œsophagus. In most cases the orifice is in the œsophagus, but in some it is in the cardiac portion of the stomach, as in *Acipenser*, or in its blind sac, as in many Clupeoids. The air-bladder may be single, or may consist of two divisions situated one behind the other (fig. 45); its inner surface may be perfectly smooth, or it may form manifold pouches and cells. If two divisions are present the anterior possesses a middle elastic membrane which is absent in the posterior; each division has a muscular layer, by which it can be separately compressed, so that part of the contents of the posterior may be driven into the elastic anterior division, and *vice versa*. The posterior division being provided with the ductus pneumaticus does not require the elasticity of the anterior.

Some Siluroids possess a peculiar apparatus for voluntarily exercising a pressure upon the air-bladder. From the first vertebra a process takes its origin on each side, expanding at its end into a large round plate; this is applied to the side of the air-bladder, and by pressing upon it expels the air through the duct; the small muscle moving the plate rises from the skull. The connexion of the air-bladder with the organ of hearing in some Physostomes has been described above, p. 653.

In the modifications of the air-bladder hitherto mentioned, the chief and most general function is a mechanical one: this organ serves to regulate the specific gravity of the fish, to aid it in maintaining a particular level in the water, in rising or sinking, in raising the front part of its body or depressing it, as occasion may require. Yet a secretion of gas from the blood into its cavity must take place; and if this be so, it is not at all impossible that an exchange of gases between the two kinds of blood is also effected by means of the extraordinary development of retia mirabilia in many air-bladders.

In all fishes the arteries of the air-bladder take their origin from the aorta or the system of the aorta, and its veins return either to the portal, the vertebral, or the hepatic veins; like the other organs of the abdominal cavity, it receives arterial blood and returns venous blood.

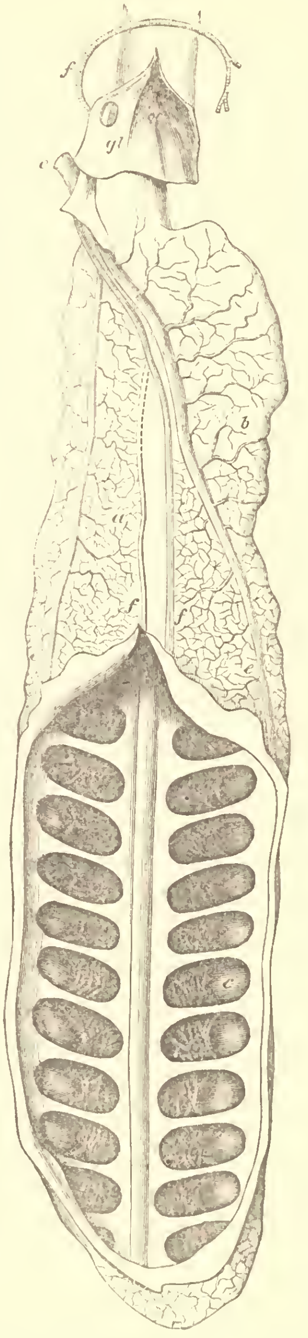

FIG. 49.—Lung of *Ceratodus*, opened in its lower half to show its cellular pouches. *a*, right half; *b*, left half; *c*, cellular pouches; *e*, vena pulmonalis; *f*, arterial blood-vessel; *oe*, œsophagus, opened to show glottis (*gl.*).

Whilst the air-bladders of some Ganoids, anatomically as well as functionally, closely adhere to the Teleosteous type, that of *Amia* is more cellular and lung-like in its interior than the Teleosteous air-bladder, and *Polypterus* approaches the *Dipnoi*, not only in having a laterally divided air-bladder, but also in its pneumatic duct entering the ventral side of the œsophagus. The air-bladder of the *Dipnoi* possesses still further the anatomical characteristics of a lung and assumes its functions, though, as it coexists with gills, only periodically or in an auxiliary manner. The ductus pneumaticus is a membranous bronchus, entering the ventral side of the œsophagus, and provided at its entrance with a glottis. In *Ceratodus* (fig. 49) the lung is still a single cavity, but with a symmetrical arrangement of its internal pouches; it has no pulmonary artery, but receives branches from the arteria cœliaca. Finally, in *Lepidosiren* and *Protopterus* the lung is completely divided into lateral halves, and by its cellular structure approaches most nearly that of a reptile; it is supplied with venous blood by a true pulmonary artery.

ORGANS OF CIRCULATION.

The blood-corpuscles of fishes, with one exception, are of an elliptic shape; this exception is *Petromyzon*, which possesses circular, flat, or slightly biconvex blood-corpuscles. They vary much in size; they are smallest in Teleosteans and Cyclostomes, those of *Acerina cernua* measuring $\frac{1}{2481}$ of an inch in their longitudinal, and $\frac{1}{3000}$ in their transverse diameter. So far as it is known at present the *Salmonidæ* have the largest blood corpuscles among Teleosteans, those of the salmon measuring $\frac{1}{1524}$ by $\frac{1}{2460}$ in., approaching those of the sturgeon. Those of the Chondropterygians are still larger; and finally, *Lepidosiren* has blood-corpuscles not much smaller than those of Perennibranchiates, viz., $\frac{1}{570}$ by $\frac{1}{941}$ in. *Branchiostoma* is the only fish which does not possess red blood-corpuscles.

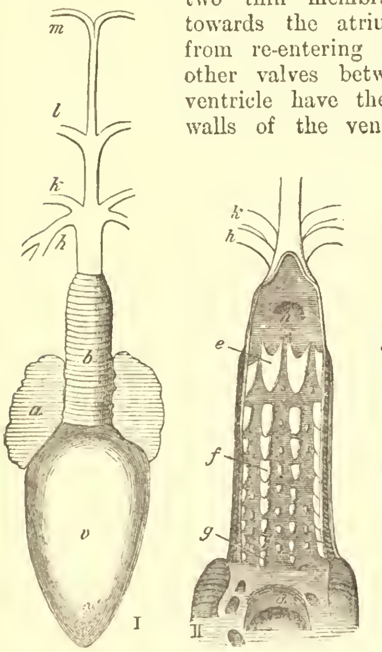
Fishes, in common with the other vertebrates, are provided with a complete circulation for the body, with another equally complete for the organs of respiration, and with a particular abdominal circulation, terminating at the liver by means of the vena portæ; but the peculiar characteristic consists in this, that the branchial circulation alone is provided at its base with a muscular apparatus or heart, corresponding to the right half of the heart of mammalia and birds.

The heart is situated between the branchial and abdominal cavities, between the two halves of the scapulary arch,—rarely farther behind, as in *Symbranchidæ*. It is enclosed in a pericardium, generally separated entirely from the abdominal cavity by a diaphragma, which is, in fact, the anterior portion of the peritoneum, strengthened by aponeurotic fibres. In some fishes, however, there is a communication between the pericardial and peritoneal sacs, viz., in the Chondropterygians and *Acipenser*, whilst in the Myxinoids the pericardial sac is merely a continuation of the peritoneum.

Relatively to the size of the body, the heart is very small. It consists of three divisions:—the atrium, with a large sinus venosus into which the veins enter; the ventricle; and a conical hollow swelling at the beginning of the arterial system, the structure of which forms one of the most important characters used in the classification of fishes. In all *Palæichthyes* (figs. 50 and 51) this swelling is still a division of the pulsating heart, being provided with a thick muscular stratum; it is not separated from the ventricle by two valves opposite to each other, but its interior is fitted with a plurality of valves, arranged in transverse series more or less numerous in the various groups of the subclass. *Lepidosiren* and *Protopterus* offer an example of a modification of this valvular arrangement, their valves being longitudinal, each valve in fact being formed by the confluence of several smaller ones situated behind one another. This Palæichthyan type is called conus arteriosus.

In Cyclostomes and Teleosteans (fig. 52) the enlargement is a swelling of the artery, without muscular stratum and without contractility; with the exception of the Myxinoids, its walls are thick and fibrous with many trabeculæ and pouches, but it has no valves in its interior, and is separated from the ventricle by two valves opposite to each other. This Teleostean type is called bulbus aortæ.

The sinus venosus sends the whole of the venous blood by a single orifice of its anterior convexity into the atrium; two thin membranous valvules turned towards the atrium prevent the blood from re-entering the sinus. A pair of other valves between the atrium and ventricle have the same function. The walls of the ventricle are strong, and, internally, it is furnished with powerful fleshy trabeculæ.



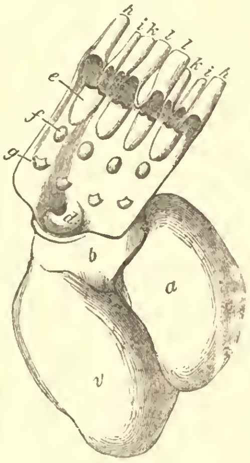


Fig. 50. Fig. 51.

FIG. 50—Heart of *Lepidosteus osseus*. I. External aspect. II. Conus arteriosus opened. *a*, atrium; *b*, conus arteriosus; *v*, ventricle; *h*, branchial artery for third and fourth gill; *k*, for the second; *l*, for the first; *m*, branch for the opercular gill; *d*, single valve at the base of the conus; *e*,*f*,*g*, transverse rows of Ganoid valves.

FIG. 51.—Heart of *Ceratodus*. *a*, atrium; *b*, conus arteriosus; *d*, papillary valve within the conus; *e*,*f*,*g*, transverse rows of Ganoid valves; *h*, *i*, anterior arcus aortæ; *k*, *l*, posterior arcus aortæ; *v*, ventricle.

The bulbus or conus arteriosus is prolonged into the branchial artery, which soon divides, sending off a branch to each branchial arch. On returning from the respiratory organ the branchial veins assume the structure and functions of arteries. Several branches are sent off to different portions of the head and to the heart, but the main trunks unite to form the great artery which carries the blood to the viscera and to all the parts of the trunk and tail, and which, therefore, represents the aorta of higher animals.

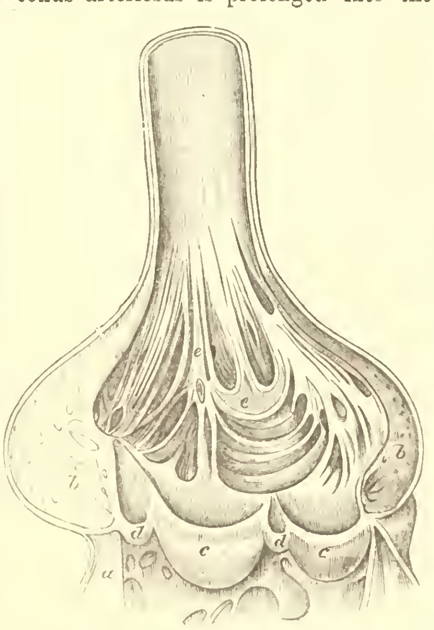

FIG. 52.—Bulbus aortæ of *Xiphias gladius*, opened. *a*, section through part of the wall of ventricle; *b*, section through the bulbus; *c*, Teleosteous valves of the ostium arteriosum; *d*, accessory valves, of rudimentary nature and inconstant; *e*, trabeculæ carneæ of the bulbus.

The circulatory system of *Branchiostoma* and of the *Dipnoi* shows essential differences from that of other fishes. *Branchiostoma* is the only fish which does not possess a muscular heart, several cardinal portions of its vascular system being contractile. A great vein extends forwards along the caudal region below the notochord, and exhibits contractility in a forward direction; it is bent anteriorly, passing into another tube-like pulsatory trunk, the branchial heart, which runs along the middle of the base of the pharynx, sending off branches on each side to the branchiæ; each of these branches has a small contractile dilatation (bulbillus) at its base. The two anterior branches pass directly into the aorta; the others are branchial arteries, the blood of which returns by branchial veins emptying into the aorta. The blood of the intestinal veins is collected in a contractile tube, the portal vein, below the intestine, and distributed over the rudimentary liver. Of all other fishes, the portal vein is contractile in Myxinoids only.

In *Dipnoi* a rudimentary partition of the heart into a right and a left division has been observed; this is limited to the ventricle in *Ceratodus*, but in *Lepidosiren* and *Protopterus* an incomplete septum has been observed in the atrium also. All *Dipnoi* have a pulmonal vein, which enters the atrium by a separate opening, provided with a valve. The pulmonal artery rises in *Lepidosiren* and *Protopterus* from an arch of the aorta, but in *Ceratodus* it is merely a subordinate branch, rising from the arteria cœliaca.

URINARY ORGANS.

In *Branchiostoma* no urinary organs have been found.

In Myxinoids these organs are of very primitive structure; they consist of a pair of ducts, extending from the urogenital porus through the abdominal cavity. Each duct sends off at regular intervals from its outer side a short wide branch (the uriniferous tube), which communicates by a narrow opening with a blind sac. At the bottom of this sac there is a small vaso-ganglion (Malpighian corpuscle), by which the urine is secreted.

In the lampreys the kidneys form a continuous gland-like body, with irregular detached small portions. The ureters coalesce before they terminate in the urogenital papilla.

In Chondropterygians the kidneys occupy the posterior half or two-thirds of the back of the abdominal cavity, outside the sac of the peritoneum (as in all fishes), which forms a firm tendinous horizontal septum. The kidneys of the two sides are never confluent, and generally show a convoluted or lobulated surface. The ureters are short; each is dilated into a pouch, and communicating with its fellow terminates by a single urethra (which also receives the vasa deferentia) behind the end of the rectum in the large common cloaca.

In Ganoids the kidneys occupy a similar position as in Chondropterygians, but these fishes differ considerably with regard to the termination and the arrangement of the ends of the urogenital ducts.

The kidneys of Teleosteans are likewise situated outside the peritoneal cavity, immediately below some part of the vertebral column, and vary exceedingly with regard to form and extent. Sometimes they reach from the skull to between the muscles of the tail, sometimes they are limited to the foremost part of the abdominal cavity (in advance of the diaphragm), but generally their extent corresponds to that of the abdominal portion of the vertebral column. The ureters terminate, either separate or united, in a urinary bladder, varying in shape, which opens by a short urethra behind the vent. The urinary opening may be separate from or confluent with that of the genital ducts, and is frequently placed on a more or less prominent papilla (papilla urogenitalis). If separate, the urinary opening is behind the genital; and if a papilla is developed, its extremity is perforated by the urethra, the genital opening being situated nearer the base. A few Teleosteans show an arrangement similar to that of Chondropterygians and *Dipnoi*, the urogenital openings being in the posterior wall of the rectum (*Symbranchidæ*, *Pediculati*, and some *Plectognathi*).

ORGANS OF REPRODUCTION.

All fishes are diœcious, or of distinct sex. Instances of so-called hermaphroditism are, with the exception of *Serranus*, abnormal individual peculiarities; such have been observed in the cod-fish, in some *Pleuronectidæ*, and in the herring. Either the generative organ of one side was found to be male and that of the other female, or the organ of one or both sides was observed to have been developed partly into an ovary, partly into a testicle. In the European species of *Serranus* a testicle-like body is attached to the lower part of the ovary; but many specimens of this genus are undoubtedly males, having normally developed testicles only.

The majority of fishes are oviparous (comparatively few viviparous), the embryos being developed either in the ovarium or in some dilated portion of the oviduct. In viviparous fishes actual copulation takes place, and the males of most of them are provided with copulatory or intromittent organs. In oviparous fishes the generative products are, during sexual excitement, discharged into the water, a very small quantity of semen being sufficient for effectual impregnation of a number of ova dispersed in a considerable quantity of water,—circumstances which render artificial impregnation more practicable than in any other class of animals.

In *Branchiostoma* the generative organs occupy the ventral side of the abdominal cavity, into which they discharge their contents. No ducts are developed in either sex.

In the Cyclostomes the generative organ is single, and fixed to or suspended from the median line of the back of the visceral cavity by a duplicature of the peritoneum (mesoarium), the testicle and ovary being distinguishable by their contents only. These escape by dehiscence of the cells or capsules and rupture of the peritoneal covering into the abdominal cavity, and are expelled, by reciprocal pressure of the intertwined sexes, through the porus genitalis.

The ova of the lampreys are small and globular, like those of Teleosteans. Those of *Myxine* have a very peculiar shape when mature; they are of an oval form, about 15 millimetres long and 8 millimetres broad, enveloped in a horny case, which at each end is provided with a bundle of short threads, each thread ending in a triple hook. Whilst in the mesoarial fold, the eggs are attached to one another by means of these hooks, and after being expelled they probably fix themselves by the same means to other objects. As in all fishes producing ova of large size, the number of ova matured in one season is but small.

In Teleosteans the generative organs are comparatively large. In some families the ovaries are without a closed covering and without oviducts, as in *Salmonidæ*, *Galaxiidæ*, *Notopteridæ*, *Murænidæ*, and others. The surface of such an open ovary—as, for instance, that of the salmon—is transversely plaited, the ova being developed in capsules in the stroma of the laminæ; after rupture of the capsules the mature ova drop into the abdominal cavity, and are expelled by the porus genitalis. The ovaries of the other Teleosteans are closed sacs, continued into oviducts. Frequently such ovaries coalesce into a single body, or one in which the division is effected internally only by a more or less complete septum. In the viviparous Teleosteans the embryos are developed within the ovary, notably in the *Embiotocidæ*, many *Blenniidæ*, and *Cyprinodontidæ*, *Sebastes viviparus*, &c.

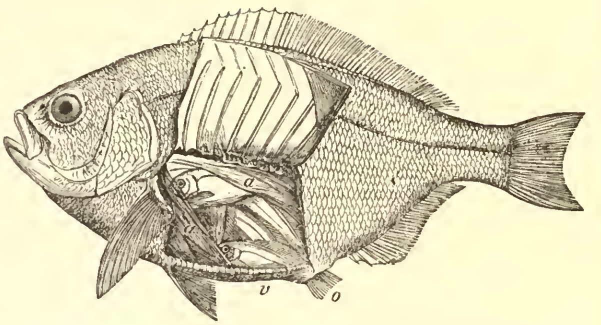

FIG. 53.—*Ditrema argenteum*, with fully developed young, ready for expulsion by the genital orifice, *o*; *a*, folds of the ovarian sac; *v*, vent.

The ova of Teleosteous fishes are extremely variable in size, quite independently of the size of the parent species. The ova of large and small individuals of the same species, of course, do not differ in size; but, on the whole, larger individuals produce a greater number of ova than smaller ones of the same species. The larger the size of the ova is in a species, the smaller is the number produced during one season. The ova of the eel are almost microscopic. The numbers of ova in the small-sized roe of the herring, lump-fish, halibut, and cod-fish have been estimated respectively at 25,000, 155,000, 3,500,000, and 9,344,000. Larger in size and fewer in number are those of *Antennarius*, *Salmo*, *Aspredo*, Lophobranchs, &c. Those of *Gastrosteus* are comparatively the largest; and the Siluroid genus *Arius*, the males of which take care of their progeny, produces ova from 5 to 10 millimetres in diameter. The ova of all Teleosteans are perfectly globular and soft-shelled. Teleosteans without oviduct deposit them separated from one another; whilst in many Teleosteans with an oviduct, the ova are enveloped in a glutinous substance, secreted by its glands, swelling in the water and forming lumps or chords, in which the ova are aggregated.

FIG. 54.—Ovum of *Arius boakii* (Ceylon), showing embryo. Nat. size.

Instances of the female taking care of her progeny are extremely rare in fishes. At present only two examples are known, that of the Siluroid genus *Aspredo*, and the *Solenostoma*. In the former (fig. 55), during the time of propagation, the integuments of the lower side of the flat trunk of the female assume a soft and spongy texture. After having deposited the eggs, the female attaches them to and presses them into the spongy integument, by merely lying over them. She carries them on her belly, as the Surinam toad (*Pipa*) carries her ova on her back. When the eggs are hatched the excrescence on the skin disappears, and the abdomen becomes as smooth as before. In *Solenostoma* the inner side of the long and broad ventral fins coalesces with the integuments of the body, a large pouch being formed for the reception of the eggs. There is a peculiar provision for the retention of the eggs in the sac, and probably for the attachment of the embryo. The inner walls of the sac are lined with long filaments, arranged in series along the ventral rays, and more numerous and longer at the base of the rays than in the middle of their length, behind which they disappear entirely.

The testicles of the Teleosteans are always paired, and occupy the same position as the ovaries. Their size varies extraordinarily at the different seasons of the year. Vasa deferentia are constant. In the males of viviparous Teleosteans the urogenital papilla is frequently enlarged, and clearly serves as an intromittent organ.

Many *Teleostei* take care of their progeny, but with the exception of *Aspredo* and *Solenostoma*, as mentioned above, it is the male on which this duty devolves. In some, as in *Cottus*, *Gastrosteus*, *Cyclopterus*, *Antennarius*, *Ophiocephalus*, *Callichthys*, the male constructs with more or less skill a nest, and jealously guards the ova deposited in it by the female. The male of some species of *Arius* carries the ova (fig. 54) about with him in his capacious pharynx. The species of *Chromis* inhabiting the sea of Galilee are said to take care of their ova in the same manner. And, finally, in the Lophobranchs, nature has aided this instinct by the development of a pouch or the abdomen or lower side of the tail. In the *Syngnathidæ* this pouch is formed by a fold of the skin developed from each side of the trunk and tail, the free margins of the fold being firmly united in the median line, whilst the eggs are being hatched in the inside of the pouch. In *Hippocampus* the pouch is completely closed, with a narrow anterior opening.

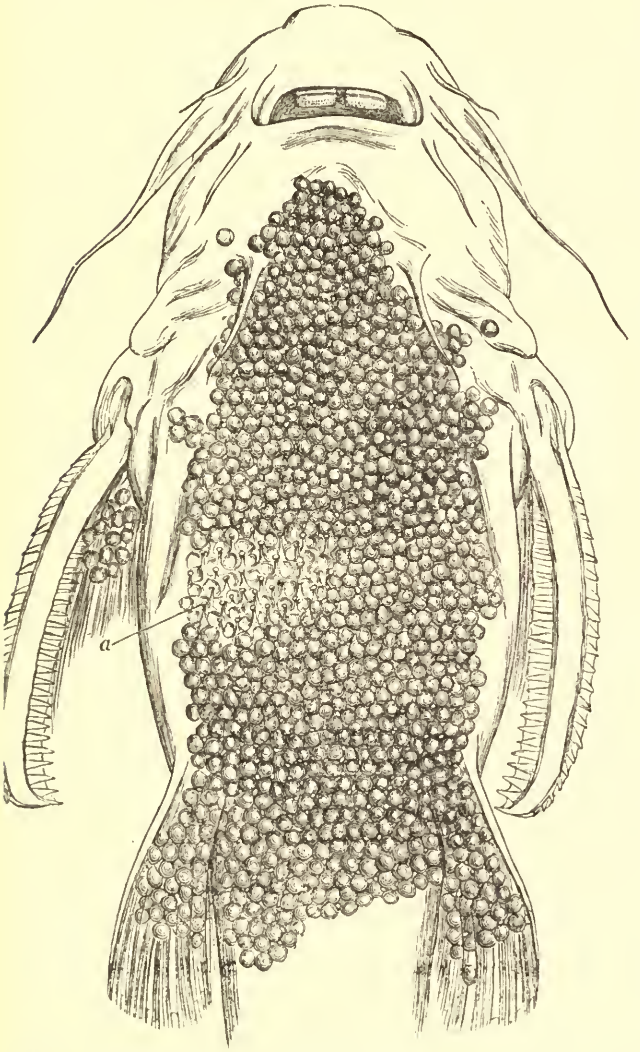

FIG. 55.—Abdomen of *Aspredo batrachus*, with the ova attached; at *a* the ova are removed, to show the spongy structure of the skin, and the processes filling the interspaces between the ova. (Natural size.)

The genital organs of Ganoids show diversity of structure similar to that found in Teleosteans, but on the whole they approach the Batrachian type. The ovaries are not closed, except in *Lepidosiren*; all Ganoids possess oviducts. In the sturgeons the oviduct as well as the vas deferens is represented by a funnel-shaped prolongation of the peritoneum, which communicates with the wide ureter. The inner aperture of the funnel is on a level with the middle of the testicle or ovary, while the outer is within the ureter; and it is a noteworthy fact that only at certain periods of the life of the fish is this outer aperture found to be open,—at other times the peritoneal funnel appears as a closed blind sac within the ureter. The mode of passage of the semen into the funnel is not known.

In *Polypterus* and *Amia* proper oviducts, with abdominal apertures in about the middle of the abdominal cavity, are developed; they coalesce with the ureters close to the common urogenital aperture.

In *Ceratodus* a long convoluted oviduct extends to the foremost limit of the abdominal cavity, where it opens by a slit at a considerable distance from the front end of the long ovary; this aperture is closed in sexually immature specimens. The oviducts unite close to their common opening in the cloaca. During their passage through the oviduct the ova receive a gelatinous covering secreted by its mucous membrane. This is probably also the case in *Lepidosiren*, which possesses a convoluted oviduct with secretory glands in the middle of its length.

The ova of Ganoids, so far as they are known at present, are small, and enveloped in a gelatinous substance. In the sturgeon as many as 7,635,200 have been counted. Those of *Lepidosteus* seem to be the largest, measuring 5 millimetres in diameter with their envelope, and 3 millimetres without it. They are deposited singly, like those of newts.

In Chondropterygians (and *Holocephali*) the organs of reproduction assume a more compact form, and are more free owing to a lengthened attachment to the back of the abdominal cavity. The ovaries of the majority are paired (single in the *Carchariidæ* and *Scylliidæ*, one remaining undeveloped). But the oviducts are always paired, with a common aperture beginning immediately behind the diaphragma. They consist of two divisions, separated by a circular valve; the upper is narrow, and is provided within its coats with a gland which secretes the leathery envelope in which

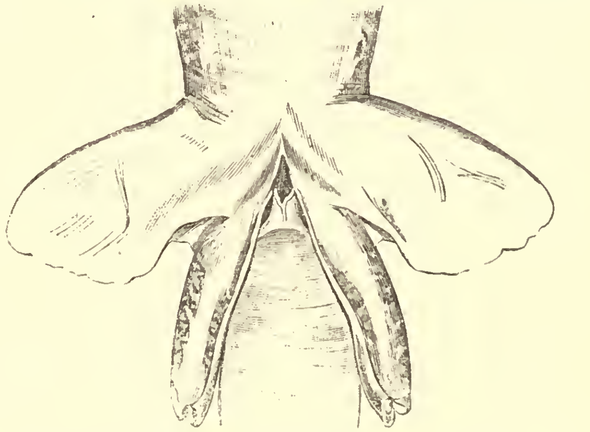

FIG. 56.—Ventral fins and claspers of *Chiloscyllium trispeculare*.

most of the Chondropterygian ova are enclosed; the lower forms the uterine dilatation in which the embryos of the viviparous species are developed. Generally the vitelline sac of the embryos is free, and has no connexion with the uterus, which in these cases has merely the function of a protecting pouch; but in *Carcharias* and *Mustelus lævis* a placenta uterina is formed, the vascular walls of the vitelline sac forming plaits fitting into those of the membrane of the uterus. The ends of the uteri open into the cloaca by a common aperture behind the ureter.

The testicles are always paired, rounded, and situated in the anterior part of the abdominal cavity, covered by the liver. The vas deferens opens with the urethra in a papilla within the cloaca.

The so-called claspers of Chondropterygians (fig. 56) are characteristic of all male individuals. They are semi-ossified appendages of the pubic, with which they are movably joined, and special muscles serve to regulate their movements. Sometimes they are armed with hook-like osseous excrescences (*Selache*). They are irregularly convoluted longitudinally, and, when closely pressed to each other, form a canal open at their extremity. A gland, which discharges a secretion abundantly during the season of propagation, is situated at the base of the canal, and opens into it. It is still doubtful whether the generally adopted opinion that their function consists in holding the female during copulation is correct, or whether they are not rather an intromittent organ, the canal of which conducts, not only the secretion of their proper gland, but also the impregnating fluid.

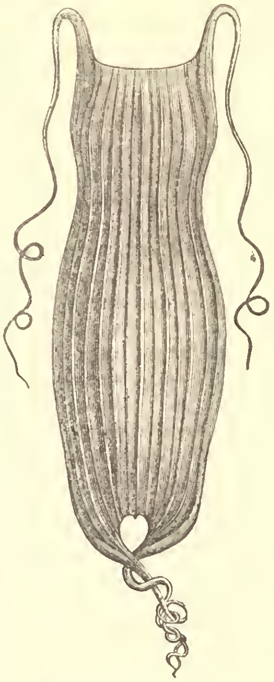

Fig. 57.—Egg of a *Scyllium* from Magellan's Straits (? *Sc. chilense*), natural size.

The ova of the oviparous Chondropterygians are large, and few in number; they are successively impregnated, and the impregnation must take place before they are invested with a tough leathery envelope, which would be impenetrable to the semen, that is, before they enter the uterus; therefore, copulation must take place in all these fishes. The form of the egg-shell differs in the various genera; usually (fig. 57) they are flattened and quadrangular, with each of the four corners produced, and frequently prolonged into, lengthy filaments which serve for the attachment of the ova to other fixed objects. In *Notidanus* the surfaces are crossed by numerous ridges. In *Cestracion* the egg is pyriform, with two broad ridges or plates wound edgewise round it, the two ridges forming five spires. The eggs of *Callorhynchus* have received a protective resemblance to a broad-leaved fucus, forming a long depressed ellipse, with a plicated and fringed margin.

Growth and Variation of Fishes.

Changes of form normally accompanying growth (after absorption of the vitelline sac) are observed in all fishes, but in the majority these affect only the proportional size of the various parts of the body. Relatively to the size of the head, the eyes in young fishes are always larger than in the adult; and again, the head is relatively larger than the body. Changes amounting to metamorphosis have been hitherto observed in *Petromyzon* only. In the larval condition (*Ammocœtes*) the head is very small, and the toothless buccal cavity is surrounded by a semicircular upper lip. The eyes are extremely small, hidden in a shallow groove; and the vertical fins form a continuous fringe. In the course of three or four years the teeth are developed, and the mouth changes into a perfect suctorial organ; the eyes grow; and the dorsal fin is separated into two divisions. In Malacopterygians and Anacanths the embryonal fringe from which the vertical fins are developed is much longer persistent than in Acanthopterygians. A metamorphosis relating to the respiratory organs, as in Batrachians, is indicated in the class of fishes by the external gills with which fœtal Plagiostomes and the young of some Ganoids, viz., the *Protopterus* and *Polypterus*, are provided.

One of the most extraordinary changes by which, during growth, the form and position of several important organs are affected, occurs in flat-fishes (*Pleuronectidæ*); their young are symmetrically formed, with a symmetrical mouth, and with one eye on each side, and therefore keep their body in a vertical position when swimming. As they grow they live more on the bottom, and their body, during rest, assumes a horizontal position; in consequence, the eye of the lower side moves towards the upper, which alone is coloured; and in many genera the mouth is twisted in the opposite direction, so that the bones, muscles, and teeth are much more developed on the blind side than on the coloured. In a great number of other *Teleostei* certain bones of the head show a very different form in the young state. Ossification proceeds in those bones in the direction of lines or radii which project in the form of spines or processes; as the interspaces between these processes are filled with bone, the processes disappear entirely, or at least project much less in the older than in the younger individuals. The young of some fishes may be armed with a long powerful præopercular or scapular spine, or may show a serrature of which nothing remains in the adult fish except some ridges or radiating lines. These processes seem to serve as weapons of defence during a period in the life of the fish in which it needs them most. In not a few instances a portion of this armature is so much developed that the disappearance of its most projecting parts with the growth of the fish is not only due to its being surrounded by other bone, but partially, at least, caused by absorption. The *Carangidæ*, *Cyttidæ*, *Squamipinnes*, *Xiphiidæ*, offer instances of such remarkable changes. A fish described as *Tholichthys osseus* (fig. 58) is probably the young of a Cyttoid, the suprascapula, humerus, and præoperculum forming enormously enlarged plates. In another fish (fig. 59) these bones appear still enlarged, and the frontals develop a remarkably long and curved horn above the orbit. In the *Tholichthys*-stage of *Pomacanthus* (specimens 10 millimetres long), the frontal bone is prolonged into a straight lancet-shaped process, nearly half as long as the body; the suprascapular and præopercular processes cover and hide the dorsal and ventral fins. The plates attached to the shoulder-girdle remain persistent until the young fish has assumed the form of the adult; thus they are still visible in young *Chætodon citrinellus*, 30 millimetres long, in which the specific characters are already fully developed (fig. 60). The sword-fishes with ventral fins (*Histiophorus*) belong to the Teleosteans of the largest size; in young individuals, 9 millimetres long (fig. 61), both jaws are produced, and armed

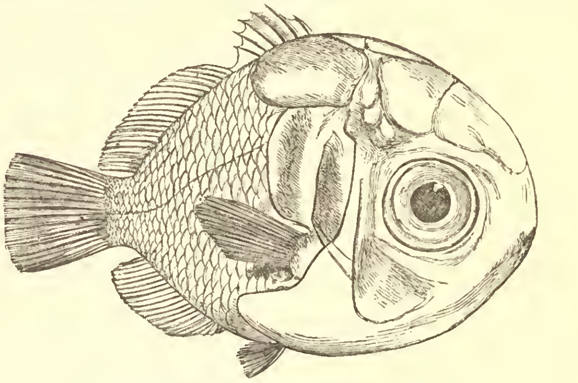

Fig. 58.—*Tholichthys osseus* (six times the natural size).

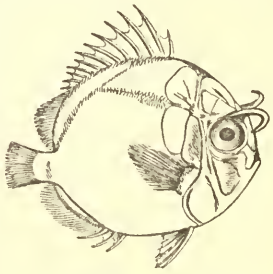

Fig. 59.—Tholichthys-stage of *Heniochus* (?).

with pointed teeth; the supraorbital margin is ciliated; the parietal and præoperculum are prolonged into long spines; the dorsal and anal fins are a low fringe; and the ventrals make their appearance as a pair of short buds. When 14 millimetres long the young fish has still the same armature on the head, but the dorsal fin has become much higher, and the ventral filaments have grown to a great length. At a third stage, when the fish has attained to a length of 60 millimetres, the upper jaw is considerably prolonged beyond the lower, losing its teeth; the spines of the head are shortened, and the fins assume nearly the shape which they retain in mature individuals. Young sword-fishes without ventral fins (*Xiphias*) undergo similar changes; and, besides, their skin is covered with small rough excrescences longitudinally arranged, which continue to be visible after the young fish has in other respects assumed the form of the mature (fig. 63).

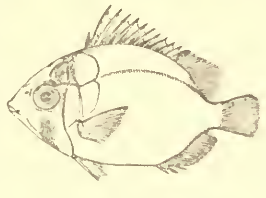

Fig. 60.—Young *Chætodon citrinellus* (30 mill. long).

Fig. 61.—Young Sword-fish (*Histiophorus*), 9 mill. long. Atlantic. (Magn.)

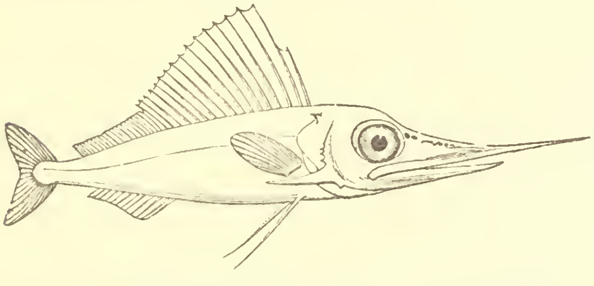

Fig. 62.—Young Sword-fish (*Histiophorus*), 60 mill. long. Mid-Atlantic.

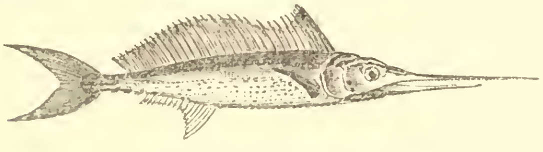

Fig. 63.—*Xiphias gladius*, young, about 8 inches long.

The Plectognaths show changes no less extraordinary: a remarkable form caught in the South Atlantic, and named *Ostracion boops*, is considered by Lütken to be the young of a sun-fish (*Orthagoriscus*). In still very young but more advanced sun-fishes (18 to 32 millimetres) the vertical diameter of the body is not much less than the longitudinal, and may even exceed it; and small conical spines are scattered over its various parts. The caudal fin is developed long after the other vertical fins.

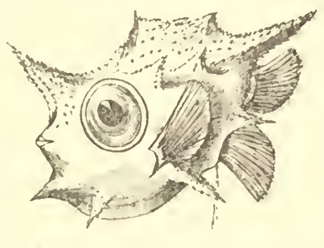

Fig. 64.—*Ostracion boops* (much magnified).

Similar changes take place in a number of other fishes, and in many cases the young are so different that they have been described as belonging to distinct genera: thus *Priacantichthys* has proved to be the young of *Serranus*, *Rhynchichthys* that of *Holocentrum*, *Cephalacanthus* of *Dactylopterus*, *Dicrotus* of *Thyrsites*, *Naucleras* of *Naucrates*, *Porthmeus* of *Chorinemus*, *Lampugus* of *Coryphæna*, *Acronurus* of *Acanthurus*, *Keris* of *Naseus*, *Porobronchus* of *Fierasfer*, *Couchia* of *Motella*, *Stomiasunculus* of *Stomias*, &c.

The fins are most frequently subject to changes during growth; but, whilst in some fishes parts of them are prolonged into filaments with age, in others the filaments exist during the early life-periods only; whilst in some a part of the dorsal or of the ventral fins is normally developed in the young only, in others those very parts are peculiar to the mature age. The integuments are similarly altered: in some species the young only have asperities on the skin, in others the young are smooth and the old have a tubercular skin; in some the young only have a hard bony head, in others (some Siluroids) the osseous carapace of the head and neck, as it appears in the adult, is more or less covered with soft skin whilst the fish is young.

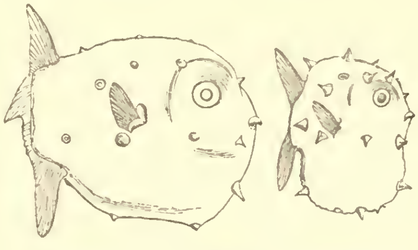

Fig. 65.—Young of *Orthagoriscus*, 18 and 32 mill. long (natural size).

In not a few fishes the external changes bear a relation to the sexual development (*Callionymus*, many *Labyrinthici* Cyprinodonts). These secondary sexual differences do not show themselves in the male individual till it commences to enter upon its sexual functions, and it may require two or more seasons before its external characteristics are fully developed. Immature males do not differ externally from the old female. The secondary sexual characters of the male consist principally in the prolongation of some of the fin-rays, or of entire fins, and in *Salmonidæ* in the greater development of the jaw-bones. The coloration of the male is in many fishes much brighter and more variegated than that of the female, but is permanent in comparatively few (as in some *Callionymus*, *Labrus mixtus*); generally it is acquired immediately before and during the season of propagation only, and lost afterwards. Another periodical change in the integuments, also due to sexual influence and peculiar to the male, is the excrescence of wart-like tubercles on the skin of many Cyprinoids; they are developed chiefly on the head, but sometimes extend over the whole body and all the fins.

With regard to size, it appears that in all Teleosteous fishes the female is larger than the male; in many Cyprinodonts the male may be only one-sixth of the bulk of the female or even less. In *Palæichthyes* we possess few observations on the relative size of the sexes, but such as have been made tend to show that, if a difference exists at all, the male is generally the larger (*Lepidosteus*). In the rays (*Raia*) the sexes, after they have attained maturity, differ in the development of dermal spines and the form of the teeth, the female being frequently much rougher than the male. There is much variation in this respect in the different species; but the males are constantly distinguished by an oblong patch of erectile clawlike spines on each pectoral fin, and by having the teeth (all, or only a portion) pointed, and not obtuse, like those of the females. In sharks no secondary sexual differences have been observed; the male *Chimæridæ* possess a singular comb-like cartilaginous appendage on the top of the head, which can be erected or depressed into a groove, both the appendage and the anterior part of the groove being armed with hooklets. The use of this singular organ is not known.

The majority of *Teleostei* are mixogamous—that is, the males and females congregate on the spawning-beds, and, the number of the former being in excess, several males attend to the same female, frequently changing from one to another. The same habit has been observed in *Lepidosteus*. *Gastrosteus* is truly polygamous, several females depositing their ova in the same nest, guarded by one male only. Some *Teleostei* (*Ophiocephalus*), and probably all Chondropterygians, are monogamous; and it is asserted that the connexion between the pair is not merely temporary, but lasts until they are separated by accident. All those Teleosteans also are probably monogamous which bring forth living young.

Hybridism is another source of changes and variations within the limits of a species, and is by no means so rare as has been hitherto believed; it is apparently of exceptional occurrence, merely because the life of fishes is more withdrawn from our direct observation than that of terrestrial animals. It has been observed among species of *Serranus*, *Pleuronectidæ*, *Cyprinidæ*, *Clupeidæ*, and especially *Salmonidæ*. As with other animals, the more certain kinds of fishes are brought under domestication, the more readily do they interbreed with other allied species. It is characteristic of hybrids that their characters are very variable, the degrees of affinity to the one or the other of the parents being inconstant; and, as these hybrids are known readily to breed with either of the parent race, the variations of form, structure, and colour are infinite. Of internal organs the teeth, the gill-rakers, and the pyloric appendages are those particularly affected by such mixture of species.

Some fishes are known to grow rapidly (in the course of from one to three years) and regularly to a certain size, growth being definitely arrested after the standard has been attained. Such fishes may be called "full-grown," in the sense in which the term is applied to warm-blooded vertebrates; the sticklebacks, most Cyprinodonts, and many Clupeoids (herring, sprat, pilchard) are examples of this regular kind of growth.[1] But in the majority of fishes the rate of growth is extremely irregular, and it is hardly possible to know when growth is actually and definitely arrested. All seems to depend on the amount of food and the more or less favourable circumstances under which the individual grows up. Fishes which rapidly grow to a definite size are short-lived, whilst those, Teleosteans as well as Chondropterygians, which steadily and slowly increase in size attain to a great age. Carp and pike have been ascertained to live beyond a hundred years.

Abundance or scarcity of food, and other circumstances connected with the localities inhabited by fishes, affect considerably the colour of their muscles and integuments; the periodical changes of colour in connexion with their sexual functions have been referred to above. The flesh of many *Teleostei* is colourless, or but slightly tinged by the blood; that of *Scombridæ*, and most Ganoids and Chondropterygians, is more or less red; but in badly-fed fishes, as well as in very young ones, the flesh is invariably white (anæmic). Many fishes, like the *Salmonidæ*, feed at times exclusively on crustaceans, and the colouring substance of these invertebrates, which by boiling and by the stomachic secretion turns red, seems to pass into their flesh, imparting to it the well-known "salmon" colour. The coloration of the integuments of many marine fishes, again, is dependent on the nature of their surroundings. In those which habitually hide themselves on the bottom, in sand, between stones, or among seaweed, the colours of the body readily assimilate to those of the vicinity, and are thus an important element in the economy of their life. The changes from one set or tinge of colours to another may be rapid and temporary, or more or less permanent; in some fishes—as in the *Pediculati*, of which the sea-devil, or *Lophius*, and *Antennarius* are members—scarcely two individuals are found exactly alike in coloration, and such differences are only too frequently mistaken for specific characters. The changes of colour are produced in two ways,—either by an increase or decrease of the pigment-cells, or chromatophors (black, red, yellow, &c.), in the skin of the fish, or by the rapid contraction or expansion of the chromatophors which happen to be developed. The former change is gradual, like every kind of growth or development; the latter, owing to the great sensitiveness of the cells, is rapid, but certainly involuntary. In many bright-shining fishes—as mackerels, mullets—the colours appear to be brightest in the time intervening between the capture of the fish and its death, a phenomenon clearly due to the pressure of the convulsively-contracted muscles on the chromatophors. External irritation readily excites the chromatophors to expand—a fact unconsciously utilized by fishermen, who, by scaling the red mullet immediately before its death, produce the desired intensity of the red colour of the skin, without which the fish would not be saleable. It does not, however, require such strong measures to prove the sensitiveness of the chromatophors to external irritation, the mere change from darkness into light is sufficient to induce them to contract, the fish appearing paler, and *vice versa*. In trout which are kept or live in dark places, the black chromatophors are expanded, and, consequently, such specimens are very dark-coloured; when removed to the light, they become paler almost instantaneously.

Total absence of chromatophors in the skin, or albinism, is very rare among fishes; much more common is incipient albinism, in which the dark chromatophors are changed into cells with a more or less intense yellow pigment. Fishes in a state of domestication, like the crucian carp of China, the carp, the tench, and the ide, are particularly subject to this abnormal coloration, and are known as the common gold-fish, the gold-tench, and the gold-orfe. But it occurs also not rarely in fishes living in a wild state, and has been observed in the haddock, flounder, plaice, carp, roach, and eel.

It will be evident from the foregoing remarks that the amount of variation within the limits of the same species—due either to natural growth and development, or to external physical conditions, or to abnormal accidental circumstances—is greater in fishes than in any of the higher classes of vertebrates. The amount of variation is greater in certain genera or families than in others, and it is much greater in Teleosteans and Ganoids than in Chondropterygians. Naturally, it is greatest in the few species that have been domesticated, which we shall mention in the following section.

Domestication, Tenacity of Life, Hibernation, &c.

Only a few fishes are thoroughly domesticated—that is, bred in captivity, and capable of transportation within certain climatic limits—viz., the carp, crucian carp (European and Chinese varieties), tench, orfe or ide, and goramy. The first two have accompanied civilized man almost to every part of the globe where he has effected a permanent settlement. Dom catic

[1] This applies only to individuals growing up under normal conditions. Dr H. A. Meyer has made observations on young herrings. Individuals living in the sea had attained at the end of the third month a length of 45 to 50 millimetres, whilst those reared from artificially impregnated ova were only from 30 to 35 millimetres long. When the latter had been supplied with more abundant food, they grew proportionally more rapidly in the following months, so that at the end of the fifth month they had reached the same length as their brethren in the sea, viz., 65 to 70 millimetres.

clima- ition. Attempts to acclimatize particularly useful species in countries in which they are not indigenous have been made from time to time, but have been permanently successful in a few instances only, the failures being due partly to the choice of a species which did not yield the profitable return expected, partly to utter disregard of the difference of climatic and other physical conditions between the original and the new homes of the fish. The first successful attempts at acclimatization were made with domestic species, viz., the carp and goldfish, which were transferred from Eastern Asia to Europe. Then, in the early part of the present century, the Javanese goramy was acclimatized in Mauritius and Guiana, but no care seems to have been taken to insure permanent advantages from the successful execution of the experiment. In these cases fully developed individuals were transported to the country in which they were to be acclimatized. The most successful attempt of recent years is the acclimatization of the trout and sea-trout, and probably also of the salmon, in Tasmania and New Zealand, and of the Californian salmon (*Salmo quinnat ?*), in Victoria, by means of artificially-impregnated ova. In transporting these ice was employed, in order to retard their development generally, and thus to preserve them from destruction during the passage across the tropical zone.

ificial preg- ion of Artificial impregnation of fish-ova was first practised by J. L. Jacobi, a native of Westphalia, in the years 1757–63, who employed exactly the same method which is followed now; and there is no doubt that this able observer of nature conceived and carried out his idea with the distinct object of advantageously restocking water-courses that had become unproductive, and increasing production by fecundating and preserving all ova which, in the ordinary course of propagation, would be left unfecundated or might accidentally perish. Physiology soon turned to account Jacobi's discovery, and artificial impregnation has proved to be one of the greatest helps to the student of embryology.

acity ife. Fishes differ in an extraordinary degree with regard to tenacity of life. Some will bear suspension of respiration —caused by removal from water, or by exposure to cold or heat—for a long time, whilst others succumb at once. Nearly all marine fishes are very sensitive to changes in the temperature of the water, and will not bear transportation from one climate to another. This seems to be much less the case with some freshwater fishes of the temperate zones; the carp may survive after being frozen in a solid block of ice, and will thrive in the warmest parts of the temperate zones. On the other hand, some freshwater fishes are so sensitive to a change in the water that they perish when transplanted from their native river into another apparently offering the same physical conditions (grayling, *Salmo hucho*). Some marine fishes may be transferred at once from salt into fresh water, like sticklebacks, some blennies, and *Cottus*, &c.; others survive the change when gradually effected, as many migratory fishes; whilst others, again, cannot bear the least alteration in the composition of the salt water (all pelagic fishes). On the whole, instances of marine fishes voluntarily entering brackish or fresh water are very numerous, whilst freshwater fishes proper but rarely descend into salt water.

Abstinence from food affects different fishes in a similarly different degree. Marine fishes are less able to endure hunger than freshwater fishes,—at least in the temperate zones, no observations having been made in this respect on tropical fishes. Goldfishes, carps, and eels are known to be able to subsist without food for months, without showing a visible decrease in bulk; whilst the Trigloids, Sparoids, and other marine fishes survive abstinence from food for a few days only. In freshwater fishes the temperature of the water has great influence on their vital functions generally, and consequently on their appetite. Many cease to feed altogether in the course of the winter; a few, like the pike, are less inclined to feed during the heat of the summer than when the temperature is lowered.

Captivity. Captivity is easily borne by most fishes, and the appliances introduced in modern aquaria have rendered it possible to keep in confinement fishes which formerly were considered to be intolerant of captivity, and even to induce them to propagate.

Injury from wounds. Wounds affect fishes generally much less than higher vertebrates. A Greenland shark continues to feed though its head is pierced by a harpoon or by the knife, so long as the nervous centre is not touched; a pike will survive the loss of its tail, or a sea-perch that of a portion of it, and a carp that of half its snout. Some fishes, however, are much more sensitive, and perish even from the superficial abrasion caused by the meshes of the net during capture (*Mullus*).

Reproduction of lost parts. The power of reproduction of lost parts in Teleosteous fishes is limited to the delicate terminations of their fin-rays and the various tegumentary filaments with which some are provided. These filaments are sometimes developed in an extraordinary degree, imitating the waving fronds of the seaweed in which the fish hides. The ends of the fin-rays and also the filaments are frequently lost, not only by accident, but also merely by wear and tear; and, as these organs are essential for the preservation of the fish, their reproduction is necessary. In *Dipnoi*, *Ceratodus*, and *Protopterus*, the terminal portion of the tail has been found to have been reproduced, but without the notochord.

Hibernation. Hibernation has been observed in many Cyprinoids and Murænoids of the temperate zones. They do not fall into a condition of complete torpidity, as reptiles and mammals do, but their vital functions are simply lowered, and they hide in sheltered holes, and cease to go abroad in search of their food. Between the tropics a great number of fishes (especially Siluroids, *Labyrinthici*, Ophiocephaloids, the *Dipnoi*) are known to survive long-continued droughts by passing the dry season in a perfectly torpid state, imbedded in the hardened mud. *Protopterus*, and probably many of the other fishes mentioned, prepare for themselves a cavity large enough to hold them, and coated on the inside with a layer of hardened mucus, which preserves them from complete desiccation. It has been stated that in India fishes may survive in this condition for more than one season, and that ponds, known to have been dry for several years and to a depth of many feet, have swarmed with fishes as soon as the accumulation of water released them from their hardened bed.

Economic uses. The principal benefit derived by man from the class of fishes consists in the abundance of wholesome and nourishing food which they yield. In the polar regions especially, whole tribes are entirely dependent on this class for subsistence; and in almost all nations fishes form a more or less essential part of food, many, in a preserved condition, being most important articles of trade. Their use in other respects is of but secondary importance. Cod-liver oil is prepared from the liver of some of the Gadoids of the northern hemisphere and of sharks, isinglass from the swim-bladder of sturgeons, Sciænoids, and Polynemoids, and shagreen from the skin of sharks and rays.

Poisonous fishes. The flesh of some fishes is constantly or occasionally poisonous. When eaten, it causes symptoms of more or less intense irritation in the stomach and intestines, inflammation of the mucous membranes, and not rarely death. The fishes which appear always to have poisonous properties are—*Clupea thrissa*, *Clupea venenosa*, and some species of *Scarus*, *Tetrodon*, and *Diodon*. There are many others which have occasionally or frequently caused symptoms of poisoning. Poey enumerates no less than seventy-two different kinds from Cuba; and various species of *Sphyræna*, *Balistes*, *Ostracion*, *Caranx*, *Lachnolæmus*, *Tetragonurus*, *Thynnus*, have been found to be poisonous in all seas between the tropics. All or nearly all these fishes acquire their poisonous properties from their food, which consists of poisonous *Medusæ* and corals, or of decomposing substances. Frequently the fishes are found to be eatable if the head and intestines are removed immediately after capture. In the West Indies it has been ascertained that all the fishes living and feeding on certain coral banks are poisonous. In other fishes the poisonous properties are developed at certain seasons of the year only, especially the season of propagation; as the barbel, pike, and burbot, whose roe causes violent diarrhœa when eaten during the season of spawning.

Poison-organs are more common in the class of fishes than was formerly believed, but they seem to have exclusively the function of defence, and are not auxiliary in procuring food, as in venomous snakes. Such organs are found in the sting-rays, the tail of which is armed with one or more powerful barbed spines. Although they have no special

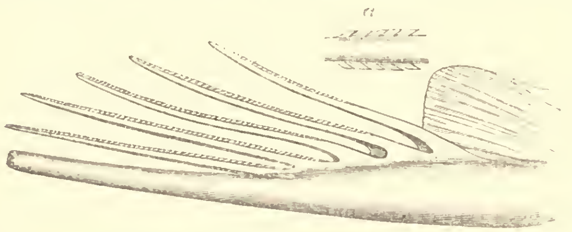

FIG. 66.—Portion of tail, with spines, of *Aetobatis narinari*, a Sting-ray from the Indian Ocean. *a*, natural size of spine.

organ secreting poison, or canal in or on the spine by which the venomous fluid is conducted, the symptoms caused by a wound from the spine of a sting-ray are such as cannot be accounted for merely by the mechanical laceration, the pain being intense, and the subsequent inflammation and swelling of the wounded part terminating not rarely in gangrene. The mucus secreted from the surface of the fish and inoculated by the jagged spine evidently possesses venomous properties. This is also the case in many Scorpænoids, and in the weever (*Trachinus*), in which the dorsal and opercular spines have the same function as the caudal spines of the sting-rays; in the weevers, however, the spines are deeply grooved, the groove being charged with a fluid mucus. In *Synanceia* the poison-organ (fig. 67) is still more developed: each dorsal spine is in its terminal half provided with a deep groove on each side, at the lower end of which lies a pear-shaped bag containing the milky poison; it is prolonged into a membranous duct, lying in the groove of the spine, and open at its point. The native fishermen, well acquainted

FIG. 67.—A dorsal spine, with poison-bags, of *Synanceia verrucosa* (Indian Ocean).

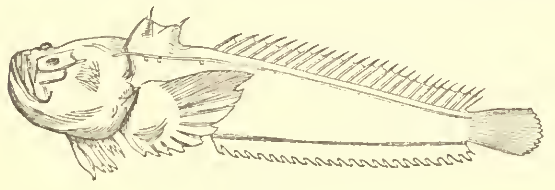

FIG. 68.—*Thalassophryne reticulata.*

with the dangerous nature of these fishes carefully avoid handling them; but it often happens that persons wading with naked feet in the sea step upon the fish, which generally lies hidden in the sand. One or more of the erected spines penetrate the skin, and the poison is injected into the wound by the pressure of the foot on the poison-bags. Death has frequently been the result.

The most perfect poison-organs hitherto discovered in fishes are those of *Thalassophryne*, a Batrachoid genus of fishes from the coasts of Central America. In these fishes again the operculum and the two dorsal spines are the weapons. The former (fig. 69) is very narrow, vertically styliform, and very mobile; it is armed behind with a spine, eight lines long, and of the same form as the hollow venom-fang of a snake, being perforated at its base and at its extremity. A sac covering the base of the spine discharges its contents through the apertures and the canal in the interior of the spine. The structure of the dorsal spines is similar. There are no secretory glands imbedded in the membranes of the sacs, and the fluid must be secreted by their mucous membrane. The sacs have no external muscular layer, and are situated immediately below the thick loose skin which envelops the spines to their extremity; the ejection of the poison into a living animal, therefore, can only be effected, as in *Synanceia*, by the pressure to which the sac is subjected the moment the spine enters another body

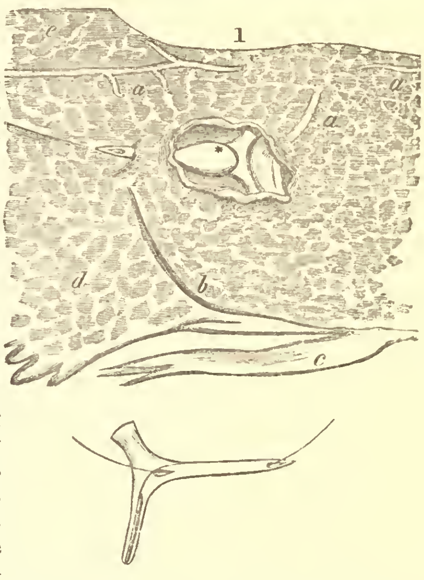

FIG. 69.—Opercular part of the poison-apparatus of *Thalassophryne* (Panama). 1. Hinder half of the head, with the venom-sac * *in situ*. *a*, lateral line and its branches; *b*, gill-opening; *c*, ventral fin; *d*, base of pectoral fin; *e*, base of dorsal. 2. Operculum with the perforated spine.

GEOLOGICAL DISTRIBUTION.

Of what kind the fishes were which were the first to make their appearance on the globe, whether or not they were identical with or similar to any of the principal types existing at present, are questions which probably will for ever remain hidden in mystery and uncertainty. The supposition that the Pharyngobranchs and Cyclostomes, the lowest of the vertebrate series, must have preceded the other subclasses, is an idea which has been held by many zoologists, and, as the horny teeth of the Cyclostomes are the only parts which under favourable circumstances could have been preserved, palæontologists have ever been searching for this evidence.

Indeed, in deposits belonging to the Lower Silurian and Devonian, in Russia, England, and North America, minute, slender, pointed horny bodies, bent like a hook, with sharp opposite margins, have been found and described under the name of "conodonts." More frequently they possess an elongated basal portion, in which there is generally a larger tooth with rows of similar but smaller denticles on one or both sides of the larger tooth, according as this is central or at one end of the base. In other examples there is no prominent central tooth, but a series of more or less similar teeth is implanted

FIG. 70.—Right dental plate of *Myxine affinis.*

on a straight or curved base. Modifications of these arrangements are very numerous, and many palæontologists still entertain doubts whether the origin of these remains is not rather from annelids and mollusks than from fishes.

The first undeniable evidence of a fish, or, indeed, of a vertebrate animal, occurs in the Upper Silurian rocks, in a bone-bed of the Downton Sandstone, near Ludlow. It consists of compressed, slightly curved, ribbed spines, of less than 2 inches in length (*Onchus*); small shagreen-scales (*Thelodus*); the fragment of a jaw-like bar with pluricuspid teeth (*Plectrodus*); the cephalic bucklers of what seems to be a species of *Pteraspis*; and, finally, coprolitic bodies of phosphate and carbonate of lime, including recognizable remains of the mollusks and crinoids inhabiting the same waters. But no vertebra or other part of the skeleton has been found. The spines and scales seem to have belonged to the same kind of fish, which probably was a Plagiostome. It is quite uncertain whether or not the jaw (if it be the jaw of a fish) belonged to the buckler-bearing *Pteraspis*, the position of which among Ganoids, with which it is generally associated, is open to doubt.

No detached undoubted tooth of a Plagiostome or Ganoid scale has been discovered in the Ludlow deposits; but this much is certain, that those earliest remains in Palæozoic rocks belonged to fishes closely allied to forms occurring in greater abundance in the succeeding formation, the Devonian, where they are associated with undoubted *Palæichthyes*, Plagiostomes as well as Ganoids.

These fish-remains of the Devonian or Old Red Sandstone can be determined with greater certainty. They consist of spines, the so-called "ichthyodorulites," which show sufficiently distinctive characters to be referred to several genera, one of them, *Onchus*, still surviving from the Silurian epoch. All these spines are believed to be those of Chondropterygians, to which order some pluricuspid teeth (*Cladodus*) from the Old Red Sandstone in the vicinity of St Petersburg have been likewise referred.

The remains of the Ganoid fishes are in a much more perfect state of preservation, so that it is even possible to obtain a tolerably certain idea of the general appearance and habits of some of them, especially of such as were provided with hard carapaces, solid scales, and ordinary or bony fin-rays. A certain proportion of them, as might have been expected, remind us, as regards their external form, of Teleosteous fishes rather than of any of the few still existing Ganoid types; but it is contrary to all analogy and to all palæontological evidence to suppose that those fishes were, in their internal structure, more nearly allied to Teleosteans than to Ganoids. If they were not true Ganoids, they may justly be supposed to have had the essential characters of *Palæichthyes*. Other forms even at that remote geological epoch exhibit so unmistakably the characteristics of existing Ganoids that no one can entertain any doubt with regard to their place in the system. In none of these fishes is there any trace of vertebral segmentation.

The *Palæichthyes* of the Old Red Sandstone, the systematic position of which is still obscure, are the *Cephalaspidæ* from the Lower Old Red Sandstone of Great Britain and Eastern Canada; *Pterichthys, Coccosteus, Dinichthys*, and *Asterolepis* (genera which have been combined in one group, *Placodermæ*); and *Acanthodes* and allied genera, which combined numerous branchiostegals with Chondropterygian spines and a shagreen-like dermal covering.

Among the other Devonian fishes (and they form the majority) two types may be recognized, both of which are unmistakably Ganoids. The first approaches the still living *Polypterus*, with which some of the genera like *Diplopterus* singularly agree in the form and armature of the head, the lepidosis of the body, the lobate pectoral fins, and the termination of the vertebral column. Other genera, as *Holoptychius*, have cycloid scales; many have two dorsal fins (*Holoptychius*), and, instead of branchiostegals, jugular scutes; others have one long dorsal confluent with the caudal (*Phaneropleuron*). In the second type the principal characters of the *Dipnoi* are manifest; and some of them—for example, *Dipterus, Palædaphus, Holodus*—approach so closely the *Dipnoi* which still survive that the differences existing between them warrant a separation into families only.

Devonian fishes are frequently found under peculiar circumstances, enclosed in the so-called nodules. These bodies are elliptical flattened pebbles, which have resisted the action of water in consequence of their greater hardness, whilst the surrounding rock has been reduced to detritus by that agency. Their greater density is due to the dispersion in their substance of the fat of the animal which decomposed in them. Frequently, on cleaving one of these nodules with the stroke of the hammer, a fish is found embedded in the centre. At certain localities of the Devonian, fossil fishes are so abundant that the whole of the stratum is affected by the decomposing remains, emitting a peculiar smell when newly opened, and acquiring a density and durability not possessed by strata without fishes. The flagstones of Caithness are a remarkable instance of this.

The fish-remains of the Carboniferous formation show a great similarity to those of the preceding. They occur throughout the series, but are very irregularly distributed, being extremely rare in some countries, whilst in others entire beds (the so-called bone-beds) are composed of ichthyolites. In the ironstones they frequently form the nuclei of nodules, as in the Devonian.

Of Chondropterygians the spines of *Onchus* and others still occur, with the addition of teeth indicative of the existence of fishes allied to the Cestracion type (*Cochliodus, Psammodus*), a type which henceforth plays an important part in the composition of the extinct marine fish faunæ. Another extinct Selachian family, that of the Hybodonts, makes its appearance, but is known from the teeth only.

Of the Ganoid fishes, the family *Palæoniscidæ* (Traquair) is numerously represented; others are Cœlacanths (*Cœlacanthus, Rhizodus*), and *Saurodipterini* (*Megalichthys*). None of these fishes have an ossified vertebral column, but in some (*Megalichthys*) the outer surface of the vertebræ is ossified into a ring; the termination of their tail is heterocercal. The Carboniferous *Uronemus* and the Devonian *Phaneropleuron* are probably generically the same; and the Devonian *Dipnoi* are continued as, and well represented by, *Ctenodus*.

The fishes of the Permian group are very similar to those of the Carboniferous. A type which in the latter was but very scantily represented, namely the *Platysomidæ*, is much developed. They were deep-bodied fish, covered with hard rhomboid scales possessing a strong anterior rib, and provided with a heterocercal caudal, long dorsal and anal, short non-lobate paired fins (when present), and branchiostegals. *Palæoniscus* appears in many species; the *Sauridæ* are represented by *Pygopterus* and *Acrolepis*, and Cestracionts by *Janassa* and *Strophodus*.

The passage from the Palæozoic into the Mesozoic era is not indicated by any marked change so far as fishes are concerned. The more remarkable forms of the Trias are shark-like fishes represented by ichthyodorulites, like *Nemacanthus, Liacanthus*, and *Hybodus*; and Cestracionts represented by species of *Acrodus* and *Strophodus*. Of the Ganoids, *Cœlacanthus, Amblypterus* (*Palæoniscidæ*), and *Saurichthys* persist from the Carboniferous epoch. *Ceratodus* appears for the first time (Muschel Kalk of Germany).

Thanks to the researches of Agassiz, and especially of Sir P. Egerton, the ichthyological fauna of the Lias is perhaps the best known of the Mesozoic era, one hundred and fifty-two species having been described. Of the various localities, Lyme Regis has yielded more than any other, nearly all the Liassic genera being represented there by no fewer than seventy-nine species. The Hybodonts and Cestracionts continue in their fullest development. Holocephales (*Ischyodus*), true sharks (*Palæoscyllium*), rays (*Squaloraia*, *Arthropterus*), and sturgeons (*Chondrosteus*) make their first appearance; but they are sufficiently distinct from living types to be classed in separate genera, or even families. The Ganoids, especially Lepidosteoids, predominate over all the other fishes: *Lepidotus*, *Semionotus*, *Pholidophorus*, *Pachycormus*, *Eugnathus*, *Tetragonolepis*, are represented by numerous species; other remarkable genera are *Aspidorhynchus*, *Belonostomus*, *Saurostomus*, *Sauropsis*, *Thrissonotus*, *Conodus*, *Ptycholepis*, *Endactis*, *Centrolepis*, *Legnonotus*, *Oxygnathus*, *Heterolepidotus*, *Isocolum*, *Osteorhachis*, *Mesodon*. These genera afford evidence of a great change since the preceding period, the majority not being represented in older strata, whilst, on the other hand, many are continued into the succeeding Oolitic formations. The homocercal termination of the vertebral column begins to supersede the heterocercal, and many of the genera have well-ossified and distinctly segmented spinal columns. The cycloid form of scales also becomes more common,—one genus (*Leptolepis*) being, with regard to the preserved hard portions of its organization, so similar to the Teleosteous type that some palæontologists refer it (with much reason) to that subclass.

As already mentioned, the Oolitic formations show a great similarity of their fish fauna to that of the Lias; but still more apparent is its approach to the existing fauna. Teeth have been found which cannot even generically be distinguished from *Notidanus*. The rays are represented by genera like *Spathobatis*, *Belemnobatis*, *Thaumas*; the *Holocephali* are more numerous than in the Lias (*Ischyodus*, *Ganodus*). The most common Ganoid genera are *Caturus*, *Pycnodus*, *Pholidophorus*, *Lepidotus*, *Leptolepis*, all of which had been more or less fully represented in the Lias. *Ceratodus* also is continued into it.

The Cretaceous group gives clear evidence of the further advance towards the existing fauna. Teeth of sharks of existing genera, *Carcharias* (*Corax*), *Scyllium*, *Notidanus*, and *Galeocerdo*, are common in some of the marine strata, whilst Hybodonts and Cestracionts are represented by a small number of species only; of the latter one new genus, *Ptychodus*, appears and disappears. A very characteristic Ganoid genus, *Macropoma*, comprises homocercal fishes with rounded ganoid scales sculptured externally and pierced by prominent mucous tubes. *Caturus* becomes extinct. Teeth and scales of *Lepidotus* (with *Sphærodus* as subgenus), clearly a freshwater fish, are widely distributed in the Wealden, and finally disappear in the Chalk; its body was covered with large rhomboidal ganoid scales. *Gyrodus* and *Aspidorhynchus* occur in the beds of Voirons, *Cœlodus* and *Amiopsis* (allied to *Amia*) in those of Comen, in Istria. But the *Palæichthyes* are now in the minority; undoubted Teleosteans have appeared for the first time on the stage of life in numerous genera, many of which are identical with still existing fishes. The most of these are Acanthopterygians, but Physostomes and Plectognaths are likewise well represented, most of them being marine. Of Acanthopterygian families the first to appear are the *Berycidæ*, represented by several very distinct genera:—*Beryx*; *Pseudoberyx*, with abdominal ventral fins; *Berycopsis*, with cycloid scales; *Homonotus*, *Stenostoma*, *Sphenocephalus*, *Acanus*, *Hoplopteryx*, *Platycornus*, with granular scales; *Podocys*, with a dorsal extending to the neck; *Acrogaster*, *Macrolepis*, *Rhacolepis*, from the Chalk of Brazil. The position of *Pycnosterynx* is uncertain; it approaches certain Pharyngognaths. True *Percidæ* are absent, whilst the *Carangidæ*, *Sphyrænidæ*, *Cataphracti*, *Gobiidæ*, *Cottidæ*, and *Sparidæ* are represented by one or more genera. Somewhat less diversified are the Physostomes, which belong principally to the *Clupeidæ* and *Dercetidæ*, most of the genera being extinct; *Clupea* is abundant in some localities. *Scopelidæ* (*Hemisaurida* and *Saurocephalus*) occur in the Chalk of Comen in Istria, and of Maestricht. Of all Cretaceous deposits none surpass those of the Lebanon for the number of genera, species, and individuals; the forms are exclusively marine, and the remains in the most perfect condition.

In the Tertiary epoch the Teleosteans have almost entirely replaced the Ganoids; a few species only of the latter make their appearance, and they belong to existing genera (*Lepidosteus*, *Acipenser*). The Chondropterygians merge more and more into recent forms; *Holocephali* continue, and still are better represented than in the present fauna. The Teleosteans show even in the Eocene a large proportion of existing genera, and the fauna of some localities of the Miocene (Oeningen) is almost wholly composed of them. Of the whole more than one-half have already been found to belong to existing genera, and there is no doubt that the number of distinct genera now seemingly extinct will be lessened as the fossils come to be examined with a better knowledge of the living forms. The distribution of the fishes differed widely from that of our period, many of our tropical genera occurring in localities which are now included within our temperate zone, and being mixed with others that nowadays are restricted to a colder climate,—a combination which continues throughout the Pliocene.

A few families of fishes, like the freshwater *Salmonidæ*, seem to have put in their appearance in Post-Pliocene times; not much attention, however, has been paid to fish-remains of these deposits; and such as have been incidentally examined furnish evidence of the fact that the distribution of fishes has not undergone any further essential change down to the present period.

GEOGRAPHICAL DISTRIBUTION.

In an account of the geographical distribution of fishes the freshwater forms are to be kept separate from the marine. When we attempt, however, to draw a line between these two kinds of fishes, we meet with a great number of species and of facts which would seem to render that distinction very vague. There are not only species which can gradually accommodate themselves to a sojourn in either salt or fresh water, but there are also some that seem to be quite indifferent to a rapid change from the one into the other; so that individuals of one and the same species (*Gastrosteus*, *Gobius*, *Blennius*, *Osmerus*, *Retropinna*, *Clupea*, *Syngnathus*, &c.) may be found some distance out at sea, whilst others live in rivers far beyond the influence of the tide, or even in inland fresh waters without outlet to the sea. The majority of these fishes belong to forms of brackish-water fauna; and, as they are not an insignificant portion of the fauna of almost every coast, we shall have to treat of them in a separate chapter.

Almost every large river offers instances of truly marine fishes ascending for hundreds of miles of their course, and not periodically, or from any apparent physiological necessity, but sporadically throughout the year. This is evidently the commencement of a change in a fish's habits; and, indeed, not a few of such fishes have actually taken up their permanent residence in fresh waters, as species of *Ambassis*, *Apogon*, *Dules*, *Therapon*, *Sciæna*, *Blennius*, *Gobius*, *Atherina*, *Mugil*, *Myxus*, *Hemirhamphus*, *Clupea*, *Anguilla*, *Tetrodon*, *Trygon*,—all forms originally marine.

On the other hand, we find fishes belonging to freshwater genera descending rivers and sojourning in the sea for a more or less limited period; but these instances are much less in number than those in which the reverse obtains. We may mention species of *Salmo* (the common trout, the northern charr), and Siluroids (as *Arius*, *Plotosus*). *Coregonus*, a genus so characteristic of the inland lakes of Europe, Northern Asia, and North America, nevertheless offers some instances of species wandering by the effluents into the sea, and taking up their residence in salt water, apparently by preference, as *Coregonus oxyrhynchus*. But of all the freshwater families none exhibit so great a capability of surviving the change from fresh into salt water as the *Gastrosteidæ* (sticklebacks) of the northern hemisphere, and the equally diminutive *Cyprinodontidæ* of the tropics; not only do they enter into, and live freely in, the sea, but many species of the latter family inhabit inland waters, which, not having an outlet, have become briny, or impregnated with a larger proportion of salts than pure sea-water. During the voyage of the "Challenger" a species of *Fundulus* (*F. nigrofasciatus*) which inhabits the fresh and the brackish waters of the Atlantic States of North America was obtained, with Scopelids and other pelagic forms, in the tow-net, midway between St Thomas and Teneriffe.

Some fishes annually or periodically ascend rivers for the purpose of spawning, passing the rest of the year in the sea, as sturgeons, many Salmonoids, some Clupeoids, lampreys, &c. The first two evidently belonged originally to the freshwater series, and it was only in the course of their existence that they acquired the habit of descending to the sea, perhaps because their freshwater home did not furnish a sufficient supply of food. These migrations of freshwater fishes have been compared with the migrations of birds; but they are much more limited in extent, and do not, as is the case with birds, impart an additional element to the fauna of the place to which the fishes migrate.

The distinction between freshwater and marine fishes is further obscured by geological changes, in consequence of which the salt water is gradually being changed into fresh, or *vice versa*. These changes are so gradual, and spread over so long a time, that many of the fishes inhabiting such localities accommodate themselves to the new conditions. One of the most remarkable and best studied instances of such an alteration is the Baltic, which, during the second half of the Glacial period, was in open and wide communication with the Arctic Ocean, and evidently had the same marine fauna as the White Sea. Since then, by the rising of the land of Northern Scandinavia and Finland, this great gulf of the Arctic Ocean has become an inland sea, with a narrow outlet into the North Sea, and, in consequence of the excess of fresh water pouring into it over the loss by evaporation, it has been so much diluted as to be nearly fresh at its northern extremities; and yet nine species, the origin of which from the Arctic Ocean can be proved, have survived the changes, propagating their species, and agreeing with their brethren in the Arctic Ocean in every point, but remaining comparatively smaller. On the other hand, fishes which we must regard as true freshwater fishes, like the rudd, roach, pike, perch, enter freely the brackish water of the Baltic. Instances of marine fishes being permanently retained in fresh water in consequence of geological changes are well known: as *Cottus quadricornis* in the large lakes of Scandinavia; species of *Gobius*, *Blennius*, and *Atherina* in the lakes of northern Italy; *Comephorus*, which seems to be a dwarfed Gadoid, in the depths of Lake Baikal. *Carcharias gangeticus* in inland lakes of the Fiji Islands, is another instance of a marine fish which has permanently established itself in fresh water.

Thus there is a constant interchange of species in progress between the freshwater and marine faunæ, and in not a few cases it would seem almost arbitrary to refer a genus or even a larger group of fishes to the one or the other; yet there are certain groups of fishes which entirely, or with but few exceptions, are, and apparently during the whole period of their existence have been, inhabitants either of the sea or of fresh water; and, as the agencies operating upon the distribution of marine fishes differ greatly from those influencing the dispersal of freshwater fishes, the two series must be treated separately. The most obvious fact that dry land, which intervenes between river systems, presents to the rapid spreading of a freshwater fish an obstacle which can be surmounted only exceptionally or by a most circuitous route, whilst marine fishes may readily and voluntarily extend their original limits, could be illustrated by a great number of instances. Without entering into details, it may suffice to state, as the general result, that no species or genus of freshwater fishes has anything like the immense range of the corresponding categories of marine fishes, and that, with the exception of the Siluroids, no freshwater family is so widely spread as the families of marine fishes. Surface temperature or climate, which is, if not the most, one of the most important physical factors in the limitation of freshwater fishes, similarly affects the distribution of marine fishes, but in a less degree, and only in the case of those which live near the shore or the surface of the ocean; it ceases to exercise its influence in proportion to the depth, the true deep-sea forms being entirely exempt from its operation. Light, which is pretty equally distributed over the localities inhabited by freshwater fishes, cannot be considered as an important factor in their distribution, but it contributes to the formation of the impassable barrier between the surface and abyssal forms of marine fishes. Altitude has stamped the fishes of the various alpine provinces of the globe with a certain character, and limited their distribution; but the number of these alpine forms is comparatively small, ichthyic life being extinguished at great elevations even before the mean temperature equals that of the high latitudes of the Arctic region, in which some freshwater fishes flourish. On the other hand, the depths of the ocean, far exceeding the altitude of the highest mountains, still swarm with forms specially adapted for abyssal life. That other physical conditions of minor and local importance, under which freshwater fishes live, and by which their dispersal is regulated, are more complicated than similar ones of the ocean, is probable, though perhaps less so than is generally supposed; for the fact is that the former are more accessible to observation than the latter, and are therefore more generally and more readily comprehended and acknowledged. It will thus be necessary to treat of the two series separately, not only because many of the most characteristic forms of the marine and the freshwater series are found, on taking a broader view of the subject, to be sufficiently distinct, but also because their distribution depends on causes different in their nature as well as in the degree of their action. Whether the oceanic areas correspond in any way to the terrestrial will be seen in the sequel.

Freshwater Fishes.

Having shown above that numerous marine fishes enter fresh waters, and that some of them have permanently established themselves therein, we have to eliminate from the category of freshwater fishes all such adventitious elements. They are derived from forms the distribution of which is regulated by other agencies, and which therefore would obscure the relations of the faunæ of terrestrial regions if they were included in them. They will be mentioned with greater propriety along with the fishes constituting the fauna of brackish water.

The true freshwater fishes are all embraced in the following families and groups :—

Dipnoi, with 4 species; Acipenseridæ and Polyodontidæ, 26; Amiidæ, 1; Polypteridæ, 2; Lepidosteidæ, 3; Percina, 46; Grystina, 11; Aphredoderidæ, 1; Centrarchina, 26; Dules, 10; Nandidæ, 7; Polycentridæ, 3; Labyrinthici, 30; Luciocephalidæ, 1; Gastrosteus, 10; Ophiocephalidæ, 31; Mastacembelidæ, 13; Chromides, 105; Comephoridæ, 1; Gadopsidæ, 1; Siluridæ, 572; Characinidæ, 261; Haplochitonidæ, 3; Salmonidæ (3 genera excepted), 135; Percopsidæ, 1; Galaxiidæ, 15; Mormyridæ (and Gymnarchidæ), 52; Esocidæ, 8; Umbridæ, 2; Cyprinodontidæ, 112; Heteropygii, 2; Cyprinidæ, 724; Kneriidæ, 2; Hyodontidæ, 1; Pantodontidæ, 1; Osteoglossidæ, 5; Notopteridæ, 5; Gymnotidæ, 20; Symbranchidæ, 5; Petromyzontidæ, 12. Total, 2270 species.

As in every other class of animals, these freshwater genera and families vary exceedingly with regard to the extent of their geographical range,—some extending over more than the half of the continental areas, whilst others are limited to one continent only, or even to a very small portion of it. As a general rule, a genus or family of freshwater fishes is regularly dispersed and most developed within a certain district, the species and individuals becoming fewer towards the periphery as the type recedes more from its central home, some outposts, however, frequently being pushed far beyond the outskirts of the area occupied by it. At the same time remarkable instances exist of closely allied forms occurring, almost isolated, at most distant points, without being connected by allied species in the intervening space, and of members of the same family, genus, or species inhabiting the opposite shores of an ocean, and separated by many degrees of abyssal depths.

The dispersal of freshwater fishes has been effected in various ways; probably all the causes are still in operation, most of them working so slowly and imperceptibly as to escape direct observation. From the great number of freshwater forms which we see at the present day already acclimatized or gradually becoming acclimatized in the sea, or periodically or sporadically migrating to it, we must conclude that, under certain circumstances, salt water may cease to be an impassable barrier at some period of the existence of freshwater species, and that many of them have passed from one river through salt water into another. Secondly, the headwaters of some of the largest rivers, the mouths of which are at opposite ends of the continents which they drain, are sometimes distant from each other a few miles only; the intervening space may easily have been bridged over for the passage of fishes by a slight geological change affecting the level of the watershed, or even by temporary floods; and a communication of this kind, if existing for a limited period only, would afford the ready means for an exchange of a number of species previously peculiar to one or the other of those river or lake systems. Some fishes provided with gill-openings so narrow that the water moistening the gills cannot readily evaporate, and endowed, besides, with an extraordinary degree of vitality, like many Siluroids (*Clarias*, *Callichthys*), eels, &c., are enabled to wander for some distance over land, and thus may reach a watercourse leading them thousands of miles from their original home. Finally, fishes or their ova may be accidentally carried by waterspouts, or by aquatic birds or insects, to considerable distances.

Freshwater fishes of the present fauna were already in existence when the great changes in the distribution of land and water took place in the Tertiary epoch; and, having seen that salt water is not an absolute barrier to the spreading of freshwater fishes, we can now more easily account for those instances of singular disconnexion of certain families or genera. It is not necessary to assume that there was a continuity of land stretching from the present coast of Africa to South America, or from South America to New Zealand and Australia, to explain the presence of identical forms in localities so distant; it suffices to assume that the distances were lessened by intervening archipelagoes, or that an alteration has taken place in the level of the land area.

Dispersal of a type over several distant continental areas may be evidence of its great antiquity, but does not prove that it is of greater antiquity than another limited to one region only. Geological evidence is the only proof of the antiquity of a type. Thus, although the *Dipnoi* occur in the continents of Africa, South America, and Australia, and their present distribution is evidently the consequence of their wide range in Palæozoic and Secondary epochs, the proof of their high antiquity can be found in their fossil remains only. The Siluroids, for example, have a still greater range, but their wide distribution is of comparatively recent date, as the few fossil remains that have been found belong to the Tertiary epoch. The rapidity of dispersal of a type depends entirely on its power to accommodate itself to a variety of physical conditions, and on the degree of vitality by which it is enabled to survive more or less sudden changes under unfavourable conditions; proof of this is afforded by the family of Siluroids, many of which can suspend for some time the energy of their respiratory functions, and readily survive a change of water.

To trace the geological sequence of the distribution of an ichthyic type, and to recognize the various laws which have governed and are still governing its dispersal, is one of the ultimate tasks of ichthyology. But the endeavour to establish by means of our present fragmentary geological knowledge the divisions of the fauna of the globe leads us into a maze of conflicting evidence; as Mr Wallace truly observes, "any attempt to exhibit the regions of former geological ages in combination with those of our own period must lead to confusion." Nevertheless, as the different types of animals found at the present day within a particular area have made their appearance therein at distant periods, we should endeavour, in giving an account of the several zoo-geographical divisions, to decide, so far as we can, the following questions :—

1. Which of the fishes of an area should be considered to be the remnants of ancient types, probably spread over much larger areas in preceding epochs?

2. Which are to be considered to be autochthonous species, that is, forms which in the Tertiary epoch or later came into existence within the area to which they are still limited, or from which they have since spread?

3. Which are the forms which must be considered to be immigrants from some other region?

It is the aim of every philosophical classification to indicate the degrees of affinity which obtain between the various categories. In dividing the earth's surface into zoological regions, the two families, *Cyprinidæ* and *Siluridæ*, the former of which yields a contingent of one-third and the latter of one-fourth of all the known freshwater species of our period, afford most important guidance for the estimation of those degrees of affinity. The Cyprinoids may be assumed to have originated in the alpine region dividing the temperate and tropical parts of Asia; endowed with a greater capability than any other family of freshwater fishes of acclimatizing themselves in a temperate as well as in a tropical region, they spread north and south as well as east and west; in the Pre-Glacial epoch they reached North America, but they have not had time to penetrate into South America, Australia, or the islands of the Pacific. The Siluroids, principally fishes of the sluggish waters of the plains, well adapted for surviving changes of the water in which they live, and for living either in mud or in sea-water, flourish most in the tropical climate in which this type evidently had its origin. They came into existence after the Cyprinoids, their fossil remains being found only in Tertiary deposits in India, none in Europe. They rapidly spread over the areas of land within the tropical zone, reaching Northern Australia from India, and one species migrating even into the Sandwich Islands, probably from South America. The coral islands of the Pacific still remain untenanted by them. Their progress into temperate regions was evidently slow, only very few species having penetrated into the temperate parts of Asia and Europe, and the North American species, although more numerous, showing no great variety of structure, all belonging to the same group (*Amiurina*). Towards the south their progress was still slower, Tasmania, New Zealand, and Patagonia being without any representative, whilst the streams of the Andes of Chili are inhabited by a few dwarfed forms identical with such as are characteristic of similar localities in the more northern and warmer parts of the South American continent.

These remarks may serve to introduce the following division of the fauna of freshwater fishes :—

I. THE NORTHERN ZONE.—Characterized by Acipenseridæ. Few Siluridæ. Numerous Cyprinidæ. Salmonidæ, Esocidæ.
   1. *Europo-Asiatic or Palæarctic Region.*—Characterized by absence of osseous Ganoidei ; Cobitidæ and Barbus numerous.
   2. *North American Region.*—Characterized by osseous Ganoidei, Amiurina, and Catostomina ; but no Cobitidæ or Barbus.

II. THE EQUATORIAL ZONE.—Characterized by the development of Siluridæ.
   A. *Cyprinoid Division.*—Characterized by presence of Cyprinidæ and Labyrinthici.
      1. *Indian Region.*—Characterized by [absence of Dipnoi[1]] Ophiocephalidæ, Mastacembelidæ. Cobitidæ numerous.
      2. *African Region.*—Characterized by presence of Dipnoi and Polypteridæ. Chromides and Characinidæ numerous. Mormyridæ. Cobitidæ absent.
   A. *Acyprinoid Division.*—Characterized by absence of Cyprinidæ and Labyrinthici.
      1. *Tropical American or Neotropical Region.*—Characterized by presence of Dipnoi. Chromides and Characinidæ numerous. Gymnotidæ.
      2. *Tropical Pacific Region.*—Characterized by presence of Dipnoi. Chromides and Characinidæ absent.

III. THE SOUTHERN ZONE.—Characterized by absence of Cyprinidæ, and scarcity of Siluridæ. Haplochitonidæ and Galaxiidæ represent the Salmonoids and Esoces of the northern zone. One region only.
   1. *Antarctic Region.*—Characterized by the small number of species ; the fishes of—
      a. The Tasmanian sub-region,
      b. The New Zealand sub-region, and
      c. The Patagonian sub-region,
   being almost identical.[2]

In the following account we begin with a description of the equatorial zone, this being the one from which the two principal families of freshwater fishes seem to have spread.

EQUATORIAL ZONE.—Roughly speaking, the borders of this zoological zone coincide with the geographical limits of the Tropics of Cancer and Capricorn ; its characteristic forms, however, extend in undulating lines several degrees both northwards and southwards. Commencing from the west coast of Africa, the desert of the Sahara forms a well-marked boundary between the equatorial and northern zones ; as the boundary approaches the Nile, it makes a sudden sweep towards the north as far as northern Syria (*Mastacembelus*, near Aleppo and in the Tigris ; *Clarias* and *Chromides*, in the Lake of Galilee), crosses through Persia and Afghanistan (*Ophiocephalus*) to the southern ranges of the Himalayas, and follows the course of the Yang-tse-Keang, which receives its contingent of equatorial fishes through its southern tributaries. Its continuation through the North Pacific may be considered as indicated by the tropic, which strikes the coast of Mexico at the southern end of the Gulf of California. Equatorial types of South America are known to extend so far northwards ; and, by following the same line, the West India Islands are naturally included in this zone.

Towards the south the equatorial zone embraces the whole of Africa and Madagascar, and seems to extend still farther south in Australia, its boundary probably following the southern coast of that continent ; the detailed distribution of the freshwater fishes of south-western Australia has been but little studied, but the few facts which we know show that the tropical fishes of that region follow the principal water-course, the Murray river, far towards the south and probably to its mouth. The boundary line then stretches to the north of Tasmania and New Zealand, coinciding with the tropic until it strikes the western slope of the Andes, on the South American continent, where it again bends southward to embrace the system of the Rio de la Plata.

The four regions into which the equatorial zone is divided arrange themselves into two well-marked divisions, one of which is characterized by the presence of Cyprinoid fishes, combined with the development of *Labyrinthici*, whilst in the other both these types are absent. The boundary between the Cyprinoid and Acyprinoid division seems to follow Wallace's line,—a line drawn from the south of the Philippines between Borneo and Celebes, and farther south between Bali and Lombok. Borneo abounds in Cyprinoids ; from the Philippine Islands a few only are known at present, and in Bali two species have been found ; but none are known from Celebes or Lombok, or from islands situated farther east.

Taking into consideration the manner in which Cyprinoids and Siluroids have been dispersed, we are obliged to place the Indian region as the first in the order of our treatment ; and indeed the number of freshwater fishes which appear to have spread from it into the neighbouring regions far exceeds that of the species which it has received from them.

The *Indian Region* comprises the whole continent of Asia south of the Himalayas and the Yang-tse-Keang, and includes the islands to the west of Wallace's line. Towards the north-east the island of Formosa, which also by other parts of its fauna shows the characters of the equatorial zone, has received some characteristic Japanese freshwater fishes, for instance, the singular Salmonoid *Plecoglossus*. Within the geographical boundaries of China the freshwater fishes of the tropics pass gradually into those of the northern zone, both being separated by a broad debateable ground. The affluents of the great river traversing this district are more numerous from the south than from the north, and carry the southern fishes far into the temperate zone. Scarcely better defined is the boundary of this region towards the north-west. Before Persia passed through the geological changes by which its waters were converted into brine and finally dried up, it seems to have been inhabited by many characteristic Indian forms, of which a few still survive in the tract intervening between Afghanistan and Syria ; *Ophiocephalus* and *Discognathus* have each at least one representative, *Macrones* has survived in the Tigris, and *Mastacembelus* has penetrated as far as Aleppo. Thus freshwater fishes belonging to India, Africa, and Europe are intermingled in a district which forms the connecting link between the three continents. Of the freshwater fishes of Arabia we are almost entirely ignorant ; we only

[1] These will probably be found.

[2] We distinguish these sub-regions, because their distinction is justified by other classes of animals ; as regards freshwater fishes they are even less distinct than Europe and northern Asia.

know that the Indian *Discognathus lamta* occurs in the reservoirs of Aden (having also found its way to the opposite African coast), and that the ubiquitous Cyprinodonts thrive in the brackish pools of northern Arabia.

In analysing the list of Indian fishes, we find that out of 40 families or groups of freshwater fishes 12 are represented in this region, and that 625 species are known to occur in it, or two-sevenths of the entire number of freshwater fishes known. This large proportion is principally due to the development of numerous local forms of Siluroids and Cyprinoids, of which the former show a contingent of about 200, and the latter of about 330 species. The combined development of those two families, therefore, and their undue preponderance over the other freshwater types, is the principal characteristic of the Indian region. The second important character of its fauna is the apparently total absence of Ganoid and Cyclostomous fishes. Every other region has representatives of either Ganoids or Cyclostomes, some of both.

Of the autochthonous freshwater fishes of the Indian region, some are still limited to it, viz., the *Nandina*, the *Luciocephalidæ* (of which one species only exists in the archipelago), of Siluroids the *Chacina* and *Bagariina*, of Cyprinoids the *Semiplotina* and *Homalopterina*; others are very nearly so, such as the *Labyrinthici*, *Ophiocephalidæ*, *Mastacembelidæ*, of Siluroids the *Silurina*, of Cyprinoids the *Rasborina* and *Danionina*, and the *Symbranchidæ*.

The regions to which the Indian has least similarity are the North American and the Antarctic, as they are the most distant. Its affinity to the other regions is of very different degrees:—

1. Its affinity to the Europo-Asiatic region is very slight, and is indicated almost solely by three groups of Cyprinoids, viz., the *Cyprinina*, *Abramidina*, and *Cobitidina*. The development of these groups north and south of the Himalayas is due to their common origin in the highlands of Asia; but the forms which descended into the tropical climate of the south are now so different from their northern brethren that most of them are referred to distinct genera. The only genera which are still common to both regions are (1) the true barbels (*Barbus*), a genus which of all Cyprinoids has the largest range over the Old World, and of which some one hundred and sixty species have been described, and (2) the mountain barbels (*Schizothorax*, &c.), which, peculiar to the alpine waters of Central Asia, descend a short distance only towards the tropical plains, but extend farther into rivers within the northern temperate districts. The origin and the laws of the distribution of the *Cobitidina* appear to have been identical with those of *Barbus*, but they have not spread into Africa.

2. There exists a great affinity between the Indian and African regions; seventeen out of the twenty-six families or groups found in the former are represented by one or more species in Africa, and many of the African species are not even generically different from the Indian. As the majority of these groups have many more representatives in India than in Africa, we may reasonably assume that the African species have been derived from the Indian stock; but probably this is not the case with the Siluroid group of *Clariina*, which with regard to species is nearly equally distributed between the two regions, the African species being referable to three genera (*Clarias*, *Heterobranchus*, *Gymnallabes*, with the sub-genus *Channallabes*), whilst the Indian species belong to two genera only, viz., *Clarias* and *Heterobranchus*. On the other hand, the Indian region has derived from Africa one freshwater form only, viz., *Etroplus*, a member of the family of *Chromides*, so well represented in tropical Africa and South America. *Etroplus* inhabits southern and western India and Ceylon, and has its nearest ally in a Madagascar freshwater fish, *Paretroplus*. Considering that other African *Chromides* have acclimatized themselves at the present day in saline water, we think it more probable that *Etroplus* should have found its way to India through the ocean than over the connecting land area, where, besides, it does not occur.

3. No closer affinity exists between the Indian and Tropical American regions than is indicated by the character of the equatorial zone generally. With two exceptions, no genus of freshwater fishes occurs in India and South America without being found in the intermediate African region. Four small Indian Siluroids (*Sisor*, *Erethistes*, *Pseudecheneis*, and *Exostoma*) have been referred to the South American *Hypostomatina*; but it remains to be seen whether this combination is based upon a sufficient agreement of their internal structure, or whether it is not rather artificial. On the other hand, the occurrence and wide distribution in tropical America of a fish of the Indian family *Symbranchidæ* (*Symbranchus marmoratus*), which is not only congeneric with, but also most closely allied to, the Indian *Symbranchus bengalensis*, furnishes one of those extraordinary anomalies in the distribution of animals of which no satisfactory explanation can at present be given.

4. The relation of the Indian to the Tropical Pacific region consists only in its having contributed a few species to the poor fauna of the latter. This immigration must have taken place within a recent period, because some species now inhabit the fresh waters of tropical Australia and the South Sea Islands without having in any way changed their specific characters, as *Lates calcarifer*, species of *Dules*, *Plotosus anguillaris*; others (species of *Arius*) differ but little from their Indian congeners. All these fishes must have migrated by the sea, a supposition which is supported by what we know of their habits. We need not add that India has not received a single addition to its freshwater fish fauna from the Pacific region.

It may be mentioned, before concluding these remarks on the Indian region, that peculiar genera of Cyprinoids and Siluroids inhabit the streams and lakes of its alpine ranges in the north. Some of them, like the Siluroid genera *Glyptosternum*, *Euglyptosternum*, *Pseudecheneis*, have a folded disk on the thorax between their horizontally spread pectoral fins; by means of this they adhere to stones at the bottom of the mountain torrents, and without it they would be swept away into the lower courses of the rivers. The Cyprinoid genera inhabiting similar localities and the lakes into which alpine rivers pass,—such as *Oreinus*, *Schizothorax*, *Ptychobarbus*, *Schizopygopsis*, *Diptychus*, *Gymnocypris*,—are distinguished by peculiarly enlarged scales near the vent, the physiological use of which has not yet been ascertained. These alpine genera extend far into the Europo-Asiatic region, where the climate is similar to that of their southern home. No observations have been made by which the altitudinal limits of fish life in the Himalayas can be fixed, but it is probable that it reaches the line of perpetual snow, as in the European Alps, which at that height are inhabited by Salmonoids. Griffith found an *Oreinus* and a loach, the former in abundance, in the Helmund at Gridun Dewar, altitude 10,500 feet, and another loach at Kaloo at 11,000 feet.

The *African Region* comprises the whole of the African continent south of the Atlas and the Sahara. It might have been conjectured that the more temperate climate of its southern extremity would have been accompanied by a conspicuous difference in the fish fauna. But this is not the case; the difference between the tropical and southern parts of Africa consists simply in the gradual disappearance of specifically tropical forms, whilst Siluroids, Cyprinoids, and even *Labyrinthici* penetrate to its southern coast; no new form has entered to impart to South Africa a character distinct from the central portion of the continent. In the north-east the African fauna passes the Isthmus of Suez and penetrates into Syria; the system of the Jordan presents so many African types that it has to be included in a description of the African region as well as of the Europo-Asiatic. This river is inhabited by three species of *Chromis*, one of *Hemichromis*, and *Clarias macracanthus*, a common fish of the upper Nile. Madagascar clearly belongs to this region. Besides some gobies and *Dules*, which are not true freshwater fishes, four *Chromides* are known. To judge from general accounts, its freshwater fauna is poorer than might be expected; but, singular as it may appear, collectors have hitherto paid but little attention to the freshwater fishes of this island. The fishes found in the freshwaters of the Seychelles and Mascarenes are brackish-water fishes, such as *Fundulus*, *Haplochilus*, *Elops*, *Mugil*, &c.

Out of the 40 families or groups of freshwater fishes 15 are represented in the African region, or three more than in the Indian region; of two of them, however, viz., the *Ophiocephalidæ* and *Mastacembelidæ*, a few species only have found their way into Africa. On the other hand, the number of species is much less, viz., 255, being only two-fifths of the known Indian species. The small degree of specialization and localization is principally due to the greater uniformity of the physical conditions of this continent, and to the almost perfect continuity of the great river systems, which take their origin from the lakes in its centre. This is best shown by a comparison of the fauna of the upper Nile with that of the West African rivers. The number of species known from the upper Nile amounts to 56, and of these not less than 25 are absolutely identical with West African species. There is an uninterrupted continuity of the fish fauna from the west to the north-east, and the species known to be common to both extremities may be reasonably assumed to inhabit also the great reservoirs of water in the centre of the continent. A greater dissimilarity is noticeable between the west and north-east fauna on the one hand and that of the Zambezi on the other; the affinity between them is merely generic, and all the fishes hitherto collected in Lake Nyassa have proved to be distinct from those of the Nile, and even from those of other parts of the system of the Zambezi.

Unlike India, Africa does not possess either alpine ranges or outlying archipelagoes, the fresh waters of which would swell the number of its indigenous species; but, when its fauna becomes better known than at present, the great difference in the number of species between this and the Indian regions may possibly be somewhat lessened.

The most numerously represented families are the Siluroids, with 61 species; the Cyprinoids, with 52; the *Mormyridæ*, with 51; the *Characinidæ*, with 35; and the *Chromides*, with 29. There is not, therefore, that great preponderance of the first two families over the rest which we noticed in the Indian region; in Africa there is a comparatively greater variety of distinct freshwater types, making the study of its fauna an unflagging pleasure such as is scarcely reached in the study of the other region. With the forms peculiar to it there are combined those of India as well as of South America.

In tropical Africa there are still remnants of Ganoids,—*Protopterus* (*Lepidosiren*) *annectens* and *Polypterus bichir*, with the singularly modified *Calamoichthys*. The first two range from east to west, and are accompanied by an Osteoglossoid (*Heterotis*), which has hitherto been found in the Nile and on the west coast only. Autochthonous and limited to this region are the *Mormyridæ*, *Pantodontidæ*, and *Kneriidæ*, a singular type somewhat akin to the loaches. Of Siluroid genera the most characteristic are *Synodontis*, *Rhinoglanis*, and the electric *Malapterurus*; of Characinoids, *Citharinus*, *Alestes*, *Xenocharax*, *Hydrocyon*, *Distichodon*, *Ichthyborus*.

The regions to which Africa (like India) has least similarity are again the North American and Antarctic. Its affinity with the Europo-Asiatic region consists only in its having received, like the latter, a branch of the Cyprinoids, the African carps and barbels, which on the whole resemble Indian more than Europo-Asiatic forms. Its similarity to Australia is limited to the two regions possessing Dipnoous and Osteoglossoid types. But its relations to the other two regions of the equatorial zone are near and of great interest.

1. Africa has in common with India the Siluroid groups of the *Clariina*, *Silurina*, and *Bagrina*, and more especially the small but very natural family of *Notopteridæ*, represented by three species in India, and by two on the west coast of Africa. It would be hazardous to state at present in which of the two regions these fishes first made their appearance, but the discovery of remains of *Notopteridæ* and *Silurina* in Tertiary deposits of Sumatra points to the Indian region as their original home. We are in less doubt about the other fishes common to the two regions; they are clearly immigrants into Africa from the east, and it is a remarkable fact that these immigrants have penetrated to the most distant limits of Africa in the west as well as in the south, viz., the *Labyrinthici*, represented by two genera closely allied to the Indian *Anabas*; the *Ophiocephalidæ* and *Mastacembelidæ*, a few species of which have penetrated to the west coast, while, singularly enough, they are absent from the eastern rivers; the *Ariina*, represented by several species, of which one or two are identical with Indian, having extended their range along the intervening coasts to the east coast of Africa. The Cyprinoids also afford an instance of an Indian species ranging into Africa, viz., *Discognathus lamta*, which seems to have crossed at the southern extremity of the Red Sea, as it is found in the reservoirs at Aden and in the hill-streams of the opposite coast-region of Abyssinia.

2. No such direct influx of species and genera has occurred from South America into Africa, yet the affinity of their freshwater fishes is striking. Two of the most natural families of fishes, the *Chromides* and *Characinidæ*, are peculiar and (with the exception of *Etroplus*) restricted to them. The African and South American *Dipnoi* are closely allied to each other. The *Pimelodina*, so characteristic of tropical America, have three representatives in Africa, viz., *Pimelodus platychir*, *P. balayi*, and *Auchenoglanis biscutatus*; the *Doradina* are another Siluroid group restricted to these two continents.[1] Yet, with all these points of close resemblance, the African and South American series are, with the exception of the two species of *Pimelodus*, generically distinct,—which shows that the separation of the continents must have been of old date. On the other hand, the existence of so many similar forms on both sides of the Atlantic affords much support to the supposition that at a former period the distance between the present Atlantic continents was much less, and that the fishes which have diverged towards the east and west are descendants of a common stock which had its home in a region now submerged under some intervening part of that ocean. Be this as it may, it is evident that the physical conditions of Africa and South America have remained unchanged for a considerable period, and are still sufficiently alike to preserve the identity of a number of peculiar freshwater forms on both sides of the Atlantic. Africa and South America are, moreover, the only continents which have produced in freshwater fishes, though in very different families, one of the most extraordinary modifications of an organ—the conversion, that is, of muscle into an apparatus creating electric force.

The boundaries of the *Neotropical* or *Tropical American Region* have been sufficiently indicated in the definition of the equatorial zone. A broad and most irregular band of country, in which the South and North American forms are mixed, exists in the north, offering some peculiarities which deserve fuller attention in the subsequent description of the relations between the South and North American faunæ.

Out of the 40 families or groups of freshwater fishes, 9 only are represented in the tropical American region. This may be accounted for by the fact that South America is too much isolated from the other regions of the equatorial zone to have received recent additions to its fauna. On the other hand, the number of species (672) exceeds that of every other region, even of the Indian, with which, in regard to the comparative development of families, the neotropical region shows a close analogy, as will be seen from the following table:—

Indian.—Siluridæ, 200 species; Cyprinidæ, 330; Labyrinthici, 25; Ophiocephalidæ, 30; Mastacembelidæ, 10.

Neotropical.—Siluridæ, 276 species; Characinidæ, 226; Chromides, 80; Cyprinodontidæ, 60; Gymnotidæ, 20.

In both regions the great number of species is due to the development of numerous local forms of two families, the *Characinidæ* in the New World taking the place of the *Cyprinidæ* of the Old. To these are added a few smaller families with a moderately large number of species, which, however, is only a fraction of that of the leading families, the remainder being represented by a few species only. The number of genera within each of the two regions belonging to the two principal families is also singularly alike; the Indian region having produced about 45 Siluroid and as many Cyprinoid genera, whilst the Neotropical region is tenanted by 54 Siluroid and 40 Chara-

[1] We have left out of consideration here the *Ariina* and Cyprinodonts, which can pass with impunity through salt water, and are spread over much larger areas.

cinoid genera. These points of similarity between the two regions cannot be accidental; they indicate that agreement in their physical and hydrographical features which in reality exists. Of Ganoids, we find in tropical America one species only, *Lepidosiren paradoxa*, accompanied by two Osteoglossoids (*Osteoglossum bicirrhosum* and *Arapaima gigas*). Autochthonous and limited to this region are the *Polycentridæ*; all the non-African genera of *Chromides* and *Characinidæ*; of Siluroids, the *Hypophthalmina*, *Aspredinina*, and *Stegophilina*, and the majority of *Pimelodina*, *Hypostomatina*, and *Doradina*; the herbivorous Cyprinodonts or *Limnophagæ*, and numerous insectivorous Cyprinodonts or *Carnivoræ*; and the *Gymnotidæ* (electric eel).

The relations to the other regions are as follows:—

1. The resemblances to the Indian and Tropical Pacific regions partly date from remote geological epochs, or are partly due to that similarity of physical conditions to which we have already referred. We have again to draw attention to the unexplained presence in South America of a representative of a truly Indian type (not found in Africa), viz., *Symbranchus marmoratus*. On the other hand, a direct genetic affinity exists between the Neotropical and African regions, as has been noticed in the description of the latter, a great part of their freshwater fauna consisting of descendants from a common stock.

2. A comparison of the specifically Neotropical with the specifically North American types shows that no two regions can be more dissimilar. It is only in the intervening borderland, and in the large West Indian islands, that the two faunæ mix with each other. We need not enter into the details of the physical features of Central America and Mexico; the broken ground, the diversity of climate (produced by different altitudes) within limited districts, the hot and moist alluvial plains surrounding the Mexican Gulf, offer a variety of conditions most favourable to the intermixture of the types from the north and the south. Still the interchange of peculiar forms appears to be only beginning; none have yet penetrated beyond the debateable ground, and it is evident that the land connexion between the two continents is of comparatively recent date,—a view which is confirmed by the identity of the marine fishes on both sides of Central America.

Cuba—which is the only island in the West Indies that has a number of freshwater fishes sufficient for the determination of its zoo-geographical relations—is inhabited by several kinds of a perch (*Centropomus*), freshwater mullets, Cyprinodonts, one species of Chromid (an *Acara*), and *Symbranchus marmoratus*. All these fishes are found in Central America, and, as they belong to forms known to enter brackish water more or less freely, it is evident that they have crossed either from that region or from the mainland of South America. But with them there came a remarkable North American type, *Lepidosteus*. *Lepidosteus viridis*, which is found in the United States, has penetrated on the mainland to the Pacific coast of Guatemala, where it is common at the mouth of the rivers and in brackish-water lakes along the coast; it probably crossed into Cuba from Florida. A perfectly isolated type of fishes inhabits the subterranean waters in the caves of Cuba (two species of *Lucifuga*). The eyes are absent, or quite rudimentary, as in most other cave animals. Singularly, it belongs to a family (*Ophidiidæ*) the members of which are strictly marine; and its nearest ally is a genus, *Brotula*, the species of which are distributed over the Indo-Pacific Ocean, one only occurring in the Caribbean Sea. This type must have witnessed all the geological changes which have taken place since Cuba rose above the surface of the sea. A similar mixture of forms of the tropical and temperate types of freshwater fishes takes place in the south of South America; its details have not yet been so well studied as in the north, but this much is evident, that, whilst in the east tropical forms follow the Plate river far into the temperate region, in the west the temperate fauna finds still a congenial climate in ranges of the Andes, situated close to, or even north of, the tropic.

Like the Indian region, the Tropical American has a peculiar alpine fauna, the freshwater fishes of which, however, belong to the Siluroids and Cyprinodonts. The former are small, dwarfed forms (*Arges*, *Stygogenes*, *Brontes*, *Astroblepus*, *Trichomycterus*, *Eremophilus*), and have a perfectly naked body, whilst the representatives in the lowlands of at least the first four genera are mailed. The alpine Cyprinodonts, on the other hand (*Orestias*), exceed the usual small size of the other members of this family, and are covered with thick scales, but have lost their ventral fins. Some of these alpine forms, like *Trichomycterus*, follow the range of the Andes far into the Southern Temperate region. The majority are found at a height of 15,000 feet above the level of the sea, and a few still higher.

The *Tropical Pacific Region* includes all the islands east of Wallace's line, New Guinea, Australia (with the exception of its south-eastern portion), and all the islands of the tropical Pacific to the Sandwich group. Comparing the area of this region with that of the others, we find it to be the poorest, not only in point of the number of its species generally (36), but also in the possession of peculiar forms. The paucity of freshwater fishes is due, in the first place, to the arid climate and the deficiency of water in the Australian continent, as well as to the insignificant size of the freshwater courses in the smaller islands. Still this cannot be the only cause; the large island of Celebes, which, by its mountainous portions, as well as by its extensive plains and lowlands, would seem to offer a favourable variety of conditions for the development of a freshwater fauna, is, so far as has been ascertained, tenanted by seven freshwater fishes only, viz., 2 *Arius*, 2 *Plotosus*, 1 *Anabas*, 1 *Ophiocephalus*, 1 *Monopterus*, all of which are the commonest species of the Indian region. New Guinea has not yet been explored, but, from the faunæ nearest to this island, we expect its freshwater fishes will prove to be equally few in number, and identical with those of Celebes and North Australia,—a supposition confirmed by the few small collections which have reached Europe. Finding, then, that even those parts of this region which are favourable to the development of freshwater fishes have not produced any distinct forms, and that the few species which inhabit them are unchanged or but slightly modified Indian species, we must conclude that the whole of this area has remained geologically isolated from the other regions of this zone since the commencement of the existence of *Teleostei*, and that, with the exception of *Ceratodus* and *Osteoglossum*, the immigration of the other species is of very recent date.

Fossil remains of *Ceratodus* have been found in the Liassic and Triassic formations of North America, England, Germany, and India; it is, therefore, a type which was widely spread in the Mesozoic epoch. Although it would be rash to conclude that its occupation of Australia dates equally far back, for it may have reached that continent long afterwards, yet it is evident that, as it is one of the most ancient of the existing types, so it is certainly the first of the freshwater fishes which appeared in Australia. *Osteoglossum*, of which no fossil remains have yet been found, is proved by its distribution to be one of the oldest Teleosteous types. There must have been a long gap of time before these ancient types were joined by the other *Teleostei*. All of them migrated through the intervening parts of the ocean from India. Most of the *Plotosina*, some of the *Arii*, *Dules*, and *Atherinichthys*, also *Nannoperca* (allied to *Apogon*), were among the earliest arrivals, being sufficiently differentiated to be specifically or even generically (*Cnidoglanis*, *Nannoperca*) distinguished; but some others, like *Anabas scandens*, *Lates calcarifer*, *Dules marginatus*, must have reached the Australian continent quite recently, for they are undistinguishable from Indian specimens.

In south-western Australia a mingling of the scanty fauna with that of the southern temperate parts takes place. *Oligorus macquariensis* (the Murray cod), which has a congener on the coast of New Zealand, ascends high up the Murray river, so that we cannot decide whether this Percoid should be located in the tropical or the temperate part of Australia. Several *Galaxias* also extend to the confines of Queensland, and will probably some day be found members of this region.

In the smaller Pacific islands the freshwater fishes exhibit a remarkable sameness ; they comprise two or three species of *Dules*, several eels, an atherine, and some gobies, mullets, and other fishes which with equal readiness exchange fresh for salt water, and which would at once reach and occupy any streams or freshwater lakes that might be formed on an island.

The Sandwich Islands are the only group among the smaller islands which are tenanted by a Siluroid, a species of *Arius*, which is closely allied to Central American species, and therefore probably migrated from tropical America.

NORTHERN ZONE.—The boundaries of the northern zone coincide in the main with the northern limit of the equatorial zone ; but, as has been already indicated, they overlap the latter at three different points. This happens in Syria, as well as east of it, where the mixed faunæ of the Jordan and the rivers of Mesopotamia demand the inclusion of this territory in the northern zone as well as in the equatorial ; in the island of Formosa, where a Salmonoid and several Japanese Cyprinoids flourish ; and in Central America, where a *Lepidosteus*, a Cyprinoid (*Sclerognathus meridionalis*), and an *Amiurus* (*A. meridionalis*) represent the North American fauna in the midst of a host of tropical forms.

There is no separate arctic zone for freshwater fishes; ichthyic life becomes extinct towards the pole wherever the fresh water remains frozen throughout the year, or thaws for a few weeks only ; and the few fishes which extend into high latitudes, in which lakes are open for two or three months in the year, belong to types in no wise differing from those of the more temperate south. The highest latitude at which fishes have been obtained is 82° N. lat., whence the late Arctic Expedition brought back specimens of charr (*Salmo arcturus* and *Salmo naresii*).

The ichthyological features of this zone are well marked. The Chondrosteous Ganoids or sturgeons, and the families of *Salmonidæ* and *Esocidæ*, are limited to and characteristic of it; Cyprinoids flourish with the Salmonoids, both families preponderating in numbers over the others, whilst the Siluroids are few in number and in variety.

The two regions into which this zone is divided are very closely related to one another, and their affinity is not unlike that which obtains between the sub-regions of the southern zone. Several species are common to both, viz., *Acipenser sturio, A. maculatus, Perca fluviatilis, Gastrosteus pungitius, Salmo salar, Esox lucius, Lota vulgaris, Petromyzon marinus, P. fluviatilis*, and *P. branchialis* ; and all recent investigations have resulted in giving additional evidence of the affinity and not of the diversity of the two regions.

In Europe and temperate Asia, as well as in North America, mountain ranges elevated above the line of perpetual snow would seem to offer physical conditions favourable for the development of a distinct alpine fauna. But this is not the case, because the difference of climate between the mountain districts and the lowlands is much less in this zone than in the equatorial. Consequently the alpine freshwater fishes do not essentially differ from those of the plains ; they are principally Salmonoids, and in Asia there are also mountain-barbels and loaches. *Salmo orientalis* was found by Griffith to abound in the tributaries of the Bamian river at an altitude of about 11 000 feet.

The Palæarctic or *Europo-Asiatic Region.*—The western and southern boundaries of this region coincide with those of the northern zone, so that only those which divide it from North America need to be indicated. Behring's Strait and the Kamtchatka Sea have been conventionally taken as the boundary, but this is shown to be artificial by the fact that the animals of both coasts, so far as they are known at present, are not sufficiently distinct to be referred to two different regions. As to the freshwater fishes, those of north-western America and of Kamtchatka are but imperfectly known, but there can be little doubt that the same agreement exists between them as is the case with other classes of animals. The Japanese islands exhibit a decided Palæarctic fish fauna, which includes *Barbus* and Cobitioids, forms strange to the North American fauna. A slight influx of tropical forms is perceived in the south of Japan, where two *Bagrina* (*Pseudobagrus aurantiacus* and *Liocassis longirostris*) have established themselves for a considerable period, for both are peculiar to the island, and have not been found elsewhere.

In the east, as well as in the west, the distinction between the Europo-Asiatic and the North American regions disappears almost entirely as we advance farther towards the north. Of four species of the genus *Salmo* known from Iceland, one (*S. salar*) is common to both regions, two are European (*S. fario* and *S. alpinus*), and one is a peculiarly Icelandic race (*S. nivalis*). So far as we know the Salmonoids of Greenland and the tract adjoining Baffin's Bay, they are all very closely allied to European species, though they may be distinguished as local races.

Finally, as we have seen above, the Europo-Asiatic fauna mingles with African and Indian forms in Syria, Persia, and Afghanistan. *Capoeta*, a Cyprinoid genus, is characteristic of this district, and well represented in the Jordan and the rivers of Mesopotamia. Out of the 40 families of freshwater fishes 13 are represented in this region; the number of species is comparatively small, viz., 360.

Assuming that the distribution of Cyprinoids has taken its origin from the alpine tract of country dividing the Indian and Palæarctic regions, we find that this type has found in the temperate region as favourable conditions for its development as in the tropical. Out of the 360 species no less than 215 are Cyprinoids. In the countries and on the plateaus immediately adjoining the Himalayan ranges those mountain forms which we mentioned as peculiar to the Indian Alps abound, and extend for a considerable distance towards the west and east, mixed with other *Cyprinina* and *Cobitidina*. The representatives of these two groups are more numerous in Central and Eastern Asia than in Europe and the northern parts of Asia, where the *Leuciscina* predominate. *Abramidina* or breams are more numerous in the south and east of Asia, but they spread to the extreme north-western and northern limits to which the Cyprinoid type reaches. The *Rhodeina* are a small family especially characteristic of the East, but with one or two offshoots in Central Europe. Very significant is the appearance in China of a species of the *Catostomina*, a group otherwise limited to North America.

The Cyprinoids, in their dispersal northwards from the south, are met from the opposite direction by the freshwater Salmonoids. These fishes are, without doubt, one of the youngest families of *Teleostei*, for they did not appear before the Pliocene era; they flourished at any rate during the Glacial period, and, as is testified by the survivors which we find in isolated elevated positions, like the trout of the Atlas, of the mountains of Asia Minor, and of the Hindu Kush, they spread to the extreme south of this region. At the present day they are most numerously represented in its northern temperate parts; towards the south they become fewer, but increase again in numbers and species wherever a great elevation offers them the snow-fed waters which they affect. In the rivers of the Mediterranean, Salmonoids are by no means rare, but they prefer the upper courses of those rivers, and do not migrate to the sea, with the exception, perhaps, of some species in the rivers of the North Adriatic.

The pike, *Umbra*, and several species of perch and stickleback are also clearly autochthonous species of this region. Others belong to marine types, and seem to have been retained in fresh water at various epochs,—as the freshwater *Cottus* (miller's thumb); *Cottus quadricornis*, which inhabits lakes of Scandinavia, whilst other individuals of the same species are strictly marine; the burbot (*Lota vulgaris*); and the singular *Comephorus*, a dwarfed and much changed Gadoid which inhabits the greatest depths of Lake Baikal.

Remnants of the Palæichthyic fauna exist in the sturgeons and lampreys. The former inhabit in abundance the great rivers of eastern Europe and Asia, periodically ascending them from the sea; their southernmost limits are the Yang-tse-Keang in the east, and towards the centre of this region the rivers flowing into the Adriatic, Black, and Caspian Seas, and Lake Aral. None are known to have gone beyond the boundaries of the northern zone. If the lampreys are justly reckoned among freshwater fishes, their distribution is unique and exceptional. In the Palæarctic region some of the species descend periodically to the sea, whilst others remain stationary in the rivers; the same has been observed in the lampreys of North America. They are entirely absent in the equatorial zone, but reappear in the temperate zone of the southern hemisphere. Many points in the organization of the Cyclostomes indicate that they are a type of great antiquity.

The remaining Palæarctic fishes are clearly immigrants from neighbouring regions: thus *Silurus*, *Macrones*, and *Pseudobagrus* have migrated from the Indian region, *Amiurus* and, as mentioned above, *Catostomus* from North America. The Cyprinodonts are restricted to the southern and warmer parts, and all belong to the carnivorous division. The facility with which these fishes accommodate themselves to a sojourn in fresh, brackish, or salt water, and even in thermal springs, renders their general distribution easily comprehensible, but it is impossible to decide to which region they originally belonged; their remains in Tertiary deposits round the Mediterranean are not rare.

The boundaries of the *North American* or *Nearctic Region* have been sufficiently indicated. The main features and the distribution of this fauna are identical with those of the preceding region. Out of the 40 families of freshwater fishes 19 are found in this region. The proportion of Cyprinoid species to the total number of North American fishes (135 : 339) appears to be considerably less than in the Palæarctic region, but we cannot admit that these figures approach the truth, as the Cyprinoids of North America have been much less studied than those of Europe; of many scarcely more than the name is known. This also applies in a great measure to the Salmonoids, of which only half as many as are found in the Palæarctic region have been sufficiently described to be worthy of consideration. North America will, without doubt, in the end show as many distinct races as Europe and Asia.

Cyprinoids belonging to living as well as extinct genera existed in North America in the Tertiary period. At present the *Cyprinina*, *Leuciscina*, and *Abramidina* are well represented, but there is no representative of the Old World genus *Barbus*, or of the *Cobitidina*;[1] *Rhodeina* are also absent. On the other hand, a well-marked Cyprinoid type is developed—the *Catostomina*, of which one species has, as it were, returned into Asia. Very characteristic is the group of *Centrarchina*, allied to the perch, of which there are some thirty species; there are two *Grystina*. Of the sticklebacks there are as many species as in Europe, and of pike not less than seven species have been distinguished. *Umbra* appears to be as local as in Europe. Some very remarkable forms, types of distinct families, though represented by one or two species only, complete the number of North American autochthonous fishes, viz., *Aphredoderus*, *Percopsis*, *Hyodon*, and the *Heteropygii* (*Amblyopsis* and *Chologaster*). The last are allied to the Cyprinodonts, differing from them in some points of the structure of their intestines. The two genera are extremely similar, but *Chologaster*, which is found in ditches in the rice-fields of South Carolina, is provided with eyes, and wants the ventral fins. *Amblyopsis* is the celebrated blind fish of the Mammoth Cave of Kentucky; it is colourless and eyeless, and has rudimentary ventral fins, which occasionally may be entirely absent.

A peculiar feature of the North American fish fauna is that it has retained, besides the sturgeons and lampreys, representatives of two Ganoid families, *Lepidosteus* and *Amia*. Both these genera occur in Tertiary formations; whilst the former is represented in Europe as well as in North America, fossil remains of *Amia* have been found in the western hemisphere only.

It is difficult to account for the presence of the *Amiurina* in North America. They form a well-marked division of the *Bagrina*, which are well represented in Africa and the East Indies, but are absent in South America; it is evident, therefore, that they should not be regarded as immigrants from the south, as is the case with the Palæarctic Siluroids. Nor again, has the connexion between South and North America been established sufficiently long to admit of the supposition that these Siluroids could have spread in the interval from the south to the northern parts of the continent, for some of the species are found as far north as Pine Islands Lake (54° N. lat.).[2]

Southern Zone.—The boundaries of this zone have been indicated in the description of the equatorial zone; they overlap the southern boundaries of the latter in South Australia and South America, but we have not at present the means of exactly defining the limits to which southern types extend northwards. This zone includes Tasmania, with at least a portion of south-eastern Australia (*Tasmanian sub-region*), New Zealand and the Auckland Islands (*New Zealand sub-region*), and Chili, Patagonia, Tierra del Fuego, and the Falkland Islands (*Fuegian sub-region*). No freshwater fishes are known from Kerguelen's Land, or from islands beyond 55° S. lat. The southern extremity of Africa has to be excluded from this zone so far as freshwater fishes are concerned.

With regard to its extent as well as to the number of species, this zone is the smallest of the three, the number of species known being 11 in the Tasmanian, 8 in the New Zealand, and 18 in the Fuegian sub-region. Yet the ichthyological features of this zone are well marked; they consist in the presence of two peculiar families, each of which is analogous to a northern type, viz., the *Haplochitonidæ*, which represent the *Salmonidæ* (*Haplochiton* being

[1] Cope has discovered in a Tertiary freshwater deposit at Idaho an extinct genus of this group, *Diastichus*. He considers this interesting fact to be strongly suggestive of continuity of territory between Asia and North America.—*Proc. Am. Phil. Soc.*, 1873, p. 55.

[2] Leidy describes a Siluroid (*Pimelodus*) from the Tertiary deposits of Wyoming territory.—*Contrib. to the Extinct Vert. Fauna of the Western Territ.*, 1873, p. 193.

the analogue of *Salmo*, and *Prototroctes* that of *Coregonus*), and the *Galaxiidæ*, which are the pikes of the southern hemisphere.

Although geographically widely separate from each other, the freshwater fishes of the three divisions are nevertheless so closely allied that conclusions drawn from this group of animals alone would hardly justify us in regarding these divisions as sub-regions. One species of *Galaxias* (*G. attenuatus*) and three of lampreys are found in all three, or at least in two of the sub regions. *Percichthys* is in Chili the autochthonous form of the cosmopolitan group of *Percina*. *Diplomystax*, an Arioid fish of Chili, and *Nematogenys* seem to have crossed the Andes from tropical America at a comparatively early period, as these genera are not represented on the eastern side of South America; *Trichomycterina* occur on both sides of the Andes, which they ascend to a considerable height. *Retropinna* is a true Salmonoid, allied to the northern smelt (*Osmerus*), and representing it in the southern hemisphere. In both these genera part of the specimens live in the sea, and ascend rivers periodically to spawn; another part remain in rivers and lakes, where they propagate, never descending to the sea, this freshwater race being constantly smaller than their marine brethren. That this small Teleostean of the northern hemisphere should reappear, though in a generically modified form, in New Zealand, without having spread over other parts of the southern zone, is one of the most remarkable and at present inexplicable facts of the geographical distribution of freshwater fishes.

Brackish-Water Fishes.

On those parts of a coast at which there is a mixture of fresh and salt water, either in consequence of some river emptying itself into the sea, or from accumulations on the land-surface forming lagoons which are in uninterrupted or temporary communication with the sea, there flourishes a peculiar brackish-water fauna characterized by the presence of fishes found sometimes in the sea, and sometimes in pure fresh water.

This fauna can be somewhat sharply defined if a limited district only is taken into consideration; thus, the species of the brackish-water fauna of Great Britain, of the Pacific coast of Central America, of the larger East India islands, &c., can be enumerated without much hesitation. But difficulties occur when we attempt to generalize in the enumeration of the forms referable to the brackish-water fauna, because the genera and families enumerated include certain species and genera which have habituated themselves exclusively either to a freshwater or a marine existence, and also because a species of fish may be at one locality an inhabitant of brackish water, at another of the sea, and at a third of fresh water. The circumstance that these fishes can live either in the sea or in fresh water has enabled them to spread readily over the globe, a few only being limited to particular regions; in dividing the earth's surface into natural zoological regions, therefore, the taxonomist receives no assistance from the brackish-water forms. The following fishes may be referred to this fauna:—

1. Species of *Raiidæ* (*Raia*, *Trygon*). 2. *Ambassis*. 3. *Therapon*. 4. Numerous *Sciænidæ* of the equatorial zone. 5. *Polynemidæ*. 6. Numerous species of *Caranx* (or horse mackerels) of the equatorial zone. 7. Species of *Gastrosteus*. 8. The most important genera of the gobies (*Gobiina*); *Gobius* (nearly cosmopolitan), *Sicydium*, *Boleophthalmus*, *Periophthalmus*, *Eleotris* (equatorial). 9. *Amblyopina*. 10. *Trypauchenina*. 11. Many species of *Blennius*. 12. The majority of *Atherinidæ*. 13. Most *Mugilidæ*. 14. Many *Pleuronectidæ*. 15. Several *Siluridæ*, as especially the genera *Plotosus*, *Cnidoglanis*, *Arius*. 16. Many *Cyprinodontidæ*. 17. Species of *Clupea*. 18. *Chatoessus*. 19. *Megalops*. 20. *Anguilla* (eels). 21. Numerous *Syngnathidæ*.

This list could be considerably increased if an enumeration of species, especially of certain localities, were attempted; but this is more a subject of local interest, and would carry us beyond the scope of a general account of the distribution of fishes.

Marine Fishes.

Marine fishes fall, with regard to their mode of life and distribution, into three distinct categories:—

1. *Shore Fishes*—that is, fishes which chiefly inhabit parts of the sea in the immediate neighbourhood of land either actually raised above, or at least but little submerged below, the surface of the water. They do not descend to any great depth,—very few to 300 fathoms, and the majority live close to the surface. The distribution of these fishes is determined, not only by the temperature of the surface water, but also by the nature of the adjacent land and its animal and vegetable products,—some being confined to flat coasts with soft or sandy bottoms, others to rocky and fissured coasts, others to living coral formations. If it were not for the frequent mechanical and involuntary removals to which these fishes are exposed, their distribution within certain limits, as it no doubt originally existed, would resemble still more that of freshwater fishes than we find it actually does at the present period.

2. *Pelagic Fishes*—that is, fishes which inhabit the surface and uppermost strata of the open ocean, and approach the shores only accidentally, or occasionally (in search of prey), or periodically (for the purpose of spawning). The majority spawn in the open sea, their ova and young being always found at a great distance from the shore. With regard to their distribution, they are still subject to the influences of light and the temperature of the surface water; but they are independent of the variable local conditions which tie the shore fish to its original home, and therefore roam freely over a space which would take a freshwater or shore fish thousands of years to cover in its gradual dispersal. Such as are devoid of rapidity of motion are dispersed over similarly large areas by the oceanic currents, more slowly than the strong swimmers, but not less surely. An accurate definition, therefore, of their distribution within certain areas equivalent to the terrestrial regions is much less feasible than in the case of shore fishes.

3. *Deep-Sea Fishes*—that is, fishes which inhabit such depths of the ocean that they are but little or not at all influenced by light or the surface temperature, and which, by their organization, are prevented from reaching the surface stratum in a healthy condition. Living almost under identical tellurian conditions, the same type, the same species, may inhabit an abyssal depth under the equator as well as one near the arctic or antarctic circle; and all that we know of these fishes points to the conclusion that no separate horizontal regions can be distinguished in the abyssal fauna, and that no division into bathymetrical strata can be attempted on the base of generic much less of family characters.

Chondropterygii, *Acanthopterygii*, Anacanths, Myxinoids, and *Pharyngobranchii* furnish the principal contingents to the marine fauna; whilst the majority of Physostomes, the Ganoids, and Cyclostomes are freshwater fishes.

Shore Fishes.

The principal types of shore fishes are the following:—

CHONDROPTERYGII.—*Holocephala*, 4 species. *Plagiostomata*—Carchariidæ (part), 12; Scylliidæ, 30; Cestraciontidæ, 4; Spinacidæ (part), 8; Rhinidæ, 1; Pristiophoridæ, 4; Pristidæ, 5; Rhinobatidæ, 14; Torpedinidæ, 15; Raiidæ, 34; Trygonidæ, 47.

ACANTHOPTERYGII.—Percidæ (part, includ. Pristipomatidæ), 625 species; Mullidæ, 35; Sparidæ, 130; Squamipinnes, 130; Cirrhitidæ, 40; Heterolepidina, 12; Scorpænidæ, 120; Cottidæ (part), 100; Cataphracti (part), 20; Trachinidæ, 100; Sciænidæ, 100; Sphyrænidæ, 15; Trichiuridæ, 17; Elacate, 1; Nomeidæ (part), 5; Cyttidæ, 8; Stromateus, 9; Mene, 1; Carangidæ (part), 130; Kurtidæ, 7; Gobiodon, 7; Callionymina, 30; Discoboli, 11; Batrachidæ, 14; Pediculati (part), 11; Blenniidæ, 90; Acanthoclinidæ, 1; Teuthididæ, 30; Acronuridæ, 60; Hoplognathidæ, 3; Malacanthidæ, 3; Plesiopina, 4; Trichonotidæ, 2; Cepolidæ, 7; Gobiesocidæ, 21; Psychrolutidæ, 2; Centriscidæ, 7; Fistulariidæ, 4.

ACANTHOPTERYGII PHARYNGOGNATHI. — Pomacentridæ, 150 species; Labridæ, 400; Embiotocidæ, 17.

ANACANTHINI.—Gadopsidæ, 1 species; Lycodidæ, 15; Gadidæ (part), 50; Ophidiidæ (part), 40; Pleuronectidæ, 160.

PHYSOSTOMI.—Saurina (part), 16 species; Salmonidæ (part), 7; Clupeidæ (part), 130; Chirocentridæ, 1; Chilobranchus, 1; Murænidæ (part), 200; Pegasidæ, 4.

LOPHOBRANCHII, 120 species.

PLECTOGNATHI, 178 species.

CYCLOSTOMATA.—*Myxinidæ*, 5 species.

LEPTOCARDII, 2 species.

Total number, 3587 species.

These types of shore fishes are distributed over the following oceanic areas:—

- I. The Arctic Ocean.
- II. The Northern Temperate Zone.
  - A. The Temperate North Atlantic.
    1. The British district.
    2. The Mediterranean district.
    3. The North American district.
  - B. The Temperate North Pacific.
    1. The Kamtchatkan district.
    2. The Japanese district.
    3. The Californian district.
- III. The Equatorial Zone.
  - A. The Tropical Atlantic.
  - B. The Tropical Indo-Pacific.
  - C. The Pacific coast of Tropical America.
    1. The Central American district.
    2. The Galapagos district.
    3. The Peruvian district.
- IV. The Southern Temperate Zone.
    1. The Cape of Good Hope district.
    2. The South Australian district.
    3. The Chilian district.
    4. The Patagonian district.
- V. The Antarctic Ocean.

As with freshwater fishes, the main divisions of the shore-fish faunæ are determined by their distance from the equator, the equatorial zone of the freshwater series corresponding entirely to that of the shore-fish series. But as marine fishes extend farther towards the poles than freshwater fishes, and as the polar types are more specialized, a distinct arctic and antarctic fauna may be separated from the faunæ of the temperate zones. The two subdivisions of the northern temperate zone in the freshwater series are quite analogous to the corresponding divisions in the coast s ries. In the southern hemisphere the shore fishes of the extremity of Africa form a separate district of the temperate zone, whilst the freshwater fishes of South Africa were found to be tropical types. The marine series of the southern temperate zone is also much more diversified than the freshwater series, and admits of further subdivision, which, although in some degree indicated in the freshwater series, does not entirely correspond to that proposed for the latter.

ARCTIC OCEAN.—The shore fishes clearly prove a continuity of the arctic circumpolar fauna, as the southern limit of which we may indicate the southern extremity of Greenland and the Aleutian Archipelago, or 60° N. lat.

Towards the north, fishes become less in variety of species and fewer in number of individuals, and only very few genera are restricted to this fauna.

The highest latitude at which shore fishes have been observed is 83° N. The late Arctic Expedition collected at and near that latitude specimens of *Cottus quadricornis*, *Icelus hamatus*, *Cyclopterus spinosus*, *Liparis fabricii*, *Gymnelis viridis*, and *Gadus fabricii*. The number would probably have been larger were it not that the difficulties of collecting fishes in these high latitudes are almost insuperable for the greater part of the year.

So far as we know, the fishes north and south of Behring's Straits belong to the same generic or family types as those of the corresponding latitudes of the eastern hemisphere, though the majority are specifically distinct. But the information we possess of the fishes of the northernmost extremity of the Pacific is extremely scanty and vague. Farther south, whence now and then a collection reaches Europe, we meet with some European species, as the herring, holibut, and hake.

Chondropterygians are very rare. Of Acanthopterygians the families of *Cottidæ*, *Cataphracti*, *Discoboli*, and *Blenniidæ* are well represented, and several of the genera are characteristic of the arctic fauna. Characteristic also is the development of Gadoid fishes, of which some thirteen species, belonging to *Gadus*, *Merluccius*, and *Molva*, form one of the principal articles of food for the inhabitants of the coasts of the Arctic Ocean. The Blennoid *Anacanthini* or *Lycodidæ* are limited to the Arctic and Antarctic coasts. *Ammodytes* and a few flat-fishes (*Hippoglossoides* and *Pleuronectes*) are common in the more temperate parts. Labroids only exceptionally penetrate so far towards the north. Physostomes are very rare, and are represented only by a few species of *Clupea* and by *Mallotus*. The arctic climate is still less favourable to the existence of Lophobranchs, only a few of *Syngnathus* and *Nerophis* being present in the more southern latitudes, to which they have been carried by oceanic currents from their more congenial home in the south. Sclerodermis and Plectognaths are entirely absent. The Gadoids are accompanied by *Myxine*, which thrives in them as a parasite.

NORTHERN TEMPERATE ZONE.—*Temperate North Atlantic.*—This part of the fauna may be subdivided into three districts:—

1. The fishes of the north-eastern shores, viz., of the British Islands, of Scandinavia so far as it is not included in the arctic fauna, and of the continent of Europe southwards to about 40° N. lat.: British district.

2. The fishes of the Mediterranean shores and of the adjoining shores of the Atlantic, including the Azores, Madeira, and the Canary Islands: Mediterranean district.

3. The fishes of the western shores, from 60° to about 30° N. lat.: North American district.

1. The British district shows scarcely any marked distinctive features; the character of its fauna is simply intermediate between that of the Arctic Ocean and the Mediterranean district; truly arctic forms disappear, while such as are also found in the Mediterranean make their appearance. With regard to the abundance of individuals and variety of fishes also, this district forms a transition from the north towards the south.

Besides the few arctic Chondropterygians, all of which extend into this district, the small shore dog-fishes are well represented (*Mustelus*, *Galeus*, *Scyllium*, *Pristiurus*); the ubiquitous *Rhina* or monk-fish is common; of rays, *Raia* predominates in a variety of species over *Torpedo* and *Trygon*, which are still rare.

Of Acanthopterygians, *Centridermichthys*, *Icelus*, *Triglops*, and *Aspidophoroides* do not extend from the north into this district; and *Cottus*, *Anarrhichas*, *Centronotus*, *Stichæus*, and the *Discoboli* disappear within its limits. Nearly all the remainder are genera which are also found in the Mediterranean district. The following are the principal forms known to propagate on these shores: *Labrax*; *Serranus*, *Polyprion*, *Dentex*; *Mullus*; *Cantharus*, *Pagrus*, *Pagellus*; *Sebastes*; *Cottus*, *Trigla*, *Agonus*; *Trachinus*; *Sciæna* (?); *Zeus*; *Trachurus*, *Capros*; *Callionymus*; *Discoboli*; *Lophius*; *Anarrhichas*, *Centronotus*, *Stichæus*; *Blenniops*, *Zoarces* (not in the Mediterranean); *Cepola*; *Lepadogaster*.

Of the *Anacanthini* the Gadoids are as numerous as in the Arctic Ocean, most being common to both districts; but, whilst the majority show their northern origin by not extending into the Mediterranean, *Ammodytes* and most *Pleuronectidæ* prove themselves to be the more southern representatives of this order. In the British district we find *Hippoglossus*, *Hippoglossoides*, *Rhombus*, *Phrynorhombus*, *Pleuronectes*, *Solea*, and only the first two are not met with in the Mediterranean.

Labroids are common; with the exception of the North American *Tautoga*, all the other genera are met with.

Physostomes are not well represented, viz., by one species of *Osmerus*, one of *Engraulis*, one of *Conger*, and about five of *Clupea*.

Syngnathus and *Nerophis* become more common as we proceed southwards; but the existence of Sclerodenns and Plectognaths is indicated by single individuals only, stragglers from their southern home, unable to establish themselves in a climate ungenial to them.

The Gadoids are accompanied by *Myxine*; and *Branchiostoma* may be found in all suitable localities.

2. The Mediterranean district is distinguished by a great variety of forms; yet, with the exception of a few genera established for single species, none of the forms can be considered peculiar to it; and even that small number of peculiar genera is more and more diminished as our knowledge of the distribution of fishes advances. Some genera are identical with those found on the western coasts of the Atlantic and in the West Indies; but a most remarkable and unexpected affinity obtains with another very distant fauna, viz., that of Japan. The number of genera common to the Mediterranean district and the Japanese coasts is larger than that of the genera common to the Mediterranean and the opposite American coasts.

The Chondropterygians found in the British district continue in the Mediterranean, their number being increased by *Centrina*, *Spinax*, *Pteroplatea*, and some species of *Rhinobatus*, a genus more numerously represented in the tropics. *Torpedo* and *Trygon* are common.

The greatest variety belong to the Acanthopterygians, which are represented by fifty-seven genera.

The *Labridæ* are as common as in the British district, or even more so, and are represented by the same genera. But, besides these, some other Pharyngognaths, properly belonging to the tropical Atlantic, have fully established themselves, though only by a few species, viz., *Glyphidodon* and *Heliastes*, *Cossyphus*, *Novacula*, *Julis*, *Coris*, and *Scarus*.

The Gadoids show a marked decrease of development; and the species of *Gadus*, *Gadiculus*, *Mora*, *Strinsia*, *Phycis*, and *Molva* which are peculiar to the Mediterranean seem to inhabit rather the colder water of moderate depths than the surface near the shore. *Motella*, however, proves also to be a true shore fish in the Mediterranean, at least in its adult state. *Ophidium* and *Fierasfer* appear now besides *Ammodytes*. As the Gadoids decrease, so the *Pleuronectidæ* increase, 9 genera being found in this district.

The variety of Physostomes is small, the following only having to be added to those of the British district: *Saurus* (a tropical genus), *Aulopus*; *Congromuræna*, *Heteroconger*, *Myrus*, *Ophichthys*, *Muræna*.

The Lophobranchs are more numerous in species and individuals than in the British district; and, besides *Syngnathus* and *Nerophis*, several species of *Hippocampus* are common. A few species of *Balistes* also occur.

Myxine is lost in this district, whilst *Branchiostoma* is abundant.

3. The shore fishes of the North American district consist, as on the eastern coasts of the North Atlantic, of northern (about 50 genera) and southern (about 30) elements; but they are still more mixed with each other than on the European coasts, so that a boundary line cannot be drawn between them. The affinity to the fauna of the eastern shores is great, but almost entirely limited to the genera composing the fauna of the British district. British genera not found on the American coasts are—*Galeus*, *Scyllium*, *Chimæra*, *Mullus*, *Pagellus*, *Trigla*, *Trachinus*, *Zeus*, *Callionymus*. The southern elements of North America are rather derived from the West Indies, and have no special affinity to Mediterranean forms; very few of the non-British Mediterranean forms extend across the Atlantic; instead of a Mediterranean we find a West Indian element. Many of the British *species* range across the Atlantic, and inhabit in an unchanged condition the northern parts of this district; and from the frequent occurrence of isolated specimens of other British species on the North American coast, we may presume that many more occasionally cross the Atlantic, but without being able to obtain a permanent footing.

The genera peculiar to this district are few in number, and composed of very few species, viz., *Hemitripterus*, *Pammelas*, *Chasmodes*, *Cryptacanthodes*, and *Tautoga*.

Temperate North Pacific.—This fauna shows a great affinity to that of the Temperate North Atlantic, not only in including a considerable proportion of identical genera, and even of species, but also in having its constituent parts similarly distributed. Our knowledge of the ichthyology of this fauna, however, is by no means complete, and the details of the distribution of the fishes of these shores have still to be worked out; nevertheless, three divisions may be recognized which, for the present, may be defined as follows:—

1. The fishes of the north-western shores, to about 37° N. lat., including the corresponding northern parts of Japan: Kamtchatkan district. This corresponds to the British district of the Atlantic.

2. The fishes of southern Japan and the corresponding shores of the continent of Asia, between 37° and 30° N. lat.: Japanese district, which corresponds to the Mediterranean.

3. The fishes of the eastern shores southwards to the latitude of San Francisco: Californian district. This corresponds to the North American district of the Atlantic.

Too little is known of the shore fishes of the coasts between San Francisco and the tropic to enable us to treat of it as a separate division.

The shore fishes of the North Pacific generally are composed of the following elements:—

a. Arctic forms which extend into the Arctic Ocean, and the majority of which are also found in the British district.

b. Peculiar forms limited to the North Pacific, like the *Heterolepidina*, *Embiotocidæ*, and certain Cottoid and Blennioid genera.

c. Forms identical with fishes of the Mediterranean.

d. Peculiar forms limited to the southern parts of Japan.

e. Tropical forms which have entered the North Pacific from the south.

1. To the Kamtchatkan district we can assign but a small list of fishes, probably because of the imperfect manner in which its fauna has been explored. At present we have positive knowledge of the occurrence of only two Chondropterygians, viz., *Chimæra* and *Raia*; the species of the latter genus seem to be much less numerous than in the Atlantic. Of Acanthopterygians 15 genera are known. Labroids are absent; they are clearly a type unable to endure great cold; of the Embiotocoids which represent them in the Pacific, one species only (a species of *Ditrema*) is known from this district.

The Gadoids are, so far as we know at present, sparsely represented, viz., by isolated species of *Gadus*, *Motella*, and *Lotella*, the last being an inhabitant of moderate depths rather than of the surface. *Hippoglossus*, *Pleuronectes*, and *Parophrys* seem to occur everywhere in suitable localities.

The Physostomes are nearly the same as in the British district, viz., a smelt (*Hypomesus*), probably also the arctic *Mallotus*, an anchovy, several species of *Clupea*, and the conger-eel. A very singular Salmonoid fish, *Salanx*, which is limited to the north-western Pacific, occurs in great abundance. The Lophobranchs also correspond in their development to those of the British district, *Nerophis* being replaced by *Urocampus*. Neither Myxinoids nor *Branchiostoma* have as yet been found.

2. The Japanese district is, like the Mediterranean, distinguished by a great variety of forms. Of 102 genera known to inhabit these coasts, 13 are peculiar to it, 53 occur in the Mediterranean, though also in other districts. This resemblance to the Mediterranean is even greater than would appear from a comparison of the genera, inasmuch as a considerable number of species are identical in both districts. Three of the Berycoid genera have hitherto been found in the Japanese and Mediterranean districts and nowhere else. Another very singular fact is that some of the most characteristic genera, like *Mullus*, *Zeus*, *Callionymus*, *Centriscus*, inhabit the Mediterranean and Japanese districts, but have never reached the opposite American coasts, either in the Atlantic or the Pacific; although, at least in the latter, the oceanic currents would rather favour than obstruct their dispersal in the direction of America. Bold as the hypothesis may appear, we can only account for the singular distribution of these shore fishes by assuming that the Mediterranean and Japanese seas were in direct and open communication with each other within the period of the existence of the present Teleosteous fauna.

Gadoids have disappeared, or are represented by forms inhabiting moderate depths. Neither *Myxine* nor *Branchiostoma* are as yet known to have been found.

3. The Californian district includes a marked northern element, the principal constituents of which are identical with types occurring in the corresponding district of the Atlantic, viz., the North American, as exemplified by *Discoboli*, *Anarrhichas*, *Centronotus*, *Cottus*, *Hippoglossus*, *Clupea* (*harengus*), &c. But it possesses also, in the greatest degree of development, some types almost peculiar to itself, as the *Heterolepidina*, some remarkable Cottoid and Blennioid genera, and more especially the Embiotocoids—viviparous Pharyngognaths—which replace the Labroids of the other hemi-

sphere. Gadoids are much less numerous than in the North American district. The southern forms are but little known, but it may be anticipated that, owing to the partial identity of the faunæ of the two coasts of the isthmus of Panama, a fair proportion of West Indian forms will be found to have entered this district from the south.

EQUATORIAL ZONE.—As we approach the tropic from the north, the types characteristic of the arctic and temperate zones become rarer, and disappear altogether, to be replaced by the greater variety of tropical types. Of Chondropterygians, the *Chimæridæ*, *Spinacidæ*, *Mustelus*, and *Raia* do not pass the tropic, or appear in single species only; and of Teleosteans, the *Berycidæ*, *Pagrus*, the *Heterolepidina*, *Cottus* and allied genera, *Lophius*, *Anarrhichas*, *Stichæus*, *Lepadogaster*, *Psychrolutes*, *Centriscus*, *Notacanthus*, the *Labridæ* and *Embiotocidæ*, the *Lycodidæ*, *Gadidæ*, and marine *Salmonidæ* either entirely disappear, or retire from the shores and surface into the depths of the ocean.

With regard to variety of forms, as well as to number of individuals, this zone far surpasses either of the temperate zones; in this respect, the life in the sea is like that on the land. Shore fishes are not confined to the actual coast line, but abound on the coral reefs with which some parts of the Atlantic and Pacific are studded, and many of which are below the surface of the water. The abundance of animal and vegetable life which flourishes on these renders them the favourite pasture grounds for the endless variety of coral-fishes (*Squamipinnes*, *Acronuridæ*, *Pomacentridæ*, *Julidæ*, *Plectognathi*, &c.) and for the larger predatory kinds. The colours and grotesque forms of the fishes of the tropics justly excited the admiration of the earliest observers. Scarlet, black, blue, pink, red, yellow, &c., are arranged in patterns of the most bizarre fashion, mingling in spots, lines, or bands, and reminding us of the words of Captain Cook when describing the coral-reefs of Palmerston Island: "The glowing appearance of the mollusks was still inferior to that of the multitude of fishes that glided gently along, seemingly with the most perfect security. The colours of the different sorts were the most beautiful that can be imagined—the yellow, blue, red, black, &c., far exceeding anything that art can produce. Their various forms, also, contributed to increase the richness of this submarine grotto, which could not be surveyed without a pleasing transport."

Of Chondropterygians the *Scylliidæ*, *Pristis* (saw-fishes), *Rhinobatidæ*, and *Trygonidæ* attain to the greatest development. Of Acanthopterygians *Centropristis*, *Serranus*, *Plectropoma*, *Mesoprion*, *Priacanthus*, *Apogon*, *Pristipoma*, *Hæmulon*, *Diagramma*, *Gerres*, *Scolopsis*, *Synagris*, *Cæsio*, *Mullidæ*, *Lethrinus*, *Squamipinnes*, *Cirrhites*, some genera of *Scorpænidæ*, *Platycephalus*, *Sciænidæ*, *Sphyræna*, *Caranx*, *Equula*, *Callionymus*, *Teuthis*, *Acanthurus*, *Naseus*, are represented by numerous species; and the majority of these genera and families are limited to this zone. Of Pharyngognaths the *Pomacentridæ*, *Julidina*, and *Scarina* are met with near every coral formation in a living condition. Of Gadoids, a singular minute form, *Bregmaceros*, is almost the only representative, the other forms belonging to deep water, and rarely ascending to the surface. Flat-fishes (*Pleuronectidæ*) are common on sandy coasts, and the majority of the genera are peculiar to the tropics. Of *Physostomi* only the *Saurina*, *Clupeidæ*, and *Murænidæ* are represented, the *Clupeidæ* being exceedingly numerous in individuals, whilst the *Murænidæ* live more isolated, but show a still greater variety of species *Lophobranchii* and *Sclerodermi* are generally distributed *Branchiostoma* has been found on several coasts.

Geographically it is convenient to describe the coast fauna of the tropical Atlantic separately from that of the Indo-Pacific Ocean. The differences between them, however, are far less numerous and important than between the freshwater or terrestrial faunæ of continental regions. The majority of the principal types are found in both, many of the species being even identical; but the species are far more abundant in the Indo-Pacific than in the Atlantic, owing to the greater extent of the archipelagoes in the former. But for the broken and varied character of the coasts of the West Indies, the shores of the tropical Atlantic would, by their general uniformity, afford but a limited variety of conditions for the development of specific and generic forms, whereas the deep inlets of the Indian Ocean, with the varying configuration of their coasts and the different nature of the bottom, its long peninsulas, and its archipelagoes, and the scattered islands of the tropical Pacific, render this part of the globe the most perfect for the development of fish life. The fishes of the Indian and Pacific Oceans (between the tropics) are almost identical, and the number of species ranging from the Red Sea and the east coast of Africa to Polynesia, even to its most westerly islands, is very great indeed. This Indo-Pacific fauna, however, does not reach the Pacific coast of South America. The wide space devoid of islands east of the Sandwich Islands and the Marquesas group, together with the current of cold water which sweeps northwards along the South American coast, has proved to be a very effectual barrier to the eastward extension of the Indo-Pacific fauna of coast fishes; and, consequently, we find an assemblage of fishes on the American coast and at the Galapagos Islands, sufficiently marked to constitute a distinct zoological division.

Tropical Atlantic.—The boundaries of the tropical Atlantic extend zoologically a few degrees beyond the northern and southern tropics, but, as the mixture with the types of the temperate zone is very gradual, no distinct boundary line can be drawn between the tropical and temperate faunæ.

Types almost exclusively limited to it and not found in the Indo-Pacific are few in number, as *Centropristis*, *Rhypticus*, *Hæmulon*, *Malthe*. A few others preponderate with regard to the number of species, as *Plectropoma*, *Sargus*, *Trachynotus*, *Batrachidæ*, and *Gobiesocidæ*. The Sciænoids are equally represented in both oceans. All the remainder are found in both, but are in a minority in the Atlantic, where they are sometimes represented by one or two species only (for instance, *Lethrinus*).

Tropical Indo-Pacific Ocean.—The ichthyological boundaries of this part of the tropical zone may be approximately given at 30° N. and S. lat.; on the Australian coasts it should probably be placed still farther south, viz., at 34°; it includes, as mentioned above, the Sandwich Islands, and all the islands of the South Sea, but not the American coasts.

Some eighty genera of shore fishes are peculiar to the Indo-Pacific, but the greater number consist of one or a few species only; comparatively few have a plurality of species, as *Diagramma*, *Lethrinus*, *Equula*, *Teuthis*, *Amphiprion*, *Dascyllus*, *Chœrops*, *Chilinus*, *Anampses*, *Stethojulis*, *Coris*, *Coilia*.

The sea-perches, large and small, which feed on crustaceans and on other small fishes, and the coral-feeding Pharyngognaths, are the types which show the greatest generic and specific variety in the Indo-Pacific. Then follow the *Squamipinnes* and *Murænidæ*, the *Clupeidæ* and *Carangidæ*,—families in which the variety is more that of species than of genus. The *Scorpænidæ*, *Pleuronectidæ*, *Acronuridæ*, *Sciænidæ*, *Syngnathidæ*, and *Teuthyes* are those which contribute the next largest contingents. Of shore-loving Chondropterygians the *Scylliidæ* and *Trygonidæ* only are represented in moderate numbers, though they are more numerous in this ocean than in any other.

Pacific Coasts of Tropical America.—As boundaries within which this fauna is comprised may be indicated 30° N. and S. lat., as in the Indo-Pacific. Its distinction from the Indo-Pacific lies in the almost entire absence of coral-feeding fishes. There are scarcely any *Squamipinnes*, Pharyngognaths, or *Acronuridæ*, and the *Teuthyes* are entirely absent. The genera that remain are such as are found in the tropical zone generally, but the species are entirely different from those of the Indo-Pacific. They are mixed with a sprinkling of peculiar genera, consisting of one or two species, like *Discopyge*, *Hoplopagrus*, *Doydixodon*, but they are too few in number to give a strikingly peculiar character to this fauna.

Three districts are distinguishable, viz., the Central American, the Galapagos, and Peruvian. We add a few remarks on the first only.[1] That district shows so close an affinity to the Tropical Atlantic that, if the two were not separated by the neck of land uniting North and South America, they would most assuredly be regarded as embracing a single fauna. With scarcely any exceptions the genera are identical, and of the species found on the Pacific side nearly one-half have proved to be the same as those of the Atlantic. The explanation of this fact has been found in the existence of communications between the two oceans by channels and straits which must have been open till within a recent period. The isthmus of Central America was then partially submerged, and appeared as a chain of islands similar to that of the Antilles; but as the reef-building corals flourished chiefly north and east of those islands, and were absent to the south and west of them, reef fishes were excluded from the Pacific shores when the communications were destroyed by the upheaval of the land.

SOUTHERN TEMPERATE ZONE.—This zone includes the coasts of the southern extremity of Africa from about 30° S lat., of the south of Australia, with Tasmania, and of New Zealand, and the Pacific and Atlantic coasts of South America between 30° and 50° S lat.

The most striking character of this fauna is the reappearance of types inhabiting the corresponding latitudes of the northern hemisphere, and not found in the intervening tropical zone. This interruption of the continuity in the geographical distribution of shore fishes is exemplified by species as well as genera, for instance—*Chimæra monstrosa*, *Galeus canis*, *Acanthias vulgaris*, *Acanthias blainvillii*, *Rhina squatina*, *Zeus faber*, *Lophius piscatorius*, *Centriscus scolopax*, *Engraulis encrasicholus*, *Clupea sprattus*, *Conger vulgaris*. Instances of genera are still more numerous:—*Cestracion*, *Spinax*, *Pristiophorus*, *Raia*; *Callanthias*, *Polyprion*, *Histiopterus*, *Cantharus*, *Box*, *Girella*, *Pagellus*, *Chilodactylus*, *Sebastes*, *Aploactis*, *Agonus*, *Lepidopus*, *Cyttus*, *Psychrolutidæ*, *Notacanthus*; *Lycodes*, *Merluccius*, *Lotella*, *Phycis*, *Motella*; *Aulopus*; *Urocampus*, *Solenognathus*, *Myxine*.

Naturally, where the coasts of the tropical zone are continuous with those of the temperate, a number of tropical genera enter the latter, and genera which we have found between the tropics, as well as in the temperate zone of the northern hemisphere, extend in a similar manner towards the south. But the truly tropical forms are absent; there are no *Squamipinnes*, scarcely any *Mullidæ*, no *Acronuri*, no *Teuthyes*, no *Pomacentridæ* (with a single exception on the coast of Chili), only one genus of *Julidina*, no *Scarina*, which are replaced by another group of Pharyngognaths, the *Odacina*. The *Labrina*, so characteristic of the temperate zone of the northern hemisphere, reappear in a distinct genus (*Malacopterus*) on the coast of Juan Fernandez.

The family of *Berycidæ*, equally interesting with regard to their distribution in time and in space, consists of temperate and tropical genera. The genus by which this family is represented in the southern temperate zone (*Trachichthys*) is much more nearly allied to the northern than to the tropical genera.

The true *Cottina* and *Heterolepidina* (forms with a bony stay of the præoperculum, which is generally armed) have not crossed the tropical zone; they are replaced by fishes extremely similar in general form, and having the same habits, but lacking that osteological peculiarity. Their southern analogues belong chiefly to the family *Trachinidæ*, and are types of genera peculiar to the southern hemisphere.

The *Discoboli* of the northern hemisphere likewise have not penetrated to the south, where they are represented by *Gobiesocidæ*. These two families replace each other in their distribution over the globe.

Nearly all the *Pleuronectidæ* (but they are not numerous) belong to distinct genera, some, however, being remarkably similar in general form to the northern *Pleuronectes*.

With Gadoids *Myxinidæ* reappear, one species being extremely similar to the European *Myxine*. *Bdellostoma* is a genus peculiar to the southern temperate zone.

As in the northern temperate zone, so in the southern the number of individuals and the variety of forms is much less than between the tropics. This is especially apparent on comparing the numbers of species constituting a genus. In this zone genera composed of more than ten species are the exception, the majority having only from one to five.

The proportion of genera limited to this zone is very high, about 65 out of a total number of 170 being peculiar to it.

1. The Cape of Good Hope district. Many of the genera found in this district are northern forms (*Chimæra*, *Galeus*, *Scyllium*, *Acanthias*, *Torpedo*, *Raia*, *Dentex*, *Cantharus*, *Box*, *Sagrus*, *Pagrus*, *Pagellus*, *Chrysophrys*; *Sebastes*, *Sphyræna*; *Lepidopus*, *Thyrsites*; *Zeus*; *Lophius*; *Motella*), which in conjunction with the peculiarly southern types (*Callorhynchus*, *Chilodactylus*, *Agriopus*, *Clinus*, *Genypterus*, *Bdellostoma*) leave no doubt that this district belongs to the southern temperate zone, whilst the freshwater fishes of South Africa are members of the tropical fauna. Only a few (*Rhinobatus*, *Narcine*, *Astrape*, and *Sphyræna*) have entered from the neighbouring tropical coasts. The development of Sparoids is greater than in any of the other districts of this zone, and may be regarded as one of its distinguishing features.

2. The South Australian district comprises the southern coasts of Australia (northwards to about the latitude of Sydney), Tasmania, and New Zealand. It is the richest in the southern temperate zone, partly in consequence of a considerable influx of tropical forms on the eastern coast of Australia, where they penetrate farther southwards than would be expected from merely geographical considerations, partly in consequence of the thorough manner in which the ichthyology of New South Wales and New Zealand has been explored. Of the 120 genera hitherto found in this district 42 are peculiar.

The shore fishes of New Zealand are not so distinct from those of south-eastern Australia as to deserve to be placed in a separate district. With the exception of the genera which enter this zone from the tropics, and which are more numerous on the Australian coast than on that of New Zealand, and a few very local genera in addition, the remainder are identical. Many of the South Australian species, too, are found also on the coasts of New Zealand. The principal points of difference are the extraordinary development of *Monacanthus* on the coast of South Australia, and the apparently total absence in Australia of Gadoids, which in the New Zealand fauna are represented by 6 genera.

3. The Chilian district extends over 20 degrees of latitude only, and is nearly straight. In its northern and warmer parts it is of a very uniform character; it is there exposed to high and irregular tides, and to remarkable and sudden changes in the levels of land and water, which must seriously interfere with fishes living and propagating near the shore. No river of considerable size interrupts the monotony of the physical conditions, to offer an additional element in favour of the development of littoral animals. In the southern parts, where the coast is lined with archipelagoes, the climate is too severe for most fishes. All these conditions combine to render this district comparatively poor as regards variety of shore fishes; they belong to 45 genera, of which 6 only are not found in

[1] For the others the reader is referred to Günther's *Introduction to the Study of Fishes*, p. 280.

other districts of this zone. Three are peculiar, viz., *Mendosoma*, *Myxodes*, and *Malacopterus*; *Porichthys* and *Agonus* have penetrated thus far southwards from the Peruvian and Californian districts; and *Polyprion* is one of those extraordinary instances in which a very specialized form occurs at almost opposite points of the globe, without having left a trace of its previous existence in, or of its passage through, the intermediate space.

4. Our knowledge of the fauna of the Patagonian district is, with the exception of the neighbourhood of the mouth of the Rio de la Plata, in too fragmentary a state to deserve further notice here.

ANTARCTIC OCEAN.—To this fauna we refer the shore fishes of the southernmost extremity of South America, from 50° S. lat., with Tierra del Fuego and the Falkland Islands, and those of Kerguelen's Land, with Prince Edward's Island. No fishes are known from the other oceanic islands of these latitudes.

In the southern hemisphere surface fishes do not extend so far towards the pole as in the northern; none are known beyond 60° S. lat., and the Antarctic fauna which is analogous to the Arctic inhabits coasts more than ten degrees nearer to the equator. It is very probable that the shores between 60° and the Antarctic Circle are inhabited by fishes sufficiently numerous to supply part of the means of subsistence for the large seals which there pass at least some portion of the year, but hitherto none have been obtained by naturalists; all that the present state of our knowledge justifies us in saying is, that the general character of the fauna of Magellan's Straits and Kerguelen's Land is extremely similar to that of Iceland and Greenland.

As in the Arctic fauna, Chondropterygians are rare, and are represented by *Acanthias vulgaris* and species of *Raia*. *Holocephali* have not yet been found so far south, but *Callorhynchus*, which is not uncommon near the northern boundary of this fauna, may prove to extend into it.

As to Acanthopterygians, *Cataphracti* and *Scorpænidæ* are represented as in the Arctic fauna, two of the genera (*Sebastes* and *Agonus*) being identical. The *Cottidæ* are replaced by six genera of *Trachinidæ*, remarkably similar in form to Arctic types; but *Discoboli* and the characteristic Arctic Blennioids are absent.

Gadoid fishes reappear, but are less developed; as usual they are accompanied by *Myxine*. The reappearance of so specialized a genus as *Lycodes* is most remarkable. Flatfishes are few as in the north, and belong to peculiar genera.

Physostomes are probably not entirely absent, but hitherto none have been met with so far south. Lophobranchs are rare, as in the Arctic zone; it is noteworthy, however, that a peculiar genus, with persistent embryonic characters (*Protocampus*), is rather common on the shores of the Falkland Islands.

Pelagic Fishes.

Pelagic fishes,—that is, fishes inhabiting the surface of mid-ocean,—belong to various orders, viz., Chondropterygians, Acanthopterygians, Physostomes, Lophobranchs, and Plectognaths. Neither Anacanths nor Pharyngognaths contribute to this series of the marine fauna. The following genera and families are included in it:—

Chondropterygii.—Carcharias, Galeocerdo, Thalassorhinus, Zygæna, Triænodon, Lamnidæ, Rhinodon, Notidanidæ, Læmargus, Euprotomicrus, Echinorhinus, Isistius; Myliobatidæ.

Acanthopterygii.—Dactylopterus, Micropteryx, Scombrina, Gastrochisma, Nomeus, Centrolophus, Coryphænina, Seriola, Temnodon, Naucrates, Psenes, Xiphiidæ, Antennarius.

Physostomi.—Sternoptychidæ, Scopelus, Astronesthes, Scombresocidæ (majority).

Lophobranchii.—Hippocampus.

Plectognathi.—Orthagoriscus, and some other Gymnodonts.

Pelagic fishes differ much from one another in their mode of life. The majority are excellent swimmers, which not only can move with great rapidity, but are also possessed of great powers of endurance, and are thus enabled to continue their course for weeks, apparently without the necessity of rest; such are many sharks, scombroids, dolphins, pilot-fish, sword-fishes. In some, as in *Dactylopterus* and *Exocœtus*, the ability to take flying leaps out of the water is superadded to the power of swimming (flying-fishes). But in others the power of swimming is greatly reduced, as in *Antennarius*, *Hippocampus*, and Gymnodonts; they frequent places in the ocean covered with floating seaweed, or drift on the surface without resistance, at the mercy of wind and current. The *Echeneis* or sucking-fishes attach themselves to other large fishes, ships, or floating objects, and allow themselves to be carried about, unless change of climate or want of food obliges them to abandon their temporary carrier. Finally, another class of pelagic fishes come to the surface of the ocean during the night only; in the day time they descend to some depth, where they are undisturbed by the rays of the sun or the agitation of the surface-water; such are *Brama*, the *Sternoptychidæ*, *Scopelus*, *Astronesthes*,—fishes the majority of which are provided with those extraordinary visual organs that we find so much developed in the true deep-sea fishes. Indeed, this last kind of pelagic fishes constitutes a connecting link with the deep-sea forms.

Pelagic fishes, like shore fishes, are most numerous in the tropical zone; and, with few exceptions (*Echinorhinus*, *Psenes*, *Sternoptychidæ*, *Astronesthes*), the same genera are represented in the tropical Atlantic as well as in the Indo-Pacific. The number of identical species occurring in both these oceans is great, and probably still greater than would appear from systematic lists, in which there are retained many specific names that were given at a time when species were believed to have a very limited range. The pelagic fauna of the tropics gradually passes into that of the temperate zones, only a few genera, like *Cybium*, *Psenes*, *Antennarius*, being almost entirely confined to the tropics. All the other tropical genera range into the temperate zones, but their representatives become fewer with the increasing distance from the equator. North of 40° N. lat. many genera have disappeared, or are met with in isolated examples only, as *Carcharias*, *Zygæna*, *Notidanus*, *Myliobatidæ*, *Dactylopterus*, *Echeneis*, *Nomeus*, *Coryphæna*, *Schedophilus*, *Seriola*, *Temnodon*, *Antennarius*, *Sternoptychidæ*, *Astronesthes*, *Exocœtus*, *Tetrodon*, *Diodon*; and only one genus of sharks, *Galeocerdo*, approaches the Arctic Circle. Some few species, like *Antennarius*, *Scopelus*, are carried by currents near to the farther confines of the temperate zones; but such occurrences are accidental, and these fishes must be regarded as entirely foreign to the fauna of those latitudes. On the other hand, some pelagic fishes inhabit the temperate zones, whilst their occurrence within the tropics is very problematical; thus, in the Atlantic, *Thalassorhinus*, *Selache*, *Læmargus*, *Centrolophus*, *Diana*, *Ausonia*, *Lampris* (all genera composed of one or two species only). Besides the shark mentioned, no other pelagic fishes are known from the Arctic Ocean.

We possess very little information about the pelagic fish-fauna of the southern oceans. This much only is certain, that the tropical forms gradually disappear; but it would be hazardous, in the present state of our knowledge, to state even approximately the limits of the southward range of a single genus. Scarcely more is known about the appearance of types peculiar to the southern temperate zone,—for instance, the gigantic shark *Rhinodon* representing the northern *Selache*, near the coasts of South Africa, and the Scombroid genus *Gastrochisma*, in the South Pacific.

The largest of marine fishes, *Rhinodon*, *Selache*, *Carcharodon*, *Myliobatidæ*, *Thynnus*, *Xiphiidæ*, *Orthagoriscus*, belong to the pelagic fauna. Young fishes are frequently found in mid-ocean, which are the offspring of shore fishes normally depositing their spawn near the coast. The manner in which this fry passes into the open sea is unknown; for it has not yet been ascertained whether it is carried by currents from the place where it was deposited originally, or whether shore fishes sometimes spawn at a distance from the coast. We may remember that shore fishes inhabit not only coasts but also submerged banks with some depth of water above, and that, by the action of the water, spawn deposited on these latter localities is very liable to be dispersed over wide areas of the ocean. Embryos of at least some shore fishes hatched under abnormal conditions seem to have an abnormal growth up to a certain period of their life, when they perish. The *Leptocephali* must be regarded as such abnormally developed forms. Fishes of a similar condition are the so-called pelagic *Plagusiæ*, young Pleuronectoids, the origin of which is still unknown. As already mentioned, flat-fishes, like all the other Anacanths, are not otherwise represented in the pelagic fauna.

Deep-Sea Fishes.

The knowledge of the existence of deep-sea fishes is one of the recent discoveries of ichthyology. It was only about twenty years ago that, from the evidence afforded by the anatomical structure of a few singular fishes obtained in the North Atlantic, an opinion was expressed that these fishes inhabited great depths of the ocean, and that their organization was specially adapted for living under the physical abyssal conditions. These fishes agreed in the character of their connective tissue, which was so extremely weak as to yield to, and to break under, the slightest pressure, so that the greatest difficulty was experienced in preserving their body in its continuity. Another singular circumstance was that some of the examples were picked up floating on the surface of the water, having met their death whilst engaged in swallowing or digesting other fishes not much smaller in size if not actually larger than themselves.

The first peculiarity was accounted for by the fact that, if those fishes really inhabited the great depths supposed, their removal from the enormous pressure under which they lived would be accompanied by such an expansion of gases within their tissues as to rupture them, and to cause a separation of the parts which had been held together by the pressure. The second circumstance was explained thus. A raptorial fish organized to live at a depth of between 500 and 800 fathoms seizes another usually inhabiting a depth of between 300 and 500 fathoms. In its struggles to escape, the fish seized, being nearly as large or strong as the attacking fish, carries the latter out of its depth into a higher stratum, where the diminished pressure causes such an expansion of gases as to make the destroyer with its victim rise with increasing rapidity towards the surface, which they reach dead or in a dying condition. Specimens in this state are not rarely picked up; and as, of course, it is but comparatively few that can by accident fall into the hands of naturalists, occurrences of this kind must happen very often.

The existence of fishes peculiarly adapted for the deep sea has thus been a fact maintained and admitted for some time in ichthyology; and as the same genera and species were found at very distant parts of the ocean, it was further stated that those deep-sea fishes were not limited in their range, and that, consequently, the physical conditions of the depths of the ocean must be the same or nearly the same over the whole globe. That deep-sea fishes were not of a peculiar order, but chiefly modified forms of surface types, was another conclusion arrived at from the sporadic evidence collected during the period which preceded systematic deep-sea dredging.

Nothing, however, was positively known as to the exact depths inhabited by those fishes until observations were made during the voyage of H.M.S. "Challenger." The results obtained by this expedition afforded a surer and more extended basis for our knowledge of deep-sea fishes.

The physical conditions of the deep sea, which must affect the organization and distribution of fishes, are the following:—

1. Absence of sunlight. Probably the rays of the sun do not penetrate to, and certainly do not extend beyond, a depth of 200 fathoms, therefore we may consider this to be the depth where the deep-sea fauna commences. Absence of light is, of necessity, accompanied by modifications of the organs of vision and by simplification of colours.

2. The absence of sunlight is in some measure compensated by the presence of phosphorescent light, produced by many marine animals, and also by numerous deep-sea fishes.

3. Depression and equality of the temperature. At a depth of 500 fathoms the temperature of the water is already as low as 40° Fahr., and perfectly independent of the temperature of the surface-water; and from the greatest depth to about 1000 fathoms beneath the surface the temperature is uniformly but a few degrees above the freezing point. Temperature, therefore, ceases to offer an obstacle to the unlimited dispersal of the deep-sea fishes.

4. The increase of pressure by the water. The pressure of the atmosphere on the body of an animal at the level of the sea is 15 ℔ per square inch of surface; but under water the pressure amounts to a ton weight for every 1000 fathoms of depth.

5. With the sunlight, vegetable life ceases in the depths of the sea. All deep-sea fishes are therefore carnivorous,—the most voracious feeding frequently on their own offspring, and the toothless kinds being nourished by the animalcules which live on the bottom, or which, "like a constant rain," settle down from the upper strata towards the bottom of the sea.

6. The perfect quiet of the water at great depths. The agitation of the water caused by the disturbances of the air does not extend beyond the depth of a few fathoms; below this surface-stratum there is no movement except the quiet flow of ocean-currents, and near the bottom of the deep sea the water is probably in a state of almost entire quiescence.

The effect upon fishes of the physical conditions described is clearly testified by the modification of one or more parts of their organization, so that every deep-sea fish may be recognized as such without the accompanying positive evidence that it has been caught at a great depth; and, *vice versa*, fishes reputed to have been obtained at a great depth, and not having any of the characteristics of the dwellers of the deep sea, must be regarded as surface fishes.

The most striking characteristic found in many deep-sea fishes is in relation to the tremendous pressure under which they live. Their osseous and muscular systems are, as compared with the same parts of surface fishes, very feebly developed. The bones have a fibrous, fissured, and cavernous texture; they are light, with scarcely any calcareous matter, so that the point of a needle will readily penetrate them without breaking. The bones, especially the vertebræ, appear to be very loosely connected with one another; and it requires the most careful handling to avoid the breaking of the connective ligaments. The muscles, especially the great lateral muscles of the trunk and tail, are thin, the fascicles being readily separated from one another or torn, and the connective tissue being extremely loose, feeble, or apparently absent. This peculiarity has been observed in the *Trachypteridæ*, *Plagyodus*, *Chiasmodus*, *Melanocetus*, *Saccopharynx*. But we cannot assume that it actually obtains whilst those fishes exist under their natural conditions. Some of them are most rapacious creatures, which must be able to execute rapid and powerful movements to catch and overpower their prey; and for that object their muscular system, thin as its layers may be, must be as firm, and the chain of the segments of their vertebral column as firmly linked together as in surface fishes. It is evident, therefore, that the change which the body of those fishes has undergone on their withdrawal from the pressure under which they live is a much aggravated form of the affection that is experienced by persons reaching great altitudes in their ascent of a mountain or in a balloon. In every living organism with an intestinal tract there are accumulations of free gases; and, moreover, the blood and other fluids, which penetrate every part of the body, contain gases in solution. Under greatly diminished pressure these gases expand, so that, if the withdrawal from a depth is not an extremely slow and gradual process, the various tissues must be distended, loosened, ruptured; and what is a vigorous fish at a depth of 500 fathoms or more appears at the surface as a loosely-jointed body which, if the skin is not of sufficient toughness, can only be kept together with difficulty. At great depths a fibrous osseous structure and a thin layer of muscles suffice to obtain the same results for which, at the surface, thickness of muscle and firm osseous or cartilaginous tissue are necessary.

The muciferous system of many deep-sea fishes is developed in an extraordinary degree. We find in fishes which are comparatively little removed from the surface (that is, to depths of from 100 to 200 fathoms) the lateral line much wider than in their congeners or nearest allies which live on the surface, as in *Trachichthys*, *Hoplostethus*, many *Scorpænidæ*. But in fishes inhabiting depths of 1000 fathoms and more the whole muciferous system is dilated; it is especially the surface of the skull which is occupied by large cavities (*Macruridæ*, deep-sea *Ophidiidæ*), and the whole body seems to be covered with a layer of mucus. These cavities collapse and shrink in specimens which have been preserved in spirit for some time, but a brief re-immersion in water generally suffices to show the immense quantity of mucus secreted by them. The physiological use of this secretion is unknown; it has been observed to have phosphorescent properties in perfectly fresh specimens.

The colours of deep-sea fishes are extremely simple, their bodies being either black or silvery; in a few only are some filaments or the fin-rays of a bright scarlet colour. Among the black forms albinoes are not rare.

The organ of sight is the first to be affected by a sojourn in deep water. Even in fishes which habitually live at a depth of only 80 fathoms, we find the eye of a proportionally larger size than in their representatives at the surface. In such fishes the eyes increase in size with the depth inhabited by them, down to the depth of 200 fathoms, the large organs being necessary to collect as many rays of light as possible. Beyond that depth small-eyed as well as large-eyed fishes occur, the former having their want of vision compensated by tentacular organs of touch, whilst the latter have no such accessory organs, and evidently see only by the aid of phosphorescence. In the greatest depths blind fishes occur, with rudimentary eyes and without special organs of touch.

Many fishes of the deep sea are provided with more or less numerous, round, shining, mother-of-pearl-coloured bodies, imbedded in the skin. These so-called phosphorescent or luminous organs are either larger bodies of an oval or irregularly elliptical shape placed on the head, in the vicinity of the eye, or smaller round globular bodies arranged symmetrically in series along the side of the body and tail, especially near the abdominal profile, less frequently along the back. The former kind of organs possess in the interior a lenticular body, like the lens of an eye, and are considered by some naturalists true organs of vision (accessory eyes), the function of the latter, which have a glandular structure, being left unexplained by them.

There is no doubt that the functions of these organs have some relation to the peculiar conditions of light under which the fishes provided with them live, these fishes being either deep-sea forms or nocturnal pelagic kinds. And it is highly probable that all produce and emit phosphorescent light, enabling the fishes to see in the darkness of the night or of the depths of the sea.

Whenever we find in a fish long delicate filaments developed in connexion with the fins or the extremity of the tail, we may conclude that it is an inhabitant of still water and of quiet habits. Many deep-sea fishes (*Trachypteridæ*, *Macruridæ*, *Ophidiidæ*, *Bathypterois*) are provided with such filamentous prolongations, the development of which is perfectly in accordance with their sojourn in the absolutely quiet waters of abyssal depths.

Some of the raptatorial deep-sea fishes have a stomach so distensible and capacious that it can receive a fish of twice or thrice the bulk of the destroyer (*Melanocetus*, *Chiasmodus*, *Saccopharynx*). Deglutition is performed in them, not by means of the muscles of the pharynx, as in other fishes, but by the independent and alternate action of the jaws, as in snakes. These fishes cannot be said to swallow their food; they rather draw themselves over their victim, after the fashion of an *Actinia*.

Before the voyage of H.M.S. "Challenger," scarcely thirty deep-sea fishes were known. This number is now much increased, six times as many new species and genera having been discovered. Modifications of certain organs, perfectly novel, and of the greatest interest, were found; but, singularly, no new types of families were discovered,—nothing but what might have been expected from our previous knowledge of this group of fishes.

The fish fauna of the deep sea is chiefly composed of forms or modifications of forms which we find represented at the surface in the cold and temperate zones, or which belong to the class of nocturnal pelagic fishes. The Chondropterygians are few in number, not descending to a greater depth than 600 fathoms. The Acanthopterygians, which form the majority of the coast and surface faunas, are also scantily represented; genera identical with surface types are confined to the same inconsiderable depth as the Chondropterygians, whilst those Acanthopterygians which are so much specialized for a life in the deep sea as to deserve generic separation range from 200 to 2400 fathoms. Three distinct families of Acanthopterygians belong to the deep-sea fauna, viz., *Trachypteridæ*, *Lophotidæ*, and *Notacanthidæ*; they consist of three, one, and two genera respectively.

Gadidæ, *Ophidiidæ*, and *Macruridæ* are very numerous, ranging through all depths; they constitute about one-fourth of the whole deep-sea fauna.

Of *Physostomi*, the families of *Sternoptychidæ*, *Scopelidæ*, *Stomiatidæ*, *Salmonidæ*, *Bathythrissidæ*, *Alepocephalidæ*, *Halosauridæ*, and *Murænidæ* are represented. Of these the Scopeloids are the most numerous, constituting nearly another fourth of the fauna. *Salmonidæ* are only represented by three small genera. *Bathythrissidæ* include one species only, which is probably confined in its vertical as well as its horizontal range; it occurs at a depth of about 350 fathoms in the sea of Japan. The *Alepocephalidæ* and *Halosauridæ*, known before the "Challenger" expedition from isolated examples only, prove to be true, widely-spread, deep-sea types. Eels are well represented, and seem to descend to the greatest depths. *Myxine* has been obtained from a depth of 345 fathoms.

The greatest depth hitherto reached by a dredge in which fishes were enclosed is 2900 fathoms. But the specimens thus obtained belong to a species (*Gonostoma microdon*) which seems to be extremely abundant in upper strata of the Atlantic and Pacific, and were therefore most likely caught by the dredge in its ascent. The next greatest depth, viz., 2750 fathoms, must be accepted as one at which fishes do undoubtedly live,—the fish obtained from this depth of the Atlantic, *Bathyophis ferox*, showing by its whole habit that it is a form living on the bottom of the ocean.

CLASSIFICATION.

The class of fishes is divided into four subclasses:—

I. *Palæichthyes.*—Heart with a contractile conus arteriosus; intestine with a spiral valve; optic nerves non-decussating, or only partially decussating.

II. *Teleostei.*—Heart with a non-contractile bulbus arteriosus; intestine without spiral valve; optic nerves decussating. Skeleton ossified, with completely separated vertebræ.

III. *Cyclostomata.*—Heart without bulbus arteriosus; intestine simple. Skeleton cartilaginous and notochordal. One nasal aperture only. No jaws; mouth surrounded by a circular lip.

IV. *Leptocardii.*—Heart replaced by pulsating sinuses; intestine simple. Skeleton membrano-cartilaginous and notochordal. No brain; no skull.

Subclass I.—Palæichthyes.

This subclass comprises the sharks and rays and the Ganoid fishes. Though it is based upon a singular concurrence of most important characters, its members exhibit as great a diversity of form, and as manifold modifications in the remainder of their organization, as the *Teleostei*. The *Palæichthyes* stand to the *Teleostei* in the same relation as the Marsupials to the *Placentalia*. Geologically, as a subclass, they were the predecessors of Teleosteous fishes; and it is a remarkable fact that all those modifications which show an approach of the ichthyic type to the Batrachians are found in this subclass. It is divided into two orders,—the *Chondropterygii* and the *Ganoidei*.

ORDER I.—*Chondropterygii.*

Skeleton cartilaginous. Body with medial and paired fins, the hinder pair abdominal. Vertebral column generally heterocercal, the upper lobe of the caudal fin produced. Gills attached to the skin by the outer margin, with several intervening gill-openings; rarely one external gill-opening only. No gill-cover. No air-bladder. Two, three, or more series of valves in the conus arteriosus. Ova large and few in number, impregnated and, in some species, developed within a uterine cavity. Embryo with deciduous external gills. Males with intromittent organs attached to the ventral fins.

This order, for which, also, the name *Elasmobranchii* has been proposed (by Bonaparte), comprises the sharks, rays, and chimæras. It is divided into two suborders,—*Plagiostomata* and *Holocephala*.

SUBORDER I. *Plagiostomata.*—From five to seven gill-openings. Skull with a suspensorium and the palatal apparatus detached. Teeth numerous.

The Plagiostomes differ greatly from each other with regard to the general form of the body. In the sharks, or *Selachoidei*, the body is elongate, more or less cylindrical, gradually passing into the tail; the gill-openings are lateral. In the rays, or *Batoidei*, the gill-openings are always placed on the abdominal aspect of the fish; the body is depressed, and the trunk, which is surrounded by the immensely developed pectoral fins, forms a broad flat disk, of which the tail appears as a thin and slender appendage. Spiracles are always present; the number of gill-openings is constantly five; there is no anal fin; the dorsal fins, if present, are situated on the tail. Some of the rays, however, approach the sharks in having the caudal portion less abruptly contracted behind the trunk.

Fossil Plagiostomes are very numerous in all formations. Some of the earliest determinable fish remains are, or are believed to be, derived from Plagiostomes. Those which can be referred to any of the families specified below will be mentioned in due course; but there are others, especially fin-spines, which leave us in doubt to which group of Plagiostomes their owners had affinity: as *Onchus*, from the Upper Silurian, continuing to Carboniferous formations; *Dimeracanthus*, *Homacanthus*, from the Devonian; *Oracanthus*, *Gyracanthus*, *Tristychius*, *Astroptychius*, *Ptychacanthus*, *Sphenacanthus*, &c., from Carboniferous formations; *Leptacanthus*, from the Coal to the Oolite; *Cladacanthus*, *Cricacanthus*, *Gyropristis*, and *Lepracanthus*, from the Coal-measures; *Nemacanthus*, *Liacanthus*, from the Trias; *Astracanthus*, *Myriacanthus*, *Pristacanthus* from the Jurassic group.

A. *Selachoidei*, Sharks.

Family 1. *Carchariidæ.*—Eye with a nictitating membrane. Mouth crescent-shaped, inferior. Anal fin present. Two dorsal fins, the first opposite to the space between the pectoral and ventral fins, without spine in front.

Genera: *Carcharias* (Blue Shark), *Galeocerdo*, *Galeus* (Tope), *Zygæna* (Hammerhead), *Mustelus* (Hound), *Hemigaleus*, *Loxodon*, *Thalassorhinus*, *Triænodon*, *Leptocarcharias*, and *Triacis*. Fossil: *Corax* and *Hemipristis*.

Family 2. *Lamnidæ.*—Eye without nictitating membrane. Anal fin present. Two dorsal fins, the first opposite to the space between the pectoral and ventral fins, without spine in front. Nostrils not confluent with the mouth, which is inferior. Spiracles absent or minute.

Genera: *Lamna* (Porbeagle), *Carcharodon*, *Odontaspis*, *Alopecias* (Fox-Shark), and *Selache* (Basking Shark). Fossil: *Carcharopsis*, *Oxytes*, *Sphenodus*, *Gomphodus*, and *Ancistrodon*.

Family 3. *Rhinodontidæ.*—No nictitating membrane. Anal fin present. Two dorsal fins, the first nearly opposite to the ventrals, without spine in front. Mouth and nostril near the extremity of the snout.

This small family comprises one species only, *Rhinodon typicus*, a gigantic shark, which is known to exceed 50 feet in length.

Family 4. *Notidanidæ.*—No nictitating membrane. One dorsal fin only, without spine, opposite to the anal. Dentition unequal in the jaws; in the upper jaw one or two pairs of awl-shaped teeth, the following six being broader, and provided with several cusps, one of which is much stronger than the others. Lower jaw with six large comb-like teeth on each side, besides the smaller posterior teeth. Gill-openings wide, six in number in *Hexanchus*, seven in *Heptanchus*. Fossil teeth belonging to this type have been found in Jurassic and later formations (*Notidanus* and *Ællopos*).

Family 5. *Scylliidæ.*—Two dorsal fins, without spine, the first above or behind the ventrals; anal fin present. No nictitating membrane. Spiracle always distinct. Mouth inferior. Teeth small, several series generally being in function.

Genera: *Scyllium* (Dog-Fishes), *Pristiurus*, *Parascyllium*, *Ginglymostoma*, *Stegostoma*, *Chiloscyllium*, *Crossorhinus*. Fossil: *Scylliodus*, *Palæoscyllium*, *Thyellina*.

Family 6. *Hybodontidæ.*—Two dorsal fins, each with a serrated spine. Teeth rounded, longitudinally striated, with one larger and from two to four smaller lateral cusps. Skin covered with shagreen.

Extinct. From Carboniferous, Liassic, and Triassic formations. Several genera have been distinguished; and, if *Cladodus* belongs to this family, it was represented even in the Devonian.

Family 7. *Cestraciontidæ.*—No nictitating membrane. Two dorsal fins, the first opposite to the space between the pectoral and ventral fins; anal fin present. Nasal and buccal cavities confluent. Teeth obtuse, several series being in function.

This family is one of particular interest, because representatives of it occur in numerous modifications in Primary and Secondary strata. Their dentition is uniformly adapted for the prehension and mastication of crustaceous and hard-shelled animals. The fossil forms far exceeded in size the species of the only surviving genus, *Cestracion* (the Port Jackson Shark); they make their appearance with *Ctenoptychius* in the Devonian; this is succeeded in the Coal-measures by *Psammodus*, *Chomatodus*, *Petrodus*, *Cochliodus*, *Polyrhizodus*, &c., and in the Trias and Chalk by *Strophodus*, *Acrodus*, *Thectodus*, and *Ptychodus*. Of the 25 genera known, 22 have lived in the periods preceding the Oolitic.

Family 8. *Spinacidæ.*—No membrana nictitans. Two dorsal fins; no anal. Mouth but slightly arched; a long, deep, straight, oblique groove on each side of the mouth. Spiracles present; gill-openings narrow. Pectoral fins not notched at their origin.

Genera: *Centrina*, *Acanthias* (Spiny Dog-Fish), *Centrophorus*, *Spinax*, *Centroscyllium*, *Scymnus*, *Læmargus* (Greenland Shark), *Echinorhinus*, *Euprotomicrus* and *Isistius*. The largest of these fishes is the Greenland shark, which attains to a length of 15 feet, and is common in the Arctic regions. Fossil genera: *Palæospinax* and *Drepanephorus*, from Cretaceous and Jurassic formations.

Family 9. *Rhinidæ.*—No anal fin; two dorsal fins. Spiracles present. Pectoral fins large, with the basal portion prolonged forwards, but not grown to the head. Gill-openings rather wide, lateral, partly covered by the base of the pectoral. Spiracles wide, behind the eyes. Teeth conical.

One genus only: the "Angel-Fish," or "Monk-Fish" (*Rhina squatina*), which approaches the rays as regards general form and habits. Extinct forms, closely allied to the "Angel-Fish," are found in the Oolite, and have been described as *Thaumas*. The Carboniferous genus *Orthacanthus* may have been allied to this family, but it was armed with a spine immediately behind the head.

Family 10. *Pristiophoridæ*.—The rostral cartilage is produced into an exceedingly long, flat lamina, armed along each edge with a series of teeth (saw).

These sharks so greatly resemble the common saw-fishes as to be easily confounded with them, but their gill-openings are lateral, and not inferior. Only one genus is known, *Pristiophorus*, which occurs in the Australian and Japanese seas. *Squaloraia*, from the Lias, is supposed to have its nearest affinities to this family.

B. *Batoidei*, Rays.

Family 1. *Pristidæ*.—The snout is produced into an exceedingly long flat lamina, armed with a series of strong teeth along each edge (saw).

One genus only: *Pristis* (Saw-Fishes).

Family 2. *Rhinobatidæ*.—Tail strong and long, with two well-developed dorsal fins, and a longitudinal fold on each side; caudal developed. Disk not excessively dilated, the rayed portion of the pectoral fins not being continued to the snout. Teeth obtuse, granular, the dental surfaces of the jaws being undulated.

Genera: *Rhynchobatus*, *Rhinobatus*, and *Trygonorhina*. Fossil: *Spathobatis* and *Trigorhina*.

Family 3. *Torpedinidæ* ((Electric Rays).—Trunk a broad, smooth disk. Tail with a longitudinal fold on each side; a rayed dorsal fin is generally, and a caudal always, present. Anterior nasal valves confluent into a quadrangular lobe. An electric organ composed of vertical hexagonal prisms between the pectoral fins and the head.

Genera: *Torpedo*, *Narcine*, *Hypnos*, *Discopyge* (from Peru), *Astrape*, and *Temera*. A large fish, with the general appearance of a torpedo, has been found at Monte Bolca; and *Cyclobatis*, from the Upper Cretaceous Limestone of Lebanon, is probably another extinct representative of this family.

Family 4. *Raiidæ*.—Disk broad, rhombic, generally with asperities or spines; tail with a longitudinal fold on each side. The pectoral fins extend to the snout. No electric organ; no serrated caudal spine.

Genera: *Raia* (Rays and Skates), *Psammobatis*, *Sympterygia*, *Platyrhina*. Fossil: *Arthropterus*.

Family 5. *Trygonidæ*.—The pectoral fins are uninterruptedly continued to, and are confluent at, the extremity of the snout. Tail long and slender, without lateral longitudinal folds; vertical fins none, or imperfectly developed, often replaced by a strong serrated spine.

Genera: *Urogymnus*, *Trygon* (Sting-Rays), *Urolophus*, *Pteroplatea*.

Family 6. *Myliobatidæ* ("Devil-Fishes," "Sea-Devils," or "Eagle-Rays").—The disk is very broad, in consequence of the great development of the pectoral fins, which, however, leave the sides of the head free, and reappear at the extremity of the snout as a pair of detached (cephalic) fins. Viviparous.

Genera: *Myliobatis*, *Aetobatis*, *Rhinoptera*, *Dicerobatis*, *Ceratoptera*. Fragmentary portions of their tessellated dentition are common in Tertiary formations.

SUBORDER II. *Holocephala*.—One external gill-opening only, covered by a fold of the skin, which encloses a rudimentary cartilaginous gill-cover; four branchial clefts within the gill-cavity. The maxillary and palatal apparatus coalescent with the skull.

This suborder is represented in the living fauna by one family only, *Chimæridæ*; it forms a connecting link with the following order of fishes, the Ganoids. In external appearance, and as regards the structure of their organs of propagation, the chimæras are sharks. The females are provided with "claspers" in connexion with the ventral fins, and the ova are large, encased in a horny capsule, and few in number; there is no doubt that they are impregnated within the oviduct, as in sharks. The males are provided with a singular erectile appendage, spiny at its extremity, and received in a groove on the top of the head. On the other hand, the relations of the chimæras to the Ganoid, and, more especially, to the Dipnoous type become manifest in their notochordal skeleton and continuity of cranial cartilage. The spine in front of the first dorsal fin is articulated to the neural apophysis, and not merely implanted in the soft parts; it is immovable as in sharks. A cartilaginous operculum makes its appearance, and the external gill-opening is single. The dentition is that of a Dipnoid, each "jaw" being armed with a pair of broad dental plates, with the addition of a pair of smaller cutting teeth in the upper "jaw." Fossils of similar dental combination are not rare in strata commencing with the Lias and the bottom of the Oolitic series; but it is impossible to decide in every case whether the fossil should be referred to the Holocephalous or the Dipnoous type. According to Newberry, Chimæroid fishes commence in the Devonian with *Rhynchodus*, the remains of which were discovered by him in Ohio. Undoubted Chimæroids are *Elasmodus*, *Psaliodus*, *Ganodus*, *Ischyodus*, *Edaphodon*, and *Elasmognathus*, principally from Mesozoic and Tertiary formations. Very similar fossils occur in the corresponding strata of North America. A single species of *Callorhynchus* has been discovered by Hector in the Lower Greensand of New Zealand.

The living chimæras are few in number, and remain within very moderate dimensions, probably not exceeding a length of 5 feet, inclusive of their long filamentous, diphycercal tail. They are referred to two genera, *Chimæra* and *Callorhynchus*.

ORDER II.—*Ganoidei*.

Skeleton cartilaginous or ossified. Body with medial and paired fins, the hinder pair abdominal. Gills free, rarely partially attached to the walls of the gill-cavity. One external gill-opening only on each side; a gill-cover. Air-bladder with a pneumatic duct. Ova small, impregnated after exclusion. Embryo sometimes with external gills.

To this order belong the majority of the fossil fish remains of Palæozoic and Mesozoic age, whilst it is very scantily represented in the recent fauna, and evidently verging towards total extinction. The knowledge of the fossil forms, based on mere fragments of the hard parts of the body only, is very incomplete, and therefore their classification is in a most unsatisfactory state. In the following list only the most important groups will be mentioned.[1]

Eight suborders may be distinguished at present.

SUBORDER I. *Placodermi*.—Extinct. The head and pectoral region of the body encased in great bony sculptured plates, with dots of enamel; the remainder of the body naked, or with ganoid scales; skeleton notochordal.

Comprises the oldest vertebrate remains, from Devonian and Carboniferous formations.

Genera: *Pterichthys*, *Coccosteus*, *Dinichthys*, *Cephalaspis*, *Auchenaspis*, *Didymaspis*, *Pteraspis*, *Scaphaspis*, *Cyathaspis*, *Astrolepis*.

SUBORDER II. *Acanthodini*.—Extinct. Body oblong, compressed, covered with shagreen; skull not ossified; caudal fin heterocercal. Large spines, similar to those of Chondropterygians, in front of some of the median and paired fins. The spines are imbedded between the muscles, and not provided with a proximal joint.

Genera: *Acanthodes*, *Chiracanthus*, from Devonian and Carboniferous formations.

SUBORDER III. *Dipnoi*.—Nostrils two pairs, more or less within the mouth; limbs with an axial skeleton. Lungs and gills. Skeleton notochordal. No branchiostegals.

Family 1. *Sirenidæ*.—Caudal fin diphycercal; no gular plates; scales cycloid. A pair of molars, above and below, and one pair of vomerine teeth.

Genera: *Lepidosiren* and *Ceratodus*.

Lepidosiren (including *Protopterus*) has the body eel-shaped, with one continuous vertical fin. The limbs are reduced to filaments. Vomerine teeth conical, pointed. Each dental lamina or molar with strong cusps, supported by vertical ridges. Conus arteriosus with two longitudinal valves. Ovaries closed sacs. Two species are known:—*L. paradoxa*, from the system of the river Amazon, and *L.* (*Protopterus*) *annectens*, which abounds in many localities of the west coast of Africa, is spread over the whole of tropical Africa, and in many districts of the central parts forms a regular article of food.

Ceratodus has the body elongate, compressed, with one continuous vertical fin. The limbs are paddle-shaped, with broad, rayed fringe. Vomerine teeth incisor-like; molars with flat, undulated surface, and lateral prongs. Conus arteriosus with transverse series of valves. Ovaries transversely lamellated.

Two species, *C. forsteri* and *C. miolepis*, are known from fresh waters of Queensland. The specimens obtained hitherto have come from the Burnett, Dawson, and Mary rivers, some from the fresh waters of the upper parts, others from the lower brackish portions. The fish is said to grow to a weight of 20 lb and to a length of 6 feet. Locally, the settlers call it "Flat-head," "Burnett-Salmon," or "Dawson-Salmon," and the aborigines "Barramunda," a name which they appear to apply also to other large-scaled freshwater fishes, as the *Osteoglossum leichardti*. In the stomach there is generally found an enormous quantity of the leaves of plants growing on the banks of rivers, evidently eaten after they had fallen into the water and when in a decomposing condition. The flesh of the fish is salmon-coloured, and is much esteemed as food. The barramunda is said to be in the habit of going on land, or at least on mud-flats; and this assertion appears to be borne out by the fact

[1] For a study of details we have to refer to Agassiz, *Poissons Fossiles*; Owen, *Palæontology*, Edin., 1861, 8vo; Huxley, "Preliminary Essay upon the Systematic Arrangement of the Fishes of the Devonian Epoch," in *Mem. Geolog. Survey*, December 10, 1861, and "Illustrations of the Structure of Crossopterygian Ganoids," *ibid.*, December 12, 1866; Traquair, *The Ganoids of the British Carboniferous Formations*, part i., "Palæoniscidæ," Palæontogr. Soc. Lond., 1877; and "On the Structure and Affinities of the Platysomidæ," in *Trans. Roy. Soc. Edin.* vol. xxix.

that it is provided with a lung. It is much more probable, however, that it rises now and then to the surface of the water in order to fill its lung with air, and descends again until the air is so much deoxygenized as to render a renewal of it necessary. As the barramunda has perfectly developed gills, as well as the lung, we can hardly doubt that, when it is in water of normal composition, and pure enough to yield the necessary supply of oxygen, these organs are sufficient for the purpose of breathing, and that the respiratory function rests with them alone. But when the fish is compelled to sojourn in thick muddy water charged with gases which are the products of decomposing organic matter (and this must very frequently be the case during the droughts which annually exhaust the creeks of tropical Australia), it commences to breathe air with its lung in the way indicated above. If the medium in which it happens to be is altogether unfit for breathing, the gills cease to have any function; if it is irrespirable in a less degree the gills may still continue to assist the lung. The barramunda, in fact, can breathe by either gills or lung alone, or by both simultaneously.

The discovery of *Ceratodus* does not date farther back than the year 1870. It proved to be of the greatest interest, not only on account of the relation of this creature to the other living *Dipnoi* and *Ganoidei*, but also because it threw fresh light on those singular fossil teeth which are found in strata of the Triassic and Jurassic formations in various parts of Europe, India, and America. These teeth vary greatly in general shape and size; they are sometimes 2 inches long, much longer than broad, depressed, with a flat or slightly undulated always punctuated crown, with one margin convex, and with from three to seven prongs projecting on the opposite margin.

Family 2. *Ctenododipteridæ.*—Caudal fin heterocercal; gular plates; scales cycloid. Two pairs of molars and one pair of vomerine teeth.

Extinct. *Dipterus* (*Ctenodus*), *Heliodus*, from Devonian strata.

Family 3. *Phaneropleuridæ.*—Caudal fin diphycercal; vertical fin continuous; gular plates; scales cycloid. Jaws with a series of minute conical teeth on the margin.

Extinct. *Phaneropleuron*, from Devonian and Carboniferous formations.

SUBORDER IV. *Chondrostei.*—Skeleton notochordal; skull cartilaginous, with dermal ossifications; branchiostegals few in number or absent. Teeth minute or absent. Integuments naked or with bucklers. Caudal fin heterocercal, with fulcra. Nostrils double, in front of the eyes.

Family 1. *Acipenseridæ.*—Body elongate, sub-cylindrical, with five rows of osseous bucklers. Snout produced, subspatulate or conical, with the mouth at its lower surface, small, transverse, protractile, toothless. Four barbels in a transverse series on the lower side of the snout. Vertical fins with a single series of fulcra in front. Dorsal and anal fins approximate to the caudal. Branchiostegals none. Air-bladder large, simple, communicating with the dorsal wall of the œsophagus.

Genera: *Acipenser* and *Scaphirhynchus* (Sturgeons, Hausen, Sterlet).

Family 2. *Polyodontidæ.*—Body naked, or with minute stellate ossifications. Mouth lateral, very wide, with minute teeth in both jaws. Barbels none. Caudal fin with fulcra. Dorsal and anal fins approximate to the caudal.

Genera: *Polyodon* and *Psephurus*. Fossil: *Chondrosteus*.

SUBORDER V. *Polypteroidei.*—Paired fins with axial skeleton, fringed; dorsal fins two or more. Branchiostegals absent, but generally gular plates. Vertebral column diphycercal or heterocercal. Body scaly.

Family 1. *Polypteridæ.*—Scales ganoid; fins without fulcra. A series of dorsal spines, to each of which an articulated finlet is attached; anal placed close to the caudal fin, the vent being near the end of the tail. Abdominal portion of the vertebral column much longer than the caudal.

Genera: *Polypterus* and *Calamoichthys*. *Polypterus* is confined to tropical Africa, occurring in abundance in the rivers of the west coast and in the upper Nile; it is rare in the middle and lower Nile. There is only one species known, *Polypterus bichir* ("Bichir" being its vernacular name in Egypt), which varies in the number of the dorsal finlets, the lowest being eight, the highest eighteen. It attains to a length of 4 feet. Nothing is known of its mode of life, observations on which are very desirable. *Calamoichthys* (from Old Calabar) is distinguished from *Polypterus* by its greatly elongated form and the absence of ventral fins.

Family 2. *Saurodipteridæ.*—Scales ganoid, smooth like the surface of the skull. Two dorsal fins; paired fins obtusely lobate. Teeth conical. Caudal fin heterocercal.

Extinct. *Diplopterus*, *Megalichthys*, and *Osteolepis*, from Devonian and Carboniferous formations.

Family 3. *Cœlacanthidæ.*—Scales cycloid. Two dorsal fins, each supported by a single two-pronged interspinous bone; paired fins obtusely lobate. Air-bladder ossified; notochord persistent, diphycercal.

Extinct. *Cœlacanthus*, from Carboniferous strata. Several other genera, from the Coal formations to the Chalk, have been associated with it:—*Undina*, *Graphiurus*, *Macropoma*, *Holophagus*, *Hoplopygus*, *Rhizodus*.

Family 4. *Holoptychidæ.*—Scales cycloid or ganoid, sculptured. Two dorsal fins; pectorals narrow, acutely lobate; dentition dendrodont.

Extinct. Genera: *Holoptychius*, *Saurichthys*, *Glyptolepis*, *Dendrodus*, *Glyptolæmus*, *Glyptopomus*, *Tristichopterus*, *Gyroptychius*, *Strepsodus*, from Devonian and Carboniferous strata.

SUBORDER VI. *Pycnodontoidei.*—Body compressed, high and short or oval, covered with rhombic scales arranged in decussating pleurolepidal lines. Notochord persistent. Paired fins without axial skeleton. Teeth on the palate and hinder part of the lower jaw molar-like. Branchiostegals, but no gular plates. Extinct.

Family 1. *Pleurolepidæ.*—Homocercal. Body less high. Fins with fulcra.

Genera: *Pleurolepis* and *Homœolepis*, from the Lias.

Family 2. *Pycnodontidæ.*—Homocercal. The neural arches and ribs are ossified; the roots of the ribs are but little expanded in the older genera, but are enlarged in the Tertiary forms, so as to simulate vertebræ. Paired fins not lobate. Obtuse teeth on the palate and the sides of the mandible; maxilla toothless; incisor-like teeth in the intermaxillary and front of the mandible. Fulcra absent in all the fins.

Genera: *Gyrodus*, *Mesturus*, *Microdon*, *Cœlodus*, *Pycnodus*, *Mesodon*, from Mesozoic and Tertiary formations.

SUBORDER VII. *Lepidosteoidei.*—Scales ganoid, rhombic; fins generally with fulcra; paired fins not lobate. Præoperculum and interoperculum developed; generally numerous branchiostegals, but no gular plate.

Family 1. *Lepidosteidæ.*—Scales ganoid, lozenge-shaped. Skeleton completely ossified; vertebræ convex in front and concave behind. Fins with fulcra; dorsal and anal composed of articulated rays only, placed far backwards, close to the caudal. Abdominal part of the vertebral column much longer than caudal. Branchiostegals not numerous, without enamelled surface. Heterocercal.

Lepidosteus.—This genus existed as early as Tertiary times; their remains have been found in Europe as well as in North America. In our period they are limited to the temperate parts of North America, Central America, and Cuba. Three species can be distinguished, which attain to a length of about 6 feet. They feed on other fishes; and their general resemblance to a pike has gained for them the vernacular names of "Gar-Pike" or "Bony Pike."

Family 2. *Sauridæ.*—Body oblong, with ganoid scales; vertebræ not completely ossified; termination of the vertebral column homocercal; fins generally with fulcra. Maxillary composed of a single piece; jaws with a single series of conical pointed teeth. Branchiostegals numerous, enamelled, the anterior forming broad gular plates.

Extinct. Genera: *Semionotus*, *Eugnathus*, *Cephenoplosus*, *Macrosemius*, *Propterus*, *Ophiopsis*, *Pholidophorus*, *Pleuropholis*, *Pachycormus*, *Ptycholepis*, *Conodus*, *Eulepidotus*, *Lophiostomus*, &c.

Family 3. *Stylodontidæ.*—Body rhombic or ovate, with ganoid scales; vertebræ not completely ossified; termination of the vertebral column homocercal; fins with fulcra. Maxillary composed of a single piece; jaws with several series of teeth, the outer ones equal, styliform. Dorsal fin very long, extending to the caudal. Branchiostegals numerous.

Extinct. *Tetragonolepis*, from the Lias.

Family 4. *Sphærodontidæ.*—Body oblong, with rhombic ganoid scales; vertebræ ossified, but not completely closed; homocercal; fins with fulcra. Maxillary composed of a single piece; teeth in several series, obtuse; those on the palate globular. Dorsal and anal fins short. Branchiostegals.

Extinct. The type genus of this family is *Lepidotus*.

Family 5. *Aspidorhynchidæ.*—Body elongate, with ganoid scales; jaws prolonged into a beak; termination of the vertebral column homocercal. Fins with fulcra; a series of enlarged scales along the side of the body. Dorsal fin opposite to the anal.

Extinct: Mesozoic. Genera: *Aspidorhynchus* and *Belonostomus*.

Family 6. *Palæoniscidæ.*—Body fusiform, with rhombic ganoid scales. Notochord persistent, with the vertebral arches ossified. Heterocercal. All the fins with fulcra; dorsal short. Branchiostegals numerous, the foremost pair forming broad gulars. Teeth small, conical, or cylindrical.

Extinct. Genera: from the Old Red Sandstone—*Chirolepis* and *Acrolepis*; from Carboniferous rocks—*Cosmoptychius*, *Elonichthys*, *Nematoptychius*, *Cycloptychius*, *Microconodus*, *Gonatodus*, *Rhadinichthys*, *Myriolepis*, *Urosthenes*; from the Permian—*Rhabdolepis*, *Palæoniscus*, *Amblypterus*, and *Pygopterus*; from the Lias—*Centrolepis*, *Oxygnathus*, *Cosmolepis*, and *Thrissonotus*.

Family 7. *Platysomidæ.*—Body generally high, compressed, covered with rhombic ganoid scales arranged in dorso-ventral bands. Notochord persistent, with the vertebral arches ossified. Heterocercal; fins with fulcra; dorsal fin long, occupying the posterior half of the back. Branchiostegals numerous. Teeth tubercular or obtuse.

Extinct. Genera: from Carboniferous and Permian formations—*Eurynotus*, *Benedenius*, *Mesolepis*, *Eurysomus*, *Wardichthys*, *Chirodus* (M'Coy), *Platysomus*.

SUBORDER VIII. *Amioidei.*—Vertebral column more or less completely ossified, heterocercal. Body covered with cycloid scales. Branchiostegals present.

Family 1. *Caturidæ.*—Notochord persistent, with partially ossified vertebræ; homocercal; fins with fulcra. Teeth in a single series, small, pointed.

Extinct. *Caturus*, from the Oolite to the Chalk.

Family 2. *Leptolepidæ.*—Scales cycloid. Vertebræ ossified; homocercal; fins without fulcra; dorsal short. Teeth minute, in bands, with canines in front.

Extinct, but leading to the living representative of this suborder. Genera: *Thrissops*, *Leptolepis*, from the Lias and Oolite. These fishes, so far as the preserved parts are concerned, cannot be distinguished from Teleosteous fishes, to which they are referred by some palæontologists.

Family 3. *Amiidæ.*—Skeleton entirely ossified; a single large gular plate; homocercal; fins without fulcra; a long soft dorsal fin. Abdominal and caudal parts of the vertebral column subequal in extent. Branchiostegals numerous.

Amia.—The "Bow-Fin" or "Mud-Fish" (*A. calva*) is not uncommon in many of the fresh waters of the United States; it grows to a length of 2 feet. Little is known about its habits; small fishes, crustaceans, and aquatic insects have been found in its stomach. Wilder has observed its respiratory actions; it rises to the surface, and, without emitting any air-bubble whatever, opens the jaws widely, and apparently gulps in a large quantity of air; these acts of respiration are more frequently performed when the water is foul or has not been changed; and there is no doubt that a conversion of oxygen into carbonic acid is effected, as in the lungs of aerial vertebrates.

Fossil remains occur in Tertiary deposits of North America, which have been distinguished as *Protamia* and *Hypamia*.

Subclass II.—Teleostei.

Heart with a non-contractile bulbus arteriosus; intestine without spiral valve; optic nerves decussating; skeleton ossified, with completely formed vertebræ; vertebral column diphycercal or homocercal; branchiæ free.

The *Teleostei* form the majority of the fishes of the present fauna, and are the geological successors of the *Palæichthyes*, undoubted *Teleostei* not ranging farther back than the Chalk period. This subclass comprises an infinite variety of forms; and as, naturally, many Ganoid fishes lived under external conditions similar to those of certain *Teleostei*, and led a similar mode of life, we find not a few analogous forms in both series,—some Ganoids resembling externally the Teleosteous Siluroids, others the Clupeoids, others the Chætodonts, others the Scombresoces, &c. But there is no direct genetic relation between these fishes, as some naturalists have been inclined to believe.

The *Teleostei* are divided into six orders:—

I. *Acanthopterygii.*—Part of the rays of the dorsal, anal, and ventral fins non-articulated spines. The lower pharyngeals separate. Air-bladder, if present, without pneumatic duct in the adult.

II. *Acanthopterygii Pharyngognathi.*—Part of the rays of the dorsal, anal, and ventral fins non-articulated spines. The lower pharyngeals coalesced Air-bladder without pneumatic duct.

III. *Anacanthini.*—Vertical and ventral fins without spinous rays. Ventral fins, if present, jugular or thoracic. Air-bladder, if present, without pneumatic duct. Lower pharyngeals separate.

IV. *Physostomi.*—All the fin-rays articulated; only the first of the dorsal and pectoral fins is sometimes ossified. Ventral fins, if present, abdominal, without spine. Air-bladder, if present, with a pneumatic duct.

V. *Lophobranchii.*—Gills not laminated, but composed of small rounded lobes, attached to the branchial arches. Gill-cover reduced to a large simple plate. A dermal skeleton replaces more or less soft integuments.

VI. *Plectognathi.*—A soft dorsal fin opposite to the anal; sometimes elements of a spinous dorsal. Ventral fins none, or reduced to spines. Gills pectinate; air-bladder without pneumatic duct. Skin with rough scutes, or with spines, or naked.

ORDER I.—*Acanthopterygii.*

Part of the rays of the dorsal, anal, and ventral fins are non-articulated, more or less sharp-pointed spines. The lower pharyngeals are generally separate. Air-bladder, if present, without pneumatic duct in the adult.

DIVISION I. *Acanthopterygii Perciformes.*—Body more or less compressed, elevated or oblong, but not elongate; the vent is remote from the extremity of the tail, behind the ventral fins if they are present. No prominent anal papilla. No superbranchial organ. Dorsal fin or fins occupying the greater portion of the back; spinous dorsal well developed, generally with stiff spines, of moderate extent, rather longer than, or as long as, the soft; the soft anal similar to the soft dorsal, of moderate extent or rather short. Ventrals thoracic, with one spine and with four or five rays.

Family 1. *Percidæ.*—The scales extend but rarely over the vertical fins, and the lateral line is generally present, continuous from the head to the caudal fin. All the teeth simple and conical; no barbels. No bony stay for the præoperculum.

A large family, represented by numerous genera and species in fresh waters, and on all the coasts of the temperate and tropical regions. Carnivorous.

Fossil Percoids abound in some formations, for instance, at Monte Bolca, where species of *Labrax*, *Lates*, *Smerdis* and *Cyclopoma* (both extinct), *Dules*, *Serranus*, *Apogon*, *Therapon*, and *Pristipoma* have been recognized. *Paraperca* is a genus recently discovered in the Marls of Aix-en-Provence. A species of *Perca* is known from the freshwater deposits of Oeningen.

The living genera are—*Perca* (Perch), *Siniperca*, *Percichthys*, *Labrax* (Bass), *Lates*, *Psammoperca*, *Percalabrax*, *Acerina* (Pope), *Lucioperca*, *Pileoma*, *Boleosoma*, *Aspro*, *Centropomus*, *Enoplosus*, *Centropristis*, *Anthias*, *Callanthias*, *Serranus* (Sea-Perch), *Anyperodon*, *Prionodes*, *Plectropoma*, *Trachypoma*, *Polyprion*, *Grammistes*, *Rhypticus*, *Aulacocephalus*, *Myriodon*, *Diploprion*, *Mesoprion*, *Glaucosoma*, *Dules*, *Therapon*, *Helotes*, *Pristipoma*, *Conodon*, *Hæmulon*, *Hapalogenys*, *Diagramma*, *Hyperoglyphe*, *Lobotes*, *Histiopterus*, *Gerres*, *Scolopsis*, *Heterognathodon*, *Dentex*, *Symphorus*, *Synagris*, *Mæna*, *Smaris*, *Cæsio*, *Erythrichthys*, *Oligorus* (Murray-Cod), *Grystes*, *Arripis*, *Huro*, *Ambassis*, *Apogon*, *Chilodipterus*, *Lanioperca*, *Acropoma*, *Scombrops*, *Pomatomus*, *Priacanthus*, *Centrarchus*, *Bryttus*, *Pomotis*, *Etelis*, *Niphon*, *Aprion*, *Apsilus*, *Pentaceros*, *Velifer*, *Datnioides*, *Percilia*.

Family 2. *Squamipinnes.*—Body compressed and elevated, covered with scales, either finely ctenoid or smooth. Lateral line continuous, not continued over the caudal fin. Mouth in front of the snout, generally small, with lateral cleft. Teeth villiform or setiform, in bands, without canines or incisors. Dorsal fin consisting of a spinous and soft portion of nearly equal development; anal with three or four spines, similarly developed as the soft dorsal, both being many-rayed. The vertical fins more or less densely covered with small scales. The lower rays of the pectoral fin branched, not enlarged; ventrals thoracic, with one spine and five soft rays.

Genera: *Chætodon*, *Chelmo*, *Heniochus*, *Holacanthus*, *Pomacanthus*, *Scatophagus*, *Ephippus*, *Drepane*, *Hypsinotus*, *Scorpis*, *Atypichthys*, *Toxotes*. Some of these genera occur also in Tertiary formations. The majority of these fishes are inhabitants of the tropical seas, and abound chiefly in the neighbourhood of coral-reefs (Coral-Fishes). The beauty and singularity of distribution of the colours in some of the genera, as *Chætodon*, *Heniochus*, *Holacanthus*, is scarcely surpassed in any other group of fishes. They are of small size, and are carnivorous, feeding on small invertebrates.

Family 3. *Mullidæ.*—Body rather low and slightly compressed, covered with large thin scales, with or without an extremely fine serrature. Two long erectile barbels are suspended from the hyoid, and are received between the rami of the lower jaw and the opercula. Mouth in front of the snout, with the cleft lateral and rather short; teeth very feeble. Eye lateral, of moderate size. Two short dorsal fins remote from each other, the first with feeble spines; anal similar to the second dorsal. Ventrals with one spine and five rays. Pectorals short.

Genera: *Mullus* and *Upeneus* (Red Mullets).

Family 4. *Sparidæ* (Sea-Breams).—Body compressed, oblong, covered with scales, the serrature of which is very minute, and sometimes altogether absent. Mouth in front of the snout, with cleft lateral. Either cutting teeth in front of the jaws, or molar teeth on the side; palate generally toothless. One dorsal fin, formed by a spinous and soft portion of nearly equal development. Anal fin with three spines. The lower rays of the pectoral fin are generally branched, but in one genus simple. Ventrals thoracic, with one spine and five rays.

Genera: *Cantharus*, *Box*, *Scatharus*, *Oblata*, *Crenidens*, *Tri-*

pterodon, *Pachymetopon*, *Dipterodon*, *Gymnocrotaphus*, *Girella*, *Tephræops*, *Doydixodon*, *Haplodactylus*, *Sargus* (Sheep's Head), *Lethrinus*, *Sphærodon*, *Pagrus*, *Pagellus*, *Chrysophrys*, and *Pimelepterus*.

The extinct forms found hitherto are rather numerous; the oldest come from the Cretaceous formation of Mount Lebanon; some belong to living genera, as *Sargus*, *Pagellus*; of others from Eocene and Miocene formations no living representative is known—*Sparnodus*, *Sargodon*, *Capitodus*, *Soricidens*, *Asima*.

The *Hoplognathidæ* are a very small family distinguished by confluent teeth, and allied to the sea-breams.

Family 5. *Cirrhitidæ*.—Body oblong, compressed, covered with cycloid scales; lateral line continuous. Mouth in front of the snout, with lateral cleft. Cheeks without a bony stay for the præoperculum. Dentition more or less complete, composed of small pointed teeth, sometimes with the addition of canines. One dorsal fin formed by a spinous and soft portion, of nearly equal development. Anal with three spines, generally less developed than the soft dorsal. The lower rays of the pectoral fins simple and generally enlarged; ventrals thoracic, but remote from the root of the pectorals, with one spine and five rays.

Genera: *Cirrhites*, *Chironemus*, *Chilodactylus*, *Mendosoma*, *Nemadactylus*, and *Latris*.

Family 6. *Scorpænidæ*.—Body oblong, more or less compressed, covered with ordinary scales or naked. Cleft of the mouth lateral or subvertical. Dentition feeble, consisting of villiform teeth, and generally without canines. Some bones of the head armed, especially the angle of the præoperculum, its armature receiving additional support by a bony stay, connecting it with the infraorbital ring. The spinous portion of the dorsal fin equally or more developed than the soft and the anal. Ventrals thoracic, generally with one spine and five soft rays, sometimes rudimentary.

Genera: *Sebastes*, *Scorpæna*, *Glyptauchen*, *Lioscorpius*, *Setarches*, *Pterois*, *Apistus*, *Agriopus*, *Synanceia*, *Micropus*, *Chorismodactylus*, *Tænianotus*, *Centropogon*, *Pentaroge*, *Tetraroge*, *Prosopodasys*, *Aploactis*, *Trichopleura*, *Hemitripterus*, *Minous*, and *Pelor*.

Family 7. *Nandidæ*.—Body oblong, compressed, covered with scales. Lateral line interrupted. Dorsal fin formed by a spinous and soft portion, the number of spines and rays being nearly equal; anal fin with three spines, and with the soft portion similar to the soft dorsal. Ventral fins thoracic, with one spine, and five or four rays. Dentition more or less complete, but feeble.

Genera: *Plesiops*, *Trachinops*, *Badis*, *Nandus*, and *Catopra*.

Family 8. *Polycentridæ*.—Body compressed, deep, scaly. Lateral line none. Dorsal and anal fins long, both with numerous spines, the spinous portion being the more developed. Ventrals thoracic, with one spine and five soft rays. Teeth feeble. Pseudobranchiæ hidden.

Genera: *Polycentrus* and *Monocirrhus*.

Family 9. *Teuthididæ*.—Body oblong, strongly compressed, covered with very small scales. Lateral line continuous. A single series of cutting incisors in each jaw; palate toothless. One dorsal fin, the spinous portion being the more developed; anal with seven spines. Ventral fins thoracic, with an outer and an inner spine, and with three soft rays between.

Genus: *Teuthis*.

DIVISION II. *Acanthopterygii Beryciformes*.—Body compressed, oblong, or elevated; head with large muciferous cavities, which are covered with a thin skin. Ventral fins thoracic, with one spine and more than five soft rays (in *Monocentris* with two only).

The family of *Berycidæ* has a very remarkable geographical distribution, which has been noticed at pp. 679, 681. Members of this family belong to the oldest Teleosteous fishes, the majority of the Acanthopterygians found in the Chalk being Berycoids. *Beryx*, *Holocentrum*, and *Myripristis* have been found in several species, with other genera now extinct:—*Pseudoberyx*, *Berycopsis*, *Homonotus*, *Stenostoma*, *Sphenocephalus*, *Acanus*, *Hoplopteryx*, *Platycormus*, *Podocys*, *Acrogaster*, *Macrolepis*, and *Rhacolepis*.

Living genera: *Monocentris*, *Hoplostethus*, *Trachichthys*, *Anoplogaster*, *Beryx*, *Melamphaes*, *Polymixia*, *Myripristis*, and *Holocentrum*.

DIVISION III. *Acanthopterygii Kurtiformes*.—One dorsal fin only, much shorter than the anal, which is long and many-rayed. No superbranchial organ.

One family, *Kurtidæ*.

Genera: *Pempheris* and *Kurtus*.

DIVISION IV. *Acanthopterygii Polynemiformes*.—Two rather short dorsal fins, somewhat remote from each other; free filaments at the humeral arch, below the pectoral fins; muciferous canals of the head well developed.

Family. *Polynemidæ*.—Body oblong, rather compressed, covered with smooth or very feebly ciliated scales. Lateral line continuous. Snout projecting beyond the mouth, which is inferior, with lateral cleft. Eye lateral, large. Villiform teeth in the jaws and on the palate. Ventrals thoracic, with one spine and five rays.

Genera: *Polynemus*, *Pentanemus*, and *Galeoides*.

DIVISION V. *Acanthopterygii Sciæniformes*.—The soft dorsal is more, generally much more, developed than the spinous and the anal. No pectoral filaments; head with the muciferous canals well developed.

Family. *Sciænidæ*.—Body rather elongate, compressed, covered with ctenoid scales. Lateral line continuous, and frequently extending over the caudal fin. Mouth in front of the snout. Eye lateral, of moderate size. Teeth in villiform bands, sometimes with the addition of canines; no molars or incisor-like teeth in the jaws; palate toothless. Præoperculum unarmed, and without bony stay. Ventrals thoracic, with one spine and five soft rays. Bones of the head with wide muciferous channels. Air-bladder frequently with numerous appendages.

Genera: *Larimus*, *Pogonias* (Drum), *Micropogon*, *Umbrina*, *Eques*, *Nebris*, *Lonchurus*, *Sciæna* (Meagre), *Pachyurus*, *Otolithus*, *Ancylodon*, and *Collichthys*.

DIVISION VI. *Acanthopterygii Xiphiiformes*.—The upper jaw is produced into a cuneiform weapon.

One family, *Xiphiidæ* (Sword-Fishes), with the genera *Xiphias* and *Histiophorus*.

DIVISION VII. *Acanthopterygii Trichiuriformes*.—Body elongate, compressed or band-like; cleft of the mouth wide, with several strong teeth in the jaws or on the palate. The spinous and soft portions of the dorsal fin and the anal are of nearly equal extent, long, many-rayed, sometimes terminating in finlets; caudal fin forked, if present.

The family of *Trichiuridæ* is composed of the following living genera: *Nealotus*, *Nesiarchus*, *Aphanopus Euoxymetopon*, *Lepidopus* (Scabbard-Fish), *Trichiurus* (Hair-Tail), *Epinnula*, *Thyrsites*, and *Gempylus*. It was well represented in the Chalk and later formations by *Enchodus*, *Anenchelum*, *Nemopteryx*, *Xiphopterus*, *Hemithyrsites*, and *Trichiurichthys*. Two other genera, *Palæorhynchus* and *Hemirhynchus*, belong to a distinct though allied family.

DIVISION VIII. *Acanthopterygii Cotto-scombriformes*.—Spines developed in one of the fins at least. Dorsal fins either continuous or close together; the spinous dorsal, if present, always short; sometimes modified into tentacles, or into a suctorial disk; soft dorsal always long, if the spinous is absent; anal similarly developed as the soft dorsal, and both generally much longer than the spinous, sometimes terminating in finlets. Ventrals, thoracic or jugular, if present, never modified into an adhesive apparatus. No prominent anal papilla.

Family 1. *Acronuridæ*.—Body compressed, oblong or elevated, covered with minute scales. Tail generally armed with one or more bony plates or spines, which are developed with age, but absent in very young individuals. Eye lateral, of moderate size. Mouth small; a single series of more or less compressed, sometimes denticulated, sometimes pointed incisors in each jaw; palate toothless. One dorsal fin, the spinous portion being less developed than the soft; anal with two or three spines; ventral fins thoracic. Nine abdominal and thirteen caudal vertebræ.

Genera: *Acanthurus* (Surgeon), *Naseus*, and *Prionurus*.

Extinct species of *Acanthurus* and *Naseus* have been discovered in the Monte Bolca formation.

Family 2. *Carangidæ*.—Body more or less compressed, oblong or elevated, covered with small scales or naked; eye lateral. Teeth, if present, conical. No bony stay for the præoperculum. The spinous dorsal is less developed than the soft or the anal, either continuous with, or separated from, the soft portion; sometimes rudimentary. Ventrals thoracic, sometimes rudimentary or entirely absent. No prominent papilla near the vent. Gill-opening wide. Ten abdominal and fourteen caudal vertebræ.

Genera: *Caranx* (Horse-Mackerel), *Argyriosus*, *Micropteryx*, *Seriola*, *Seriolella*, *Seriolichthys* (Yellow-Tails), *Naucrates* (Pilot-Fish), *Chorinemus*, *Lichia*, *Temnodon* (Blue-Fish), *Lactarius*, *Paropsis*, *Trachynotus*, *Pammelas*, *Psettus*, *Platax*, *Zanclus*, *Anomalops*, *Capros* (Boar-Fish), *Antigonia*, *Diretmus*, *Equula*, and *Gazza*.—Members of this family appear first in Cretaceous formations, where they are represented by *Platax* and some caranx-like genera (*Vomer* and *Aipichthys*). They are more numerous in Tertiary formations, especially in the strata of Monte Bolca, where some still existing genera occur, as *Zanclus*, *Platax*, *Caranx* (*Carangopsis*), *Argyriosus* (*Vomer*), *Lichia*, *Trachynotus*. Of extinct genera the following belong to this family:—*Pseudovomer* (Licata), *Amphistium*, *Archæus*, *Ductor*, *Pionemus* (?), and *Semiophorus*.

Family 3. *Cyttidæ*.—Body elevated, compressed, covered with small scales, or with bucklers, or naked; eye lateral. Teeth conical, small. No bony stay for the præoperculum. Dorsal fin composed of two distinct portions. Ventrals thoracic. No prominent papilla near the vent. Gill-opening wide. More than ten abdominal and more than fourteen caudal vertebræ.

Genera: *Zeus* (John Dory) and *Cyttus*.

Family 4. *Stromateidæ*.—Body more or less oblong and compressed, covered with very small scales; eye lateral. Dentition very feeble; œsophagus armed with numerous horny, barbed processes. No bony stay for the præoperculum. Dorsal fin single, long, without distinct spinous division. More than ten abdominal and more than fourteen caudal vertebræ.

Genera : *Stromateus* and *Centrolophus.*

Family 5. *Coryphænidæ.*—Body compressed ; eye lateral. Teeth small, conical, if present ; œsophagus smooth. No bony stay for the præoperculum. Dorsal fin single, long, without distinct spinous division. More than ten abdominal and more than fourteen caudal vertebræ.

Genera : *Coryphæna* (Dolphin), *Brama, Taractes, Lampris* (Sun-Fish), *Pteraclis, Schedophilus, Diana, Ausonia, Mene.* Fossil : *Goniognathus.*

Family 6. *Nomeidæ.*—Body oblong, more or less compressed, covered with cycloid scales of moderate size ; eye lateral. No bony stay for the præoperculum. Dorsal fin with a distinct spinous portion separated from the soft ; sometimes finlets ; caudal forked. More than ten abdominal and more than fourteen caudal vertebræ.

Genera : *Gastrochisma, Nomeus, Psenes,* and *Cubiceps.*

Family 7. *Scombridæ.*—Body oblong, scarcely compressed, naked or covered with small scales ; eye lateral. Dentition well developed. No bony stay for the præoperculum. Two dorsal fins ; generally finlets. Ventrals thoracic, with one spine and five rays. More than ten abdominal and more than fourteen caudal vertebræ.

Genera : *Scomber* (Mackerel), *Thynnus* (Tunny, Bonito, Albacore), *Pelamys, Auxis, Cybium, Elacate,* and *Echeneis* (Sucking-Fish).

Family 8. *Trachinidæ.*—Body elongate, low, naked or covered with scales. Teeth small, conical. No bony stay for the præoperculum. One or two dorsal fins, the spinous portion being always shorter and much less developed than the soft ; the anal similarly developed as the soft dorsal ; no finlets. Ventrals with one spine and five rays. Gill-opening more or less wide. Ten or more than ten abdominal and more than fourteen caudal vertebræ.

Genera : *Uranoscopus, Leptoscopus, Agnus, Anema, Kathetostoma, Trachinus* (Weever), *Champsodon, Percis, Sillago, Bovichthys, Bathydraco, Chœnichthys, Aphritis, Acanthaphritis, Eleginus, Chimarrhichthys, Cottoperca, Percophis, Trichodon, Pinguipes, Latilus, Opisthognathus, Pseudochromis, Cichlops, Pseudoplesiops, Notothenia,* and *Harpagifer.* Fossil : *Callipteryx, Trachinopsis,* and *Pseudoeleginus.*

Malacanthus is the type of a family allied to the *Trachinidæ.*

Family 9. *Batrachidæ.*—Head broad and thick ; body elongate, compressed behind ; skin naked or with small scales. No bony stay for the præoperculum. Teeth conical, small or of moderate size. The spinous dorsal consists of two or three spines only ; the soft and the anal long. Ventrals jugular, with two soft rays ; pectorals not pediculated. Gill-opening a more or less vertical slit before the pectoral, rather narrow.

Genera : *Batrachus, Thalassophryne,* and *Porichthys.*—*Psychrolutes* and *Neophrynichthys* are allied forms.

Family 10. *Pediculati.*—Head and anterior part of the body very large, without scales. No bony stay for the præoperculum. Teeth villiform or rasp-like. The spinous dorsal is advanced forwards, composed of a few more or less isolated spines, often transformed into tentacles, or entirely absent. Ventral fins jugular, with four or five soft rays, sometimes absent. The carpal bones are prolonged, forming a sort of arm, terminating in the pectoral. Gill-opening reduced to a small foramen, situated in or near the axil. Gills two and a half, three, or three and a half ; pseudobranchiæ generally absent.

Genera : *Lophius* (Fishing-Frog, Angler), *Ceratias, Himantolophus, Melanocetus, Oneirodes, Antennarius, Brachionichthys, Saccarius, Chaunax, Malthe, Halieutæa, Halieutichthys, Dibranchus,* and *Ægæonichthys.*

Family 11. *Cottidæ.*—Form of the body oblong, sub-cylindrical. Cleft of the mouth lateral. Dentition feeble, generally in villiform bands. Some bones of the head are armed ; and a bony stay connects the præopercular spine with the infraorbital ring. Two dorsal fins (rarely one), the spinous being less developed than the soft and the anal. Ventrals thoracic, with five or less soft rays.

Genera : *Cottus* (Bull-head, Miller's Thumb), *Centridermichthys, Icelus, Platycephalus, Hoplichthys, Bunocottus, Rhamphocottus, Triglops, Podabrus, Blepsias, Nautichthys, Scorpænichthys, Hemilepidotus, Artedius, Ptyonotus, Polycaulus, Bembras,* and *Trigla* (Gurnards).

Family 12. *Cataphracti.*—Form of the body elongate, sub-cylindrical. Dentition feeble. Body completely cuirassed with osseous keeled scales or plates. A bony stay connects the angle of the præoperculum with the infraorbital ring. Ventrals thoracic.

Genera : *Agonus, Aspidophoroides, Siphagonus, Peristethus, Dactylopterus* (Flying Gurnard).

Family 13. *Pegasidæ.*—Body entirely covered with bony plates, anchylosed on the trunk and movable on the tail. Barbels none. The margin of the upper jaw is formed by the intermaxillaries and their cutaneous prolongation, which extends downwards to the extremity of the maxillaries. Gill-cover formed by a large plate, homologous to the operculum, præoperculum, and suboperculum ; interoperculum a long fine bone, hidden below the gill-plate. One rudimentary branchiostegal. The gill-plate is united to the isthmus by a narrow membrane ; gill-openings narrow, in front of the base of the pectoral fin. Gills four, lamellated. Pseudobranchiæ and air-bladder absent. One short dorsal and a similar anal fin, opposite to each other. Ventral fin present. Ovarian sacs closed.

One genus only is known, *Pegasus.*

Division IX. *Acanthopterygii Gobiiformes.*—The spinous dorsal, or spinous portion of the dorsal, is always present, short, either composed of flexible spines, or much less developed than the soft ; the soft dorsal and anal of equal extent. No bony stay for the angle of the præoperculum. Ventrals thoracic or jugular, if present, composed of one spine and five, rarely four, soft rays. A prominent anal papilla.

Family 1. *Discoboli* (Lump-Suckers).—Body thick or oblong, naked or tubercular. Teeth small. Ventral fins with one spine and five rays, all being rudimentary and forming the osseous support of a round disk, which is surrounded by a cutaneous fringe. Gill-openings narrow, the gill-membranes being attached to the isthmus.

Genera : *Cyclopterus* and *Liparis.*

Family 2. *Gobiidæ* (Gobies).—Body elongate, naked or scaly. Teeth generally small, sometimes with canines. The spinous dorsal fin, or portion of the dorsal fin, is the less developed, and composed of flexible spines ; anal similarly developed as the soft dorsal. Sometimes the ventrals are united into a disk. Gill-opening more or less narrow, the gill-membranes being attached to the isthmus.

Genera : *Gobius, Latrunculus, Euctenogobius, Lophiogobius, Doliichthys, Apocryptes, Evorthodus, Gobiosoma, Gobiodon, Triænophorichthys, Sicydium, Periophthalmus, Boleophthalmus, Eleotris, Lentipes, Trypauchen, Callionymus* (Dragonet), *Benthophilus, Amblyopus, Orthostomus, Platyptera, Luciogobius, Oxymetopon,* and, perhaps, *Oxuderces.*

Division X. *Acanthopterygii Blenniiformes.*—Body low, subcylindrical or compressed, elongate. Dorsal fin very long ; the spinous portion of the dorsal, if distinct, is very long, as well developed as the soft, or much more ; sometimes the entire fin is composed of spines only ; anal more or less long ; caudal fin subtruncated or rounded, if present. Ventral fins thoracic or jugular, if present.

Family 1. *Cepolidæ.*—Body very elongate, compressed, covered with very small cycloid scales ; eyes rather large, lateral. Teeth of moderate size. No bony stay for the angle of the præoperculum. One very long dorsal fin, which, like the anal, is composed of soft rays. Ventrals thoracic, composed of one spine and five rays. Gill-opening wide. Caudal vertebræ exceedingly numerous.

Genus: *Cepola* (Band-Fishes). An allied family are the *Trichonotidæ,* with *Trichonotus* and *Hemerocœtes.*

Family 2. *Heterolepidotidæ.*—Body oblong, compressed, scaly ; eyes lateral ; cleft of the mouth lateral ; dentition feeble. The angle of the præoperculum connected by a bony stay with the infraorbital ring. Dorsal long, with the spinous and soft portions equally developed ; anal elongate. Ventrals thoracic, with one spine and five rays.

Genera : *Chirus, Ophiodon, Agrammus, Zaniolepis.*

Family 3. *Blenniidæ.*—Body elongate, low, more or less cylindrical, naked or covered with scales, which generally are small. One, two, or three dorsal fins occupying nearly the whole length of the back, the spinous portion, if distinct, being as much developed as the soft, or more ; sometimes the entire fin is composed of spines ; anal fin long. Ventrals jugular, composed of a few rays, and sometimes rudimentary or entirely absent. Pseudobranchiæ generally present.

Genera : *Anarrhichas* (Wolf-Fish), *Blennius* (Blenny), *Chasmodes, Petroscirtes, Salarias, Clinus, Cristiceps, Cremnobates, Tripterygium, Stichæus, Blenniops, Centronotus, Xiphidion, Cryptacanthodes, Patœcus, Zoarces, Blennophis, Nemophis, Plagiotremus, Neoclinus, Cebidichthys, Myxodes, Heterostichus, Dictyosoma, Lepidoblennius, Dactyloscopus, Gunellichthys, Urocentrus, Stichæopsis, Sticharium, Notograptus, Pholidichthys,* and *Pseudoblennius.*—Closely allied is *Acanthoclinus.*

Family 4. *Mastacembelidæ.*—Body elongate, eel-like, covered with very small scales. Mandible long, but little movable. Dorsal fin very long, the anterior portion composed of numerous short isolated spines ; anal fin with spines anteriorly. Ventrals none. The humeral arch is not suspended from the skull. Gill-openings reduced to a slit at the lower part of the side of the head.

Genera : *Rhynchobdella* and *Mastacembelus.*

Division XI. *Acanthopterygii Mugiliformes.*—Two dorsal fins more or less remote from each other ; the anterior either short, like the posterior, or composed of feeble spines. Ventral fins with one spine and five rays, abdominal.

Family 1. *Sphyrænidæ.*—Body elongate, sub-cylindrical, covered with small cycloid scales ; lateral line continuous. Cleft of the mouth wide, armed with strong teeth. Eye lateral, of moderate size. Vertebræ twenty-four.

Genera : *Sphyræna* (Barracuda) Fossil: *Sphyrænodus, Hypsodon, Portheus, Saurocephalus.*

Family 2. *Atherinidæ.*—Body more or less elongate, sub-cylindrical, covered with scales of moderate size ; lateral line indistinct. Cleft of the mouth of moderate width, with the dentition feeble.

Eye lateral, large or of moderate size. Gill-openings wide. Vertebræ very numerous.

Genera: *Atherina*, *Atherinichthys*, and *Tetragonurus*.

Family 3. *Mugilidæ* (Grey Mullets).—Body more or less oblong and compressed, covered with cycloid scales of moderate size; lateral line none. Cleft of the mouth narrow or of moderate width, with or without feeble teeth. Eye lateral, of moderate size. Gill-opening wide. The anterior dorsal fin composed of four stiff spines. Vertebræ twenty-four.

Genera: *Mugil*, *Agonostoma*, and *Myxus*.

DIVISION XII. *Acanthopterygii Gastrosteiformes*.—The spinous dorsal is composed of isolated spines, if present; the ventrals are either thoracic or have an abdominal position in consequence of the prolongation of the pubic bones which are attached to the humeral arch. Mouth small, at the end of the snout, which is generally more or less produced.

Family 1. *Gastrosteidæ*.—Body elongate, compressed. Cleft of the mouth oblique; villiform teeth in the jaws. Opercular bones not armed; infraorbitals covering the cheek; parts of the skeleton forming incomplete external mail. Scales none, but generally large scutes along the side. Isolated spines in front of the soft dorsal fin. Ventral fins abdominal, joined to the pubic bone, composed of a spine and a small ray. Branchiostegals three.

One genus only: *Gastrosteus* (Sticklebacks).

Family 2. *Fistulariidæ*.—Fishes of greatly elongated form; the anterior bones of the skull are much produced, and form a long tube, terminating in a narrow mouth. Teeth small; scales none, or small. The spinous dorsal fin is either formed by feeble isolated spines or entirely absent; the soft dorsal and anal of moderate length; ventral fins thoracic or abdominal, composed of five or six rays, without spine; if abdominal, they are separate from the pubic bones, which remain attached to the humeral arch. Branchiostegals five.

Genera: *Fistularia*, *Aulostoma*, *Auliscops*, and *Aulorhynchus*. The first three occur also in Eocene formations. Other fossil genera are *Urosphen* and *Rhamphosus*.

DIVISION XIII. *Acanthopterygii Centrisciformes*.—Two dorsal fins; the spinous short, the soft and the anal of moderate extent. Ventral fins truly abdominal, imperfectly developed.

One family, *Centriscidæ*, with two genera, *Centriscus* (Trumpet-Fish, Bellows-Fish) and *Amphisile*.

DIVISION XIV. *Acanthopterygii Gobiesociformes*.—No spinous dorsal; the soft and the anal short or of moderate length, situated on the tail; ventral fins subjugular, with an adhesive apparatus between them. Body naked.

Genera: *Chorisochismus*, *Cotylis*, *Sicyases*, *Gobiesox*, *Diplocrepis*, *Crepidogaster*, *Trachelochismus*, *Lepadogaster*, and *Leptopterygius*.

DIVISION XV. *Acanthopterygii Channiformes*.—Body elongate, covered with scales of moderate size; no spine in any of the fins; dorsal and anal long. No superbranchial organ, only a bony prominence on the anterior surface of the hyomandibular.

Genera: *Ophiocephalus* and *Channa*.

DIVISION XVI. *Acanthopterygii Labyrinthibranchii*.—Body compressed, oblong or elevated, with scales of moderate size. A superbranchial organ in a cavity accessory to that of the gills.

Family 1. *Labyrinthici*.—Dorsal and anal spines present, but in variable number; ventrals thoracic. Lateral line absent, or more or less distinctly interrupted. Gill-opening rather narrow, the gill-membranes of both sides coalescent below the isthmus, and scaly; gills four; pseudobranchiæ rudimentary or absent.

Genera: *Anabas*, *Spirobranchus*, *Ctenopoma*, *Polyacanthus*, (Paradise-Fish), *Osphromenus* (Gouramy), *Trichogaster*, *Betta*, and *Micracanthus*.—Allied to this family is *Luciocephalus*.

DIVISION XVII. *Acanthopterygii Lophotiformes*.—Body ribbon-shaped, with the vent near its extremity; a short anal behind the vent; dorsal fin as long as the body.

Only one genus is known of this division or family, *Lophotes*.

DIVISION XVIII. *Acanthopterygii Tæniiformes* (Ribbon-Fishes).—Body ribbon-shaped; dorsal fin as long as the body; anal absent; caudal rudimentary, or not in the longitudinal axis of the fish.

Genera: *Trachypterus*, *Stylophorus*, and *Regalecus*.

DIVISION XIX. *Acanthopterygii Notacanthiformes*.—Dorsal fin short, composed of short, isolated spines, without a soft portion. Anal fin very long, anteriorly with many spines; ventrals abdominal, with more than five soft and several unarticulated rays.

One genus only: *Notacanthus*.

ORDER II.—*Acanthopterygii Pharyngognathi*.

Part of the rays of the dorsal, anal, and ventral fins are non-articulated spines. The lower pharyngeals coalesced. Air-bladder without pneumatic duct.

Family 1. *Pomacentridæ*.—Body short, compressed, covered with ctenoid scales. Dentition feeble; palate smooth. The lateral line does not extend to the caudal fin, or is interrupted. One dorsal fin, with the spinous portion as well developed as the soft, or more. Two, sometimes three, anal spines; the soft anal similar to the soft dorsal. Ventral fins thoracic, with one spine and five soft rays. Gills three and a half; pseudobranchiæ and air-bladder present. Vertebræ, twelve abdominal and fourteen caudal.

Genera: *Amphiprion*, *Premnas*, *Dascyllus*, *Lepidozygus*, *Pomacentrus*, *Glyphidodon*, *Parma*, and *Heliastes*. Fossil: *Odonteus*.

Family 2. *Labridæ*.—Body oblong or elongate, covered with cycloid scales. The lateral line extends to the caudal, or is interrupted. One dorsal fin, with the spinous portion as well developed as the soft, or more so. The soft anal similar to the soft dorsal. Ventral fins thoracic, with one spine and five soft rays. Palate without teeth. Branchiostegals five or six; gills three and a half; pseudobranchiæ and air-bladder present. Pyloric appendages none; stomach without cæcal sac.

Genera: *Labrus* and *Crenilabrus* (Wrasses), *Tautoga*, *Ctenolabrus*, *Acantholabrus*, *Centrolabrus*, *Lachnolæmus*, *Malacopterus*, *Cossyphus*, *Chilinus*, *Epibulus*, *Anampses*, *Platyglossus*, *Novacula*, *Julis*, *Coris*, *Chœrops*, *Xiphochilus*, *Semicossyphus*, *Trochocopus*, *Decodon*, *Pteragogus*, *Clepticus*, *Labrichthys*, *Labroides*, *Duymæria*, *Cirrhilabrus*, *Doratonotus*, *Pseudochilinus*, *Hemigymnus*, *Gomphosus*, *Cheilio*, *Cymolutes*, *Pseudodax*, *Scarus*, *Scarichthys*, *Callyodon*, *Pseudoscarus*, *Odax*, *Coridodax*, *Olistherops*, and *Siphonognathus*. Fossil: *Nummopalatus*, *Phyllodus*, *Taurinichthys*, and *Egertonia*.

Family 3. *Embiotocidæ*.—Body compressed, elevated or oblong, covered with cycloid scales; lateral line continuous. One dorsal fin, with a spinous portion, and with a scaly sheath along the base, which is separated by a groove from the other scales; anal with three spines and numerous rays; ventral fin thoracic, with one spine and five rays. Small teeth in the jaws, none on the palate. Pseudobranchiæ present. Stomach siphonal; pyloric appendages none. Viviparous.

Genera: *Ditrema* and *Hysterocarpus*.

Family 4. *Chromides*.—Body elevated, oblong or elongate, scaly, the scales being generally ctenoid. Lateral line interrupted or nearly so. One dorsal fin, with a spinous portion; three or more anal spines; the soft anal similar to the soft dorsal. Ventral fins thoracic, with one spine and five rays. Teeth in the jaws small, palate smooth. Pseudobranchiæ none. Stomach cæcal; pyloric appendages none.

Genera: *Etroplus*, *Chromis*, *Hemichromis*, *Paretroplus*, *Acara*, *Heros*, *Neetroplus*, *Mesonauta*, *Pelcnia*, *Uaru*, *Hygrogonus*, *Cichla*, *Crenicichla*, *Chætobranchus*, *Mesops*, *Satanoperca*, *Geophagus*, *Symphysodon*, and *Pterophyllum*.

ORDER III.—*Anacanthini*.

Vertical and ventral fins without spinous rays. The ventral fins, if present, are jugular or thoracic. Air-bladder, if present, without pneumatic duct.

DIVISION I. *Anacanthini Gadoidei*.—Head and body symmetrically formed.

Family 1. *Lycodidæ*.—Vertical fins confluent. Ventral fin, if present, small, attached to the humeral arch, jugular. Gill-opening narrow, the gill-membrane being attached to the isthmus.

Genera: *Lycodes*, *Gymnelis*, *Uronectes*, *Microdesmus*, *Blennodesmus*, and *Maynea*.

Family 2. *Gadidæ*.—Body more or less elongate, covered with small smooth scales. One, two, or three dorsal fins, occupying nearly the whole of the back; rays of the posterior dorsal well developed; one or two anal fins. Caudal free from dorsal and anal, or, if they are united, the dorsal with a separate anterior portion. Ventrals jugular, composed of several rays, or, if they are reduced to a filament, the dorsal is divided into two. Gill-opening wide; the gill-membranes generally not attached to the isthmus. Pseudobranchiæ none, or glandular, rudimentary. An air-bladder and pyloric appendages generally present.

Genera: *Gadus* (Cod-Fish, Haddock, Whiting, Pollack, Coal-Fish), *Gadiculus*, *Mora*, *Strinsia*, *Halargyreus*, *Melanonus*, *Merluccius* (Hake), *Pseudophycis*, *Lotella*, *Physiculus*, *Uraleptus*, *Læmonema*, *Phycis*, *Haloporphyrus*, *Lota* (Burbot), *Molva* (Ling), *Motella* (Rockling), *Raniceps*, *Bregmaceros*, *Murænolepis*, *Chiasmodus*, and *Brosmius*. Fossil remains are rare: *Nemopteryx* and *Palæogadus* from the schists of Glarus, a formation believed to have been the bottom of a very deep sea. In the clay of Sheppey species occur allied to *Gadus*, *Merluccius*, and *Phycis*.

Family 3. *Ophidiidæ*.—Body more or less elongate, naked or scaly. Vertical fins generally united; no separate anterior dorsal or anal; dorsal occupying the greater portion of the back. Ventral fins rudimentary or absent, jugular. Gill-openings wide, the gill-membranes not attached to the isthmus.

1. *Brotulina*: Ventral fins present, attached to the humeral arch. Genera: *Brotula*, *Lucifuga*, *Bathynectes*, *Acanthonus*, *Typhlonus*, *Aphyonus*, *Rhinonus*, *Sirembo*, *Pteridium*, *Brotulophis*, *Halidesmus*, *Dinematichthys*, and *Bythites*.

2. *Ophidiina*: Ventral fins replaced by a pair of bifid filaments (barbels) inserted below the glossohyal. Genera: *Ophidium* and *Genypterus*.

3. *Fierasferina*: No ventral fins whatever; vent at the throat. Genera: *Fierasfer* and *Encheliophis*.

4. *Ammodytina*: No ventral fins whatever; vent remote from the

head; gill-openings very wide, the gill-membranes not being united. Genera: *Ammodytes* (Sand-Eels) and *Bleekeria*.

5. *Congrogadina*: No ventral fins whatever; vent remote from the head; gill-openings of moderate width, the gill-membranes being united below the throat, not attached to the isthmus. Genera: *Congrogadus* and *Haliophis*.

Family 4. *Macruridæ*.—Body terminating in a long, compressed, tapering tail, covered with spiny, keeled, or striated scales. One short anterior dorsal; the second very long, continued to the end of the tail, and composed of very feeble rays; anal of an extent similar to that of the second dorsal; no caudal. Ventral fins thoracic or jugular, composed of several rays. Deep-sea Gadoids.

Genera: *Macrurus, Coryphænoides, Macruronus, Malacocephalus*, and *Bathygadus*.

DIVISION II. *Anacanthini Pleuronectoidei*.—Head and part of the body unsymmetrically formed. This division consists of one family only: *Pleuronectidæ* (Flat-Fishes).

Genera: *Psettodes, Hippoglossus* (Holibut), *Hippoglossoides, Tephritis, Rhombus* (Turbot, Brill, Whiff), *Phrynorhombus* (Top-Knot), *Arnoglossus, Pseudorhombus, Rhomboidichthys, Citharus, Anticitharus, Brachypleura, Samaris, Psettichthys, Citharichthys, Hemirhombus, Paralichthys, Liopsetta, Lophonectes, Lepidopsetta, Thysanopsetta, Pleuronectes* (Plaice, Dab, Flounder), *Rhombosolea, Parophrys, Psammodiscus, Ammotretis, Peltorhamphus, Nematops, Lœops, Pœcilopsetta, Solea* (Sole), *Synaptura, Æsopia, Gymnachirus, Cynoglossus, Soleotalpa, Apionichthys, Ammopleurops, Aphoristia*, and *Plagusia*

ORDER IV.—*Physostomi*.

All the fin-rays articulated, only the first of the dorsal and pectoral fins is sometimes ossified. Ventral fins, if present, abdominal, without spine. Air-bladder, if present, with a pneumatic duct (except in *Scombresocidæ*).

Family 1. *Siluridæ*.—Skin naked or with osseous scutes, but without scales. Barbels always present; maxillary bone rudimentary, almost always forming a support to a maxillary barbel. Margin of the upper jaw formed by the intermaxillaries only. Suboperculum absent. Air-bladder generally present, communicating with the organ of hearing by means of the auditory ossicles. Adipose fin present or absent.

A large family of freshwater fishes, represented by numerous genera, which exhibit a great variety of form and structure of the fins. Their first appearance is indicated by some fossil remains in Tertiary deposits of the highlands of Padang in Sumatra, where *Pseudeutropius* and *Bagarius*, types well represented in the living Indian fauna, have been found. In North America also spines referable to "Cat-Fishes" have been found in Tertiary formations.

From the great number of different generic types this family has been arranged under eight subdivisions:—

1. *Siluridæ Homalopteræ*.
   - A. *Clariina*: Clarias, Heterobranchus.
   - B. *Plotosina*: Plotosus, Cnidoglanis, Copidoglanis, Chaca.
2. *Siluridæ Heteropteræ*.
   - A. *Silurina*: Saccobranchus, Silurus, Schilbe, Eutropius, Silurichthys, Wallago, Belodontichthys, Eutropiichthys, Cryptopterus, Callichrous, Hemisilurus, Siluranodon, Ailia, Schilbichthys, Lais, Pseudeutropius, Pangasius, Helicophagus, Silondia.
3. *Siluridæ Anomalopteræ*.
   - A. *Hypophthalmina*: Hypophthalmus, Helogenes.
4. *Siluridæ Proteropteræ*.
   - A. *Bagrina*: Bagrus, Chrysichthys, Clarotes, Macrones, Pseudobagrus, Liocassis, Bagroides, Bagrichthys, Rita, Acrochordonichthys, Akysis.
   - B. *Amiurina*: Amiurus, Hopladelus, Noturus.
   - C. *Pimelodina*: Platystoma, Sorubim, Hemisorubim, Platystomatichthys, Phractocephalus, Piramutana, Platynematichthys, Piratinga, Bagropsis, Sciades, Pimelodus, Pirinampus, Conorhynchus, Notoglanis, Callophysus, Lophiosilurus, Auchenoglanis.
   - D. *Ariina*: Arius, Galeichthys, Genidens, Paradiplomystax, Diplomystax, Ælurichthys, Hemipimelodus, Ketengus, Osteogeniosus, Batrachocephalus, Atopochilus.
   - E. *Bagariina*: Bagarius, Englyptosternum, Glyptosternum.
5. *Siluridæ Stenobranchiæ*.
   - A. *Doradina*: Ageniosus, Tetranematichthys, Euanemus, Auchenipterus, Glanidium, Centromochlus, Trachelyopterus, Cetopsis, Astrophysus, Doras, Synodontis.
   - B. *Rhinoglanina*: Rhinoglanis, Callomystax.
   - C. *Malapterurina*: Malapterurus.
6. *Siluridæ Proteropodes*.
   - A. *Hypostomatina*: Stygogenes, Arges, Brontes, Astroplebus, Callichthys, Chaetostomus, Plecostomus, Hypoptopoma, Loricaria, Acestra, Sisor, Erethistes, Exostoma, Pseudecheneis.
   - B. *Aspredinina*: Aspredo, Bunocephalus, Bunocephalichthys, Harttia.
7. *Siluridæ Opisthopteræ*.
   - A. *Nematogenyina*: Heptapterus, Nematogenys.
   - B. *Trichomycterina*: Trichomycterus, Eremophilus, Parіodon.
8. *Siluridæ Branchicolæ*: Stegophilus, Vandellia.

Family 2. *Scopelidæ*.—Body naked or scaly. Margin of the upper jaw formed by the intermaxillary only; opercular apparatus sometimes incompletely developed. Barbels none. Gill-opening very wide; pseudobranchiæ well developed. Air-bladder none. Adipose fin present. The eggs are enclosed in the sacs of the ovary, and excluded by oviducts. Pyloric appendages few in number or absent. Intestinal tract very short.

Genera: *Saurus, Bathysaurus, Bathypterois, Harpodon, Scopelus, Ipnops, Paralepis, Sudis, Plagyodus, Aulopus, Chlorophthalmus, Scopelosaurus, Odontostomus*, and *Nannobrachium*. Fossil: *Osmeroides, Hemisaurida, Parascopelus*, and *Anapterus*.

Family 3. *Cyprinidæ*.—Body generally covered with scales; head naked. Margin of the upper jaw formed by the intermaxillaries. Belly rounded, or, if trenchant, without ossifications. No adipose fin. Stomach without blind sac. Pyloric appendages none. Mouth toothless; lower pharyngeal bones well developed, falciform, subparallel to the branchial arches, provided with teeth, which are arranged in one, two, or three series. Air-bladder large, divided into an anterior and posterior portion by a constriction, or into a right or a left portion, enclosed in an osseous capsule. Ovarian sacs closed.

The family of "Carps" is the one most numerously represented in the fresh waters of the Old World and of North America. Numerous fossil remains are also found in Tertiary freshwater formations; the majority can be referred to existing genera: *Barbus, Thynnichthys, Gobio, Leuciscus, Tinca, Amblypharyngodon, Rhodeus, Cobitis, Acanthopsis*; only a few showing characters different from those of living genera: *Cyclurus, Hexapsephus, Mylocyprinus*.

There is much less diversity of forms and habits in this family than in the Siluroids; but the genera are sufficiently numerous to demand a further subdivision of the family into groups.

1. *Catostomina*: Catostomus, Moxostoma, Sclerognathus, Carpiodes.
2. *Cyprinina*: Cyprinus (Carp), Carassius, Catla, Cirrhina, Dangila, Osteochilus, Labeo, Barynotus, Tylognathus, Abrostomus, Discognathus, Crossochilus, Gymnostomus, Epalzeorhynchus, Capoeta, Barbus (Barbel), Thynnichthys, Barbichthys, Amblyrhynchichthys, Albulichthys, Oreinus, Schizothorax, Ptychobarbus, Gymnocypris, Schizopygopsis, Diptychus, Aulopyge, Gobio (Gudgeon), Ceratichthys, Bungia, Pimephales, Hyborhynchus, Campostoma, Hybognathus, Ericymba, Pseudorasbora, Cochlognathus, Exoglossum, Rhinichthys.
3. *Rhoteichthyina*: Rhoteichthys.
4. *Leptobarbina*: Leptobarbus.
5. *Rasborina*: Rasbora, Luciosoma, Nuria, Aphyocypris, Amblypharyngodon.
6. *Semiplotina*: Cyprinion, Semiplotus.
7. *Xenocypridina*: Xenocypris, Paracanthobrama, Mystacoleucus.
8. *Leuciscina*: Leuciscus (White-Fish, Roach, Chub, Dace, Rudd, Minnow), Myloleucus, Ctenopharyngodon, Mylopharodon, Paraphoxinus, Meda, Graodus, Tinca (Tench), Leucosomus, Chondrostoma, Orthodon, Acrochilus.
9. *Rhodeina*: Achilognathus, Rhodeus, Pseudoperilampus.
10. *Danionina*: Danio, Pteropsarion, Aspidoparia, Barilius, Bola, Schacra, Opsariichthys, Squaliobarbus, Ochetobius.
11. *Hypophthalmichthyina*: Hypophthalmichthys.
12. *Abramidina*: Abramis (Bream), Aspius, Alburnus (Bleak), Leucaspius, Rasborichthys, Elopichthys, Pelotrophus, Acanthobrama, Osteobrama, Chanodichthys, Smiliogaster, Culter, Pelecus, Eustira, Chela, Pseudolabuca, Cachius.
13. *Homalopterina*: Homaloptera, Psilorhynchus.
14. *Cobitidina* (Loaches): Misgurnus, Nemachilus, Cobitis, Lepidocephalichthys, Acanthopsis, Botia, Oreonectes, Lepidocephalus, Acanthophthalmus, Apua, Paramisgurnus.

Family 4. *Kneriidæ*.—Body scaly, head naked. Margin of the upper jaw formed by the intermaxillaries. Dorsal and anal fins short, the former belonging to the abdominal portion of the vertebral column. Teeth none, either in the mouth or pharynx. Barbels none. Stomach siphonal; no pyloric appendages. Pseudobranchiæ none. Branchiostegals three; air-bladder long, not divided. Ovaries closed.

One genus: *Kneria*.

Family 5. *Characinidæ*.—Body covered with scales, head naked; barbels none. Margin of the upper jaw formed by the intermaxillaries in the middle and by the maxillaries laterally. Generally a small adipose fin behind the dorsal. Pyloric appendages more or less numerous; air-bladder transversely divided into two portions, and communicating with the organ of hearing by means of the auditory ossicles. Pseudobranchiæ none.

1. *Erythrinina*: Macrodon, Erythrinus, Lebiasina, Nannostomus, Pyrrhulina, and Corynopoma.

2. *Curimatina*: Curimatus, Prochilodus, Cænotropus, Hemiodus, Saccodon, Parodon.
3. *Citharinina*: Citharinus.
4. *Anastomatina*: Leporinus, Anostomus, Rhytiodus.
5. *Nannocharacina*: Nannocharax.
6. *Tetragonopterina*: Alestes, Tetragonopterus, Chirodon, Megalobrycon, Gastropelecus, Piabucina, Scissor, Pseudochalceus, Aphyocharax, Chalceus, Brycon, Chalcinopsis, Bryconops, Creagrutus, Chalcinus, Piabuca, Paragoniates, Agoniates, Nannæthiops, and Bryconæthiops.
7. *Hydrocyonina*: Hydrocyon, Cynodon, Anacyrtus, Hystricolon, Salminus, Oligosarcus, Xiphorhamphus, Xiphostoma, and Sarcodaces.
8. *Distichodontina*: Distichodus.
9. *Ichthyborina*: Ichthyborus and Phago.
10. *Crenuchina*: Crenuchus and Xenocharax.
11. *Serrasalmonina*: Mylesinus, Serrasalmo, Myletes, and Catoprion.

Family 6. *Cyprinodontidæ.*—Head and body covered with scales; barbels none. Margin of the upper jaw formed by the intermaxillaries only. Teeth in both jaws; upper and lower pharyngeals with cardiform teeth. Adipose fin none; dorsal fin situated on the hinder half of the body. Stomach without blind sac; pyloric appendages none. Pseudobranchiæ none; air-bladder simple, without ossicula auditus.

1. *C. Carnivoræ*: Cyprinodon, Characodon, Fitzroyia, Haplochilus, Fundulus, Limnurgus, Lucania, Rivulus, Cynolebias, Orestias, Jenynsia, Gambusia, Pseudoxiphophorus, Belonesox, Anableps.
2. *C. Limnophagæ*: Pœcilia, Mollienesia, Platypœcilus, Girardinus. Fossil remains are referable to Cyprinodon and Pœcilia.

Family 7. *Heteropygii.*—Head naked; body covered with very small scales; barbels none. Margin of the upper jaw formed by the intermaxillaries. Villiform teeth in the jaws and on the palate. Adipose fin none. Dorsal fin belonging to the caudal portion of the vertebral column, opposite to the anal. Ventral fins rudimentary or absent. Vent situated before the pectorals. Stomach cæcal; pyloric appendages present. Pseudobranchiæ none; air-bladder deeply notched anteriorly.

Genera: *Amblyopsis* (Blind-Fish of the Mammoth Cave) and *Chologaster.*

Family 8. *Umbridæ.*—Head and body covered with scales; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Adipose fin none; the dorsal fin belongs partly to the abdominal portion of the vertebral column. Stomach siphonal; pyloric appendages none; pseudobranchiæ glandular, hidden; air-bladder simple.

One genus: *Umbra.*

Family 9. *Scombresocidæ.*—Body covered with scales; a series of keeled scales along each side of the belly. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Lower pharyngeals united into a single bone. Dorsal fin opposite the anal, belonging to the caudal portion of the vertebral column. Adipose fin none. Air-bladder generally present, simple, sometimes cellular, without pneumatic duct. Pseudobranchiæ hidden, glandular. Stomach not distinct from the intestine, which is quite straight, without appendages.

Genera: *Belone* (Gar-Pike), *Scombresox*, *Hemirhamphus*, *Arrhamphus*, *Exocœtus* (Flying-Fish). Fossil: *Holosteus.*

Family 10. *Esocidæ.*—Body covered with scales; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Adipose fin none; the dorsal fin belongs to the caudal portion of the vertebral column. Stomach without blind sac; pyloric appendages none. Pseudobranchiæ glandular, hidden; air-bladder simple; gill-opening very wide.

One genus only: *Esox* (Pike).

Family 11. *Galaxiidæ.*—Body naked; barbels none. Margin of the upper jaw chiefly formed by the intermaxillaries, which are short, and continued by a thick lip, behind which are the maxillaries. Belly rounded; adipose fin none; dorsal opposite to anal. Pyloric appendages in small number. Air-bladder large, simple; pseudobranchiæ none. The ova fall into the cavity of the abdomen before exclusion.

Genera: *Galaxias* and *Neochanna.*

Family 12. *Mormyridæ.*—Body and tail scaly; head scaleless; barbels none. The margin of the upper jaw is formed in the middle by the intermaxillaries, which coalesce into a single bone, and laterally by the maxillaries. Suboperculum and interoperculum present, the latter very small. On each side of the single parietal bone a cavity leading into the interior of the skull, and covered with a thin bony lamella. All the fins are well developed (*Mormyrus*); or caudal, anal, and ventral fins are absent (*Gymnarchus*). No adipose fin. Pseudobranchiæ none; gill-openings reduced to a short slit. Air-bladder simple. Two cæca pylorica behind the stomach.

Genera: *Mormyrus* and *Gymnarchus.*

Family 13. *Sternoptychidæ.*—Body naked, or with very thin deciduous scales; barbels none. Margin of the upper jaw formed by the maxillary and intermaxillary, both of which are toothed; opercular apparatus not completely developed. Gill-opening very wide; pseudobranchiæ present or absent; air-bladder simple, if present. Adipose fin present, but generally rudimentary. Series of phosphorescent bodies along the lower parts. The eggs are enclosed in the sacs of the ovarium, and excluded by oviducts.

Genera: *Sternoptyx*, *Argyropelecus*, *Polyipnus*, *Coccia*, *Maurolicus*, *Chauliodus*, *Gonostoma*, *Photichthys*, and *Diplophos.*

Family 14. *Stomiatidæ.*—Skin naked, or with exceedingly delicate scales; a hyoid barbel. Margin of the upper jaw formed by the intermaxillary and maxillary, which are both toothed; opercular apparatus but little developed. Gill-opening very wide; pseudobranchiæ none. The eggs are enclosed in the sacs of the ovarium, and excluded by oviducts.

Genera: *Astronesthes*, *Stomias*, *Echiostoma*, *Malacosteus*, and *Bathyophis.*

Family 15. *Salmonidæ.*—Body generally covered with scales; head naked; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Belly rounded. A small adipose fin behind the dorsal. Pyloric appendages generally numerous, rarely absent. Air-bladder large, simple; pseudobranchiæ present. The ova fall into the cavity of the abdomen before exclusion.

Genera: *Salmo* (Salmon, Trout, Charr), *Oncorhynchus*, *Brachymystax*, *Luciotrutta*, *Plecoglossus*, *Osmerus* (Smelt), *Retropinna*, *Hypomesus*, *Thaleichthys*, *Mallotus* (Capelin), *Coregonus* (Gwyniad, Pollan), *Thymallus* (Grayling), *Salanx*, *Argentina*, *Microstoma*, *Bathylagus*. Fossil: *Osmeroides*, *Acrognathus*, and *Aulolepis.*

Family 16. *Percopsidæ.*—Body covered with ctenoid scales; head naked. Margin of the upper jaw formed by the intermaxillaries only; opercular apparatus complete. Barbels none. Gill-openings wide. Adipose fin present.

One genus only: *Percopsis.*

Family 17. *Haplochitonidæ.*—Body naked or scaly (cycloid). Margin of the upper jaw formed by the intermaxillary; opercular apparatus complete. Barbels none. Gill-opening wide; pseudobranchiæ. Air-bladder simple. Adipose fin present. Ovaries laminated; the eggs fall into the cavity of the abdomen, there being no oviduct. Pyloric appendages none.

Genera: *Haplochiton* and *Prototroctes.*

Family 18. *Gonorhynchidæ.*—Head and body entirely covered with spiny scales; mouth with barbels. Margin of the upper jaw formed by the intermaxillary, which, although short, is continued downwards as a thick lip, situated in front of the maxillary. Adipose fin none; the dorsal fin is opposite to the ventrals, and short, like the anal. Stomach simple, without blind sac; pyloric appendages in small number. Pseudobranchiæ; air-bladder absent. Gill-openings narrow.

One genus only: *Gonorhynchus.*

Family 19. *Hyodontidæ.*—Body covered with cycloid scales; head naked; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally, the latter being articulated to the end of the former. Opercular apparatus complete. Adipose fin none; the dorsal fin belongs to the caudal portion of the vertebral column. Stomach horseshoe-shaped, without blind sac; intestine short; one pyloric appendage. Pseudobranchiæ none; air-bladder simple. Gill-openings wide. The ova fall into the abdominal cavity before exclusion.

One genus only: *Hyodon* (Moon-Eye).

Family 20. *Pantodontidæ.*—Body covered with large cycloid scales; sides of the head osseous. Margin of the upper jaw formed by the single intermaxillary mesially and by the maxillaries laterally. The dorsal fin belongs to the caudal portion of the vertebral column, is short, and opposite and similar to the anal. Gill-openings wide; gill-covers consisting of a præoperculum and operculum only. Branchiostegals numerous. Pseudobranchiæ none; air-bladder simple. Stomach without cæcal sac; one pyloric appendage. Sexual organs with a duct.

One genus: *Pantodon.*

Family 21. *Osteoglossidæ.*—Body covered with large hard scales, composed of pieces like mosaic. Head scaleless; its integuments almost entirely replaced by bone; lateral line composed of wide openings of the mucous duct. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. The dorsal fin belongs to the caudal portion of the vertebral column, is opposite and very similar to the anal fin; both approximate to the rounded caudal (with which they are abnormally confluent). Gill-openings wide; pseudobranchiæ none; air-bladder simple or cellular. Stomach without cæcal sac; pyloric appendages two.

Genera: *Osteoglossum*, *Arapaima*, and *Heterotis.*

Family 22. *Clupeidæ.*—Body covered with scales; head naked; barbels none. Abdomen frequently compressed into a serrated edge. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally; maxillaries composed of at least three movable pieces. Opercular apparatus complete. Adipose fin none; dorsal not elongate; anal sometimes very long Stomach with a blind sac; pyloric appendages numerous. Gill-apparatus much developed, the gill-openings being generally very wide. Pseudobranchiæ generally present. Air-bladder more or less simple.

Genera: *Engraulis* (Anchovies), *Coilia*, *Chatoessus*, *Clupea* (Herring, Sprat, Shad, Mossbanker, Menhaden, Ale-Wife, Pilchard, Sardine), *Clupeoides*, *Pellonula*, *Clupeichthys*, *Pellona*, *Pristigaster*, *Albula*, *Elops*, *Megalops*, *Chanos*, *Dussumieria*, *Etrumeus*. Several of these genera have been found in Tertiary formations; other fossils are: *Thrissopater*, *Leptosomus*, *Opisthopteryx*, *Spaniodon*, *Halec*, *Platinx*, *Cœlogaster*, *Rhinellus*, *Scombroclupea*, *Crossognathus*, *Spathodactylus*, *Chirocentrites*, and *Hemitrichas*.

Family 23. *Bathythrisidæ*.—Allied to the herrings—*Bathythrissa*.

Family 24. *Chirocentridæ*.—Body covered with thin, deciduous scales; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally, both bones being firmly united in juxtaposition. Opercular apparatus complete. Adipose fin none: the dorsal fin belongs to the caudal portion of the vertebral column. Stomach with a blind sac; intestine short, the mucous membrane forming a spiral fold; pyloric appendages none. Pseudobranchiæ none; air-bladder incompletely divided into cells; gill-opening wide.

One genus only: *Chirocentrus*.

Family 25. *Alepocephalidæ*.—Body with or without scales; head naked; barbels none. Margin of the upper jaw formed by the intermaxillaries and maxillaries, the former being placed along the upper anterior edge of the latter. Opercular apparatus complete. Adipose fin none; the dorsal fin belongs to the caudal portion of the vertebral column. Stomach curved, without blind sac; pyloric appendages in moderate number. Pseudobranchiæ; air-bladder absent. Gill-openings very wide.

Genera: *Alepocephalus*, *Bathytroctes*, *Platytroctes*, and *Xenodermichthys*.

Family 26. *Notopteridæ*.—Head and body scaly; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Opercular apparatus incomplete. Tail prolonged, tapering. Adipose fin none. Dorsal short, belonging to the caudal portion of the vertebral column; anal very long. Stomach without blind sac; two pyloric appendages. Pseudobranchiæ none; air-bladder present, divided in the interior. The ova fall into the cavity of the abdomen before exclusion. On each side a parieto-mastoid cavity leading into the interior of the skull.

One genus only: *Notopterus*.

Family 27. *Halosauridæ*.—Body covered with cycloid scales; head scaly; barbels none. Margin of the upper jaw formed by the intermaxillaries mesially and by the maxillaries laterally. Opercular apparatus incomplete. Adipose fin none. The short dorsal belongs to the abdominal part of the vertebral column; anal very long. Stomach with a blind sac; intestine short; pyloric appendages in moderate number. Pseudobranchiæ none. Air-bladder large, simple; gill-openings wide. Ovaries closed.

One genus only: *Halosaurus*.

Family 28. *Hoplopleuridæ*.—Body generally with four series of subtriangular scutes, and with intermediate scale-like smaller ones. One (?) dorsal only; head long, with the jaws produced.

Extinct. Genera: *Dercetis*, *Leptotrachelus*, *Pelargorhynchus*, *Plinthophorus*, *Saurorhamphus*, *Eurypholis*, *Ischyrocephalus*.

Family 29. *Gymnotidæ*.—Head scaleless; barbels none. Body elongate, eel-shaped. Margin of the upper jaw formed in the middle by the intermaxillaries and laterally by the maxillaries. Dorsal fin absent or reduced to an adipose strip; caudal generally absent, the tail terminating in a point. Anal fin exceedingly long. Ventrals none. Extremity of the tapering tail capable of being reproduced. Vent situated at, or at a short distance behind, the throat. Humeral arch attached to the skull. Ribs well developed. Gill-openings rather narrow. Air-bladder present, double. Stomach with a cæcal sac and pyloric appendages. Ovaries with oviducts.

Genera: *Sternarchus*, *Ramphichthys*, *Sternopygus*, *Carapus*, *Gymnotus* (Electric Eel).

Family 30. *Symbranchidæ*.—Body elongate, naked or covered with minute scales; barbels none. Margin of the upper jaw formed by the intermaxillaries only, the well-developed maxillaries lying behind and parallel to them. Paired fins none. Vertical fins rudimentary, reduced to more or less distinct cutaneous folds. Vent situated at a great distance behind the head. Ribs present. Gill-openings confluent into one slit situated on the ventral surface. Air-bladder none. Stomach without cæcal sac or pyloric appendages. Ovaries with oviducts.

Genera: *Amphipnous*, *Monopterus*, *Symbranchus*, *Chilobranchus*.

Family 31. *Murænidæ* (Eels).—Body elongate, cylindrical or band-shaped, naked or with rudimentary scales. Vent situated at a great distance from the head. Ventral fins none. Vertical fins, if present, confluent, or separated by the projecting tip of the tail. Sides of the upper jaw formed by the tooth-bearing maxillaries, the fore part by the intermaxillary, which is more or less coalescent with the vomer and ethmoid. Humeral arch not attached to the skull. Stomach with a blind sac; no pyloric appendages. Organs of reproduction without efferent ducts.

Genera: *Nemichthys*, *Cyema*, *Saccopharynx*, *Synaphobranchus*, *Anguilla*, *Conger*, *Congromuræna*, *Murænesox*, *Nettastoma*, *Saurenchelys*, *Oxyconger*, *Hoplunnis*, *Myrus*, *Myrophis*, *Paramyrus*, *Chilorhinus*, *Murænichthys*, *Ophichthys*, *Moringua*, *Muræna*, *Enchelycore*.

Order V.—*Lophobranchii*.

The gills are not laminated, but composed of small rounded lobes attached to the branchial arches. Gill-cover reduced to a large simple plate. Air-bladder simple, without pneumatic duct. A dermal skeleton, composed of numerous pieces arranged in segments, replaces more or less soft integuments. Muscular system not much developed. Snout prolonged. Mouth terminal, small, toothless, formed as in Acanthopterygians.

Family 1. *Solenostomidæ*.—Gill-openings wide. Two dorsal fins, the rays of the anterior not articulated. All the other fins well developed.

One genus only: *Solenostoma*, which was preceded in the Tertiary epoch by *Solenorhynchus* (Monte Postale).

Family 2. *Syngnathidæ*.—Gill-openings reduced to a very small opening near the upper posterior angle of the gill-cover. One soft dorsal fin; no ventrals, and sometimes one or more of the other fins are also absent.

Pipe-Fishes and Seahorses. Fossil remains occur at Monte Bolca. Besides species of *Siphonostoma* and *Syngnathus* (*Pseudosyngnathus*), remains of an extinct genus, *Calamostoma*, allied to *Hippocampus*, but with a distinct caudal fin, have been found.

Genera: *Siphonostoma*, *Syngnathus*, *Doryichthys*, *Nerophis*, *Protocampus*, *Ichthyocampus*, *Nannocampus*, *Urocampus*, *Leptoichthys*, *Cœlonotus*, *Stigmatophora*, *Gastrotokeus*, *Solenognathus*, *Phyllopteryx*, *Hippocampus*.

Order VI.—*Plectognathi*.

Teleosteous fishes with rough scales, or with ossifications of the cutis in the form of scutes or spines; skin sometimes entirely naked. Skeleton incompletely ossified, with the vertebræ in small number. Gills pectinate; a narrow gill-opening in front of the pectoral fins. Mouth narrow; the bones of the upper jaw generally firmly united. A soft dorsal fin, belonging to the caudal portion of the vertebral column, opposite to the anal; sometimes elements of a spinous dorsal besides. Ventral fin none, or reduced to spines. Air-bladder without pneumatic duct.

Family 1. *Sclerodermi*.—Snout somewhat produced; jaws armed with distinct teeth in small number. Skin with scutes, or rough. The elements of a spinous dorsal and ventral fin generally present.

Genera: *Triacanthus*, *Balistes* (File-Fish), *Monacanthus*, *Anacanthus*, *Ostracion* (Coffer-Fish). Fossil: *Acanthoderma*, *Acanthopleurus*, *Glyptocephalus*.

Family 2. *Gymnodontes*.—Body more or less shortened. The bones of the upper and lower jaw are confluent, forming a beak with a trenchant edge, without teeth, with or without median suture. A soft dorsal, caudal, and anal are developed, approximate. No spinous dorsal. Pectoral fins; no ventrals.

Genera: *Triodon*, *Tetrodon* (Globe-Fish), *Diodon* (Sea-Hedgehog), *Orthagoriscus* (Sun-Fish)

Subclass III.—*Cyclostomata*.

Skeleton cartilaginous and notochordal, without ribs and without real jaws. Skull not separate from the vertebral column. No limbs. Gills in the form of fixed sacs, without branchial arches, six or seven in number on each side. One nasal aperture only. Heart without bulbus arteriosus. Mouth anterior, surrounded by a circular or subcircular lip, suctorial. Alimentary canal straight, simple, without cæcal appendages, pancreas, or spleen. Generative outlet peritoneal. Vertical fins rayed.

The Cyclostomes are most probably a very ancient type. Unfortunately the organs of these creatures are too soft to be preserved, with the exception of the horny denticles with which the mouth of some of them is armed.

Family 1. *Petromyzontidæ* (Lampreys).—Body eel-shaped, naked. Subject to a metamorphosis; in the perfect stage with a suctorial mouth armed with teeth, simple or multicuspid, horny, sitting on a soft papilla. Maxillary, mandibulary, lingual, and suctorial teeth may be distinguished. Eyes present (in mature animals). External nasal aperture in the middle of the upper side of the head. The nasal duct terminates without perforating the palate. Seven branchial sacs and apertures on each side behind the head; the inner branchial ducts terminate in a separate common tube. Intestine with a spiral valve. Eggs small. The larvæ without teeth, and with a single continuous vertical fin.

Genera: *Petromyzon*, *Mordacia*, and *Geotria*.

Family 2. *Myxinidæ*.—Body eel-shaped, naked. The single nasal aperture is above the mouth, quite at the extremity of the head, which is provided with four pairs of barbels. Mouth without lips. Nasal duct without cartilaginous rings, penetrating the palate. One median tooth on the palate, and two comb-like series of teeth on the tongue. Branchial apertures at a great distance from the head; the inner branchial ducts lead into the œsophagus. A series of mucous sacs along each side of the abdomen. Intestine without spiral valve. Eggs large, with a horny case provided with threads for adhesion.

Genera: *Myxine* and *Bdellostoma* (Hag-Fish).

Subclass IV.—*Leptocardii.*

Skeleton membrano-cartilaginous and notochordal, ribless. No brain. Pulsating sinuses in place of a heart. Blood colourless. Respiratory cavity confluent with the abdominal cavity; branchial clefts in great number, the water being expelled by an opening in front of the vent. Jaws none.

This subclass is represented by a single family (*Cirrostomi*) and by one or two genera (*Branchiostoma* and *Epigonichthys*); it is the lowest in the scale of fishes, and lacks so many characteristics, not only of this class, but of the vertebrata generally, that Haeckel, with good reason, separates it into a distinct class, that of *Acrania.* The various parts of its organization have been duly noticed in the former parts of this article. (A. C. G.)

ICHTHYOSAURUS (from ἰχθύς, a fish, and σαῦρος, a lizard), a genus of extinct reptiles, the species of which are the only known representatives of the order *Ichthyopterygia.* Upwards of thirty of these have been described, all of Mesozoic age, the genus so far as is certainly known appearing for the first time in the Liassic formation where it most abounds, continuing throughout the Oolitic, and disappearing before the close of the Cretaceous period. In Britain its remains have been found in greatest abundance in the Lias of Lyme Regis, although it occurs more or less commonly throughout the whole of that formation from the south of Dorsetshire through Somerset and Leicester to the Yorkshire coast. They are found in rocks of similar age in France and Germany; and Sir Edward Belcher obtained remains of a Liassic ichthyosaur from an island in 77° 16′ N. lat.,—one of many proofs that in Mesozoic times a comparatively warm climate must have prevailed within the Arctic Circle. Remains of true ichthyosaurs have not yet been found on the American continent, although Professor Marsh lately (1877) described portions of the skeleton of a saurian obtained from strata of Jurassic age in the Rocky Mountains which seems to have differed from Old World ichthyosaurs chiefly in the absence of teeth, the jaws being "entirely edentulous and destitute even of a dentary groove." For the reception of this form Professor Marsh proposes to institute a new order—*Sauranodonta*; but it has been suggested, on the other hand, that *Sauranodon* should rather be regarded as the type of a new family of the old order *Ichthyopterygia.*

Owing to the comparative abundance and excellent preservation of ichthyosaurian remains, the hard parts of those creatures have been studied under exceptionally favourable circumstances, and much has thus been learnt of their structure and, by inference therefrom, of their life history. They were large marine reptiles, measuring in some instances 30 feet in length, and somewhat resembling in appearance the dolphins of the present day. Like these they were air-breathers, and must therefore have come to the surface to breathe, although being cold-blooded they were no doubt able, like the aquatic saurians of our own period, to remain much longer under water than the warm-blooded *Cetacea.* The ichthyosaurian head was large, and was prolonged into a more or less elongated snout, certain species rivalling in this respect the gavial of the Ganges. The brain cavity, on the other hand, was remarkably small. The eyes were enormously large, the orbit in *Ichthyosaurus platyodon*—the largest known species—having been found to measure 14 inches in long diameter. This huge eyeball was protected by a ring of bony sclerotic plates similar to those found in rapacious birds and in turtles and lizards of the present day. The jaws, which in *Ichthyosaurus platyodon* have been known to measure 6 feet in length, were rendered still more formidable by their array of strong, conical, pointed teeth, numbering in some instances over one hundred and eighty, and placed not in distinct sockets, as in the crocodile, but in a common alveolar groove. These, as they became worn, were replaced by a succession of young teeth, which budded up at the base of the old. The neck in the ichthyosaurus was extremely short, and not marked by any constriction. The vertebræ resembled those of fishes in being deeply biconcave. The tail was long and tapering; in many specimens this organ has been found to be fractured at about a fourth of its length from the extremity, and, as the vertebræ of the same region seem to have been flattened vertically, Professor Owen regards it as probable that these reptiles were provided with a tegumentary caudal fin like that of the *Cetacea*, only vertical instead of horizontal; the sole evidence of the presence of such a horizontal fin in extinct whales would be the horizontally flattened condition of the last caudal vertebræ, should any of these chance to be preserved. Ichthyosaurians were provided with two pairs of limbs in the form of paddles, which externally must have borne considerable resemblance to the anterior limbs of dolphins and other *Cetacea.* They differed, however, very markedly from these in the possession of a bony apparatus, stretching, in the case of the front pair, from one shoulder joint to the other, on which the anterior paddles were supported. This "scapular arch," according to Professor Owen, resembled, "in the number, shape, and disposition of its bones," the same parts in the Australian *Ornithorhynchus*, a mammal which leads, as *Ichthyosaurus* did, an aquatic life, obtaining its food at the bottom of lakes and rivers, but having to rise frequently to the surface to breathe. The hind limbs were in almost all the species much smaller than the pair in front. The skeleton of each of the paddles consisted mainly of a large number—in some species exceeding a hundred—of small polygonal bones arranged in more than five closely packed longitudinal rows, the whole covered with skin, and forming a highly elastic organ of locomotion. The ichthyosaur was provided with slender ribs along the vertebral column from the anterior part of the neck to the tail; a sternum, however, was wanting, the abdominal walls being strengthened by the development of transverse arcuated bones. As no trace of horny scales or bony scutes has ever been detected in connexion with those reptilian remains, it may be assumed that these sea-saurians, as they have been called, were, like the *Cetacea* of the present day, covered with a smooth or wrinkled skin unprovided with any of those dermal appendages.

From a study of their bony structure it may be inferred that these huge aquatic reptiles inhabited the open sea, occasionally visiting the shores, where their powerful paddles enabled them to crawl on land, and where, like seals, they probably loved to bask in the sunshine. That they were predatory in their habits—the tyrants indeed of Mesozoic seas—might be inferred from our knowledge of their jaws and teeth; and this is amply confirmed by an examination of the half-digested contents of their stomachs.

Their food seems to have consisted chiefly of ganoid fishes and the smaller reptiles, and as the vertebræ and other remains of young ichthyosaurs have occasionally been found mixed with these, there is reason to believe that they, like many other marine animals, did not hesitate to devour the weaker members of their own species. In several instances tolerably complete skeletons of small ichthyosaurs have thus been found enclosed within the ribs of larger individuals of the same species, and their occurrence gave rise to the evidently erroneous conjecture that those reptiles might have been viviparous. The fact that the entombed specimens have in almost every case been found with the head turned towards the tail of the enclosing animal was supposed to favour this view; the discovery, however, of additional specimens may at any time deprive this argument of the little value it has, and recently Professor Merian described a specimen from the Upper Lias of Würtemberg in which the included ichthyosaur lay with its head towards that of the enveloping specimen. The nature of their food is indicated, not only by the occurrence, in what from its position must have been the stomach, of the half-digested remains of fishes and reptiles, but also by the presence of similar relics, and especially of the scales of fishes, in their fæces. The coprolites of the ichthyosaurians are oval bodies measuring usually from 2 to 4 inches in length, and exhibiting on their surface the impression of the spirally convoluted internal surface of the intestine. These coprolites consist chiefly of phosphate of lime, and occur in great abundance in certain Liassic beds, where, says Buckland, they look "like potatoes scattered on the ground."

The species of the genus *Ichthyosaurus* differ from each other chiefly in the proportion of certain parts of the body and of the teeth. Professor Huxley has divided them into two groups:—(1) those which have relatively short snouts and short paddles, with four carpalia, including therein such forms as *I. intermedius* and *I. communis*, the latter remarkable as having its anterior paddles three times the length of the pair behind; and (2) those with longer snouts, long paddles, and three carpalia, including such forms as *I. longirostris* and *I. tenuirostris*, which in the length of their snouts rival the gavial of the Ganges, and *I. platyodon*, in which the fore and hind limbs are of equal length.

ICONIUM (Greek Ἰκόνιον), an ancient city of Asia Minor, now, under the name of Cogni, Konieh, Koniyeh, Konijah, or Konia, the capital of the Turkish vilayet of Caramania, is situated 310 miles east from Smyrna, at the entrance to an extensive and elevated plain which forms the centre of Asia Minor. To the eastward this plain stretches beyond the horizon, but the city is enclosed on other sides by a semicircle of snow-covered mountains. It lies at the foot of Mount Taurus, and the country immediately around it, watered by streams from the surrounding mountains, is occupied by fruitful gardens and orchards, forming an oasis in the midst of wide-stretching barrenness and desolation. The numerous richly adorned mosques, chapels, shrines, and monuments attest the former importance of the city when in the zenith of its power and prosperity, and lend additional brightness and picturesqueness to its appearance as seen from a distance; but on closer inspection the splendour is seen to be so intermixed with squalor and decay as to degenerate into tawdriness. Ancient walls about 2 miles in circumference surround the older part of the town, but one half of the inhabited portion is outside their boundaries. These walls were built by the Seljuk sultans in the 13th century of large square blocks of stone which have evidently formed part of more ancient edifices; and they are flanked by square towers richly adorned with cornices, demi-lions couchant, eagles with outspread wings, and Arabic inscriptions. The gateways are ornamented with alto-rilievos representing figures in procession. Great part of the space inside the walls is occupied by crumbling ruins of houses, and by dilapidated mosques half-buried in rubbish and overgrown by weeds. Of the ancient Greek city there are now no remains, but Greek inscriptions are to be found in the ancient walls erected by the Turkish conquerors, and bas-reliefs and other relics have been dug up at various periods. Modern Konieh lies to the south-west of the old town, half of it being outside the walls. The houses are one-storied, unplastered, and built mostly of sun-dried bricks and wood. Among the numerous monuments of saints and sheiks is the famous green monument of Mevlana-Djelâl-eddin-Rûmi, the poet and founder of the spinning dervishes, large numbers of whom have taken up their quarters in the surrounding gardens. The most beautiful building of the city is the court mosque, with a lofty and finely tapering minaret glittering with porcelain. Of the old residence castle situated on the hill within the boundaries there are now only a few remains, great part of it having been used in building the Konak or palace of the pasha. Adjoining the ruins of the castle there is an old Byzantine chapel dedicated to St Thecla. Below the castle, and forming part of the western wall of the town, there is another fortress in a pretty good state of preservation, and for many years used as a state prison. The bazaar has a miserable appearance, and the principal goods exposed for sale are English and Swiss cottons and Nuremberg wares, the oppressive regulations of the Turkish Government in regard to the importation of salt having rendered the rearing of sheep wholly unprofitable, and thus entirely destroyed the native cloth-weaving industry. The number of dwelling-houses is about 7000, of which 150 are Armenian; and the population numbers in all probability between 40,000 and 50,000.

Iconium was situated on the military road between Antioch of Pisidia and Derbe. By Strabo (xii. 6, 1) it is spoken of as a small town (πολίχνιον), but by Pliny (*H. N.*, v. 25) as a very celebrated city. Xenophon (*Anab.*, i. 2, 19) mentions it as the nearest town to Phrygia; but Cicero (*Ad Div.*, iii. 6–8; xv. 4) calls it the capital of Lycaonia; while Ammianus Marcellinus (xiv. 2) reckons it as belonging to Pisidia. In the time of Pliny its territory formed a tetrarchy which embraced fourteen cities, many of them of considerable size. The apostle Paul visited Iconium on his first missionary tour from Antioch, and founded a Christian community there, but on account of the hostility of the Jews he deemed it expedient to retire to Lystra. Subsequently he twice visited the city; and it is the scene of the apocryphal story of Paul and Thecla, mentioned by many of the early fathers. About this time it became a Roman *colonia*, its Roman name being *Claudia* or *Claudiconium*. A Christian synod met at Iconium in 235. Under the rule of the Byzantine emperors the city continued to flourish, but in 708 it was conquered by the Arabs and incorporated in the caliphate. Having been conquered by the Seljuk Turks in 1074, Kilidj Arslan I. in 1097 made it his residence, and the capital of a kingdom whose rulers were named sultans of Iconium, and which may be regarded as the cradle of the Ottoman power. On May 18, 1190, Frederick Barbarossa, after a victory over the Turks on the 7th, captured the town, but failed to storm the castle. From 1244 the sultans were alternately deposed and reinstated by the khans of the Mongols, until the dismemberment of the sultanate on the death of Masoud II. in 1294, when their territories were added to Caramania, which in 1392 acknowledged the sovereignty of the Porte, and in 1486 was incorporated with the Ottoman empire. On 30th December 1832 the city was the scene of a victory over the Turks by Ibrahim Pasha. See Kinneir, *Travels in Asia Minor*; Hamilton, *Researches in Asia Minor*; Leake, *Geography of Asia Minor*; Chesney, *Euphrates Expedition*; Texier, *Asie Mineure*; and E. Sherling in the Berlin *Zeitschrift für allgemeine Erdkunde* for 1864.

ICONOCLASTS. See Image Worship.

ICTERUS, a bird so called by classical authors, and supposed by Pliny to be the same as the *Galgulus*, which nearly all writers agree in considering to be what we now know as the Golden Oriole (*Oriolus galbula*).[1] At any

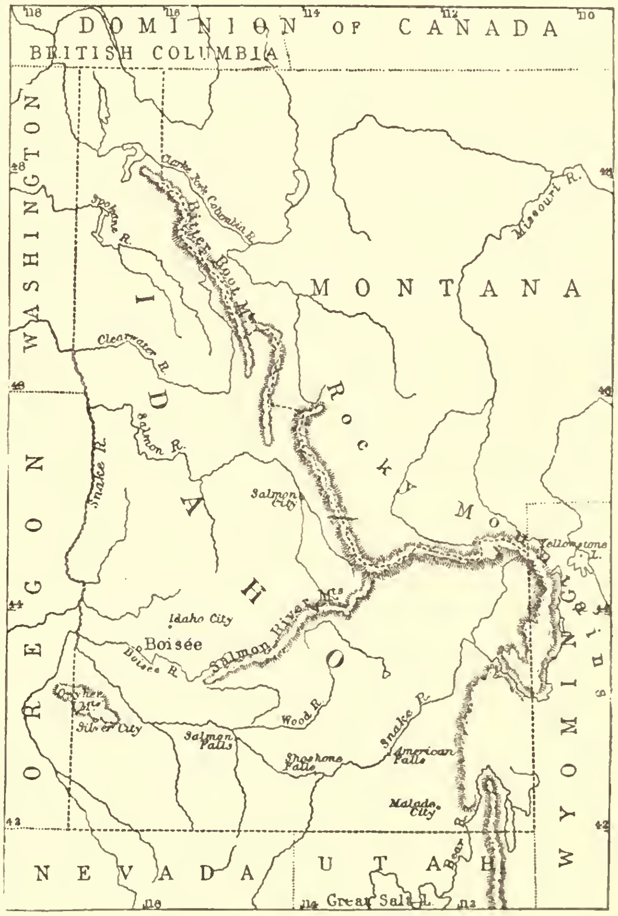
[1] The number of names by which this species was known in ancient times—*Chloris* or *Chlorion*, *Galbula* (akin to *Galgulus*), *Parra*, and

rate it signified one in the plumage of which yellow or green predominated, and hence Brisson did not take an unhappy liberty when he applied it in a scientific sense to some birds of the New World of which the same could be said. These are now held to constitute a distinct Family, *Icteridæ*, intermediate it would seem between the BUNTINGS (vol. iv. p. 525) and STARLINGS (*q. v.*); and, while many of them bear the vulgar name of Troopials (the English equivalent of the French *Troupiales*, first used by Brisson), others are known as the American GRACKLES (vol. xi. p. 26). The typical species of *Icterus* is the *Oriolus icterus* of Linnæus, the *Icterus vulgaris* of Daudin and modern ornithologists, an inhabitant of northern Brazil, Guiana, Venezuela, occasionally it is said visiting some of the Antilles and of the United States, but without much apparent proof. Thirty-three species of the genus *Icterus* alone, and more than seventy others belonging to upwards of a score of genera, are recognized by Messrs Sclater and Salvin (*Nomenclator*, pp. 35–39) as belonging to the Neotropical Region, though a few of them emigrate to the northward in summer. It would of course be impossible here to dwell upon them, but *Cassicus* and *Ostinops* may perhaps be named as the most remarkable. They are nearly all gregarious birds, many of them with loud and in most cases, where they have been observed, with melodious notes, rendering them favourites in captivity, for they readily learn to whistle simple tunes, which are admirably reproduced by their clear voice. Some have a plumage wholly black, others are richly clad, as is the well-known Baltimore Oriole, Golden Robin, or Hangnest of the United States, *Icterus baltimore*, whose brightly contrasted black and orange have conferred upon it the name it most commonly bears in North America, those colours being, says Catesby (*Birds of Carolina*, i. p. 48), the tinctures of the armorial bearings of the Calverts, Lords Baltimore, the original grantees of Maryland, but probably more correctly those of their liveries. The most divergent form of *Icteridæ* seems to be that known in the United States as the Meadow-Lark, *Sturnella magna* or *S. ludoviciana*, a bird which in aspect and habits has considerable resemblance to the Larks of the Old World, *Alaudidæ*, to which, however, it has no near affinity, while *Dolichonyx oryzivorus*, the Rice-bird, with its very Bunting-like bill, is not much less aberrant. (A. N.)

IDAHO, a north-western territory of the United States, was originally a part of Oregon, from which it was separated in 1863. It lies on the Pacific slope, with the exception of a small portion in its south-eastern corner, which is drained into the Great Salt Lake of Utah. It is bounded on the N. by British Columbia and N.E. by Montana; on the E. by Wyoming; on the S. by Utah and Nevada; and on the W. by Oregon and Washington. The boundaries are the meridians (111° and 117° W. long.) and the 42d and 49th parallels of N. lat., except that in the N.E. the Bitterroot range separates the territory from Montana, and the Snake river forms part of the western limit. The area of the territory is imperfectly known, but may be set down approximately at 86,300 square miles. The mean elevation is about 4700 feet. The lowest point, which is on Snake river, at the mouth of the Clearwater, is about 1000 feet above the sea, while the highest mountains rise nearly to 10,000 feet. The surface is very diversified; the northern portion is largely mountainous, with several fine broad valleys. In the southern portion a large area within the great bend of the Snake river is occupied by an immense plain of basalt. South of the Snake the country is an alternation of broad valleys and narrow abrupt mountain ranges.

The principal mountains are the Bitterroot and Salmon River chains, with their spurs and subordinate ranges. They attain a height of from 8000 to nearly 10,000 feet. The Snake River plain lies south of these mountains, extending east and west nearly across the territory. This is a field of basalt, seamed and crevassed, with little vegetation, and that consisting principally of *Artemisia*. The soil here is a shifting sand; and there is little surface water, as the streams sink and flow underneath.

The principal river is the Snake, the south fork of the Columbia. It is a rapid stream with numerous falls, three of which, the American, Shoshone, and Salmon or Fishing, are very considerable. It is navigable only in its lower course. Several of the branches of the Snake, the Salmon, Clearwater, and Spokane, are large streams, but are not navigable, and are of value only for irrigation and mining purposes.



Map of Idaho.

The climate, like that of other portions of the north-western United States, is characterized by great aridity of atmosphere and slight rainfall. In the south the aridity is such that large areas are almost desert; but in the mountainous regions of the north the rainfall is much greater, and agricultural operations can be carried on to some extent without irrigation. The northern part, being principally mountainous, is covered with forests of conifers, chiefly species of pine, spruce, fir, and tamarack. In the open valleys the vegetation consists mainly of the various kinds of grasses known collectively as "bunch grass." On the Snake River plains there is little vegetable growth

Vireo—may be readily explained by its being a very common and conspicuous bird, as well as one which varied in plumage according to age and sex (*cf.* ORIOLE). Owing to its general colour, *Chloris* was in time transferred to the GREENFINCH (vol. xi. p. 165), while the names *Galbula*, *Parra*, and *Vireo* have since been utilized by ornithologists (*cf.* JACAMAR and JACANA).

except *Artemisia*, while the country south and east of the Snake is covered with this and with grasses, with a little scattered timber (*Coniferæ* and aspens) on the mountains. A rough estimate gives as the area covered by forest 40,000 square miles, by useful grasses 25,000 square miles, and by *Artemisia* 21,300 square miles.

Though the bison formerly ranged over this whole region, it is now practically extinct. The moose is still occasionally seen, and, rarely the Rocky Mountain goat (*Aploceras montanus*). The wapiti, the mountain sheep (*Ovis montana*), and various species of deer are still abundant in the mountains, while the antelope or pronghorn abounds in the plains. Grizzly, black, and cinnamon bears, the American panther, the wild cat, and the wolverine are not unfrequently met with in the unsettled regions. Among the smaller quadrupeds, the prairie dog and gopher are abundant in the valleys and on the plains. Birds of many species are plentiful, especially in the mountain regions. Of reptiles, several species of rattlesnakes and lizards, including horned toads (*Phrynosoma*), are characteristic of the arid plains, where they are numerous.

The southern portion of this territory has been the scene of comparatively recent volcanic action, which has covered enormous areas with basalt. The mountains of this portion are mainly of the Silurian and Carboniferous ages. The ranges of the northern portion are known to be mainly Eozoic; but the geology of that section has yet to be investigated.

The administration of the territory is in the hands of a governor, secretary, and chief justice, all appointed by the president of the United States, and a treasurer, comptroller, and superintendent of public instruction, who, as well as the members of the two houses of the legislature, are elected by the people. The territory is represented in Congress by a delegate, also elective. The population in 1880 was 32,946, distributed thus in the several counties :—

County.	Population.	County.	Population.
Ada	4674	Nez Percé	4483
Alturas	1693	Oneida	6952
Bear Lake	3242	Owyhee	1427
Boisé	3213	Shoshone	469
Cassia	1315	Washington	877
Idaho	2371		
Kootenai [1]		Total	32,946
Lemhi	2230		

The principal settlements are Malade, Boisé (the capital of the territory), Idaho, Buenavista, and Silver City.

The agricultural, grazing, and mining interests of Idaho are but commencing their development. In the valleys of the southern portion the Mormons are raising abundant crops of cereals, with the aid of irrigation. In the valleys of the lower Snake, the Boisé, Clearwater, Salmon, and Spokane rivers, wheat, oats, rye, and other grains are cultivated to some extent. Large portions of the territory are well adapted for grazing, and this is now being turned to account.

The mineral wealth has not yet, owing to difficulty of transportation, been developed to any great extent; but it is known to be important. Gold and silver are found, the former both in vein and in placer deposits. The principal vein deposits now being worked are in the Salmon River and Owyhee mountains. Placers have been worked in nearly every county of the territory, and have paid well. During the year 1880 many new and rich deposits have been discovered in the Wood River district, in the Salmon River mountains, and there has been a considerable influx of mining population.

The Utah and Northern Railroad crosses the south-eastern portion of the territory, from Utah to Montana.

The total number of Indians in Idaho is about 6000, consisting of the tribes known as the Nez Percé, Bannack, Shoshone, Cœur d'Alène, Spokane, Pend' Oreille, and Kootenai. They are under the control of the Government, and most are settled on reservations. (H. G.*)

IDIOCY. See INSANITY.

IDLE, a town of the West Riding of Yorkshire, in the parish of Calverley, is pleasantly situated on an eminence near the river Aire, on the Great Northern Railway, 9 miles north-west of Leeds and 3 north of Bradford. The staple manufacture is woollen cloth; there are also worsted mills, and a cotton-warp factory. There are several stone and slate quarries in the neighbourhood. The church of the Holy Trinity, erected in 1830 in the Later English style, is a handsome structure with embattled tower crowned with pinnacles; and there are national and other schools, an oddfellows' hall, a mechanics' institute, and a church institute. The population (including Windhill, which is a separate vicarage) in 1861 was 9155, and in 1871 it had reached 12,036.

IDOLATRY. The word εἰδωλολατρεία (*idololatria*, afterwards shortened occasionally to εἰδολατρεία, *idolatria*) occurs in all four times in the New Testament, viz., in 1 Cor. x. 14, Gal. v. 20, 1 Pet. iv. 3, Col. iii. 5. In the last of these passages it is used, obviously in a typical sense, to describe the sin of covetousness or "mammon-worship." In the other places it is employed in its natural sense, but with the utmost generality, to indicate all the rites and practices of those special forms of Paganism with which Christianity first came into collision. It can only be understood by reference to the LXX., where εἴδωλον (like the word "idol" in A.V.) occasionally translates indifferently no fewer than sixteen words by which in the Old Testament the objects of what the later Jews called "strange worship" (עֲבוֹדָה זָרָה) are denoted (see Trommius, *Concordantiæ*). In the widest acceptation of the word, idolatry in any form is absolutely forbidden in the second commandment, which runs "Thou shalt not make unto thee a graven image; [and] to no visible shape in heaven above, or in the earth beneath, or in the water under the earth, shalt thou bow down or render service" (see DECALOGUE, vol. vii. p. 15). For some account of the various interesting questions connected with the many practical departures from this law which are recorded in the history of the Israelites the reader is referred to the article JEWS; those differences as to the interpretation of the prohibition which have so seriously divided Christendom are discussed under the head of IMAGE WORSHIP.

In the ancient church, idolatry was naturally reckoned among those magna crimina or great crimes against the first and second commandments which involved the highest ecclesiastical censures. Not only were those who had gone openly to heathen temples and partaken in the sacrifices (sacrificati) or burnt incense (thurificati) held guilty of this crime; the same charge, in various degrees, was incurred by the libellatici, whose renunciation of idolatry had been private merely, or who otherwise had used unworthy means to evade persecution, by those also who had feigned themselves mad to avoid sacrificing, by all promoters and encouragers of idolatrous rites, and by idol makers, incense sellers, and architects or builders of structures connected with idol worship. Idolatry was made a crime against the state by the laws of Constantius (*Cod. Theod.*, xvi. 10. 4, 6) forbidding all sacrifices on pain of death, and still more by the statutes of Theodosius (*Cod. Theod.*, xvi. 10. 12) enacted in 392, in which sacrifice and divination were declared treasonable and punishable with death; the use of lights, incense, garlands, and libations was to involve the forfeiture of house and land where they were used; and all who entered heathen temples were to be fined. See Bingham, *Antiqq.*, bk. xvi. c. 4.

[1] Unorganized, and attached to Nez Percé county.

IDRIA, a mining town in Austria, in the duchy of Carniola and circle of Loitsch, situated in a narrow Alpine valley on the river Idrizza, 28 miles north-north-east of Trieste. It is the seat of a circle court and of an office of mines, the building used for which is the old castle of Gewerkenegg or Gewerkenburg, built in 1527 by the miners during the lordship of the Venetian republic. The town also possesses a handsome church, a high school, a mining school, and a theatre. Linen weaving, lace making, and gin distilling employ a considerable number of the inhabitants, but the origin and prosperity of the town are due to the rich mines of quicksilver which were accidentally discovered in 1497. Since 1580 they have been under the management of the Government. The mercurial ore lies in a bed of clay slate, and is found both mingled with schist and in the form of cinnabar. A special excellence of the ore is the greatness of the yield of pure metal compared with the amount of the refuse. The mine is reached by a shaft 150 fathoms deep, and the descent is accomplished partly by means of ladders and partly by steps cut out of the solid rock. The number of miners employed is about five hundred; they wear a peculiar uniform. Formerly the mines were wrought by state prisoners, but notwithstanding the unhealthiness of the employment it is now largely sought after on account of the high wages offered to the workmen, as well as the pension allowed them when disabled, and the provision that is made for their widows and orphans. In 1870 improved ovens for smelting the ore were erected. The yearly yield of the mines is about 290 tons. The population of Idria in 1869 was 3813.

IDRISI. See EDRISI.

IDUMEA (Ἰδουμαία) is the Greek form of the Hebrew Edom (אֱדֹם), a district south of the Holy Land. The name Edom is restricted in the Bible to the mountain country south-east of the Dead Sea, and to the chain of Mount Hor near Petra. The word means "red," and the title was no doubt derived from the red colour of the cliffs of Nubian sandstone, which form the greater part of this chain. The coast or desert of Edom was bounded by the desert of Zin (the present *'Arabah*) on the W., by the desert of Paran on the S.W., and extended as far as Ezion-geber and Eloth, at the head of the Gulf of Akabah. It is identified with Mount Seir, the possession of Esau (Gen. xxxii. 3). In later times, however, we find that the term Idumea receives a considerable extension, embracing all the pastoral country south of Judæa, and extending even within the borders of Philistia. Bethsura (*Beit Sûr*), Acrabattine (Acrabbim), and Hebron are in 1 Macc. iv. and v. alluded to as within or near its limits.

By Josephus the term Idumea is used with this more extended meaning, embracing an area of 3000 square miles. It answers to the Biblical term Negeb ("dry") applied to the south country, where the formation is a soft chalk, and which is inhabited by nomadic pastoral tribes. Josephus divides the Idumean district into minor divisions, viz., (1) Gobalitis ("mountains"), the original Seir or Edom; (2) Amalekitis ("the land of Amalek"), west of the former; (3) Acrabattine ("the scorpion land"), the ancient Acrabbim south-west of the Dead Sea. The frontier towns on the north were Tekoa, Bethsura, and Bethgubrin (*Beit jibrîn*), and among the more important places within the district were Hebron, Petra, Arad, Malatha (*Tell el Milh*), Beersheba, Rehoboth, Elusa (*Khalasah*), Eboda (*'Abdeh*), &c. Josephus speaks of Upper Idumea, apparently the district round Hebron, and enumerates Begabris (*Beit jibrîn*) and Caphar Topha (*Tuffûh*, near Hebron) among its towns.

In the Talmud Eleutheropolis (*Beit jibrîn*) is placed in Idumea (*Midrash Yalkut*, Gen. xxxiii., and *Bereshith Rabba*, ch. vi.). Jerome defines Idumea as extending from Eleutheropolis to Petra and Eloth. The south boundary of the Holy Land, as defined in the Talmud, included Idumea, the reason being that the Idumeans had embraced Judaism about 140 B.C. (Joseph., *Ant.*, xiii. 9, 1). Strabo (lib. xvi.) speaks of the Edomites as of Nabathean or Arab origin. Pliny (*H. N.*, v. 12) makes the country extend southwards to the Serbonian bog (near the present Port Said). Ptolemy (v. 15), in the middle of the 2d century, restricts the name to a district west of Jordan, including Elusa (*Khalasah*) and Gemmaruris (probably *Jemrûrah* in the Hebron hills). The original Edom is called by this geographer Arabia Petræa.

The aboriginal inhabitants of Idumea were the Horim or "cave dwellers" expelled by Esau. Mount Seir is said to have been named after one of their chiefs (Gen. xxxvi. 20, Deut. ii. 12). Jerome speaks of the natives of this country as still dwelling in caves, and in common with the Talmudic writers attributes to them the great caverns at Eleutheropolis. The inhabitants appear to have been always nomadic and pastoral, they were mingled with the Jews (tribe of Simeon) and with the Hittites. At the time of the great siege of Jerusalem the Idumeans fought in concert with the Jews (Jos., *B. J.*, vi. 8, 2), and the Romans applied the name Idumea very loosely to the whole of southern Palestine, including even Jerusalem. At the present day the habit of living in caverns is very marked in this district, the rock being soft and easily excavated. The soil is generally a soft white marl, producing a rich herbage in spring, and supporting numerous flocks. (C. R. C.)

IFFLAND, AUGUST WILHELM (1759-1814), a German actor and dramatic author, was born in Hanover on the 19th of April 1759. His father was registrar at the war office of Hanover, and intended that his son should be a clergyman. Young Iffland, however, preferred the stage to theology, and at the age of eighteen went to Gotha in order to prepare himself for a theatrical career. At that time the greatest actor in Germany was Eckhof, a man of undoubted genius, for whom Lessing repeatedly expressed the warmest admiration in his *Hamburgische Dramaturgie*. Iffland was fortunate enough to receive instruction from him in Gotha, and under his guidance made such rapid progress that he was able in 1779 to accept an engagement at the theatre in Mannheim, then the most famous of the German theatres. He soon stood high in his profession, and extended his reputation by frequently appearing at the leading theatres in different parts of the country. In 1796 he settled in Berlin, where he became director of the national theatre of Prussia; and in 1811 he was made general director of all representations before royalty. On the 22d of September 1814 he died. His plays are almost entirely destitute of imagination; but they display a thorough mastery of the technical necessities of the stage, and a remarkable power of devising effective situations. His best characters are simple and natural, fond of domestic life, but too much given to the utterance of sentimental commonplace. His best known plays are *Die Jäger*, *Dienstpflicht*, *Die Advocaten*, *Die Mündel*, and *Die Hagestolzen*, all of which are still occasionally represented. Iffland was a dramatic critic as well as a dramatic author, and German actors place high value on the reasonings and hints respecting their art which are to be found in his *Almanach für das Theater*. As an actor he fell far short of his master, Eckhof, whose style was marked by spontaneity and passion, while Iffland's acting always bore traces of elaborate study. Hence he failed in great tragical parts; but he was unexcelled in his day in the skill with which he interpreted dramatic conceptions representing the course of ordinary middle class life. Within these limits he was almost equally distinguished in his capacity for rendering comic and pathetic effects. In 1798-1802 Iffland issued his *Dramatic Works* (with an autobiography) in 16 volumes, to which, in 1807–9, he added 2 volumes of *New Dramatic Works.* Two selections from his writings were afterwards published, the one in 10, the other in 11 volumes.

See K. Duncker, *Iffland in seinen Schriften als Künstler, Lehrer, und Director der berliner Bühne*; and Koffka, *Iffland und Dalberg.*

IGLAU, or Jihlava, one of the oldest towns of Moravia, and second only to Brünn in respect of size and population, is situated about 50 miles west-north-west of that city, and on the right bank of the Iglawa, close to the Bohemian frontier, in 49° 25′ N. lat. and 15° 34′ E. long. Iglau is the capital of a circle of the same name, the seat of the judicial authorities, and the military headquarters of the district. It consists of the town proper and the suburbs of Frauen, Pirnitzer, and Spital. Among the principal buildings are the churches of St James, St Ignatius, St John, and St Paul, the town-hall, a gymnasium, a high school, a military seminary, civil and criminal courts, several hospitals, and the barracks formed from a monastery abolished by order of the emperor Joseph II. There is also a fine cemetery, containing some remarkable monuments. The industrial establishments comprise cloth and linen weaving, paper, earthenware, and glass factories; potash, vinegar, and dye works; tanneries, iron foundries, a large brewery, and an extensive cigar factory, employing over 2000 hands. Fairs are periodically held in the town; and the trade in timber, cereals, and linen and woollen goods is generally brisk. The population in 1870 amounted to about 20,200, most of whom were Germans or of German extraction.

At a very early date Iglau enjoyed exceptional privileges, and they were confirmed by King Wenceslaus III. in the year 1250. The town-hall contains a collection of municipal and mining laws dating as far back as 1389. At Iglau, on July 5, 1436, the treaty was made with the Hussites, by which Sigismund was acknowledged King of Bohemia. A granite column near the town marks the spot where Ferdinand I., in 1527, swore fidelity to the Bohemian states. During the Thirty Years' War Iglau was twice captured by the Swedes. In 1742 it fell into the hands of the Prussians, and in December 1805 the Bavarians under Wrede were defeated near the town by the archduke Ferdinand d'Este.

IGLESIAS, a town of Sardinia, capital of a district in the province of Cagliari, is beautifully situated amongst limestone hills about 3 miles from the west coast, and at the terminus of a railway line from Cagliari, 34 miles west-north-west from that town. It is the seat of the suffragan bishop of Cagliari, and possesses a cathedral, an episcopal palace, four convents, a Jesuit college, and the ruins of old fortifications. The town is abundantly supplied with water from various springs. The surrounding country is highly productive, and there is an active trade in wine, oil, fruits, cheese, corn, and other agricultural products. Lead and zinc are obtained in the neighbourhood. The population of the town in 1871 was 6630.

IGLÓ, formerly Neudorf, a mining town of North Hungary, in the county of Szepes or Zips, is pleasantly situated on the Hernád, and on the Kaschau-Oderberg line of railway, about 5 miles south of Löcse (Leutschau), in 48° 56′ N. lat. and 20° 33′ E. long. Among the few public buildings are Lutheran and Roman Catholic churches, a gymnasium, a teachers' seminary, a circuit court, and the usual Government offices. There are, moreover, factories for the manufacture of stoneware, fuller's earth, linen, and paper; also sawmills, steam flour mills, and iron foundries. In the vicinity are extensive iron and copper mines and stone quarries. The inhabitants of the town and neighbourhood are chiefly employed in mining, bee-keeping, flax-growing, agriculture, and trade. The population (including that of Great and Little Igló-Hnilecz) amounts to 6691, mostly German by nationality and Lutheran by creed. Igló was formerly the capital of the sixteen privileged Zips towns, and its origin may be traced to Saxon colonists of the 12th century.

IGNATIUS, St. See Apostolic Fathers, vol. ii. p. 196.

IGNATIUS DE LOYOLA, St. See Loyola.

IGNORANTINES (*Frères Ignorantins*), as the Brethren of the Christian Schools (*Frères des Écoles Chrétiennes*) are commonly though improperly called, are a religious fraternity founded at Rheims in 1679, and formally organized in 1683, by the priest Jean-Baptiste de La Salle, for the purpose of affording a free education, especially in religion, to the children of the poor. The name Ignorantine was given either on account of the low class of the pupils, or from a clause in the rules of the order forbidding its members to learn or teach Latin. Other popular names applied to the order are *Frères de Saint-Yon*, from the house at Rouen, which was their headquarters from 1705 till 1770, *Frères à quatre bras*, from their hanging sleeves, and *Frères Fouetteurs*, from their former use of the whip (*fouet*) in punishments. The brethren, although not allowed by their rules to enter holy orders, take the usual vows of chastity, poverty, and obedience. They are distinguished by a peculiar coarse black dress, consisting of a cassock, a hooded cloak with hanging sleeves, and a broad-brimmed hat. The order, approved by Pope Benedict XIII. in 1725, rapidly spread over France, and although expelled after the Revolution of 1789, was recalled by Napoleon in 1803, and formally recognized by the French Government in 1808. Since then its members have penetrated into nearly every country of Europe, and into America, Asia, and Africa. In France alone they number more than 1300 schools for young and old, attended by upwards of 300,000 pupils, taught by some 8000 masters. See *Histoire du Vénérable J.-B. de la Salle*, by A. Ravelet, 2d ed., Paris, 1874.

IGUALADA, a town of Spain, in the province of Barcelona, is situated on the left bank of the Noya, in a rich agricultural and vinebearing country, 32 miles north-west of Barcelona. It consists of an old and a new town, the former dilapidated and dirty, with narrow and irregular streets and the remains of a fortress and ramparts, while the latter possesses regular and spacious streets and many fine houses. Among the public buildings are an old Gothic church, a town-hall, two conventual buildings, a clerical college, a hospital, and military barracks. The former commercial prosperity of Igualada has now much declined, but its industries are still considerable, and comprise cotton spinning, cotton and woollen weaving, and the manufacture of firearms, leather, hats, and brandy. There is also some trade in corn. Population in 1877, 11,882.

IGUANA (*Iguanidæ*), a family of lizards belonging to the suborder *Pachyglossæ* or "thick-tongued," and comprising 56 genera and 236 species. With a single undoubted exception, all the genera of this extensive family belong to the New World, being specially characteristic of the Neotropical region, where they occur as far south as Patagonia, while extending northward into the warmer parts of the Nearctic region as far as California and British Columbia. The single non-American genus—*Brachylophus*—occurs in the Fiji Islands. The iguanas are characterized by the peculiar form of their teeth, these being round at the root and blade-like, with serrated edges towards the tip, resembling in this respect the gigantic extinct reptile iguanodon. The typical forms belonging to this family are distinguished by the large dewlap or pouch situated beneath the head and neck, and by the crest, composed of slender elongated scales, which extends in gradually diminishing height from the nape of the neck to the extremity of the tail. The latter organ is very long, slender, and compressed, while its vertebræ, in common with those of certain other lizards, possess thin unossified septa traversing their centres. It is owing to the weakness thus produced in their vertebral column that, when caught by the tail, they are able to part so readily with the portion seized. The tongue is generally short and not deeply divided at its extremity, nor is its base retracted into a sheath; it is always moist and covered with a glutinous secretion. The prevailing colour of the iguanas is green; and, as the majority of them are arboreal in their habits, such colouring may be generally regarded as protective. Those on the other hand which reside on the ground have much duller, although as a rule equally protective hues; thus Darwin observed on the shore at Bahia a terrestrial member of this family, which from its mottled appearance could hardly be distinguished from the surrounding surface. Iguanas, however, possess to an extent only exceeded by the chameleon the power of changing their colours, their brilliant green becoming transformed in an instant, under the influence of fear or irritation, into more sombre hues and even into black. They differ greatly in size, from a few inches to several feet in length. One of the largest and most widely distributed is the common iguana (*Iguana tuberculata*), which occurs in South America and the West Indies. It attains a length of 5 feet, and is of a greenish

Iguana.

colour occasionally mixed with brown, while the tail is surrounded with alternate rings of those colours. Its food consists of vegetable substances, which it obtains from the forest trees among whose branches it lives and in the hollows of which it deposits its eggs. These are of an oblong shape, about an inch and a half in length, and are said by travellers to be very pleasant eating, especially when taken raw, as they usually are, and mixed with farina. They are timid, defenceless animals, depending for safety on the comparative inaccessibility of their arboreal haunts and their protective colouring, which is rendered even more effective by their remaining still on the approach of danger. Otherwise they exhibit few signs of animal intelligence. "The iguana," says Bates (*The Naturalist on the Amazon*), "is one of the stupidest animals I ever met. The one I caught dropped helplessly from a tree just ahead of me; it turned round for a moment to have an idiotic stare at the intruder, and then set off running along the path. I ran after it and it then stopped as a timid dog would do, crouching down and permitting me to seize it by the neck and carry it off." Along with several other species the common iguana is much sought after in tropical America; the natives esteem its flesh a delicacy, and capture it by slipping a noose round its neck as it sits in fancied security on the branch of a tree. Although chiefly arboreal, many of the iguanas take readily to the water; and there is at least one species, *Oreocephalus cristatus*, which leads for the most part an aquatic life. These marine lizards occur only in the Galapagos Islands, where they are never seen more than 20 yards inland, while they may often be observed in companies several hundreds of yards from the shore, swimming with great facility by means of their flattened tails. Their feet are all more or less webbed, but in swimming they are said to keep these organs motionless by their sides. Their food consists of marine vegetation, to obtain which they dive beneath the water, where they are able to remain, without coming to the surface to breathe, for a very considerable time. Though they are thus the most aquatic of lizards, Mr Darwin, who studied their habits during his visit to those islands, states that when frightened they will not enter the water. Driven along a narrow ledge of rock to the edge of the sea, they preferred capture to escape by swimming, while if thrown into the water they immediately returned to the point from which they started. A land species belonging to the allied genus *Trachycephalus* also occurs in the Galapagos, which differs from most of its kind in forming burrows in the ground.

IGUANODON, a genus of extinct Dinosaurian reptiles, the remains of which have been found in greatest abundance in the Wealden, a delta formation of the south-east of England. They also occur, though more sparingly, in the Lower Greensand, where lately (1879) Professor Prestwich announced the discovery in the "Kimmeridge Clay" of what are as yet the earliest known remains of these reptiles. Although no complete skeleton of the iguanodon has been found, such bones of it as have been obtained prove it to have been one of the largest terrestrial animals known. Thus its femur in one instance measured from 4 to 5 feet in length, with a circumference of 22 inches at its narrowest part. These and other measurements led Dr Mantell—the original discoverer of *Iguanodon*—and others to conclude that it probably attained a length of from 50 to 60 feet. Its front limbs appear to have been small, while the hind pair attained enormous development, and from the structure of the latter, which may be regarded as intermediate between those of existing reptiles and of birds, the iguanodon is supposed to have either habitually or occasionally walked on its hind legs like a bird. This supposition is rendered all the more probable by the discovery in the same strata of gigantic three-toed footsteps in pairs such as might have been formed by the iguanodon had it walked in this bipedal manner. The teeth of these animals formed one of their most marked characteristics,—bearing a striking resemblance to the teeth of existing iguanas in their blade-like form and serrated edges, but differing from these as well as from those of all other known reptiles in internal structure. Like existing iguanas they were probably herbivorous, using their teeth for cutting and tearing their tough vegetable food; unlike these, however, they appear to have used their teeth also for the purpose of mastication. This is shown by the deeply worn condition in many cases of the crowns of their teeth, which, from being sharp and incisor-like, gradually assumed a molar-like form. As the old teeth were thus reduced by "tear and wear," they were gradually replaced by a fresh dental crop. The front portion of the jaws was destitute of teeth, the upper part being beak-like, while the lower was hollowed out like the same region in the parrot.

Professor Owen regards this as an arrangement to facilitate the protrusion of what was probably a long prehensile tongue—an organ which the iguanodon may be supposed to have employed in stripping the foliage from the trees. There is no fossil evidence to show that it possessed either scutes, scales, or any other form of dermal armour.

IGUVIUM. See Eugubine Tables and Gubbio.

ILCHESTER, formerly Ivelchester, a market-town of Somersetshire, is situated in the valley of the river Ivel or Yeo, 33 miles south-south-west of Bath, and 5 miles north-north-east of Yeovil railway station. It is connected by a stone bridge with the village of Northover on the other side of the river. The principal buildings are the parish church of St Mary, an old edifice in the Early English style, with a small octagonal tower, and the town-hall. It possesses almshouses, founded in 1426, and national schools. There are no manufactures or trade, and the importance of the town belongs wholly to the past. Under the Romans it was a military station, and bore the name of *Ischalis*. Anciently it was a place of considerable extent, and was defended by walls and a deep moat. Traces of these fortifications are still to be found, and numerous Roman remains have been discovered at different periods. During a rebellion against William Rufus in 1088, the town was successfully defended against Robert Mowbray, one of the leaders of the insurgents. Before the Reform Act of 1832, when it was disfranchised, Ilchester returned two members to parliament. The county jail was there until 1846. The population of the town in 1871 was 751.

ÎLE-DE-FRANCE, an old district of France, forming a kind of island, bounded by the Marne, the Seine, the Oise, the Aisne, and the Ourcq. Until the end of the Carlovingian dynasty it was included in the domains of the crown. The government of Île-de-France, named after this district, now embraces the department of the Seine, together with the greater part of Seine-et-Oise, Seine-et Marne, Oise, and Aisne, and a small part of Loiret and Nièvre. It was bounded on the N. by Picardy, on the W. by Normandy, on the S. by Orléannais and Nivernais, and on the E. by Champagne. Its capital was Paris.

ILFRACOMBE, a market-town, seaport, and watering-place of Devonshire, is picturesquely situated on the Bristol Channel, and at the terminus of a branch of the London and South-Western Railway, 11 miles north by west of Barnstaple, and 50 miles north-west by west of Exeter. The parish is under the government of a local board of health, established in 1857. The old town, built on the cliffs above the harbour, consists of a principal street about a mile in length, with smaller streets branching off from it. Behind the old town many fine villas and marine residences rise in beautiful terraces commanding picturesque and magnificent views. The heights or torrs overspread with foliage form a sort of semicircle round the town, stretching westwards to a considerable distance; and it is sheltered from the sea by the Capstone Rock. Hillsborough Rock, on the east side of the harbour, with a height of about 500 feet, has near its summit some remains supposed to be of Celtic origin. On Lantern Rock, at the west side of the harbour, a lighthouse has been erected. For access to the bathing ground, which is confined to a few small coves at the foot of the rocks, three tunnels have been cut through the solid rock. Inland the country presents a beautiful variety of hill and dale, clothed with woods and possessing a rich and luxuriant vegetation. The principal public buildings are the parish church, dating from the 12th century, and recently restored, and St Philip and St James's Church, recently erected at a cost of over £10,000, the town-hall erected in 1860, the market-house of the same date, the baths, and the assembly rooms. Waterworks were completed in 1866 at a cost of £7000. The harbour, formed wholly of a natural basin, admits vessels of more than 200 tons burden, and there is a pier 850 feet in length. Herring fishing is prosecuted, but the shipping trade has considerably declined. The population of the parish, which in 1861 was 3851, was 4721 in 1871.

The name of the town is differently spelt in old documents, the variations being Ilfordscombe, Alfredscombe, Alfrincombe, Ilfarcombe, and Ilfridcombe. In the latter part of the 13th century it obtained a grant for holding a fair and market, and in the reign of Edward III. it was a place of such importance as to supply him with six ships and ninety-six men for his armament against Calais. During the Parliamentary war, being garrisoned for the Roundheads, it was in 1644 captured by the Royalists, but in 1646 it fell into the hands of Fairfa

ILHAVO, a town of Portugal, province of Beira and district of Alveiro, is situated on the Atlantic Ocean, 8 miles south-west of Alveiro and 34 north-west of Coimbra. It is inhabited chiefly by fishermen, but has a celebrated manufactory of glass and porcelain, the Vista-Alegre, at which the art of glass-cutting has reached a high degree of perfection. Salt is largely exported. The population is about 6000.

ILI, one of the principal rivers of Central Asia, in what is now the Russian province of Semiryetchensk. The head-stream, called the Tekes (French form, Tekesse), rises at a height of 11,600 feet in the Ulabas mountains, which lie to the E. of Lake Issyk-kul, about 79° 50′ E. long. and 42° 40′ N. lat. At first it flows eastward and north-eastward through a mountainous gorge which gradually widens into a valley of considerable breadth between the Tian-Shan range on the south and the Kara-Tau and the Temur-lik or Nan-Shan on the north. Meeting the Kunges (French form, Koungesse) from the east, the river takes a westerly direction; and under the name of Ili it continues to hold westward for about 300 miles, to the neighbourhood of the military post of Ili or Ilijsk in 77° 5′ E. long. The valley between 79° 30′ and 82° E. long. is about 50 miles wide, and the portion above the town of Kuldja (Old Kuldja) is fertile and populous, Tarantchi villages following each other in rapid succession, and the pastures being well stocked with sheep and cattle and horses. At Ilijsk the river turns north-west, and at length, after traversing a district of desert and marsh, it falls by at least seven mouths into the Balkhash Lake, the first bifurcation of the delta taking place about 115 miles up the river. From Old Kuldja to New Kuldja, according to Captain Fischer (1871), the Ili is navigable for only two and a half months at most, and even then considerable difficulty is occasioned by the shoals and banks. From New Kuldja to Ilijsk (280 miles) navigation is easy when the water is high, and practicable even at its lowest condition. The section from Ilijsk to Lake Balkhash (about 240 miles) was explored in 1856 at the instance of Mr Kutznezoff, who had a boat built on the lake and towed up stream; he found a passable channel all the way, but no practical use has since been made of it. Except in the deltaic portion, the river has a rapid current and the water is turbid. At Ilijsk there is a ferry on the road from Kopal to Vyernoe. The principal tributaries of the Ili are the Kash, the Belluluko, and the Kur-Tcharyn. A vast number of streams flow towards it from the mountains on both sides, but the great proportion of them are used up by the irrigation canals, and never reach their natural goal. The wealth of coal in the valley is said to be great, and the Chinese worked gold and silver with profit. Fort Ili or Ilijsk, a modern Russian establishment, must not be confounded with Ili, the old capital of the Chinese province of the same name. The latter, otherwise known as Hoi-yuan-tchen, New Kuldja (Gulja), or Mantchu Kuldja, was formerly a city of 70,000 inhabitants, but now lies completely deserted. Old Kuldja, Tatar Kuldja, or Nin Yuan is now the principal town of the district. See Kuldja.

ILIOS, or ILIUM. See TROY.

ILKESTON, a market-town of Derbyshire, is situated on a hill commanding fine views of the Erewash valley, and on the Erewash branch line of the Midland Railway, 8 miles west by north of Nottingham, and 9 east-north-east of Derby. The town is under the government of a local board of health, and has a county court. The principal buildings are the parish church of St Mary's in the Norman and Early English style, with lofty pinnacled tower; the town-hall erected in 1868; and the mechanic's institute. National schools have been recently erected. The manufactures of the town are principally hosiery and lace, and various kinds of stoneware. Coal and iron are wrought in the neighbourhood. An alkaline mineral spring, resembling the seltzer water of Germany, was discovered in 1830, and baths were then erected, which were afterwards extended. The waters are used both externally and internally, and are efficacious in rheumatism, gout, spinal affections, liver complaints, and kindred ailments. The principal constituents of the water are carbonic acid, sulphuric acid, muriatic acid, lime, magnesia, and soda. The town, which is very ancient, obtained a grant for a market and fair in 1251. It was formerly the seat of the assizes, which were transferred to Nottingham on account of the plague. The population of the parish in 1861 was 8374, and of the town 3330, and the population of the parish and local board district in 1871 was 9662.

ILLE-ET-VILAINE, a maritime department of France, formed out of part of the old province of Brittany, is situated on the north-west coast, between 47° 38′ and 48° 37′ N. lat. and 1° and 2° 14′ W. long. It is bounded on the N. by the sea and the department of Manche, on the E. by Mayenne, on the S. by Loire-Inférieure, and on the W. by Morbihan and Côtes-du-Nord. It takes its name from its two principal rivers, the Ille and the Vilaine. The former joins the Vilaine at Rennes after a course of 18 miles through the department, and the latter, which rises in Mayenne, flows past the towns of Vitré, Rennes, and Redon. The stream is tidal up to the port of Redon, and is navigable for barges as far as Rennes. The Vilaine receives the Meu and the Seiche, which are both navigable. There are two other navigable streams, the Airon and the Rance. The Ille-et-Rance canal connects the town of Rennes with those of Dinan and St Malo. The department forms one vast plateau, broken by ranges of low hills, which decline on the one side to the English Channel and on the other to the Bay of Biscay. The sea-coast line is partly rocky and partly marshy, the marshy portions being in many places defended against the encroachments of the sea by artificial dams. There are also morasses in many parts of the interior, with a number of stagnant lakes, a circumstance which renders the atmosphere very humid. The sky is seldom bright, for the south-west winds, while they keep the temperature mild, also bring frequent showers, and in spring and autumn thick fogs prevail. The soil is thin and not very fertile, but lately has been improved by the use of artificial manure. The only truly fruitful portion is that round Dol. About two-thirds of the soil is under culture, one-ninth in meadows, one-fifteenth in wood, and one-sixth waste. Cereals of all kinds are grown, but the principal are wheat, rye, and barley. Potatoes, flour, and hemp are also largely grown, and tobacco is cultivated to some extent. Apples and pears are the principal fruit, and the cider of the canton of Dol has a high reputation. The vine is cultivated in the southern districts. Cheese, said to equal Gruyère, is made in considerable quantities, and the butter of Rennes has a reputation equal to that of the best in France. Large numbers of horses and cattle are raised. The horses belong to the small hardy Breton breed, and are much in demand as post and artillery horses. Notwithstanding the extent of heath land very few sheep are kept. The principal manufactures are leather, sea-salt, glass, paper, and linen. Iron ore is obtained in considerable quantities, and there are also lead and zinc mines, as well as slate quarries. The population is of Celtic origin, and the dialect is a mixture of Celtic and French. Ille-et-Vilaine is divided into the arrondissements of Fougères, St Malo, Montfort, Redon, Rennes, and Vitré, with 43 cantons and 350 communes. The chief town is Rennes, and the principal seaport St Malo. The department has an area of 2597 square miles. The population in 1872 was 589,532, and in 1876 it had reached 602,712.

ILLINOIS

ILLINOIS, the twenty-first in the order of admission and the fourth in rank of population of the States of the American Union, is one of the group of States formed out of the "North-West Territory." Its boundaries, beginning at the point where the Wabash river joins the Ohio, pass thence north by that river, by the west line of Indiana, and by Lake Michigan to 42° 30′ N. lat., thence west to the Mississippi river, thence south by that river to its confluence with the Ohio river, and thence, by that, north-easterly to the mouth of the Wabash. It has an area of 55,414 square miles, extending with varying width from 42° 30′ to 36° 59′ N. lat. Plate V

Surface and Soil.—Illinois is a great plain, with its highest section in the north, on Lake Michigan; thence it imperceptibly declines to the south-west, in which direction its principal rivers flow to the Mississippi. A small tract in the north-west, which includes the lead mines, is hilly and broken, and there are bluffs along the Mississippi, some of which rise 300 to 400 feet. A ridge extends across the south end of the State, constituting the fruit district of the region, called "Egypt" on account of its never-failing fertility. On this ridge or swell of clay land are grown all the varieties of berries, grapes, plums, peaches, apples, and all kinds of vegetables in great profusion, which find prompt sale in Chicago and the northern counties by reason of reaching market at early dates in the season. Excepting along the rivers, and where there has been extensive tree planting, the greater part of the State consists of a vast level or slightly undulating treeless prairies. Much of this has been reclaimed from swamp land by systematic drainage, and is found to be the strongest and most productive soil of the State. To the eye the surface of the State is as level as that of an ocean in calm. The general slope from the watershed rarely exceeds 1 foot to the mile, and the fall of the Illinois river in a course of 300 miles to the south-west, is, for most of the distance, but 1 inch to the mile. The origin of the prairies is still a matter of speculation, but there is an opinion that in a former geological age the whole State was the bed of a vast shallow freshwater lake. The prairie soil is a black fine humus mould, formed of the decayed vegetation, and underlain at varying depths by clay. The soil is of great fertility, and much of it seemingly inexhaustible. Over these prairies for hundreds of miles the plough never touches stone, pebble, or even sand. A luxuriant native grass formerly sustained herds of buffalo, and from the still unbroken prairie surface are annually mown thousands of tons of the wild grass for hay, which is as nutritious and brings as high a price in market as "tame hay." All the cereals, roots, fruits, grasses, and vegetables of the temperate zone are grown in Illinois, and some of the semi-tropical productions, as cotton and amber cane. Because of the richness of the soil, cultivators still plough very shallow, and neglect manuring, or even rotation of crops, in the larger portion of the State. It is usual to plant maize for ten or twenty years in succession, only changing the crop to wheat, oats, barley, buckwheat, or rye when the market prices of these cereals promise larger profits than maize. Upon any sign of exhaustion, the productiveness may be restored by deeper ploughing, grassing, fallowing, and applying barnyard manure. In half a century there has never been a bad failure of crops; twice or thrice there has been insufficient rain, and as often too much, and once a frost in summer; but the injury in no one year was so great or so widespread as to produce general distress among farmers.

Minerals.—Coal is found in nearly all parts of the State; it is bituminous, a small proportion being cannel. The beds vary from 3½ to 8 feet in thickness. The Coal-measures are part of the general formation extending from beyond the Mississippi river in Missouri, across Illinois and parts of Indiana and Ohio, and into Kentucky. It is estimated that three-fourths of the surface area of the State are underlain by beds of coal. There are twelve separate and well-defined beds of from 4 to 8 feet in thickness. The State is supplied with coal for consumption, not only from the mines of Illinois, but also from those of Indiana and Ohio by rail, and with anthracite from Pennsylvania by lake. The coal mined in the State is between 3,500,000 and 4,000,000 tons annually. Near Galena, in the north-west part of the State, are lead mines which have been worked for half a century, and which at one time made Galena the most prosperous city in the State. Salt springs are found in the south-east counties. Stone suitable for building is found in various parts of the State. An inexhaustible field of limestone, called "Lemont marble," is found near Chicago, and has been largely used in rebuilding that city.

State Lands.—The lands in the State were thus classified in the years 1878 and 1880:—in the former year there were 25,639,304 acres of improved and 8,635,953 of unimproved lands (total, 34,275,257), while in the latter year the numbers were 26,174,566 and 8,204,505 (total, 34,379,071 acres). The city and town lots numbered 365,344 improved and 486,731 unimproved in 1878, and 374,664 improved and 484,932 unimproved in 1880. The railroads hold 13,253 acres of land and 3028 city and town lots.

The improved lands were under cultivation in 1878 and 1880, as follows:—

	1878.	1880.
	Acres.	Acres.
Wheat	2,118,000	2,702,380
Maize	7,062,502	7,592,152
Oats	1,582,387	1,703,843
Meadows	2,102,990	2,267,945
Other field products	698,116	567,890
Enclosed pasture	4,034,551	4,242,713
Orchards	271,565	293,593
Woodland	3,982,807	3,708,567

Agricultural Products.—The great crops of Illinois are maize or Indian corn, wheat, and hay; and much attention is also given to the raising of live stock. The State produces more wheat than any other State in the Union. The farms number about 247,000. We give full agricultural returns for 1879, and those for 1880 so far as completed to December of that year:—

	Acres.	Average per Acre. Bushels.	Bushels Produced.	Total Value.
Wheat.				
1879	2,440,800	18¾	45,417,661	$39,930,639
1880	3,256,350	17½	56,508,309	46,497,160
Maize.				
1879	7,918,881	38	305,913,377	97,483,052
1880	Returns not	complete	d.	
Oats.				
1879	1,631,139	33½	54,664,569	12,059,162
1880	1,749,391	35	62,709,062	12,858,247
Hay.			Tons.	
1879	2,332,278	...	2,578,736	16,428,012
1880	2,259,857	...	3,486,584	22,589,691

The following table gives returns for 1879:—

	Acres.	Quantity.	Value.
Rye	235,073	4,238,824 bush.	$1,991,401
Barley	...	578,911 ,,	265,951
Pasture	4,193,884	...	12,319,620
Orchards	290,646	...	2,497,687
Potatoes	90,351	7,125,932 ,,	3,506,758
Sorghum	14,949	1,524,705 galls.	579,257
Flax seed	...	990,447 bush.	1,296,758
Hogs sold	...	1,984,194	16,640,061
Fat cattle sold	...	...	16,751,450
Fat sheep sold	...	...	513,884

Railways.—In 1850 Congress granted to the State, to aid in the construction of a railway from Cairo to Galena and Chicago, alternate sections of land along the route; the State transferred the grant of land to the Illinois Central Railroad Company, a corporation composed mainly of English capitalists, conspicuous among whom was Richard Cobden. These capitalists furnished the money and constructed the road, and they and their successors still own the property. The railway lies wholly within the State, though it works other lines extending south to New Orleans and west to the Missouri river. Its completion gave that impetus to the construction of railways to Chicago and across the State which has contributed so largely to the rapid development of the resources of Illinois. The State is now admirably supplied with railways, their extent reaching 6849 miles. They cross every county in the State; indeed, they are so numerous and so interlaced that there are few if any localities more than 10 miles from a railway, while a large proportion of the shipping points have the benefit of more than one route by which to ship and receive merchandise. The great trunk lines leading west from the Atlantic and from Canada have their termini at Chicago, or at some other point in Illinois, while those leading from the States west of the Mississippi also terminate in Illinois, or crossing the State run further east. The system of railway government somewhat resembles that of England. A railway commission, appointed by the State, exercises a general supervision, and enforces the penalties for violations of law. The receipts of the forty-six railways doing business in Illinois amounted in 1879–80 to $138,659,155; the working expenses to $73,089,185; and the net income to $61,093,612.

Inland Navigation.—In addition to the railway traffic, there is much business done by steamboats at Cairo, East St Louis, Alton, Quincy, Rock Island, and other points on the Ohio and Mississippi rivers, though transportation by river has declined much of late years. The Illinois and Michigan canal is 93 miles long, and connects Lake Michigan at Chicago with the Illinois river, at the head of the navigation of that river. This canal has cost $17,000,000, but is now too small for the service needed. The Illinois river is formed by the union of the Kankakee and Des Plaines rivers, which junction occurs 45 miles south-west of Chicago. It receives, besides the rivers named, the waters of the Fox, Sangamon, and Vermilion rivers, and of some smaller streams. Its general direction is south-west to the Mississippi, into which it falls. The State has expended much money improving the navigation by locks and dams, and this improvement when completed, with the enlargement of the canal to the capacity of steamboat navigation, will be one of the most extensive works of interior water communication in the world, being over 400 miles long, and connecting the waters of the Atlantic, through the St Lawrence river and the lakes, and through the Mississippi river, with the Gulf of Mexico. Rock river rises in Wisconsin, flows rapidly to the south-west through Illinois, and joins the Mississippi near Rock Island. On this river manufacturing establishments are rapidly increasing, the water power being regarded as equal to any in the country. The other rivers are the Kaskaskia, Embarras, Little Wabash, Big Muddy, and Chicago river, the last-named an inlet from Lake Michigan, furnishing a commodious harbour, 8 miles long, in which an average of 400 vessels find shelter during the winter season. The extent of the commerce on the lake is shown by the custom-house returns. During 1880 the steam vessels arriving at Chicago had a total burthen of 2,141,879 tons, the sailing vessels 2,456,337 tons; the clearances showed about the same figures.

Manufactures.—The statistics of manufactures for 1870 give as results 13,597 establishments, employing 82,979 operatives. Since that date the increase in manufactures throughout the State has been general, embracing all branches of manufacturing industry. The following are the statistics for Cook county (including Chicago) in 1880:—number of establishments, 3752; capital, $80,693,102; average number of hands, 113,507; wages paid, $37,615,381; value of material used, $180,807,706; value of products, $253,405,695. These figures for Cook county alone in 1880 exceed in several particulars those for the whole State in 1870; and the increase in the State during the ten years may be regarded as proportionate to that in Cook county. The abundance of coal, the proximity to the Lake Superior iron and copper mines, the unlimited means of transportation, the supply of lumber, the cheapness of food, the superior water power in various parts of the State, have all tended to make Illinois a large and convenient seat of manufactures. The iron and steel establishments of the State rank with the largest in the country. On Rock Island, in the Mississippi river, the U. S. Government has an arsenal for the manufacture of ordnance. The establishment is the most extensive in the United States, and the buildings and workshops cover nearly the entire island.

Administration.—The territory embraced in the present State of Illinois was ceded in 1765 by France to Great Britain; then it became a possession of the colony of Virginia; in 1787 it was made a county in the North-West Territory; from 1800 to 1809 it was a county in the territory of Indiana; in 1809 it was erected into a territory; and in December 1818 was admitted into the Union as a State. On its admission to the Union a constitution providing a form of government was adopted; in 1848 this was superseded by another, and this again was set aside in 1870 by the third and present constitution, which provides the ordinary State government of three departments, executive, legislative, and judicial. The executive, consisting of a governor and other officers, are elected every four years; the legislature, or general assembly, consists of a senate of 51 members, elected by as many districts; the term of senators is four years, one half, or as near as may be, retiring every two years. The house of representatives consists of 153 members, 3 elected in each senatorial district every two years. In electing representatives, the voter may give his three votes for one, two, or three candidates. This cumulative voting is peculiar to the constitution of Illinois; it has become popular. The judiciary consists of one supreme court of seven judges, several district appellate courts of limited jurisdiction, circuit courts in such number as may be needed, and one county court, including probate jurisdiction, in each county. Each county and each township has its own local government. Every male citizen resident one year in the State may vote. This constitution when adopted was regarded as a great improvement and advance in State government, and many of its provisions have since been adopted by other States. The sessions of the legislature are held at Springfield, which since 1836 has been the capital of the State.

Revenue, Debts, Taxation.—In 1836–38 the State was seduced into a scheme of internal improvements. The population was then less than half a million, but the debt created was $14,000,000, to construct railways and a canal. In three years the scheme was abandoned, and the State in July 1841 suspended payment of interest. In 1845 the legislature levied a tax to pay the current interest; in 1848 an irrepealable tax was levied to pay the principal; all the overdue and unpaid interest was funded in interest-bearing bonds. Credit was restored, and in December 1880 the State was free of all debt. Taxation is imposed by a rate levied on all real and personal property, according to a previous valuation, made by local assessors, revised by county boards, and again revised and equalized by a State board. The total assessment or valuation of the property in the State for taxation averages not more than one-fourth of the value at which the property can be sold. The constitution limits the rate of taxation (except to pay debts) by counties to 75 cents on each $100 of the official valuation. The same valuation governs all taxation, the maximum rate being fixed by law. In like manner all municipal corporations are (since 1870) prohibited from incurring any debt, for any purpose, exceeding, with previous debts, 5 per cent. on the official valuation of the property within their territorial jurisdiction. An annual tax is required in each municipality to pay the interest and a portion of the principal of all existing debts. Under these stringent requirements, municipal debts in Illinois are gradually decreasing. The State, without becoming responsible for municipal debts, acts as trustee, and through its officers collects and disburses the taxes to pay principal and interest of these local debts. The latter were contracted mainly in aid of railroads, and bore an average rate of 9 per cent. interest.

The gross taxation for all purposes, including schools, for 1878 and 1879 was as follows:—

	1878.	1879.
State taxes	$3,614,855	$2,712,626
County taxes	5,557,446	4,730,095
City taxes	7,576,882	6,182,420
Town taxes and others	10,941,658	9,327,959
Totals	$27,690,841	$22,953,100

The valuation of all the property in the State for taxable purposes, for the year 1880, was $786,616,394. The rate of tax levied for State purposes, and to pay cost of assessment and collection, is 36 cents on each $100 of the property valuation given, which, as above stated, is about one-fourth of the real value. In 1880 lands (except railroad lands) were valued at $390,594,627, and city and town lots at $182,808,928; total lands and lots, $573,403,555.

The State is in receipt of a permanent revenue from the Illinois Central Railroad Company. In consideration of the cession of land, in 1850, by the State, the company contracted to pay into the State treasury half-yearly 7 per cent. of the gross annual earnings of the line. This was to be in lieu of all other taxes on the property of the company. This contract is now a source of large revenue to the State. Up to November 1, 1855, the payment to the State was $29,752; the payment in 1880 was $368,349. The total payments to the State, at the close of 1880, amounted to $8,307,217.

Education and Charities.—The public school system is liberally supported in Illinois. The permanent school fund yields about $60,000, to which the State adds $1,000,000 annually, and this is distributed among the counties. Many counties and districts have invested school funds. The aggregate of these local funds is $5,500,000, the interest of which is applied to support schools. In addition each school district levies such taxes as may be needed for its schools, and may borrow money to build schoolhouses. In

1878 the receipts of revenue for schools amounted to $9,634,727, the expenditure to $7,526,109. The number of children in the State (1878) of the school age, six to twenty-one years, was 1,102,021; of these 706,733 were enrolled as attending the public schools, and 41,406 as attending private and parochial schools; total attending schools, 748,139. The whole number of school districts in the State was 11,714; male teachers 9475, female teachers 12,817, teachers in private schools 1017—total teachers 23,309. Salaries of male teachers range from $15 to $225 per month, of female teachers from $10 to $115 per month. Five months in each year is the minimum term of the public schools, ten months the general term. Except the income from invested funds, school revenues are obtained from direct taxation. The State has established two normal universities, providing the buildings and grounds,—one at Normal, M'Lean county, the other at Carbondale, Jackson county. There is an industrial university at Champaign, maintained and liberally endowed by the State. There are also several other universities and colleges, including medical and theological, in various parts of the State. All schools supported in whole or in part by public money must be non-sectarian in their instruction and government.

Under the general supervision of a board of charities, the State maintains four hospitals for the insane, at Jacksonville, Elgin, Anna, and Kankakee; an institution for educating the blind, and one for educating the deaf and dumb, both at Jacksonville; an asylum for imbecile children; an eye and ear infirmary; a home for soldiers' orphans; and a correctional or reformatory school for boys. All these institutions are provided with spacious grounds and extensive buildings. The annual expenditure for the maintenance of these charities is about $1,000,000. This does not include the cost of buildings and grounds, on which over $5,000,000 have been expended. Several other asylums for the insane are maintained by local authorities.

The population of Illinois, which now comprises 102 counties, was as follows at the dates given:—

1800	2,458	1850	851,470
1810	12,282	1860	1,711,951
1820	55,162	1870	2,539,891
1830	157,445	1880	3,080,824
1840	476,183		

The following cities had a population in 1880 exceeding 5000:—

Chicago	503,304	Decatur	9,449
Peoria	29,315	Cairo	9,017
Quincy	27,275	Elgin	8,606
Springfield	19,746	Galena	8,205
Bloomington	17,184	Streator	8,088
Joliet	16,145	Ottawa	8,010
Rockford	13,136	Danville	7,751
Aurora	11,825	Moline	7,740
Rock Island	11,660	La Salle	7,250
Galesburg	11,446	Pekin	6,508
Jacksonville	10,927	Mattoon	6,106
Belleville	10,682	Kankakee	6,027
East St Louis	10,054	Sterling	5,841
Freeport	10,016	Princeton	5,440
Alton	9,500	Monmouth	5,004

The density of the population in 1880 was 55·6 persons per square mile. (J. W. S.—J. ME.)

ILLUMINATI, or "Enlightened," is a title which at different times has been given to, or assumed by, various sects or orders of mystics, on the ground of the superior knowledge of God and of divine things which they claimed. Among these may be mentioned that of the Spanish "Alombrados" or "Alumbrados," which arose about the year 1520, and which before its final disappearance about a century later afforded numerous victims to the Inquisition, especially at Cordova. Ignatius Loyola, while a student at Salamanca (1527), was tried by an ecclesiastical commission for alleged sympathy with its views, but was acquitted with an admonition. Under the name of Illuminés a similar sect appeared in Picardy in 1623, and afterwards entered into close relations with the Guérinets or followers of Pierre Guérin; but by its antinomianism it soon provoked repressive measures, to which it finally succumbed in 1635. The history of another sect of Illuminés, which appeared in the south of France about 1722, is very obscure, but it is said to have subsisted until 1794. The title of Illuminati has often been popularly bestowed also on Rosicrucians, Martinists, and Swedenborgians; but one of the most recent as well as most important applications of this elastic word has been to denote a secret society, or semi-political semi-religious order, which made some stir in Germany, especially in the southern and Catholic portions of it, from 1776 to 1784. It was founded on May 1, 1776, by Adam Weishaupt, professor of canon law at Ingolstadt, and an ex-Jesuit, and set before it as its general purpose the discouragement of tyranny, superstition, and ignorance, and the furtherance of the cause of reason, freedom, and virtue. The name originally assumed for the order was the Society of the Perfectibilists (Gesellschaft der Perfectibilisten). Politically its tendencies were republican, and in religion it was free-thinking, having a distinct aversion to Christian ritual and Christian dogmas alike. The entire subserviency of its members (who on admission were pledged to blind obedience to the orders of their superiors) was secured by a strict system of secret confessions and monthly reports, checked by mutual espionage. Beginning with a narrow circle of disciples carefully chosen from among his own students, Weishaupt gradually extended his propaganda from Ingolstadt to Eichstädt, Freising, Munich, and elsewhere, special attention being given to the enlistment of young men of wealth, rank, and social importance. As the order increased in numbers its organization naturally became more complicated, and was ultimately considerably influenced by the intimate relations which were established with masonic lodges at Munich and Freising in 1780. About the same time an important impulse was given to its prosperity in middle and northern Germany by the ambition and energy of a newly acquired member, Baron Adolf von Knigge, who had his headquarters at Frankfort-on-the-Main. It was to him that the society was indebted for the extremely elaborate constitution (never, however, actually realized) according to which the entire membership was divided into three great classes, in the first of which were to be included the "novices," the "minervals," and the "lesser illuminati," while the second consisted of "freemasons" ("ordinary," "Scotch," and "Scotch knights"), and the third or "mystery class" was subdivided into the two grades of priests and regents and of magus and king. Each member of the order had given him a special name, generally classical, by which alone he was referred to in official communications; all correspondence was conducted in cipher; to increase the mystification, towns and provinces were invested with new and altogether arbitrary designations. At its period of greatest development the order included in its operations a very wide area, extending from Italy to Denmark, and from Warsaw to Paris; at no time, however, do its numbers appear to have exceeded two thousand. Its aims and method, which, as plainly appears in portions of Goethe's *Wilhelm Meister*, were somewhat in accordance with the taste of the period, met with more or less sympathy and approval from Goethe himself and from Herder,[1] from the grand-dukes Ernest II. of Gotha and Karl August of Weimar, as well as from other persons of influence and repute (Bode, Nicolai). A rupture which

[1] Perthes, *Das Deutsche Staatsleben vor der Revolution*, p. 262.

took place between Weishaupt and Knigge in 1784 greatly accelerated the public expression of a counter feeling of suspicion and dislike which had been slowly gathering strength, and in 1785 the Bavarian Government issued an edict which proved fatal to the order. Many of its members were imprisoned or compelled to leave their homes; Weishaupt himself was deprived of his chair and banished the kingdom.

See *Grosse Absichten des Ordens der Illuminaten* (with Appendices, Munich, 1786); and Weishaupt's *Vollständige Geschichte der Verfolgung der Illuminaten* (1787), and *Kurze Rechtfertigung meiner Absichten* (1787).

ILLUMINATION is a term which has long been used to signify the embellishment of written or printed text or design with colours, and especially with gold, more rarely also with silver. The lustre of the former metal may probably have led to the adoption of the word in this sense. The Latin verb *illuminare*, with the meaning of "to decorate," occurs as early as the 8th century; and in the first portion of the *Roman de la Rose*, composed before 1260, *enluminer* is found with a similar meaning, while Dante (*Purgat.*, xi. 79) alludes to this kind of painting and its French designation as "quell' arte, che alluminar è chiamata in Parisi." In Early English we find the forms *enlomyne, luminen, limnen*, whence *limn*. Of synonymous use with these terms we find in the Middle Ages the words *miniare* and *miniatura*, from *minium*, a red pigment, in early use for decorating MSS. Miniature employed in connexion with the art of illumination now, however, generally signifies a picture or portrait as distinguished from mere ornament or ornate letters.

The research into the past which has characterized the present century has extended to the art of illumination, and, following the lead of D'Agincourt, Mabillon, and others, has by the examination of mediæval decorated manuscripts thrown a vast amount of light upon the arts of the past. In spite of iconoclasm in the East, the burning of Arabic MSS. in Spain, and the destruction and dissipation of libraries which unhappily accompanied the Reformation, a considerable number of beautiful and elaborate volumes have come down to us where larger and more exposed works of art have perished. They therefore supply many a lacuna in art history. Conformably to the unity which pervaded all art work in the Middle Ages, a close correspondence in style has been recognized between the ornamentation of MSS. of different periods and contemporaneous architecture and other arts. The architect, the decorator, the glass-stainer, and other artists have consequently learned, and with great profit, to search their pages for ornamental motives, details, and colouring, in thorough harmony with ancient styles, which no other source supplies so copiously. Invaluable materials too for the history of costume are found in the miniatures with which they abound.

The earliest writing of which monuments exist, the Egyptian, was often enhanced by the use of colour. In the ritual papyri, directions, &c., are written in red to distinguish them from the main text, just as was subsequently done in mediæval liturgical MSS.—a practice from which the term *rubric* is derived. A few scattered passages in Latin classic authors (notably Ovid, Seneca, Varro, Martial, Pliny the Elder, J. Capitolinus) prove the occasional use of rubrication and of pictorial embellishment of MSS. among the Romans. The earliest decorated MSS., at least of European execution, which have reached us date from the 4th and 5th centuries of our era, and are of extreme rarity. Of these one of the most celebrated is the *Virgil* written in elegant capitals preserved in the Vatican, in which the adornment is limited to rectangular pictures (miniatures) painted in the antique manner seen in the Pompeian frescos, the body colour laid on with a free brush and without black outlines. It may be taken as the type of a class of MSS. of which very few specimens are extant. A different type of early calligraphy, which was much esteemed, is found in the *Codex Argenteus*, now at Upsala, written about 360, containing Ulfila's Mœso-Gothic version of part of the Scriptures. It is written in gold and silver letters on vellum stained a red purple. The art of thus staining vellum, perhaps with the murex, was afterwards lost, and in the 8th and 9th centuries was imitated by painting the vellum.

After the 2d century art rapidly declined in the West, owing to the corruption and anarchy of the empire. It found a home, however, at Constantinople, where intercourse with Persia resulted in a style which blends Oriental magnificence with Western vigour and variety, and is destined, as we are about to see, to exercise a dominant influence upon the art of Europe for many centuries. This style, known as the Byzantine, is distinguished by very characteristic details, and by its lavish use of gold, especially in backgrounds. Meanwhile Christianity had been planted in remote Ireland, which proved such favourable soil that the isle was already at the beginning of the 6th century renowned for its learning and sanctity, and was the seat of numerous monasteries and seminaries, where a native style of art was developed, wholly distinct from anything else which the world has seen. Its principal features are spirals, extremely ingenious plaits, and interlacements of attenuated lacertine animals and birds of conventional form. The human figure is sometimes introduced, but becomes objectionable, through the ignorance of drawing and of anatomy usually characteristic of semi-civilized attempts to portray the higher organisms. The work is further distinguished by a degree of minuteness, intricacy, and precision baffling to the modern draughtsman. It is seen in its highest perfection in the *Book of Kells*, preserved in the library of Trinity College, Dublin, and in the Lindisfarne Gospels in the British Museum. This style, known as the Celtic or Anglo-Celtic, was transplanted by Irish missionaries to Lindisfarne, Bobbio, St Gall, Würzburg, Luxeuil, and other places, where volumes displaying this peculiar ornamentation are still treasured. The influence of Anglo-Celtic art is very apparent in the subsequent "Carlovingian style" which arose in France and Germany under the fostering care of Charlemagne, and of Alcuin, whom he had invited to France to direct the progress of learning and the arts. The gospels found upon the knees of the great emperor when his tomb at Aix-la-Chapelle was opened, the gospels of St Servin de Toulouse, those of St Medard de Soissons, the Bible of San Calisto monastery at Rome, and the Harleian *Codex aureus* of the British Museum are justly renowned examples of this majestic and magnificent style, in which the pages glow with gold and purple, and the Roman acanthus, Celtic interlacements, and Byzantine details combine in harmonious variety. A text written wholly or partially in gold ink is another characteristic of the epoch. About this period too are found those gigantic initials which from containing figures relating to the text have been called in France *Historiées*. A new style had also arisen in England, in which the debased Roman acanthus was largely developed. This conventional foliage is here seen skilfully combined with gold bars, which surround the page, and form a border at the commencement of books, &c. This style has been called the *Opus Anglicum*. It often displays a masterly freedom and spirit, and a peculiar "fluttering outline," which also characterizes the spirited pen-drawings frequently found in MSS. of the period. The finest specimens of this style, among which are the benedictional of St Ethelwold, belonging to the duke of Devonshire, and a couple of volumes in the public library, Rouen, were probably executed at Hyde Abbey, Winchester.

The apprehensions of the year 1000 as the end of the world tended greatly to paralyse art. As these fears died away, however, the Romanesque style of architecture was being developed, especially in the Rhine-lands. This was favoured by numerous Greek artists who, deprived of their livelihood by Eastern iconoclasm, had migrated westwards, and deeply impressed the Byzantine character upon the architecture of central and western Europe. Simultaneously there arose a bold sweeping style of ornament, characterized by fine rounded curves and Byzantine details, but also by a tendency to naturalism, and, in books, by large initials. The Byzantine gold backgrounds were still a glowing feature, which indeed continued through the whole subsequent progress of illumination. From the 11th century gold leaf was applied to the vellum upon a substratum of fine plaster, and could be so highly burnished as to exhibit the rich lustre of a polished lamina of the solid metal. As skill in drawing increased, nature was more copied, and towards the 14th century natural foliage, conventionally treated, constitutes the main portion of the ornament. The oak, the vine, and especially the ivy, are frequent, springing in free spirited curves from decorated initials, or extending into a border round the whole or part of the page. The initials decrease in size whilst they gain in excellence of execution, and illumination, considered as decorative design, is generally considered to have reached its highest perfection about this period. The pictures of sacred subjects gradually lose Byzantine rigidity and assume dramatic expression, pose, and grouping. And towards the 15th century the blue or gold background begins to be abandoned for natural scenery and accessories. Towards the commencement of the 15th century illumination was liberally fostered by John, duke of Berri, brother of Charles V. His magnificence in this branch of art awoke the emulation of Philip the Bold, duke of Burgundy, and of the duke of Bedford, the regent of France, in the same direction. For the last-named was painted the celebrated *Bedford Hours*, now in the British Museum, part of the workmanship of which has been ascribed to Jan, Hubert, and Margaretta van Eyck. As perfect mastery of drawing and facility of realistic execution were gained, illumination as a decorative art became debased in design. Borders of gold or richly coloured grounds, over which are scattered exquisitely painted flowers, fruit, and insects, surround pages of text or miniatures wrought with supreme manual dexterity, but not unfrequently of meretricious composition. In juxtaposition with this rich and copious ornamentation (the primary end of the book), the text, already less black and massive than in preceding centuries, too often dwindles into insignificance. The *Hours of Anne of Brittany*, preserved at the Louvre, is one of the most celebrated specimens of 16th century illumination of this style.

The character of Italian illumination differs considerably from that which marked the art in central or northern Europe. It had arisen by slow degrees from the devastation which Italy had suffered in the early centuries of the Christian era. The scriptoria of Ravenna, Siena, Florence, Bologna, Perugia, Ferrara, in the 13th and 14th centuries, produced illuminated volumes worthy of their growing schools of painting, and were especially celebrated for the elaboration of large choral books.

The Renaissance, with its revival and enrichment of classical forms, was fully reflected in the illuminator's art, which was largely employed in smaller volumes for secular subjects, and was patronized by the Italian princely families, and finally reached its culmination in the hands of such artists as Girolamo dei Libri, whose drawing is very accurate, and attains a microscopic delicacy of stippling, and his pupil Giulio Clovio, who in his composition makes large use of the human figure, and with an imitation of Michelangelo's manner combines unrivalled minuteness of execution. Long after the invention of printing the popes and doges retained official illuminators in their service; and some of the most elaborate and costly volumes were executed subsequently to the introduction of the press. The typographical multiplication of books, however, proved fatal to the art. The early productions of the press, indeed, had blank spaces left for initials and miniatures, which were painted in by hand, often very roughly. These were soon replaced by printed designs intended to be gilt and coloured, which reflected the character of contemporaneous art, as far as the technical difficulties of the yet imperfect press allowed. The custom of adorning sumptuous volumes with engraved initials and other ornament has continued to the present time, with an increasing tendency to naturalism.

The visitor to the public libraries and museums of Moscow and St Petersburg will have there admired the rich display of Slavonic illuminated MSS. of peculiar style, intricate design, careful execution, and frequently fine colour. The leading features of Russian art were derived from Byzantium, but, as Russian archæologists maintain, were blended with a native element, and a true national style arose in the 12th and continued to the 16th century, when the influence of the Renaissance began to be felt.

The fecund art of Constantinople was also the parent of another style—the Arabian or Mahometan—which, however, contains a previously existing Oriental element. The style began to develop in the 7th century. It is geometrical or constructive in character, the use of symbolism or representations of animals or plants being forbidden in the sect of Omar. Inscriptions in cufic characters are often happily used as a decorative feature; rich colouring of red blue and gold prevails. The Turkish and Moresque styles are modifications of the Arabian. Illumination was carried in this style to the highest degree of splendour. Casiri's *Bibliotheca Arabico-Hispana Escurialensis* conveys some idea of the former magnificence of the Moorish libraries in Spain.

In India illumination, though of great antiquity, does not present those transitions of style which mark the development of western art. Like Indian art generally, its special characteristics are profusion, richness, harmony, repose, and perhaps monotony, with very extensive employment of flowers. Persian art was derived from India. It reflects the Persian love of flowers and symbolism, and the treatment is more free and natural than in India. It seems to have reached its highest perfection about the 15th and 16th centuries of our era, but is still continued. The execution of a magnificent MS. of the *Thousand and One Nights* was undertaken under the auspices of the present shah. The absence of any attempt to shade or give relief to the design is, it should here be mentioned, a characteristic of all Oriental design.

During the earlier part of the Middle Ages the art of illumination was in Europe mostly practised in the scriptorium or apartment devoted to the elaboration of MSS. which was attached to each monastery. In later times the art was practised by lay artists. Illuminators as well as patrons of illumination were occasionally found among the highest ranks; Saint Dunstan and King René may be instanced. And some distinguished painters were also illuminators. All Western MSS. of fine quality were executed upon vellum. Materials were mostly prepared with great care by the artists themselves, or under their direction, and as a rule are found to have well stood the test of time.

The price given in recent years for MS. volumes valuable for their beauty or antiquity often reaches many hundreds of pounds sterling. A folio Vulgate of the 9th century was purchased by the British Museum in 1836 for £750. The *Bedford Hours*, acquired with other MSS. for the same establishment, has been valued at over £2000. At the Didot sale in Paris a MS. executed in the highest style of French art fetched above £3000.

Bibliography.—Among a large number of works on the subject the following may here be mentioned:—C. G. Schwarzius, *De ornamentis librorum*, Leipsic, 1756; N. Humphreys, *Illuminated Books of the Middle Ages*; Silvestre and Champollion, *Universal Palæography*; Westwood, *Palæographia Sacra Pictoria*; Madden, *Illuminated Ornaments*; Tymms, *The Art of Illuminating*; Bastard, *Peintures des Manuscrits*; Westwood, *Facsimiles of Anglo-Saxon and Irish MSS.* Information upon Eastern styles, with coloured plates, will be found in Racinet, *Polychromatic Ornament*, and O. Jones, *Grammar of Ornament*, and upon Russian art in V. Boutowsky's *Histoire de l'Ornement Russe, d'après les Manuscrits*, Paris, 1870. For the technical part of the subject, see Theophilus, *De diversis artibus*, several editions, with translation and notes; *Original Treatises from the 12th to 18th Centuries on the Arts of Miniature, &c.*, edited, with translation and notes, by Mrs Merrifield; Bradley, *Manual of Illumination*; Shaw, *Art of Illumination.* (H. B. W.)

ILLYRIA is the name applied to the country that lies to the east of the Adriatic Sea. The usual Greek name is Illyris, though the older writers generally use the expression οἱ Ἰλλύριοι. The common name in Latin is Illyricum. The term Illyria is occasionally used in both languages, and has become the recognized name in English. The boundaries of the country thus known varied very much at different periods, and can be described only along with its history. For a short time, in the 4th and 3d centuries B.C., there was some slight government under monarchs whose power was acknowledged by the whole country; but in general the land was either a province of some conquering race or the abode of isolated tribes with little or no common feelings or aims.

The origin and character of its oldest inhabitants are involved in the obscurity that still shrouds the ethnology and early history of all south-eastern Europe. The Greeks acknowledged some affinity of race between themselves and the Illyrians in the legend that Cadmus retired from Thebes with his wife Harmonia and settled in Illyria, where he became the father of Illyrius, the eponymous ancestor of the whole race. In harmony with this myth, the general consensus of modern investigation tends to the view that at an early period the whole of Europe south of the Danube, together with the centre and west of Asia Minor, were peopled by kindred races, some of whose names are preserved to us as Leleges, Thracians, Pelasgi, Illyrians, &c. If we divide the Indo-European tribes that peopled Europe into two great families, the northern and the southern, we shall find that the Thraco-Illyrian tribes must be distinguished from the Slavonic tribes who dwelt immediately north of them, and who are closely akin to the Lithuanian and other tribes of the northern family. On the other hand, it would not be easy to draw any line of demarcation at this early time between the Illyrians and their neighbours on the west, south, and east. Separation of nationalities was produced afterwards by growing civilization, which developed distinct national characters and well-defined countries.

At this early period then we may say that the Danube, as the boundary between the northern and the southern family, was the limit of the Illyrian tribes towards the north. In other directions they shaded off into kindred tribes of similar manners and language. Various causes led to a very unequal development of civilization among these tribes. Intercourse with stranger races like the Phœnicians, and amalgamation with kindred immigrant races, such as the Ionians and Dorians, raised some of these tribes rapidly to the highest stage of civilization. But these new races were attracted by the more favourable conditions of the Greek peninsula, and few of them found their way to the northern countries. Some traces of early Ionian settlers in Illyria are found (see Curtius, *Die Ionier vor der ionischen Wanderung*, p. 46); but they do not seem to have permanently affected the character of the natives. As Greece became civilized, it sent forth its own colonists to occupy most of the favourable sites along the Mediterranean coasts. But, whereas Thrace with its rich mines had a line of Hellenic colonies along its southern shore, very few were planted in Illyria. According to Strabo, the shore was full of fine harbours, and the coast land was very fertile; but he adds that the people were barbarous and warlike. On this account it was that Greek colonization never spread on the Illyrian coast. Dyrrachium or Epidamnus was almost the only Greek colony, and its history for centuries showed one continuous conflict with the barbarous natives, which prevented its growth. Macedonia again found a family of Greek refugees who established themselves as petty chiefs, and gradually spread their power, with civilization and settled rule, over the whole country. Nothing of the kind happened to Illyria; the chiefs who rose at times to power were always apparently as barbarous as their followers. In these unpropitious circumstances, the Illyrian tribes remained in their primitive barbarous condition later than almost any of their neighbours, and when many of the surrounding states had become civilized, Illyria was divided from them by the line separating barbarism from civilization. Naturally their characteristics resembled closely those of the ruder Thracian tribes, and both are described by the Greek historians as tattooing their bodies and offering human victims to their gods. Their women seem to have had a high position socially, and to have even exercised political power. Queens are mentioned more than once as their rulers. This reminds us of the German tribes, whose women also were much respected; and we know that among the Greeks women were much freer and more respected in the older time before Oriental influence had affected native customs. It is said that chastity was not held in much account by the women of Illyria; but it must be remembered that people whose women are kept more secluded are very apt to ascribe such a character to the freer life of other races.

The Illyrians are said by Herodotus (ix. 43) to have attacked the temple of Delphi. Brasidas with his small army of Spartans was assaulted by them on his adventurous march (424 B.C.) across Thessaly and Macedonia to attack the Athenian colonies in Thrace. The earlier history of the Macedonian kings is one constant struggle against the Illyrian tribes. The migrations of the Gauls at the beginning of the 4th century disturbed the country between the Danube and the Adriatic. The Scordisci and other Gallic tribes settled there, and forced the Illyrians towards the south. The necessities of defence seem to have united the Illyrians under a chief Bardylis (about 383 B.C.) and his son Clitus. Bardylis nearly succeeded in destroying the rising kingdom of Macedonia; King Amyntas was defeated, and a few years later Perdiccas was defeated and slain. But the great Philip crushed them completely, and annexed part of their country. During the next century we hear of them as pirates. Issuing from the secluded harbours of the coast, they ravaged the shores of Italy and Greece, and preyed on the commerce of the Adriatic. The Greeks applied to Rome for help. Hellenism had proved too weak to civilize the northern races; it was left to the stronger organization of Rome to absorb them. Teuta, the Illyrian queen, at first scorned the Roman demands for redress, and even murdered the ambassadors; but the two Illyrian wars (229 and 219 B.C.) ended in the submission of the Illyrians, a considerable part of their frontier being annexed by the conquerors. In 168 B.C. Gentius, the Illyrian king, provoked the third Illyrian war, the result of which was the annexation of the whole country by the Romans. Frequent rebellions occurred, but at last the natives accepted the Roman civilization. During the empire, the country was one of the best recruiting grounds for the Roman legions; and in troubled times many Illyrian soldiers fought their way up from the ranks to the imperial purple. Claudius, Aurelian, Probus, Diocletian, and Maximian were all sons of Illyrian peasants.

In the time of the republic Illyricum comprised the country between the Liburnians, a kindred race, on the north and Epirus on the south. Under the empire the importance of the country made its name spread over all the surrounding districts. In the 2d century after Christ, the Illyricus Limes included Noricum, Pannonia, Mœsia, Dacia, and Thrace. Constantine added Greece, Epirus, and Macedonia, taking from it Thrace and part of Mœsia, and made it one of the four divisions of the Roman empire governed by a "præfectus prætorio." When the empire was divided, Illyricum was halved. Illyris Barbara or Romana, including Noricum, Pannonia, &c., was annexed to the Western empire; while Illyris Græca, including Macedonia, Epirus, and Greece, formed part of the Eastern empire. The Via Egnatia, the great line of road which connected Rome with Constantinople and the East, led across Illyricum from Dyrrachium to Thessalonica.

In the wreck of the Roman empire Illyria suffered severely. In the 4th century the Goths ravaged it repeatedly, but these, the most civilized of the barbarian invaders of Rome, with their warlike aristocracy, passed on, and were succeeded by wilder tribes. Slavs, as also Huns and other nomadic races from the East, in succession devastated the country. An agricultural population could no longer maintain itself, and all the elements of civilization disappeared. Justinian (527–565) tried in vain to defend the country by a series of forts; his armies were defeated time after time, and at last he allowed the Huns to make settlements south of the Danube. Rome gave up the defence of civilization against the inroads of barbarism, and bribed the barbarians to be quiet. Still the Via Egnatia was defended, as the artery of communication and the highway of commerce between Constantinople and the west. The open country, however, even south of the great road, was abandoned to the Slavs and Huns. The older Illyrians partly united with these races, partly went farther south, encroaching on the Greek people, and the name of one of their tribes, Albani, is preserved in the modern name of their descendants, the Albanians.

Heraclius (610–641 A.D.) settled Slavonic peoples all along the coast of Illyria as far south as Dyrrachium. The states which were thus created were of great importance in the Dark Ages. The republic of Narenta vied for a time with that of Venice; and the commerce of Ragusa was so rich that it has given its name to all wealthy merchant vessels or "argosies." The name of Illyria had by this time disappeared from history; and the country was now divided between these powerful merchant cities and the states of Bosnia, Croatia, Servia, Rascia, and Dalmatia. In literature the name was preserved, and the scene of Shakespeare's comedy *Twelfth Night* is laid in Illyria. Politically the name was revived in the beginning of this century, when the small kingdom of Illyria to the north of the Adriatic was constituted at the peace of Vienna, 1809. In 1849 the territorial distribution of the Austrian empire was remodelled, and Illyria again disappeared. (W. M. RA.)

ILORI, or ILORIN (the Alourie of the Landers' expedition), an important town of the Yoruban territory of Western Africa, situated about 60 or 70 miles south of the Niger, and about 160 miles north-north-east of Lagos. The wall has a circuit of 12 miles, but is badly kept in repair. Along the south-eastern side flows a small stream which joins the Asa, a tributary of the Niger. The inhabitants are Yorubas, Fellatah (Pullo), Houssas, Gambarees, Bornuese, and Nufes or Papas. Most of them speak Yoruban. An extensive native trade is carried on at Ilorin, the Houssa caravans importing manufactured goods of various sorts, not only from Central Africa, but even from the coasts of the Mediterranean. The trade from the Guinea coast on the other hand is confined to brandy, guns, and powder. The variety of local industries is very considerable: Rohlfs mentions beautiful leather goods, carved wooden vessels, finely plaited mats, embroidered work, pottery of various kinds, shoes of yellow and red leather, and, what was unique in his experience of Negro tribes, the manufacture of cheese. The population is estimated at from 60,000 to 70,000, exclusive of the resident traders from foreign parts. There are a number of mosques in the town, and the Mahometans are the dominant power, but the lower classes maintain their pagan customs. About 1820 Ilori declared itself independent of Yoruba, and assisted in the destruction of Oyo.

IMAGE WORSHIP. In the present article the word "image" will be employed to denote any artificial representation, whether pictorial or sculptural, of any person or thing, real or imaginary, which is used as a direct adjunct of religious services. This definition of the word shuts out from present consideration, though at some points by an almost imperceptible boundary, the worship of all merely natural symbols, whether animate or inanimate, conventional or the reverse. Thus, for example, every form of animal worship is excluded by it, and also the cultus connected with memorial stones of which traces so unmistakable are found in the Old Testament and in almost every other ancient literature (the λίθοι λιπαροί or ἀληλιμμένοι, βαίτυλοι, *lapides uncti*, *batyli*, of classical writers). So far as images (εἰκόνες, *imagines*) are merely more or less perfect productions of pictorial or plastic art, they fall to be treated under PAINTING, SCULPTURE, MOSAIC, &c.; so far as they have been regarded as aids to devotion and spiritual instruction, or made the objects of religious veneration, the history of their introduction and of the various aspects under which they have been viewed forms a large and not unimportant chapter in the history of religion in general and of the Christian church in particular. Only the outlines of that history can be indicated here.

Most religions of which the history has been traced give distinct indications of a primitive period in which "idols" were unknown. Thus in India "the worship of idols is a secondary formation, a later degradation of the more primitive worship of ideal gods" (M. Müller). In the Vedic hymns it is the appearances of nature themselves that are worshipped as symbols of unseen deity; and the present image worship of the Hindus is most probably Post-Buddhistic in its origin. The testimonies of the Greek historians (Herod., i. 131; Strabo, p. 732; Diog. Laer., *De Vit. Phil.*, procem. 6) as to the absence of religious images from the worship of the ancient Persians is confirmed by all the more recent direct investigations into the primitive life of that branch of the Aryan race. There is the same concurrence of testimony as regards the ancient Greeks;[1] the powers of nature were in the first instance

[1] See Schoemann, *Griech. Alterthümer*, ii. 197 *sqq*

worshipped through natural symbols,—such as serpents, trees, meteoric stones,—and in some cases temples occurred which contained no visible symbol at all. Even in the Homeric poems, the allusions to images of the gods are but few: where an image is mentioned (as in *Il.* vi. 301), it is evident that it was of the rudest description, and but little indebted to human art. The same remark applies to the cultus of ancient Rome. It was carried on without the use of images until the comparatively late period at which the state entered into relations with Etruria, Magna Græcia, and Sicily.[1] The date of the oldest statue in Rome, that of Diana on the Aventine, can be given with considerable precision as between 577 and 534 B.C. As regards the ancient Germans also, we have the testimony of Tacitus that down to his time at least their gods were still invisible and had neither temples nor images.[2] And, whatever be our construction of the primitive history of the Semitic races, there can be little doubt, so far as the Jews at least are concerned, of the correctness of their own impression that "idolatry," in the strict etymological sense of that word, was not the most primitive form of religion practised among them.

The decalogue contains a direct precept against the making of any "graven image" (*pesel* or *pasil*), for religious uses at least (Ex. xx. 4, 5; Deut. v. 8, 9; with which compare Deut. iv. 15–18). The "graven images" contemplated in the passage last cited are images of men, quadrupeds, birds, reptiles, and fishes; and the manner in which the prohibition is made is fitted to suggest that all these "likenesses" had made their appearance and already become objects of religious veneration prior to its promulgation. Nothing certain, however, is known as to the "strange gods" alluded to in Gen. xxxv. 4 as having been buried by Jacob under the oak at Shechem; nor can much be said with regard to the "teraphim" which are first mentioned as having been worshipped in one of the branches of the family of Terah (Gen. xxxi. 19), but are often subsequently referred to as having been used in the time of the judges (Judg. xvii. 5; *cf.* xviii. 30), and at various stages throughout the history both of the northern and of the southern kingdom (Hos. iii. 4; Zech. x. 2; 2 Kings xxiii. 24). Sometimes they must have been but small; but from other passages it may be inferred that they may have been, occasionally at least, of human form and size (1 Sam. xix. 13, 16). Much obscurity attaches also to the calf worship of which an instance occurred in the wilderness (Ex. xxxii. 4), and which was a prominent feature in the religion of the northern kingdom from the days of Jeroboam to the end; it is a disputed question whether the cult was of Egyptian or of purely Semitic origin. The difficulty in Lev. xvii. 7, and perhaps also in Deut. xxxii. 17, Ps. cvi. 37, is by some interpreters explained by a reference to the Egyptian goat worship (Mendes); if so, these passages contain no allusion to image worship. The various forms of the Baal cultus so often referred to in the Old Testament were no doubt Semitic; there are no explicit references to any images, however, in this connexion; and in point of fact (see BAAL) that deity was generally represented in his "high-places," not by images, but by obelisks or pillars. That the plastic arts, even in a religious connexion, were not wholly discouraged among the Jews, appears from what we read, not only about the brazen serpent in the wilderness, but also about the existence in tabernacle and temple of such figures as cherubs (Ex. xxv. 18–20; xxvi. 1; xxxvi. 35; 1 Kings vi. 23, 32, 35) executed in various materials, lions, oxen, lotus flowers, and pomegranates (*cf.* Ex. xxxi. 4, 5). The graphic descriptions of the process of idol-making, both "graven images" and "molten images" in Isa. xl. and xliv. (with which may be compared Wisd. xv.; see also the reference in Isa. xxx. 22 to molten images overlaid with a precious metal) show that the exercise of those arts was far from being confined, at the periods to which these passages relate, within the limits fixed by the second commandment. After the captivity, however, there developed itself among the Jews a steadily growing tendency to interpret the language of the law with the most stringent literality; and at the time of the Roman occupation the masses, under Pharisaic influences, showed a sensitiveness on the subject of images which in certain recorded instances led to very striking results. Thus, the existence of trophies in the theatre at Jerusalem was violently objected to; Vitellius found it necessary to avoid Judæa in his march from Antioch to Petra, lest the Holy Land should be defiled by the presence of the Roman eagles; at the outbreak of the Jewish war the house of Antipas at Tiberias was destroyed because it was adorned with sculptures (Joseph., *Ant.*, xv. 8. 1, 2; xviii. 3. 1; *Vit.*, 12). This aversion to every exercise of the imitative arts, as regards living things at least, passed over from Judaism to Mahometanism.[3]

As regards the attitude towards religious images assumed by the primitive Christian church, several questions have often been treated as one which cannot too carefully be kept quite apart. There can be no doubt, for example, that the early Christians were absolutely unanimous in utterly condemning all heathen image-worship and the various customs, many of them obviously immoral, with which it was associated; it is needless to multiply citations from the fathers in proof of so undisputed a fact. A form of iconolatry specially deprecated in the New Testament was the then prevalent adoration of the images of the reigning emperors (see Rev. xv. 2). It is also tolerably certain that, if for no other reasons besides the fewness, obscurity, and poverty of the early converts to Christianity, the works of art seen in their meeting houses cannot possibly at first have been numerous. Along with these reasons would certainly cooperate towards the exclusion of visible aids to devotion, not only the church's vivid recollection of what Christ had been, and its living sense of His continued real though unseen presence, but also, during the first years, its constant expectation of His second advent as imminent. In point of fact it was a common accusation brought against the Christians by their enemies that they had "no altars, no temples, no known images" (Min. Fel., *Oct.*, c. 10), that "they set up no image or form of any god" (see Arnob., *Adv. Gent.*, vi. 1; similarly Celsus); and this charge was never denied. At a comparatively early date indeed we read of various Gnostic sects calling in the fine arts to aid their worship; thus Irenæus (*Hær* i. 25, 6), speaking of the followers of Marcellina, says that "they possess images, some of them painted, and others formed from different kinds of material; and they maintain that a likeness of Christ was made by Pilate at that time when Jesus lived among men. They crown these images, and set them up along with the images of the philosophers of the world; that is to say, with the images of Pythagoras and Plato and Aristotle and the rest. They have also other modes of honouring these images after the same manner as the Gentiles" (*cf.* Aug., *De Hær.*, c. 7). It is

[1] See Preller, *Röm. Mythologie*, p. 10, &c. The statement of Plutarch (*Numa*, 8), that for 170 years after the foundation of the city images were unknown, recurs in many later writers.

[2] The statements of Tacitus on this head, as well as those of later historians are discussed very fully in Grimm's *Deutsche Mythologie*, i. p. 93 *sqq.*

[3] On the pre-Islamitic polytheism of Arabia, and the extent to which it consisted in the worship of living animals or their images, see a suggestive paper by Prof. W. Robertson Smith on "Animal Worship and Animal Tribes among the Arabs and in the Old Testament" in the *Journal of Philology*, vol. ix. p. 75–100 (1880).

also well known that the emperor Alexander Severus found a place for several Scripture characters and even for Christ in his lararium (Lamprid., *Vit. Alex. Sev.*, c. 29). But there is no evidence that such a use of images extended itself at that early period to orthodox Christian circles; and the presumption is all the other way. The first unmistakable indication of the actual public use of the painter's art for directly religious ends does not occur indeed until the year 306 A.D., when the synod of Elvira, Spain, decreed (can. 36) that "pictures ought not to be in a church, lest that which is worshipped and adored be painted on walls."[1] The scope of this prohibition has been very differently viewed by interpreters,—some thinking that all that is forbidden is any attempt at delineating the divine; others considering that the synod contemplated frescos only and not pictures, which could be more readily hidden from profanation in times of persecution; others taking the canon in the broadest sense as directed against the exhibition in churches of pictures of sacred subjects. In any case, and particularly if the last theory be adopted, it is evident that the use of sacred pictures in public worship was not at the beginning of the 4th century a thing wholly unknown within the orthodox church in Spain; and the presumption is that in other places, about the same period, the custom was looked upon with a more tolerant eye. Indications of the existence of allied forms of sacred Christian art prior to this period are not wholly wanting. It seems possible to trace some of the older and ruder frescos in the catacombs back to a very early century; and it is certain that Bible manuscripts were often copiously illuminated and illustrated even before the middle of the 4th century. An often-quoted passage from Tertullian (*De Pudic.*, c. 10, *cf.* c. 7) shows that in his day the communion cup was wont to bear a representation of the Good Shepherd. Clement of Alexandria (*Pædag.*, iii. 11) mentions the dove, fish, ship, lyre, anchor, as suitable devices for Christian signet rings.

During the 4th and following centuries the tendency to enlist the fine arts in the service of religion and the church may be said to have steadily advanced; not, however, so far as appears, with the formal sanction of any regular ecclesiastical authority, and certainly not without strong protests raised by more than one powerful voice. From a passage in the writings of Gregory of Nyssa (*Orat. de Laudibus Theodori Martyris*, c. 2) it is easy to see how the stories of recent martyrs would offer themselves as tempting subjects for the painter, and at the same time be considered to have received from him their best and most permanent expression; that this feeling was very widespread is shown in many places by Paulinus of Nola (*ob.* 431), from whom we gather that not only martyrdoms, and Bible histories, but also symbols of the Trinity were in his day freely represented pictorially. Augustine (*De Cons. Ev.*, i. 10) speaks less approvingly of those who look for Christ and His apostles "on painted walls" rather than in His written word. How far the Christian feeling of the 4th and 5th centuries was from being thoroughly settled in favour of the employment of the fine arts is instructively shown by such a case as that of Eusebius of Cæsarea, who in reply to a request of Constantia, sister of Constantine, for a picture of Christ, wrote that it was unlawful to possess images pretending to represent the Saviour either in His divine or in His human nature, and added that to avoid the reproach of idolatry he had actually taken away from a lady friend the pictures of Paul and of Christ which she had.[2] Similarly Epiphanius in a letter to John, bishop of Jerusalem, tells how in a church at Anablatha near Bethel he had found a curtain painted with the image "of Christ or of some other saint," which he had torn down and ordered to be used for the burial of some pauper. The passage, however, reveals, not only what Epiphanius thought on the subject, but also the fact that such pictures must have been becoming frequent. Nilus, the disciple and defender of Chrysostom, permitted the symbol of the cross in churches and also pictorial delineations of Old and New Testament history, but deprecated other symbols, pictures of martyrs, and most of all the representation of Christ. In the time of Gregory the Great the Western Church at last obtained something like an authoritative declaration on the vexed question about images, but in a sense not quite the same as that of the synod of Elvira: Serenus of Marseilles, on account of what he considered to be flagrant abuses, had ordered the removal and destruction of all sacred images within his diocese; this vigorous action called forth several letters from Pope Gregory (viii. 2, 111; ix. 4, 11), in which he utterly disapproved of that violent course, and, for the first time clearly drawing the distinction which has ever since been authoritative for the Roman Church, pointed out that "it is one thing to worship a picture and another to learn from the language of a picture what that is which ought to be worshipped. What those who can read learn by means of writing, that do the uneducated learn by looking at a picture. . . . That, therefore, ought not to have been destroyed which had been placed in the churches, not for worship, but solely for instructing the minds of the ignorant." Here it may be mentioned with regard to the symbol of the cross, that its public use dates from the time of Constantine, though, according to many Christian archæologists it had, prior to that date, a very important place in the so-called "disciplina arcani." The introduction of the crucifix was decidedly later, and originally the favourite combination was that of the figure of a lamb lying at the foot of the cross; the Trullan council in 692 by its 82d canon enjoined that this symbol should be discontinued, and that where Christ was shown in connexion with His cross He should be represented in His human nature.

It was not until the 8th century that the religious and theological questions which seem naturally to connect themselves with image worship were at last distinctly raised in the Eastern Church in their entirety, and argued in what from some points of view might fairly be called an exhaustive manner. The controversy began with the edict by which Leo the Isaurian, in the tenth year of his reign (726), sought to deliver the church from what he called "the idolatry of image worship." The text of that edict is not extant, but it seems to have been directed exclusively against such "idolatrous" homage as appeared to be involved in the established custom of prostration before them. The use of the strong word "idolatrous" at once led to a keen controversy, in which it was urged by the theologians that a "relative worship" (προσκύνησις σχετική) might, without idolatry, be given to the image of Christ. Among those who took this ground was the famous John of Damascus, who retorted upon the iconoclastic emperor with charges of Judaizing and even of Manichæan leanings. Leo, unconvinced, but finding that his first edict had been wholly ineffectual, four years later (730) issued a second decree, of a more sweeping character than the first, inasmuch as all the holy images were ordered to be removed, and all recalcitrant bishops summarily ejected from their posts. This proceeding called forth further arguments from the theologian of Damascus, through whose influence the iconoclasts were anathematized in such churches as were not too directly and entirely under the political influence of Constantinople. At the same time (730) Pope Gregory

[1] Placuit picturas in ecclesia esse non debere, ne quod colitur et adoratur in parietibus depingatur. See Hefele, *Conciliengesch.*, i. 170.

[2] The letter, which is most probably, though not certainly, genuine, appears in the *Acta* of the second council of Nice.

II. addressed to the emperor two important controversial letters in favour of images. They are preserved in the *Acta* of the second council of Nice. Apart from their direct historical importance, they are of considerable interest as literary and theological curiosities. To the objection which had of course been urged from the decalogue, he replied that the prohibition there was directed simply against the idolatry of Canaan, and could not have been intended in a sense inconsistent with the fact that Moses had been commanded to make cherubim and the like. Christ Himself was an image, the image of God. The charge that the iconoduli prayed to stones, walls, and pictures was easily met; and the further difficulty that six œcumenical councils had met and separated, but enjoined nothing about images, it was held, told distinctly against the iconoclasts, for the same councils had equally failed to urge upon men the duty of taking their necessary food. Heedless of Gregory's remonstrances, the emperor continued, during the remaining twelve years of his life, to carry on the struggle with but little effect; the religious use of images was too intimately interwoven, not only with the church life, but also with the domestic habits of his people, to yield even to the most determined efforts of an arbitrary despotism. In 741 Leo was succeeded by Constantine Copronymus (741–775), who fully shared the iconoclastic views of his father, and in 754 convoked a council, attended by three hundred and thirty-eight bishops, but never recognized as œcumenical, which under his influence declared all reverencers of images to be men who had lapsed into idolatry; decreed that "Christ in His glorified humanity, though not incorporeal, was yet exalted above all the limits and defects of a sensuous nature, too exalted therefore to be figured by human art in an earthly material after the analogy of any other human body"; and pronounced anathema on all who attempted to express by visible colours the form of the Logos in His incarnation, and on all who delineated dumb and lifeless pictures of the saints, which could never serve any profitable end. All images whatsoever of sacred persons or things were ordered to be ejected from Christian churches; and to set them up either in public or in private buildings was forbidden under the gravest ecclesiastical penalties. The stringency of these decrees was justified by arguments drawn from reason and Scripture, as well as by appeals to such names as those of Gregory, Chrysostom, Athanasius, Epiphanius, and Eusebius. The attempt to enforce the decisions of the council as imperial laws was in many instances marked by oppressiveness and cruelty, and the general feeling of the community, fostered diligently by a numerous class of its most energetic and pious members, the monks, continued unchanged in its aversion to iconoclasm; and, although at the end of his reign Constantine succeeded in imposing upon every citizen of Constantinople an oath never again to worship an image, there can be little doubt that in a vast number of households secret leanings to image worship had been intensified rather than weakened by repressive measures. During the early part of the brief reign (775–779) of Leo IV. Chazarus, the stringency of the law was somewhat relaxed, until it was discovered that the empress (Irene) was herself a secret iconolater, when she was brought into disgrace, and numbers of her accomplices were seized and imprisoned. On the death of Leo, Irene became regent for her infant son Constantine, and, as was to be expected, used the power which she now possessed in favour of the cause she had long had at heart. With the assistance of the monks, after an abortive attempt to hold a synod at Constantinople in 786, there met at Nice in 787 a general council (the seventh œcumenical), the proceedings of which are of considerable historical importance. It was there decided that, not only the figure of the cross, but also other holy images (Christ, the Virgin Mary, angels, and saints), whether painted or executed in mosaic or other material, might be set up in churches, placed on holy vessels and vestments, on walls and panels, in houses and by highways, and were to be honoured with ἀσπασμός and προσκύνησις, though not with λατρεία, which is given to the divine nature alone. The decrees, which were signed by all present, were afterwards solemnly ratified at a final session (the eighth) held in Constantinople, and thus, after a struggle of sixty-one years, the worship of images asserted in the Greek Church that ascendency which, with only one brief interruption of a few years, it has ever since maintained.

The decisions of this Eastern council were in full harmony with the personal views and practices of the popes, who, however, were compelled to show considerable moderation in the attitude they assumed. The Latin Church also, as is shown by the writings of Agobard of Lyons and Claudius of Turin, contained strongly iconoclastic elements, which, if full scope had been given them, might conceivably have altered very considerably the current of Western opinion. On political as well as on religious grounds, however, it was felt to be inexpedient to push matters on either side to extremes; very important therefore at this juncture was the step taken by the emperor Charlemagne in the publication of his *De Impio Imaginum Cultu Libri IV.*, commonly called the *Libri Carolini*, in which, condemning alike the fanaticism of iconoclasts and the superstition of iconoduli, he maintained the right of images to exist for purposes of commemoration and ornament (propter memoriam rerum gestarum et ornamentum). At the synod of Frankfort-on-the-Main, held in 794, his general position was maintained, and adoration of images (*adoratio et servitus imaginum*) was wholly condemned. Great injustice was done, however, to the fathers of the second Nicene council when they were accused of maintaining that the same worship ought to be given to images of saints as to the Holy Trinity,—a doctrine which they had been at special pains to repudiate. The settlement which had been obtained in 787 did not subsist entirely undisturbed even in the Eastern Church. In 815, two years after Leo the Armenian had ascended the throne, a council convoked by him at Constantinople formally abolished the decrees of Nice, and again banished the images from the churches. The new controversy, with which the name of Theodore of the Studium is still more prominently associated than was that of John of Damascus with its previous phase, went on with vicissitudes very similar to those which had formerly occurred during the reign of Leo and his successors Michael (820–830) and Theophilus (830–842). At length, during the regency of the empress Theodora, the decrees of Nice were reaffirmed by a synod at Constantinople, and the banished images were triumphantly and finally reintroduced into the metropolitan church on the day which on the first Sunday in Lent is still celebrated throughout the Greek Church as a great festival under the name of ἑορτή or πανήγυρις τῆς ὀρθοδοξίας. One incident in this second iconoclastic controversy had been the mission of an embassy by Michael Balbus to Louis the Pious in 825. The reply was given through the synod of Paris, held in that year: in open disagreement with the opinions of Pope Hadrian I., the relatively neutral ground taken up at the synod of Frankfort was maintained.

Down to the close of this period the "images" spoken of in ecclesiastical controversy are almost entirely pictures or mosaics,—the religious use of sculptures, and particularly of statues (ἀγάλματα, ἀνδριάντες, στῆλαι), being little known, and, so far as known, disapproved. This distinction does not indeed appear in the actual decrees of the council of Nice; but it is clearly drawn in the statements of the patriarch Germanus and by Stephen Bostrenus, as quoted in the proceedings (*Act.* ii.). Such remains of Christian antiquity as the statue of Hippolytus, recently dug up at Ostia, and usually assigned to a date not later than the 5th century, as also the sitting figure of St Peter, dating from the same period, now seen in St Peter's, Rome, have no immediate connexion with the subject of this article. The same remark applies to the still earlier statue at Paneas referred to by Eusebius (*H. E.*, vii. 18), said to have been raised in honour of Christ by the woman mentioned in Matt. ix. 20; if it was really intended to represent Christ at all and not rather the emperor Hadrian, it was, at all events, obviously no object of special veneration. About the 9th century, however, "graven images" seem to have become more common. Thus in the treatise *De Imaginibus* (c. 31) of Agobard of Lyons (*ob.* 840), there is an obvious controversial allusion to molten or moulded statues of angels or holy men. With the gradual introduction of the architecture commonly known as Gothic, there came in a great advance in plastic art. The new cathedrals gave scope for and even demanded a wealth of decoration formerly unknown, until it seemed as if, not only the entire Biblical history, but all the *Acta Sanctorum*, were to be artistically told in wood and stone. The earliest extant sculptures in stone or stucco cannot be carried farther back than the 11th century. But the discussion of their date and character belongs to the artistic rather than to the religious side of the subject.[1]

At the period of the Reformation it was unanimously felt by the reforming party that, with the invocation of saints and the practice of reverencing their relics, the adoration of images ought also as matter of course to cease. The leaders of the movement were not all, however, perfectly agreed on the question as to whether these might not in some circumstances be retained in churches. Luther, it is well known, had no sympathy with the iconoclastic outbreaks which history mentions as having taken place with some frequency at this period; he classed images in themselves as among the "adiaphora," and condemned only their cultus; so also the "Confessio Tetrapolitana" leaves Christians free to have them or not, if only due regard be had to what is expedient and edifying. The "Heidelberg Catechism," on the other hand, emphatically declares that images are not to be tolerated at all in churches. This position, which is that of all the reformed churches, has an obvious connexion with their view as to the division of the decalogue, they following Origen on this question while the Lutherans adhere to the Philonic arrangement (see DECALOGUE).

At the council of Trent (session xxv.) the Church of Rome finally formulated the doctrine on the subject of images which is still of authority within its communion. That doctrine is avowedly based on the decrees of the second council of Nice. It is declared that images of Christ, the Virgin Mary, and other saints are to be set up and retained, especially in churches, and that "due" honour and veneration are to be accorded them by kissing and prostration. Warnings are appended, however, against their superstitious abuse somewhat in the spirit of Gregory the Great's letter and of the decision of the Frankfort synod.

The Greek Church continues tenaciously to adhere to the decrees of the second Nicene council, and has not yielded to any of the artistic impulses which have elsewhere made themselves so powerfully felt. The sacred pictures which abound everywhere, and are treated with extraordinary reverence and affection, are for the most part very defective æsthetically. Indeed the preference seems to be given to those executed in rude archaic style, and even now the painter of pictures intended for religious uses must bear in mind the monk's famous criticism on Titian. Nude or incompletely draped figures are forbidden, and only half lengths are permitted "ut omnis stultæ cogitationis occasio tollatur." No representation of the Godhead or of the Trinity is attempted. Although it is in the records of a Constantinopolitan council that the earliest extant notice of the crucifix occurs, that symbol is not now used in the East.

[1] Such works as Lubke's *Kunstgeschichte* may be consulted in this connexion; also Didron's *Iconographie* and Jameson's *Sacred and Legendary Art*.

The literature of the subject is immense. The most important monographs are—from the Catholic point of view, Maimbourg, *Histoire de l'Hérésie des Iconoclastes* (Paris, 1679–82); from the Protestant, Daillé, *De Imaginibus* (Leyden, 1642), and Spanheim, *Historia Imaginum restituta* (Leyden, 1686). For the acts of the councils, Labbé or Mansi must be consulted; the learned compilation of Goldast, *Imperialia decreta de cultu imaginum in utroque imperio promulgata collecta et illustrata* (Frankfort, 1608), will also be found useful. Compare Schlosser, *Gesch. der bilderstürmenden Kaiser* (Frankfort, 1812). The sections relating to image worship in the great work of Chemnitz (*Examen Conc. Trid.*, pars 4) are characterized by learning and moderation. The whole subject is treated, of course, in all the church histories; with most fulness and insight in that of Neander. The iconoclastic controversy is dealt with also in the histories of Gibbon and Milman. Copious archæological details are also given in Augusti's *Denkwürdigkeiten*, vol. xii. (Leipsic, 1831). (J. S. BL.)

IMÁM is the name given to the priest who leads the prayers of a Mahometan congregation, and is exactly equivalent to Antistes. In the Koran, chap. ii. v. 118, it is said of Abraham, "Verily, I will set thee as an imám (high priest or model) for men." In Turkey the imám, besides his function as a minister, performs the rites of circumcision, marriage, and burial. He is distinguished only by avoiding gay colours in his dress and wearing a white turban. In Persia the imám is also called a mujtahid; he has no secular duties. The title has been always borne by the caliphs or successors of Mahomet, the earlier ones having, like the Prophet himself, conducted the services in person, and addressed the people in a *khutbah* or homily on the great weekly gathering on Fridays. The title thus came to signify head of the faith, and as such is claimed and used by the present sultans of the Osmanli dynasty in Turkey, the last of the legitimate caliphs, El Mutawakkel, having in 1517 A.D. ceded his prerogatives to Selim I., the first Ottoman sultan, and his heirs. The caliphate (see CALIPH) is also called *El Imámah*, the imamate. The Shiah sect hold that the office of imám was specially assigned by Mahomet to Ali ibn Abi Tálib, his cousin and son-in-law, and passed from him to his legitimate male issue by Fatima Mahomet's daughter. The first imám then was Ali; the next two were Ali's sons Hasan and Husein (see HASAN); then came Ali Zein el 'Ábidîn, son of Husein. His son Zeid founded the sect called the Zeidîyeh, who recognized him as imám. This sect split into two subdivisions, one of which declared that the imám ought to be designated by his predecessor, the other that the imamate was elective, but must be confined to the descendants of Fatima. The twelve imáms generally received by the Shiahs do not, however, include Zeid, but are the following:—(1) Ali ibn Abi Tálib; (2) El Hasan his son; (3) El Husein, Ali's other son; (4) Ali Zein el 'Abidîn, son of Husein; (5) Mohammed el Bakir, son of Zein el Ábidîn; (6) Jaafer es Sádik, son of El Bakir; (7) Musá el Kadhim, son of Jaafer; (8) Ali er Ridhá, son of Musa; (9) Mohammed et Takí, son of Er Ridhá; (10) Ali el Hádí, son of Et Takí; (11) Hasan el Askarí, son of El Hádi. Here the chain of succession breaks off, the twelfth imám being Mohammed el Mehdi, surnamed Abu Kasim, who was predicted by the Prophet, and who is yet to come. The title imám is also applied to the founders of the four great orthodox sects of Mahometans.

IMBROS, or IMVRO, an island in the Ægean Sea, lying west of the southern end of the Thracian Chersonese, about 14 miles from the mouth of the Dardanelles. To the north-west, at a distance of 17 miles, lies the island of Samothraki; and about the same distance to the south-east is Lemnos. The area of Imbros is estimated at 105 square miles, and its population, which is mainly of Greek origin, is about 10,000. With its bare mountain ridges and sides it has no small similarity to Attica. Hagios Ilias, or St Elias, is the highest summit, 1859 feet above the sea-level. According to Franz von Loher about a third of the island could be turned into a very garden by an industrious and skilful race; but at present not more than one-tenth is under cultivation. Wheat, barley, and oats are grown, as well as a dye-plant locally called bouia. A German company is working lignite in the island. The only stream of importance has surrendered its ancient name of Ilissus for the simple appellation of *μεγάλος ποταμός* or Big River. The valley through which it flows is the only considerable tract of arable land in the island, and contains the four villages of Theodoro, Kastro, Gliki, and Panagia. Kastro, which lies on the coast, is the site of the ancient town which bore the same name with the island; but the only remains of antiquity are part of the mole, portions of the town-wall, and a number of tombstones. A hill above the town presents with its summit so great a likeness to a mediæval castle that it has frequently been described as such. The archæological investigations of Conze have brought to light a few inscriptions of secondary interest, which mainly serve to confirm the Attic character of Imbrian civilization. Attic and Trojan coins are not unfrequent; and traces are found of the worship of the Cabiri, Cybele, and Zeus Hypsiotes. Imbros plays no great part in history; though the name occurs as early as the *Iliad* and the Homeric *Hymns*. Herodotus mentions its subjugation to the Persians by Otanes. In later times it was distinctly recognized as an Athenian colony. The numerous watch-towers and diminutive strongholds observed throughout the island would indicate that it had its share in the busy warlike existence of the Middle Ages. Along with Samothraki, Lemnos, and Hagiostrati, Imbros belongs administratively to the Vilayet of the Islands, or Jesair bahr i Safid of Asiatic Turkey. It is the seat of a metropolitan of the Greek Church, with the title of exarch of the Ægean.

IMERITIA, a district in Transcaucasia, extends from the left bank of the Tzhenys-tzkalys to the range of hills that separate it from Georgia on the east, and is bounded on the south by Akhalzikh. Anciently a part of Colchis, and included in Lazia during the Roman empire, Imeritia was nominally under the dominion of the Greek emperors. In the early part of the 6th century it became the theatre of wars between Justinian and Chosroes, and was devastated by subsequent hostile incursions, reviving only on becoming united to Georgia. It flourished until the reign of Queen Thamar, but after her death (1212) the country became impoverished through strife and internal dissensions. Reunited to Georgia, it became known in 1259 as Imier, whence Imeritia (1469). In 1621 was made the earliest appeal to Russia for aid; in 1650 the first Russian envoys were received at Koutais, the capital; and in 1769 a Russian force expelled the Turks. In 1804 the monarch declared himself a vassal of Russia, and in 1810 the little kingdom was definitively annexed to that empire. Imeritia, Mingrelia, and Gouria, provinces not officially recognized as distinct, are now included in the Russian government of Koutais. See GEORGIA.

IMMACULATE CONCEPTION. The dogma of the immaculate conception of the Virgin Mary, as held by the Church of Rome, is to the effect that "the most blessed Virgin was, in view of the merits of Jesus Christ the Saviour of the human race, by the singular grace and favour of Almighty God, from the first moment of her conception in the womb of her mother, preserved free from all taint of original sin." The "pious opinion" that the mother of Christ had during her life been preserved from sin in a way in which no other human being ever had been may be traced back to a comparatively early period: indeed, without it her cultus (for some account of the growth of which see MARY) as it had developed itself long before the 9th century, would have been impossible. The actual history of an explicit doctrine of her immaculate conception, however, so far as has hitherto been discovered, may be said to begin, in the year 1140,[1] with the letter of remonstrance which Bernard of Clairvaux wrote to the canons of the cathedral at Lyons (*Ep.* 174), who, without consulting the Roman see, had recently introduced into their church a festival in celebration of that doctrine. Bernard argued vigorously against this on the ground of its novelty, its unscripturalness (Ps. li. 5), and its absurdity:—"On the same principle," said he, "you would be obliged to hold that the conception of her ancestors, in an ascending line, was also a holy one, since otherwise she could not have descended from them worthily, and there would then be festivals without number." How the recipients, who, it is stated, claimed to have learned their peculiar rite from a document communicated by the Virgin herself, were affected by this letter, is not recorded. Among controversial treatises which appeared shortly afterwards are mentioned those of Potho of Prüm and the Abbot de la Celle against the doctrine, and that of the English monk Nicolas in its favour. In the 13th century all the leading theologians, such as Alexander Halensis (p. iii., qu. 10, membr. 2), Albertus Magnus (*Comm. in Sent.*, iii. 3), Bonaventura (*Comm. in Sent.*, iii. 3. 1, 2), and Thomas Aquinas (*Summa*, p. iii., qu. 27, art. 1–3), took the view of St Bernard, their contribution to the theology of the subject consisting in an accurate definition of the moment at which the Virgin's sanctification in the womb must be held to have taken place. During the same century the feast of the Conception became very popular, and in 1263 it was accepted by a general chapter of the Franciscans at Pisa, without reference, however, to the question of immaculacy. Of great importance to the subsequent history of the dogma was the appearance in the theological world, towards the beginning of the 14th century, of Duns Scotus, the "subtle doctor" of the Franciscans, who, as in so many other points, so also in this, came into conflict with the still more illustrious "Doctor Angelicus," the Dominican Aquinas. In one part of his *Commentary* on the *Sentences* of Peter of Lombardy (lib. iii., dist. 3, qu. 1, sec. 9) he declares for the thinkableness and even probability of Mary's having been preserved intact from original sin; in a later passage (dist. 18, qu. 1, sec. 13) the doctrine is categorically stated. It was upon this disputed point that the long and bitter controversy between the two great mendicant orders chiefly turned. In 1389, the Spanish Dominican Joannes de Montesono having maintained in a disputation at Paris that the view of the Scotists was unscriptural and heretical, the university, without committing itself on the main point, condemned his violent theses, and this condemnation was concurred in by the Avignon pope, Clement VII. The members of the entire

[1] The allegation that it was taught by Anselm of Canterbury is based partly upon a spurious tract attributed to him and partly on unauthentic legend. His actual opinion is explicitly enough stated in the treatise *Cur Deus Homo*, c. 18:—"Virgo tamen ipsa, unde assumptus est, est in iniquitatibus concepta, et in peccatis concepit eam mater ejus."

Dominican order, for their refusal to acquiesce, were for several years excluded from the privileges of the university. In the beginning of the 15th century the famous chancellor, John Gerson, accepted the new dogma, and applied in its favour the well-known doctrine of development. At the council of Basel (in the 36th session, held September 17, 1439) it was defined and declared that the doctrine was consistent with faith, reason, and Scripture, and therefore to be approved and embraced; the contrary doctrine was not condemned, but it was forbidden to preach or to teach it. The university of Paris now made subscription to the doctrine of the Immaculate Conception a condition for its degrees, and various other universities entered into a solemn compact to use every exertion for its spread, but the controversy was far from having been brought to a close even by the action of Pope Sixtus IV., who in 1483 published a bull threatening with excommunication any one who should accuse of heresy either the advocates or the impugners of the doctrine, the point having not yet been decided by the apostolical see. In its fifth session (1546) the council of Trent, after formulating its decree on the subject of original sin, sought to effect a compromise between Dominicans and Franciscans by appending a declaration that it did not intend that this doctrine should be applied to the blessed and immaculate Virgin Mary, but that the constitutions of Sixtus IV. were still to be observed. In the beginning of the 17th century the field of battle was transferred to Spain, where, under the predominant influence of the Franciscans and Jesuits, medals were struck, pictures painted, statues erected, and persecutions set on foot in honour of the Virgin "sin pecado concebida"; and embassies were sent to Rome, both by Philip III. and by Philip IV., to obtain more explicit recognition of the popular doctrine. The popes continued for a long time, however, to maintain their attitude of reserve. Paul V. (1617) forbade all public dispute on the subject, and Gregory XV. (1622) extended the prohibition even to private discussions, except in the case of Dominicans "*inter se.*" But gradually the papal sympathies became more pronounced under Jesuit influences; Clement IX. gave the feast of the Conception an octave; Clement XI., in 1708, made it a festival "de præcepto" for all Christendom; while Benedict XIV. endeavoured to reconcile St Bernard with the more modern tendencies of Roman Catholic theology, by insisting upon subtle distinctions between the "conceptio activa" and the "conceptio passiva" of Mary. In the pontificate of Gregory XVI. several prelates received papal permission to describe her conception as immaculate; and in 1849 Pius IX. was induced to address to his bishops from Gaeta an encyclical, inviting them to state how far the dogmatic definition of the dogma would meet their wishes and the wishes of those under their charge. A large majority declared themselves strongly in favour of the proposal, and the ultimate result was that in December 8, 1854, the pope, in presence of a numerous concourse of cardinals, patriarchs, archbishops, and bishops assembled in St Peter's, Rome, solemnly promulgated the bull "Ineffabilis Deus," by which the doctrine of the Immaculate Conception finally became for the Roman communion an article of faith, the denial of which is accounted to be heresy.[1]

The feast of the Immaculate Conception is observed in the Roman Church on December 8. In the Greek Church there is a festival in honour of the conception of St Anne (the mother of Mary), for which December 9 was fixed by a constitution of the emperor Emanuel Comnenus in the 12th century. Her deliverance from the reproach of sterility is what is celebrated; there is no reference to anything analogous to the Roman doctrine. It may be remarked that strong expressions as to the absolute purity of Mary are found in the Koran (iii. 37), and still more in later Mahometan writings; but the Christian doctrine of sin is so utterly foreign to Islam that no precise theological construction of these expressions is possible.

[1] The words are "Auctoritate Domini Nostri Jesu Christi, beatorum Apostolorum Petri et Pauli, ac Nostra, declaramus, pronuntiamus et definimus, doctrinam, quæ tenet Beatissimam Virginem Mariam in primo instanti suæ Conceptionis fuisse singulari Omnipotentis Dei gratia et privilegio, intuitu meritorum Christi Jesu, Salvatoris humani generis, ab omni originalis culpæ labe præservatam immunem, esse a Deo revelatam, atque idcirco ab omnibus fidelibus firmiter constanterque credendam.

IMMERMANN, Karl Lebrecht (1796-1840), dramatist and novelist, was born April 24th, 1796, at Magdeburg. From the gymnasium of his native city he passed in 1813 to study law at the university of Halle, but his career there was interrupted by the commotions consequent upon Napoleon's escape from Elba. Immermann was prevented by illness from taking part in the earlier campaign, but he served in the Prussian army in 1815, was present at Ligny and Waterloo, and marched into Paris with Blücher. He went back to Halle to finish his studies, and held official positions at Oschersleben, Münster, and Magdeburg successively, before he became judge of a district on the Rhine, near Düsseldorf. The attention which his writings had already excited won him a warm welcome from the artistic circle which then made Düsseldorf famous, and there he spent the rest of his life, dividing his time amongst his judicial duties, his unsuccessful attempt to raise the theatre there to a permanent classic level of art and refinement, and a platonic literary friendship with the countess of Ahlefeldt. The last, begun at Münster and terminated only at his marriage with a granddaughter of the chancellor Niemeyer in 1839, exercised a marked influence over his genius. Immermann died at Düsseldorf, August 25, 1840. His dramas are perhaps better suited for the study than for the stage. Though sometimes rough and forbidding, they are marked by considerable insight into character; the comedies are by no means destitute of comic force. Signs of a close study of Shakespeare are abundant. In his semi-humorous romances Immermann is at his best, and it is by those that he will be chiefly remembered.

His chief works are the following: the tragedies—*Vale of Ronceval*, *Edwin*, *Petrarca*, 1822; *King Periander*, 1823; *Cardenio and Celinde*, 1826; *Frederick II.*, 1828; and *Ghismonda*, 1839; and the comedies—*Princes of Syracuse*, 1821; *Eye of Love*, 1824; *Disguises*, 1828; *School of the Pious*, 1829. Besides these he wrote the mythical play, *Merlin*, 1831; the trilogy of *Alexis*, 1832; the dramatic poem, *The Tragedy in the Tyrol*, 1827; and the romances—*Tulifäntchen*, 1827, *Die Epigonen*, 1836 (perhaps his best work), and *Münchhausen, a Story in Arabesques*, 1839. He published two volumes of poems (1822 and 1832), and began *Tristan and Isolde*, 1842. His miscellaneous writings include a translation of *Ivanhoe*; *On the Mad Ajax of Sophocles*, 1826; *Miscellen*, 1830; *The Hermit's Window*, 1822; *Journal of a Traveller*, 1833; *Memorabilien* (unfinished), 1840; and *Theaterbriefe*, 1851. The collected works were published in 14 vols. in 1835-43. See Putlitz's *Karl Immermann, sein Leben und seine Werke*, 1870.

IMMORTELLE, or Everlasting. The immortelle plant belongs to the division *Tubuliflorœ* of the natural family *Compositœ*, and is scientifically known as *Gnaphalium* (*Helichrysum*) *orientale* of Linnæus. It is a native of North Africa, Crete, and the parts of Asia bordering on the Mediterranean; and it is cultivated in many parts of Europe. It first became known in Europe about the year 1629, and has been cultivated since 1815. In common with several other plants of the same group, known as "everlastings," the immortelle plant possesses a large involucre of dry scale-like or scarious bracts, which preserve their appearance when dried, provided the plant be gathered in proper condition. The chief supplies of *Helichrysum orientale* come from Lower Provence, where it is cultivated in large quantities on the ground sloping to the Mediterranean, in positions well exposed to the sun, and usually in plots surrounded by dry stone walls. The finest flowers are grown on the slopes of Bandols and Ciotat, where the plant begins to flower in June. It requires a light sandy or stony soil, and is very readily injured by rain or heavy dews. It can be propagated in quantity by means of offsets from the older stems. The flowering stems are gathered in June, when the bracts are fully developed, all the fully-expanded and immature flowers being pulled off and rejected. After being dried, they are sent to Paris in boxes containing 100 bundles, with the flowers placed outwards and the stems in the centre. The immortelle is sold by weight or by the bundle, the price varying from 1½d. to 3d. per bundle, according to size, or from 12s. to 18s. per hundredweight, according to quality. A well-managed plantation is productive for eight or ten years. The plant is tufted in its growth, each plant producing 60 or 70 stems, while each stem produces an average of 20 flowers. About 400 such stems weigh a kilogramme. A hectare of ground will produce 40,000 plants, bearing from 2,400,000 to 2,800,000 stems, and weighing from 5½ to 6½ tons, or from 2 to 3 tons per acre. The colour of the bracts is a deep yellow. The natural flowers are commonly used for garlands for the dead, or plants dyed black are mixed with the yellow ones. The plant is also dyed green or orange-red, and thus employed for bouquets or other ornamental purposes.

The following is a list of the more important everlasting flowers:—*Acroclinium roseum*; *Ammobium alatum*; *Gnaphalium orientale* and other species; *Helichrysum bracteatum*, *macranthum*, and *compositum*, from Australia, and *H. vestitum*, from the Cape of Good Hope; *Helipterum canescens* and *Sandforti*, from South Africa; *Rhodanthe Manglesii*, *maculata*, and *atrosanguinea*, from Swan River; *Waitzia nitida* and *nivea*, from Swan River; and *Xeranthemum annuum*. Frequently these everlastings are mixed with bleached grasses, as *Lagurus ovatus*, *Briza maxima*, *Bromus brizæformis*, or with the leaves of the Cape silver tree (*Leucadendron argenteum*), to form bouquets or ornamental groups.

IMOLA, the ancient *Forum Cornelii*, a town of Italy, capital of a circle in the province of Bologna, is situated in a fruitful and charming plain on the old Æmilian way, near the river Santerno (ancient *Vatrenus*), 21 miles south-east of Bologna and 46 north-west of Rimini, on the railway connecting those towns. It is the seat of a bishop and of a subprefecture. The town is surrounded by walls flanked with towers, and its streets are spacious and lined with arcades. It possesses a cathedral with an octagonal tower, an old castle, a gymnasium, a technical school, a school of music, a public library, orphanages for boys and girls, a hospital, and a corn exchange. The manufacture of wine is the principal industry, but a special kind of cream of tartar is also made, and there is considerable trade in corn, hemp, flax, rice, and silk. The population of the town in 1871 was 9355 and of the commune 28,398. In 1876 the population of the commune was 28,678.

The ancient *Forum Cornelii* is said to have derived its name from its founder the dictator Sulla. According to Cicero, it was occupied by Octavian during the civil war which followed the death of Cæsar, and Martial mentions it in the third book of his epigrams as the place where he was at that time residing. The modern name of the town is, according to Paulus Diaconus, derived from that of the old citadel. The town, after its destruction in 538 by Narses, general of the emperor Justinian I., was rebuilt by the Lombards, after which it remained under the lordship of Bologna till the end of the 13th century. In 1272 it was taken possession of by the Pagani, and in 1292 by the Alidosii, from whom it was seized in 1472 by Duke Philip Maria Visconti of Milan. Under the pontificate of Alexander VI. it was incorporated with the States of the Church. In 1708 it was captured by the imperialists, and in 1797 by the French.

IMPEACHMENT, an exceptional, and now rare, form of procedure against criminals in England, in which the House of Commons are the prosecutors and the House of Lords the judges. It differs from procedure by bill of attainder, which follows the ordinary forms of legislation in both Houses, and takes effect in an Act of Parliament. In impeachment the form of procedure is strictly judicial. When the House of Commons has accepted a motion for impeachment, the mover is ordered to proceed to the bar of the House of Lords, and there impeach the accused "in the name of the House of Commons, and of all the Commons of the United Kingdom." The charges are formulated in articles, to each of which the accused may deliver a written answer. The prosecution must confine itself to the charges contained in the articles, though further articles may be adhibited from time to time. The Commons appoint managers to conduct the prosecution, but the whole House in committee attends the trial. The defendant may appear by counsel. The president of the House of Lords is the lord high steward, in the case of peers impeached for high treason; in other cases the lord chancellor. The hearing takes place as in an ordinary trial, the defence being allowed to call witnesses if necessary, and the prosecution having a right of reply. At the end of the case the president "puts to each peer, beginning with the junior baron, the questions upon the first article, whether the accused be guilty of the crimes charged therein. Each peer in succession rises in his place when the question is put, and standing uncovered, and laying his right hand upon his breast, answers, 'Guilty' or 'Not guilty,' as the case may be, 'upon my honour.' Each article is proceeded with separately in the same manner, the lord high steward giving his own opinion the last" (May's *Parliamentary Practice*, c. xxiii.). Should the accused be found guilty, judgment follows if the Commons move for it, but not otherwise. The Commons thus retain the power of pardon in their own hands, and this right they have in several cases expressly claimed by resolution, declaring that it is not parliamentary for their lordships to give judgment "until the same be first demanded by this House." An impeachment, unlike other parliamentary proceedings, is not interrupted by prorogation, nor even by dissolution. Proceedings in the House of Commons preliminary to an impeachment are subject to the ordinary rules, and in the Warren Hastings case an Act was passed to prevent the preliminary proceedings from discontinuance by prorogation and dissolution. A royal pardon cannot be pleaded in bar of an impeachment. The point was raised in the case of the earl of Danby in 1679, and the rule was finally settled by the Act of Settlement. Persons found guilty on impeachment may be reprieved or pardoned like other convicts. Impeachment will lie against all kinds of crimes and misdemeanours, and against offenders of all ranks. In the case of Simon de Beresford, tried before the House of Lords 4 Edward III., the House declared "that the judgment be not drawn into example or consequence in time to come, whereby the said peers may be charged hereafter to judge others than their peers," from which Blackstone and others have inferred that "a commoner cannot be impeached before the Lords for any capital offence, but only for high misdemeanours." In the case of Fitzharris in 1681, the House of Commons in answer to a resolution of the Lords suspending the impeachment, declared it to be their undoubted right "to impeach any peer or commoner for treason or any other crime or misdemeanour." And the House of Lords has in practice recognized the right of the Commons to impeach whomsoever they will. The procedure has, however, been reserved for great political offenders whom the ordinary powers of the law might fail to reach. It has now fallen into desuetude. The last impeachments were those of Warren Hastings (1788–95) and Lord Melville (1805), but an unsuccessful attempt was made by Mr Austey to impeach Lord Palmerston in 1848. The earliest recorded instances of impeachment are those of Lord Latimer in 1376, and of Pole, earl of Suffolk, in 1386. From the time of Edward IV. to Elizabeth it fell into disuse, "partly," says Hallam, "from the loss of that control which the Commons had obtained under Richard II. and the Lancastrian kings, and partly from the preference the Tudor princes had given to bills of attainder or pains and penalties when they wished to turn the arm of parliament against an obnoxious subject." Revived in the reign of James I., it became an instrument of parliamentary resistance to the crown, and it was not unfrequently resorted to in the first three reigns after the Revolution.

In the constitution of the United States the procedure of impeachment is an almost exact copy of that described above. The House of Representatives are the accusers, and appoint managers to conduct the prosecution at the bar of the senate. The vote of the senate is taken by putting the question separately to each member, and a majority of two-thirds is required for a conviction. In the separate States it partakes of the same quasi-political character—neither the prosecutors nor the judges being the same as in ordinary criminal offences. The most noted instances of impeachment in the United States are those of Associate Justice Chase in 1804, of President Andrew Johnson in 1868, and of Judge Barnard, New York, in 1872. The object of impeachment is the removal of public officers for malversation in office, which is followed sometimes by disqualification for any future appointment.

INCENSE[1] is the perfume (fumigation) arising from certain resins and gum-resins, barks, woods, dried flowers, fruits, and seeds, when burnt, and also the substances so burnt. In its literal meaning the word "incense" is one with the word "perfume," the aroma given off with the smoke (per fumum[2]) of any odoriferous substance when burnt. But, in use, while the meaning of the word "perfume" has been extended, so as to include everything sweet in smell, from smoking incense to the invisible fresh fragrance of fruits and exquisite scent of flowers, that of the word "incense," in all the languages of modern Europe in which it occurs, has, by an opposite process of limitation, been gradually restricted almost exclusively to frankincense (see Frankincense). Frankincense has always been obtainable in Europe in greater quantity than any other of the aromatics imported from the East; it has therefore gradually come to be the only incense used in the religious rites and domestic fumigations of many countries of the West, and at last to be popularly regarded as the only "true" or "genuine" (*i.e.*, "franc") incense (see Littré's *Fr. Dict.*, and Skeat's *Etym. Dict. of Engl. Lang.*).[3]

The following is probably an exhaustive list of the substances available for incense or perfume mentioned in the Hebrew Scriptures:—Algum or almug wood (almug in 1 Kings x. 11, 12; algum in 2 Chron. ii. 8, and ix. 10, 11), generally identified with sandalwood (*Santalum album*), a native of Malabar and Malaya; aloes, or lign aloes (Heb. *ahâlim, ahâlôth*), produced by *Aloexylon Agallochum*, a native of Cochin-China, and *Aquilaria Agallocha*, a native of India beyond the Ganges (compare vol. i. p. 597); balm (Heb. *tsori*), the oleo-resin of *Balsamodendron Opobalsamum* and *B. gileadense*; bdellium (Heb. *bdôlah*), the resin produced by *Balsamodendron roxburghii, B. Mukul*, and *B. pubescens*, all natives of Upper India (Lassen, however, identifies *bdôlah* with musk); calamus (Heb. *kanch*; sweet calamus, *kench bosem*, Ex. xxx. 23, Ezek. xxvii. 19; sweet cane, *kanch hattob*, Jer. vi. 20, Isa. xliii. 24), identified by Royle with the *Andropogon Calamus aromaticus* or roosa grass of India; cassia (Heb. *kiddah*) the *Cinnamomum Cassia* of China (see vol. v. p. 184); cinnamon (Heb. *kinnamon*), the *Cinnamomum zeylanicum* of the Somali country, but cultivated largely in Ceylon, where also it runs wild, and in Java; costus (Heb. *ketzioth*), the root of the *Aucklandia Costus*, native of Cashmere; frankincense (Heb. *lebônah*), the gum-resin of *Boswellia Frereana* and *B. Bhau-Dajiana* of the Somali country, and of *B. Carterii* of the Somali country and the opposite coast of Arabia (compare vols. viii. p. 122, and ix. p. 709); galbanum (Heb. *helbenah*), yielded by *Ophoidia galbanifera* of Khorassan, and *Galbanum officinale* of Syria; ladanum (Heb. *lôt*, translated "myrrh" in Gen. xxxvii. 25, xliii. 11), the resinous exudation of *Cistus creticus, C. ladaniferus*, and other species of "rock rose" or "rose of Sharon"; myrrh (Heb. *môr*), the gum-resin of the *Balsamodendron Myrrha* of the Somali country and opposite shore of Arabia; onycha (Heb. *shecheleth*), the celebrated odoriferous shell of the ancients, the operculum or "nail" of a species of *Strombus* or "wing shell," formerly well-known in Europe under the name of *Blatta byzantina*; it is still imported into Bombay to burn with frankincense and other incense to bring out their odours more strongly; saffron (Heb. *karkôm*), the stigmata of *Crocus sativus*, a native originally of Cashmere; spikenard (Heb. *nerd*), the root of the *Nardostachys Jatamansi* of Nepal and Bhutan; stacte (Heb. *nataf*), generally referred to the *Styrax officinale* of the Levant, but Hanbury has shown that no stacte or storax is now derived from *S. officinale*, and that all that is found in modern commerce is the product of the *Liquidambar orientale* of Cyprus and Anatolia.

Besides these aromatic substances named in the Bible, the following must also be enumerated on account of their common use as incense in the East; benzoin or gum benjamin (see vol. iii. p. 581), first mentioned among Western writers by Ibn Batuta (1325–1349) under the name of *lubân d' Javi* (*i.e.*, olibanum of Java), corrupted in the parlance of Europe into benjamin and benzoin; camphor, produced by *Cinnamomum Camphora*, the "camphor laurel" of China and Japan, and by *Dryobalanops aromatica*, a native of the Indian Archipelago, and widely used as incense throughout the East, particularly in China (compare vol. iv. p. 761); elemi, the resin of an unknown tree of the Philippine Islands, the elemi of old writers (see vol. viii. p. 122) being the resin of *Boswellia Frereana*; gum-dragon or dragon's blood, obtained from *Calamus Draco*, one of the ratan palms of the Indian Archipelago, *Dracæna Draco*, a liliaceous plant of the Canary Islands, and *Pterocarpus Draco*, a leguminous tree of the island of Socotra (see vol. vii. p. 389); rosemalloes, a corruption of the Javanese *rasamala*, or liquid storax, the resinous exudation of *Liquidambar Altingia*, a native of the Indian Archipelago (an American *Liquidambar* also produces a rosemalloes-like exudation); star anise, the starlike fruit of the *Illicium anisatum* of Yunan and south-western China (compare vol. ii. p. 58), burnt as incense in the temples of Japan; sweet flag, the root of *Acorus Calamus*, the *bach* of the Hindus, much used for incense in India (see vol. ix. p. 280). An aromatic earth, found on the coast of Cutch, is used as incense in the temples of western India. The animal excreta, musk and civet, also enter into the composition of modern European pastils and clous fumants. Balsam of Tolu, produced by *Myroxylon toluiferum*, a native of Venezuela and New Granada; balsam of Peru, derived from *Myroxylon Pereiræ*, a native of San Salvador in Central America; Mexican and Brazilian elemi, produced by various species of *Icica* or "incense trees," and the liquid exudation of an American species of *Liquidambar*, are all used as incense in America. Hanbury quotes a faculty granted by Pope Pius V. (August 2, 1571) to the bishops of the West Indies permitting the substitution of balsam of Peru for the balsam of the East in the preparation of the chrism to be used by the Catholic Church in America. The *Sangre del drago* of the Mexicans is a resin resembling dragon's blood obtained from a euphorbiaceous tree, *Croton Draco*.

Probably nowhere can the actual historical progress from the primitive use of animal sacrifices to the later refinement of burning incense be more clearly traced than in the pages of the Old Testament, where no mention of the latter solemnity occurs before the period of the Mosaic legislation; but in the monuments of ancient Egypt the authentic traces of the use of incense which still exist carry us back to a much earlier date. From Meroe to Memphis the

[1] *Incensum* (or *incensum thuris*) from *incendere*; Ital. and Portug. *incenso*; Span. *incienso*; Fr. *encens*. The substantive occurs in an inscription of the Arvalian brotherhood (Marini, *Gli Atti e Monumenti de' fratelli Arvali*, p. 639), but is frequent only in ecclesiastical Latin. Compare the classical *suffimentum* and *suffitus* from *suffio*. For "incense" Ulfila (Luke i. 10, 11) has retained the Greek *θυμίαμα* (thymiama); all the Teutonic names (Germ. *Weihrauch*; Old Saxon *Wirôc*; Icel. *Reykelsi*; Dan. *Rögelse*) seem to belong to the Christian period (Grimm, *Deutsche Mythologie*, i. 50).

[2] The etymological affinities of *θύω, θύος, thus, fuffio, fumus*, and the Sanskr. *dhuma*, are well known. See Max Müller, *Chips*, i. 99.

[3] Classical Latin has but one word (*thus* or *tus*) for all sorts of incense. *Libanus*, for frankincense, occurs only in the Vulgate. Even the "ground frankincense" or "ground pine" (*Ajuga Chamæpitys*) was known to the Romans as *Tus terræ* (Pliny), although they called some plant, from its smelling like frankincense, *Libanotis*, and a kind of Thasian wine, also from its fragrance, *Libanios*. The Latino-barbaric word *Olibanum* (quasi *Oleum Libani*), the common name for frankincense in modern commerce, is used in a bull of Pope Benedict IX. (1033). It may here be remarked that the name "European frankincense" is applied to *Pinus Tæda*, and to the resinous exudation ("Burgundy pitch") of the Norwegian spruce firs (*Abies excelsa*). The "incense tree" of America is the *Icica guianensis*, and the "incense wood" of the same continent *I. heptaphylla*.

commonest subject carved or painted in the interiors of the temples is that of some contemporary Phrah or Pharaoh worshipping the presiding deity with oblations of gold and silver vessels, rich vestments, gems, the firstlings of the flock and herd, cakes, fruits, flowers, wine, anointing oil, and incense. Generally he holds in one hand the censer, and with the other darts the pastils or osselets of incense into it; sometimes he offers incense in one hand and makes the libation of wine with the other. One of the best known of these representations is that carved on the memorial stone placed by Thothmes IV. (1533 B.C.) on the breast of the Sphinx at Gizeh.[1] The tablet represents Thothmes before his guardian deity, the sun-god Ra, pouring a libation of wine on one side and offering incense on the other. The ancient Egyptians used various substances as incense. They worshipped Ra at sunrise with resin, at mid-day with myrrh, and at sunset with an elaborate confection called *kuphi*, compounded of no fewer than sixteen ingredients, among which were honey, wine, raisins, resin, myrrh, and sweet calamus. While it was being mixed, holy writings were read to those engaged in the operation. According to Plutarch, apart from its mystic virtues arising from the magical combination of 4×4, its sweet odour had a benign physiological effect on those who offered it.[2] The censer used was a hemispherical cup or bowl of bronze, supported by a long handle, fashioned at one end like an open hand, in which the bowl was, as it were, held, while the other end within which the pastils of incense were kept was shaped into the hawk's head crowned with a disk, as the symbol of Ra.[3] In embalming their dead the Egyptians filled the cavity of the belly with every sort of spicery, except frankincense (Herod., ii. 86), which was regarded as specially consecrated to the worship of the gods. In the burnt offerings of male kine to Isis, the carcase of the steer, after evisceration, was filled with fine bread, honey, raisins, figs, frankincense, myrrh, and other aromatics, and thus stuffed was roasted, being basted all the while by pouring over it large quantities of sweet oil, and then eaten with great festivity.

How important the consumption of frankincense in the worship of the gods became in Egypt is shown by two of its monuments, which are of the greatest interest and value for the light they throw on the early history of the commerce of the Indian Ocean. One is an inscription in the rocky valley of Hammamat, through which the desert road from the Red Sea to the valley of Egypt opens on the green fields and palm groves of the river Nile near Coptos. It was cut on the rocks by an Egyptian nobleman named Hannu, who states that he was sent by Pharaoh Sankhara, 2500 B.C., with a force gathered out of the Thebaid, from Coptos to the Red Sea, there to take command of a naval expedition to the Holy Land of Punt, "to bring back odoriferous gums." Punt is identified with the Somali country, which is now known to be the native country of the trees that yield the bulk of the frankincense of commerce. The other bears the record of a second expedition to the same land of Punt, undertaken by command of Queen Hasop, 1600 B.C. It is preserved in the vividly chiselled and richly coloured decorations which portray the history of the reign of this famous Pharaoh on the walls of the "Stage Temple" at Thebes. The temple is now in ruins, but the entire series of gorgeous pictures recording the expedition to "the balsam land of Punt," from its leaving to its returning to Thebes, still remains intact and undefaced.[4] These are the only authenticated instances of the export of incense trees from the Somali country until Colonel Playfair, then political agent at Aden, in 1862–64, collected and sent to Bombay the specimens from which Dr Birdwood prepared his descriptions of them for the Linnean Society in 1868. King Antigonus is said to have had a branch of the true frankincense tree sent to him.

Homer tells us that the Egyptians of his time were emphatically a nation of druggists (*Od.* iv. 229, 230). This characteristic, in which, as in many others, they remarkably resemble the Hindus, the Egyptians have maintained to the present day; and, although they have changed their religion, the use of incense among them continues to be as familiar and formal as ever. The *kohl* or black powder with which the modern, like the ancient, Egyptian ladies paint their languishing eyelids, is nothing but the smeeth of charred frankincense, or other odoriferous resin, which is brought with frankincense, and phials of water from the well of Zem-zem, by the returning pilgrims from Mecca. They also melt frankincense as a depilatory, and smear their hands with a paste into the composition of which frankincense enters, for the purpose of communicating to them an attractive perfume. Herodotus (iv. 75) describes a similar artifice as practised by the women of Scythia (compare also Judith x. 3, 4). In cold weather the Egyptians warm their rooms by placing in them a brazier, "chafing-dish," or "standing-dish," filled with charcoal, in which incense is burnt; and in hot weather they refresh them by occasionally swinging a hand censer by a chain through them—frankincense, benzoin, and aloe wood being chiefly used for the purpose.[5]

In the authorized version of the Bible, the word "incense" translates two wholly distinct Hebrew words. In various passages in the latter portion of Isaiah (xl.–lxvi.), in Jeremiah, and in Chronicles, it represents the Hebrew *lebônah*, more usually rendered "frankincense"; elsewhere the original word is *ketoreth* (Ex. xxx. 8, 9, Lev. x. 1, Num. vii. 14, &c.), a derivative of the verb *kitter* (Pi.) or *hiktir* (Hiph.), which verb is used, not only in Ex. xxx. 7, but also in Lev. i. 9, iii. 11, ix. 13, and many other passages, to denote the process by which the "savour of satisfaction" in any burnt offering, whether of flesh or of incense is produced. Sometimes in the authorized version (as in 1 Kings iii. 3, 1 Sam. ii. 28) it is made to mean explicitly the burning of incense with only doubtful propriety. The expression "incense (ketoreth) of rams" in Ps. lxvi. 15 and the allusion in Ps. cxli. 2 ought both to be understood, most probably, of ordinary burnt offerings.[6] The "incense" (ketoreth), or "incense of sweet scents" (ketoreth sammim), called, in Ex. xxx. 35, "a confection after the art of the apothecary," or rather "a perfume after the art of the perfumer," which was to be regarded as most holy, and the imitation of which was prohibited under the severest penalties, was compounded of four "sweet scents" (sammim),[7] namely stacte (nataph), onycha (sheheleth), galbanum (helbenah), and "pure" or "fine" frankincense (lebonah zaccah), pounded together in equal proportions, with (perhaps) an admixture of salt (memullah).[8] It was then to be "put before the testimony" in the "tent of meeting." It was burnt on the altar of incense (see ALTAR, vol. i. p. 640) by the priest every morning when the lamps were trimmed in the holy place,

[6] See Wellhausen, *Gesch. Israels*, i. 70 *sqq.*, who from philological and other data infers the late date of the introduction of incense into the Jewish ritual.

[7] According to Philo (*Opera*, i. 504, ed. Mangey), they symbolized respectively water, earth, air, and fire.

[8] Other accounts of its composition, drawn from Rabbinical sources, will be found in various works on Jewish antiquities; see, for example, Reland, *Antiq. Sacr. Vet. Hebr.*, pp. 39–41 (1712).

and every evening when they were lighted or "set up" (Ex. xxx. 7, 8). A handful of it was also burnt once a year in the holy of holies by the high priest on a pan of burning coals taken from the altar of burnt-offering (Lev. xvi. 12, 13). Pure frankincense (lebonah) formed part of the meat offering (Lev. ii. 16, vi. 15), and was also presented along with the shew bread (Lev. xxiv. 7) every Sabbath day (probably on two golden saucers; see Jos., *Ant.*, iii. 10, 7). The religious significance of the use of incense, or at least of its use in the holy of holies, is distinctly set forth in Lev. xvi. 12, 13.

The Jews were also in the habit of using odoriferous substances in connexion with the funeral obsequies of distinguished persons (see 2 Chron. xvi. 14, xxi. 19; Jer. xxxiv. 5). In Am. vi. 10 "he that burneth him" probably means "he that burns perfumes in his honour." References to the domestic use of incense occur in Cant. iii. 6, Prov. xxvii. 9, *cf.* vii. 17.

The "marbles" of Nineveh furnish frequent examples of the offering of incense to the sun-god and his consort (2 Kings xxiii. 5). The kings of Assyria united in themselves the royal and priestly offices, and on the monuments they erected they are generally represented as offering incense and pouring out wine to the tree of life. They probably carried the incense in the sacred bag which is so frequently seen in their hands and in those also of the common priests. According to Herodotus (i. 183), frankincense to the amount of 1000 talents' weight was offered every year, during the feast of Bel, on the great altar at his temple in Babylon.

The monuments of Persepolis and the coins of the Sassanians show that the religious use of incense was as common in ancient Persia as in Babylonia and Assyria. Five times a day the priests of the Persians (Zoroastrians) burnt incense on their sacred fire altars. In the Avesta (*Vendidad*, Fargard xix. 24, 40), the incense they used is named *vohu gaono.* It has been identified with benzoin, but was probably frankincense. Herodotus (iii. 97) states that the Arabs brought every year to Darius as tribute 1000 talents of frankincense. The Parsees still preserve in western India the pure tradition of the ritual of incense as followed by their race from probably the most ancient times.

The *Ramayana* and *Mahabharata* afford evidence of the employment of incense by the Hindus, in the worship of the gods and the burning of the dead, from the remotest antiquity. Its use was obviously continued by the Buddhists during the prevalence of their religion in India, for it is still used by them in Nepal, Tibet, Ceylon, Burmah, China, and Japan. These countries all received Buddhism from India, and a large proportion of the porcelain and earthenware articles imported from China and Japan into Europe consists of innumerable forms of censers. The Jains all over India burn sticks of incense before their Jina. The commonest incense in ancient India was probably frankincense. The Indian frankincense tree, *Boswellia thurifera*, Colebrooke (which certainly includes *B. glabra*, Roxburgh), is a doubtful native of India. It is found chiefly where the Buddhist religion prevailed in ancient times, in Bihar and along the foot of the Himalayas and in western India, where it particularly flourishes in the neighbourhood of the caves of Ajanta. It is quite possible therefore that, in the course of their widely extended commerce during the one thousand years of their ascendency, the Buddhists imported the true frankincense trees from Africa and Arabia into India, and that the accepted Indian species are merely varieties of them. Now, however, the incense in commonest use in India is benzoin. But the consumption of all manner of odoriferous resins, gum resins, roots, woods, dried leaves, flowers, fruits, and seeds in India, in social as well as religious observances, is enormous. The grateful perfumed powder *abir* or *randa* is composed either of rice, flour, mango bark or deodar wood, camphor, and aniseed, or of sandalwood or wood aloes, zerumbet, zedoary, rose flowers, camphor, and civet. The incense sticks and pastils known all over India under the names of *ud-buti* ("benzoin-light") or *aggar-ki-buti* ("wood aloes light") are composed of benzoin, wood aloes, sandalwood, rock lichen, patchouli, rose-malloes, *Flacourtia* leaf (*talisput-tree*), mastic, and sugar candy or gum. The *abir* and *aggir butis* made at the Mahometan city of Bijarpur in the Mahratta country are celebrated all over western India. The Indian Mussulmans indeed were rapidly degenerating into a mere sect of Hindus before the Wahabi revival, and the more recent political propaganda in support of the false caliphate of the sultans of Turkey; and we therefore find the religious use of incense among them more general than among the Mahometans of any other country. They use it at the ceremonies of circumcision, *bismillah* (teaching the child "the name of God"), virginity, and marriage. At marriage they burn benzoin with *nim* seeds to keep off evil spirits, and prepare the bride-cakes by putting a quantity of benzoin between layers of wheaten dough, closed all round, and frying them in clarified butter. For days the bride is fed on little else. In their funeral ceremonies, the moment the spirit has fled incense is burnt before the corpse until it is carried out to be buried. The begging fakirs also go about with a lighted stick of incense in one hand, and holding out with the other an incense-holder (literally, "incense chariot"), into which the coins of the pious are thrown. Large "incense trees" resembling our Christmas trees, formed of incense-sticks and pastils and osselets, and alight all over, are borne by the Shiah Mussulmans in the annual procession of the Mohurrum, in commemoration of the martyrdom of the sons of Ali. The worship of the *tulsi* plant, or holy basil, by the Hindus is popularly explained by its consecration to Vishnu and Krishna. It grows on the four-horned altar before the house, or in a pot placed in one of the front windows, and is worshipped every morning by all the female members of every Hindu household. It is possible that its adoration has survived from the times when the Hindus buried their dead in their houses, beneath the family hearth. When they came into a hot climate the fire of the sacrifices and domestic cookery was removed out of the house; but the dead were probably still for a while buried in or near it, and the *tulsi* was planted over their graves, at once for the salubrious fragrance it diffuses and to represent the burning of incense on the altar of the family lar.

As to the θύεα mentioned in Homer (*Il.* ix. 499, and elsewhere) and in Hesiod (*Works and Days*, 338), there is some uncertainty whether they were incense offerings at all, and if so, whether they were ever offered alone, and not always in conjunction with animal sacrifices. That the domestic use, however, of the fragrant wood θύον (the *Arbor vitæ* or *Callitris quadrivalvis* of botanists, which yields the resin sandarach) was known in the Homeric age, is shown by the case of Calypso (*Od.* v. 60), and the very similarity of the word θύον to θύος may be taken as almost conclusively proving that by that time the same wood was also employed for religious purposes. It is not probable that the sweet smelling gums and resins of the countries of the Indian Ocean began to be introduced into Greece before the 8th or 7th century B.C., and doubtless λίβανος or λιβανωτός first became an article of extensive commerce only after the Mediterranean trade with the East had been opened up by the Egyptian king Psammetichus (670 B.C.). The new Oriental word is frequently employed by Herodotus; and there are abundant references to the use of the thing among the writers of the golden age of Attic literature (see, for example, Aristophanes, *Plut.*, 1114; *Frogs*, 871, 888; *Clouds*, 426; *Wasps*, 96, 861). Frankincense, however, though the most common, never became the only kind of incense offered to the gods among the Greeks. Thus the Orphic Hymns are careful to specify, in connexion with the several deities celebrated, a great variety of substances appropriate to the service of each; in the case of many of these the selection seems to have been determined not at all by their fragrance but by some occult considerations which it is now difficult to divine.

Among the Romans the use of religious fumigations long preceded the introduction of foreign substances for the purpose (see, for example, Ovid, *Fast.* i. 337 *sq.*, "Et non exiguo laurus adusta sono"). Latterly the use of frankincense ("mascula thura," Virg., *Ecl.* viii. 65) became very prevalent, not only in religious ceremonials, but also on various state occasions, such as in triumphs (Ovid, *Trist.* iv. 2, 4), and also in connexion with certain occurrences of domestic life. In private it was daily offered by the devout to the *lar familiaris* (Plaut., *Aulul.*, prol., 23); and in public sacrifices it was not only sprinkled on the head of the victim by the pontifex before its slaughter, and afterwards mingled with its blood, but was also thrown upon the flames in which it was roasted.

No perfectly satisfactory traces can be found of the use of incense in the ritual of the Christian Church during the first four centuries. It obviously was not contemplated by the author of the epistle to the Hebrews; its use was foreign to the synagogue services on which, and not on those of the temple, the worship of the primitive Christians is well known to have been originally modelled; and its associations with heathen solemnities, and with the evil repute of those who were known as "thurificati," would still further militate against its employment. Various authors of the ante-Nicene period have expressed themselves as distinctly unfavourable to its religious, though not of course to its domestic, use. Thus Tertullian, while (*De Cor. Mil.*, 10) ready to acknowledge its utility in counteracting unpleasant smells ("si me odor alicujus loci offenderit, Arabiæ aliquid incendo"), is careful to say that he scorns to offer it as an accompaniment to his heartfelt prayers (*Apol.*, 30, *cf.* 42). Athenagoras also (*Legat.*, 13) gives distinct expression to his sense of the needlessness of any such ritual ("the Creator and Father of the universe does not require blood, nor smoke, nor even the sweet smell of flowers and incense"); and Arnobius (*Adv. Gent.*, vii. 26) seeks to justify the Christian neglect of it by the fact, for which he vouches, that among the Romans themselves incense was unknown in the time of Numa, while the Etruscans had always continued to be strangers to it. Cyril of Jerusalem, Augustine, and the Apostolic Constitutions make no reference to any such feature either in the public or private worship of the Christians of that time. The earliest mention, it would seem, occurs in the Apostolic Canons (can. 3), where the θυμίαμα is spoken of as one of the requisites of the eucharistic service. It is easy to perceive how it should inevitably have come in along with the whole circle of ideas involved in such words as "temple," "altar," "priest," which about this time came to be so generally applied in ecclesiastical connexions. Evagrius (vi. 21) mentions the gift of a θυμιατήριον by Chosroes the king of Persia to the church of Jerusalem; and all the Oriental liturgies of this period provide special prayers for the thurification of the eucharistic elements. The oldest *Ordo Romanus*, which perhaps takes us back to within a century of Gregory the Great, enjoins that in pontifical masses a subdeacon, with a golden censer, shall go before the bishop as he leaves the secretarium for the choir, and two, with censers, before the deacon gospeller as he proceeds with the gospel to the ambo. And less than two centuries afterwards we read an order in one of the capitularies of Hincmar of Rheims, to the effect that every priest ought to be provided with a censer and incense. That in this portion of their ritual, however, the Christians of that period were not universally conscious of its direct descent from Mosaic institutions may be inferred perhaps from the "benediction of the incense" used in the days of Charlemagne, which runs as follows: "May the Lord bless this incense to the extinction of every noxious smell, and kindle it to the odour of its sweetness." Even Thomas Aquinas (p. iii. qu. 83, art. 5) gives prominence to this idea.

The character and order of these historical notices of incense would certainly, were there nothing else to be considered, justify the conclusion which has been generally adopted, that its use was wholly unknown in the worship of the Christian Church before the 5th century. On the other hand, we know that in the first Christian services held in the catacombs under the city of Rome, incense was burnt as a sanitary fumigation at least. Tertullian also distinctly alludes to the use of aromatics in Christian burial: "the Sabæans will testify that more of their merchandise, and that more costly, is lavished on the burial of Christians, than in burning incense to the gods." And the whole argument from analogy is in favour of the presumption of the ceremonial use of incense by the Christians from the first. It is natural that little should be said of so obvious a practice until the fuller development of ritual in a later age. The slighting references to it by the Christian fathers are no more an argument against its existence in the primitive church, than the similar denunciations by the Jewish prophets of burnt offerings and sacrifices are any proof that there were no such rites as the offering of incense, and of the blood of bulls and fat of rams, in the worship of the temple at Jerusalem. There could be no real offence to Christians in the burning of incense. Malachi (i. 11) had already foretold the time when among the Gentiles, in every place, incense should be offered to God. Gold, with myrrh and frankincense were offered by the Persian Magi to the infant Jesus at his birth; and in Revelation viii. 3, 4 the image of the offering incense with the prayers of the saints, before the throne of God, is not without its significance. If also the passage in Ambrose of Milan (on Luke i. 11), where he speaks of "us" as "adolentes altaria" is to be translated "incensing the altars," and taken literally, it is an unequivocal testimony to the use of incense by the Christian Church in, at least, the 4th century.

The Missal of the Roman Church now enjoins incensation before the introit, before the gospel, and again at the offertory, in every high mass; the use of incense also occurs when the sacrament is exhibited, at consecrations of churches and the like, in processions, in the office for the burial of the dead, and at the exhibition of relics. On high festivals the altar is censed at vespers and lauds.

In the Church of England the use of incense was gradually abandoned after the reign of Edward VI., until the ritualistic revival of the present day. Its use, however, has never been abolished by law. A "Form for the Consecration of a Censer" occurs in Sancroft's *Form of Dedication and Consecration of a Church or Chapel* (1685). In various works of reference (as, for example, in *Notes and Queries*, 3d ser., vol. viii. p. 11) numerous sporadic cases are mentioned in which incense appears to have been burnt in churches; the evidence, however, does not go so far as to show that it was used during divine service, least of all that it was used during the communion office. At the coronation of George III., one of the king's grooms appeared "in a scarlet dress, holding a perfuming pan, burning perfumes, as at previous coronations."

For the manufacture of the incense now used in the Christian churches of Europe there is no fixed rule. The books of ritual are agreed that Ex. xxx. 34 should be taken as a guide as much as possible. It is recommended that frankincense should enter as largely as possible into its composition, and that if inferior materials be employed at all they should not be allowed to preponderate. In Rome olibanum alone is employed; in other places benzoin, storax, aloes, cascarilla bark, cinnamon, cloves, and musk are all said to be occasionally used. In the Russian Church, benzoin is chiefly employed. The Armenian liturgy, in its benediction of the incense, speaks of "this perfume prepared from myrrh and cinnamon."

The preparation of pastils of incense has probably come down in a continuous tradition from ancient Egypt, Babylonia, and Phœnicia. Cyprus was for centuries famous for their manufacture, and they were still known in the middle ages by the names of pastils or osselets of Cyprus.

Maimonides, in his *More Nevochim*, states that the use of incense in the worship of the Jews originated as a corrective of the disagreeable odours arising from the slaughter and burning of the animals offered in sacrifice. There can be no doubt that its use throughout the East is based on sanitary considerations; and in Europe even, in the time when the dead were buried in the churches, it was recognized that the burning of incense served essentially to preserve their salubrity. But evidently the idea that the odour of a burnt-offering (*cf.* the κνίσης ἡδὺς ἀϋτμή of *Odyss.* xii. 369) is grateful to the deity, being indeed the most essential part of the sacrifice, or at least the vehicle by which alone it can successfully be conveyed to its destination, is also a very early one, if not absolutely primitive; and survivals of it are possibly to be met with even among the most highly cultured peoples where the purely symbolical nature of all religious ritual is most clearly understood and maintained. Some such idea plainly underlies the familiar phrase "a sweet savour," more literally "a savour of satisfaction," by which an acceptable offering by fire is so often denoted in the Bible (Gen. viii. 21, Lev. i. 9, *et passim*; *cf.* Eph. v. 2). It is easy to imagine how, as men grew in sensuous appreciation of pleasant perfumes, and in empirical knowledge of the sources from which these could be derived, this advance would naturally express itself, not only in their domestic habits, but also in the details of their religious ceremonial, so that the custom of adding some kind of incense to their animal sacrifices, and at length that of offering it pure and simple, would inevitably arise. Ultimately, with the development of the spiritual discernment of men, the "offering of incense" became a mere symbolical expression for prayer (see Rev. v. 8, viii. 3, 4). Clement of Alexandria expresses this in his well-known words: "The true altar of incense is the just soul, and the perfume from it is holy prayer." (So also Origen, *Cont. Cels.*, viii. 17, 20.) The ancients were familiar with the sanitary efficacy of fumigations. The energy with which Ulysses, after the slaughter of the suitors, calls to Euryclea for "fire and sulphur" to purge (literally "fumigate") the dining-hall from the pollution of their blood (*Od.* xxii. 481, 482) would startle those who imagine that sanitation is a peculiarly modern science. There is not the slightest doubt that the censing of things and persons was first practised for acts of purification, and thus became symbolical of consecration, and finally of the sanctification of the soul. The Egyptians understood the use of incense as symbolical of the purification of the soul by prayer. Catholic writers generally treat it as typifying contrition, the preaching of the gospel, the prayers of the faithful, and the virtues of the saints. (G. B.)

INCEST, carnal connexion between persons so related that marriage could not take place between them according to the Levitical rules. In England incest has not generally been treated as a crime, although, along with other offences against morals, it was made punishable by death in 1650. Since the Restoration it has, to use Blackstone's phrase, been left to the "feeble coercion of the spiritual courts." Under the divorce law, incest is one of the aggravations of adultery which entitle a wife to divorce her husband. In the law of Scotland, it is a crime nominally punishable with death, but the penalty usually inflicted is penal servitude for life. This sentence was actually pronounced on a man in 1855. In the United States, as in England, incest is not an indictable offence at common law, but it has been made so by the legislation of some of the States.

INCHBALD, Mrs Elizabeth (1753–1821), an English actress, dramatic author, and novelist, was born 15th October 1753. She was the daughter of a farmer at Standingfield, near Bury St Edmunds, Suffolk, her maiden name being Simpson. On account of the death of her father in her eighth year, she and her sisters never enjoyed the advantages of school training or of any regular supervision in their studies, but they nevertheless seem to have acquired at an early period refined and literary tastes. A favourite amusement of the family was readings, chiefly of a dramatic kind, and Elizabeth, notwithstanding that she was afflicted with an impediment of speech, which drove her into solitude, soon conceived a strong desire, not only to see the great world, but to become an actress. After making an attempt with little success to secure an engagement in a Norwich theatre, she in April 1772 left secretly for London, where she made the acquaintance of several managers and actors, but with no better fortune. In June she, however, married Mr Inchbald, a comedian in Drury Lane Theatre, and in September following she made her debut as an actress in the character of Cordelia, her husband taking the part of Lear. For several years she acted along with her husband in the provinces, but notwithstanding her great beauty and her good mental aptitude for acting, the impediment in her speech, by rendering rapidity and ease of utterance impossible, prevented her from attaining to more than very moderate excellence. After the death of her husband in 1778 she continued for some time on the stage, but her success as a dramatic author led her to retire in 1789. She died at Kensington, August 1, 1821.

Mrs Inchbald's plays amount to nineteen in all. Some of them were for a time very successful, especially *Wives as they were and Maids as they are*. Among the others may be mentioned *Such Things Are*; *The Married Man*; *The Wedding Day*; *The Midnight Hour*; *Everyone has his Fault*; and *Lovers' Vows*. She also edited a collection of the *British Theatre*, with biographical and critical remarks, 25 vols., 1806–1809; a *Collection of Farces*, 7 vols., 1809; and *The Modern Theatre*, 10 vols., 1809. Her fame, however, now rests chiefly on her two novels, *A Simple Story*, and *Nature and Art*. These works possess many minor faults and inaccuracies, but on the whole their style is easy, natural, and graceful; and if they are tainted in some degree by a morbid and exaggerated sentiment, and display none of that faculty of creation possessed by the best writers of fiction, the pathetic situations, and the deep and pure feeling pervading them, secured for them a wide but now a waning popularity. Some time before her death Mrs Inchbald destroyed an autobiography for which she had been offered £1000 by Phillips the publisher; but her *Memoirs*, compiled by J. Boaden, chiefly from her private journal, appeared in 1833 in two volumes. An interesting account of Mrs Inchbald is contained in *Records of a Girlhood*, by Frances Ann Kemble, 1878.

INCUBATION. See Birds, vol. iii. p. 775, and Reproduction. For Artificial Incubation, see Poultry.

INDEPENDENTS, a religious denomination whose distinctive ecclesiastical principle is that the individual congregation or church is a society strictly voluntary and autonomous, standing directly under the authority of Jesus Christ, living in immediate dependence on Him, and responsible to Him alone for its beliefs and acts as a Christian society. Its ideal stands distinguished, on the one hand, from Episcopacy by having no gradations of ministerial or clerical orders, or persons above the individual congregation invested with administrative or judicial authority, and, on the other hand, from Presbytery by having no gradation of courts or representative bodies possessed of legislative and judicial functions. These distinctions imply others. Episcopacy and Presbytery are essentially organized and incorporative systems, building all the societies they comprehend into a political unity, but Independency is essentially voluntary and individualizing, satisfied with a spiritual unity, refusing to permit its various societies to be built into a political organism, lest it should do violence to the rights of conscience, or prevent or even supersede the duty of the exercise by the individual of his own judgment in matters of religion. Episcopacy and Presbytery regard the collective organization as the church, but Independency the individual congregation, investing it with the attributes and prerogatives the other systems reserve for the organized whole. Its members possess equal rights, and are bound by equal obligations. They constitute a state whose citizens are all enfranchised, and are so because citizenship is limited to the qualified, who, having sought it voluntarily, voluntarily retain it. Independency may be said to affirm its ecclesiastical in order that it may realize its religious principle, that religion is purely a matter of the conscience, not to be created, extended, or reformed by any political mechanism or agencies, but by moral means, through men who seek to have it believed and embodied by men for reasons that commend themselves to the conscience, free and unconstrained. It thus holds that the best service the state can render to religion is to leave it free to live and act according to its own nature, in obedience to its own laws, prompted by its own impulses, guided by its own spirit and judgment.

Independency rose in the reign of Elizabeth, and may be said to have been born of the despair of seeing religion reformed and vivified on any one of the then followed lines. The peculiar condition of the Anglican Church at this period is well enough known. There were men in it who wished it to be independent of Rome, but to remain as far as possible Catholic while Anglican, and there were men who wished it to be conformed in doctrine and polity to those churches of the Continent that were by pre-eminence the Reformed. These latter were the Puritans, and their endeavour was to reform the church through the state, to persuade or compel the constitutive and sovereign will to make it such as they could conscientiously approve. But it was inevitable in a time of strong religious feeling that some more daring spirits should endeavour to break through the anomalies of the Puritan position. If their consciences demanded, and the civil authority refused, reform, was it either right or dutiful to submit to the civil authority as against the conscience? Was there no other way of reformation than by its consent? Was the Christian man relieved from all responsibility and obligation to obey conscience when the magistrate forbade him to do so? In so forbidding, was not the magistrate stepping out of his own province? Was the church he could so rule as to prevent the realization of the Scriptural ideal a rightly conceived and constituted church? Was it the apostolical way so to work as to plant, to purge, to organize churches only as Cæsar gave consent? And could any but the apostolical way be right?

These were the questions that created Independency. In the writings of the first Independent, Robert Browne (see BROWN, ROBERT), lies the first crude attempt at an answer. He is possessed with the idea that reformation is necessary, and is to be accomplished, not by the state, but by the action and cooperation of men who are themselves reformed and renewed. The Puritans have committed two great mistakes: they have imagined that reformation is a thing of polity only, to be carried out by changes in the organism, as it were, or structure of the church, leaving many, perhaps the immense majority, of the individuals who constitute it unreformed; and they have waited and are waiting to have the work done through and by the magistrate. Browne sets himself absolutely against both positions. "The kingdom of God," he says, "was not to be begun by whole parishes, but rather of the worthiest, be they ever so few."[1] This means that a church cannot be created by any political act out of such material as it finds in a parish, but only of the godly, men who are consciously and sincerely Christian. So he defines a church as "a companie or number of Christians or believers, who, by a willing covenant made with their God, are under the government of God and Christ, and kepe his lawes in one holie communion."[2] This idea of a church was as unlike as possible to the Church of England ideal, and made it as it actually existed so offensive to Browne that he held communion with it to be a cardinal sin. But it also made him particularly impatient with what he called the "wickednesse of those preachers which will not reforme themselves and their charge, because they will tarie till the magistrate commaunde and compell them."[3] This led him to discuss principles and state positions that curiously anticipate some of the most modern views as to the relation of the civil authority to religion and the church.[4] But the times were not ripe for either the criticism or the realization of Browne's ideas. They were extravagances to his own day; failure attended him everywhere—due partly, perhaps, to the angularities of the man, and partly to the prematurity of the system; his name was covered with ridicule; and Brownist became the epithet the early Independents most disliked and resented.

But the problems that had exercised Browne were too vital to religion to be his alone. They occupied many minds, and of these not a few looked in a similar direction for a solution. Geneva was at once the strength and the weakness of the Puritans;—their strength, because it gave them their ideal realized; their weakness, because it made them think that the only method of realization was in and through the state. The Puritan leaders were mainly scientific theologians, like Cartwright and Travers, Perkins and Rainolds, men who strenuously adhered alike in doctrine and polity to the principles and methods of their school. But the earliest Independents were men of simpler minds, educated indeed as well as the English universities could educate them, but of less specific and elaborate training. They studied their own times and interpreted their own duties in the light of the New Testament, and

[3] So runs the sub-title of one of the tracts he published while at Middleburg—*A Treatise of Reformation without Tarying for Anie* (1582).

[4] "Thus," he says, "they (the magistrates) may doe nothing concerning the Church, but onelie civilie, and as civile Magistrates; that is, they have not that authoritie ouer the church, as to be Prophetes or Priestes, or spirituall Kings, as they are Magistrates over the same; but onelie to rule the common wealth in all outwarde Justice, to maintaine the right welfare and honor thereof with outwarde power, bodily punishment, and civill forcing of men."—*A Treatise of Reformation*, p. 12.

inferred that as the apostles had proceeded they ought to proceed, that the methods proper to the apostolic age were also the methods proper to their own. These methods were individual, not national; churches were founded, religion created and reformed, not by civil authorities or agencies, but by preachers who persuaded men to believe, gathered the believers into communities or brotherhoods, each standing in a fraternal relation to all the rest, none occupying a position of political superiority or dependence. The early Independents believed that in this way only was it possible to reform religion in England, and they acted on their belief, separating themselves from the Anglican Church, forming themselves into communities on what they regarded as the Scriptural model, and working in what was conceived to be the apostolic method. But separation from the church was a capital crime, equal to a denial of the royal supremacy; and so every inveterate separatist became liable to death. And early Independency was not without its martyrs. In the summer of 1583 two men, Thacker and Coppin, were executed at Bury St. Edmunds for refusing to conform to the church, and "dispersinge of Brownes bookes and Harrisons bookes." They justified their refusal on the ground that "her Majestie was chieffe ruler civilie, but no further." Two much more remarkable men, who met with a similar fate, were John Greenwood and Henry Barrowe. Both were graduates of Cambridge; Greenwood had been ordained a priest; Barrowe was a barrister, a member of Gray's Inn. "He made," as we know on the authority of Lord Bacon,[1] "a leap from a vain and libertine youth to a preciseness in the highest degree, the strangeness of which alteration made him very much spoken of." Both became separatists, and were very active in the numerous conventicles that were then being held in and about London. Their principles were not so extreme as Browne's, their position being, as it were, intermediate between his and the Puritan. In his notion of the church as a society of the godly or the converted, politically independent alike as regards other churches and the state, they agree with him; in his notion of its rigidly democratic constitution, they differ, inclining more to leave its government in the hands of certain specially chosen men. Their ideal is a sort of Presbyterial Independency. They think of the church as "A companie of Faithfull people; separated from the vnbelievers and heathen of the land: gathered in the name of Christ, whome they truelie worship, and redily obey as their only King, Priest, and Prophet: ioyned together as members of one bodie: ordered and gouerned by such officers and lawes as Christ in His last will and Testament hath thereunto ordeyned," &c.[2]

Of course, this conception placed them in direct antagonism to both the Genevan and Anglican ideals and methods. They condemn "Mr Calvine" because "he made no scruple to receave all the whole state, even all the profane ignorant people, into the bozome of the church, to administer the sacramentes vnto them."[3] They condemn the Church of England because it comprehends "all the profane and wicked of the land,"[4] and maintain that "Christ is onely head of His church, and His lawes may no man alter"; that the prince is no more than a mere member of it; that, if he sin, not to excommunicate him is to neglect "God's judgmentes, their dutie and the prince's salvation." The Anglican Church was thus conceived as founded on a wrong principle, worked in a wrong method, and hindered rather than helped by its dependence on the state. Whitgift asked Barrowe whether, if the prince delayed or refused to reform abuses, the church should proceed without him; and his answer was, "it might and ought, though all the princes of the world should prohibit the same upon pain of death." Ideas like these logically involved separation as a duty; the ideas they contradicted as logically made it a crime. The age was not without the courage of its convictions; and Barrowe and Greenwood died for theirs, April 6, 1593. Shortly afterwards (May 29) John Penry or Ap Henry, a friend and associate, expiated the same sin in the same way.

In spite of the severely repressive measures of the Government, the Independents continued to multiply. In the last decade of the 16th century numerous separatist communities were formed,[5] especially in London and the eastern and north-eastern counties. Their conventicles were often surprised, and in 1596 it was reckoned that as many as twenty-four had died in prison, representing of course but a small proportion of those actually confined. Plainly England had as yet no room for Independency, and the Independents who wished to keep a good conscience were forced to think of seeking a home elsewhere. Certain of their leaders had, indeed, in 1592 organized a church in London, with Francis Johnson as its pastor, and Greenwood as its teacher; but they were so watched and hunted and harassed—fifty-six of its members having been seized at one time and imprisoned—that they resolved, convinced by the fate of Barrowe, Greenwood, and Penry that a peaceable life in England was impossible, to emigrate in a body. Holland was then the common refuge of the distressed for conscience' sake, the place where the outcasts alike of France and Spain and England found a free and even generous home. The Independents, after trying Campen and Naarden, settled finally at Amsterdam. There they completed their church organization, appointing Francis Johnson pastor and Henry Ainsworth teacher. Johnson was a native of Richmond in Yorkshire, had been a fellow of Christ's College, Cambridge, had been expelled the university for publicly teaching the Presbyterian polity, and had become pastor of the English merchants' church at Middleburg. There he had been zealous against the Independents, had helped to seize and destroy an edition of one of Barrowe's works, but, preserving a copy, had read it and been persuaded to adopt its views. He returned to England, associated himself with the author, and became, as we have seen, the pastor of the first Independent church in England. He was a pragmatic man, self-willed, emphasizing his separatism, easily drifting into controversies and consequent divisions on minute questions alike of conduct and opinion. Ainsworth (see AINSWORTH, HENRY) was an
